When you move one compartment to another, resource quotas in the destination compartment are not verified and are not enforced. Therefore, if the compartment move results in a quota violation in the destination compartment, the move is not blocked. After the move is complete, the destination compartment will be in an over-quota state. You will not be able to create new resources that are over-quota until you either adjust the quotas for the destination compartment or remove resources to comply with the existing quota. For more information on managing compartment quotas, see Compartment Quotas on page 243.

Understanding Tagging Implications When You Move a Compartment

Tags are not automatically updated after a compartment move. If you have implemented a tagging strategy based on compartment, you must update the tags on the resources after the move. For example, assume CompartmentA has a child compartment, CompartmentB. CompartmentA is set up with tag defaults so that every resource in CompartmentA is tagged with TagA. Therefore CompartmentB and all its resources are tagged with default tag, TagA. When you move CompartmentB to CompartmentC, it will still have the default tags from CompartmentA. If you have set up default tags for CompartmentC, you'll need to add those to the resources in the moved compartment.

Using the Console

To create a compartment

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A list of the compartments you have access to is displayed.
2. Navigate to the compartment in which you want to create the new compartment:
   - To create the compartment in the tenancy (root compartment) click Create Compartment.
   - Otherwise, click through the hierarchy of compartments until you reach the detail page of the compartment in which you want to create the compartment. On the Compartment Details page, click Create Compartment.
3. Enter the following:

- **Name:** A unique name for the compartment (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores). The name must be unique across all the compartments in your tenancy. Avoid entering confidential information.
- **Description:** A friendly description. You can change this later if you want to.
- **Compartment:** The compartment you are in is displayed. To choose another compartment to create this compartment in, select it from the list.
- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Compartment.**

Next, you might want to write a policy for the compartment. See To create a policy on page 2454.

**To update a compartment's name**

You can't update the name of a compartment that is associated with a security zone. For more information, see Security Zones.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.

   A list of the compartments in your tenancy is displayed.

2. For the compartment you want to rename, click the Actions icon (three dots), and then click **Rename Compartment**.

   **Tip:**
   
   You can't change the name of your root compartment.

3. Enter the new **Name**. The name must be unique across all the compartments in your tenancy. The name can have a maximum of 100 characters, including letters, numbers, periods, hyphens, and underscores. Avoid entering confidential information.

4. Click **Rename Compartment**.

**To update a compartment's description**

You can't update the description of a compartment that is associated with a security zone. For more information, see Security Zones.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.

   A list of the compartments in your tenancy is displayed.

2. For the compartment you want to update, click the Actions icon (three dots), and then click **Edit Compartment Description**.

3. Enter the new description. Avoid entering confidential information.

4. Click **Save**.

**To view the contents of a compartment**

1. Open the Console,

2. Open the navigation menu and select the type of resource you want to view. For example, click **Compute** to view all your Compute resources.

3. Choose the compartment from the list on the left side of the page. The page updates to show only the resources in that compartment.

Remember that most IAM resources reside in the tenancy (this includes users, groups, and compartments). Policies can reside in either the tenancy (root compartment) or other compartments.

**To move a compartment**

To move a compartment, you must belong to a group that has **manage all-resources** permissions on the lowest shared parent compartment of the current compartment and the destination compartment.
1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A list of the compartments in your tenancy is displayed. If the compartment you want to move is not directly beneath the root compartment, click through the hierarchy of compartments to view the wanted compartment.

2. For the compartment you want to move, click the Actions icon (three dots), and then click Move Compartment.

3. Select the destination compartment.

4. Confirm that you are aware of the implications of the move.

5. Click Move Compartment.

To move a resource to a different compartment

1. Open the Console.

2. Open the navigation menu and select the type of resource you want to work with. For example, click Compute to view all your Compute resources.

3. In the List Scope section, select a compartment. Resources in the selected compartment are displayed.

4. Find the resource in the list, click the the Actions icon (three dots), and follow the prompts to move the resource to a new compartment. See the resource documentation for specific steps.

The resource is moved immediately. If attached resource dependencies move with the parent resource, the resource dependencies are moved asynchronously, and do not appear in the new compartment until the move is complete.

To apply tags to a compartment

For instructions, see Resource Tags on page 211.

To manage tag defaults for a compartment

See Managing Tag Defaults on page 3927.

To delete a compartment

You must remove all resources from a compartment before you can delete it.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A list of the compartments in your tenancy is displayed.

2. For the compartment you want to delete, click the Actions icon (three dots), and then click Delete Compartment.

3. At the prompt, click OK.

After you click OK, a work request is submitted to delete the compartment. The compartment state changes to Deleting. If the work request fails, the state returns to Active.

To recover a compartment

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A list of the compartments in your tenancy is displayed.

2. In State, select Deleted.

3. For the compartment you want to recover, click the Actions icon (three dots), and then click Recover.

4. At the prompt, click OK.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage compartments:

- CreateCompartment
- ListCompartments
- GetCompartment: Returns the metadata for the compartment, not its contents.
- UpdateCompartment
- DeleteCompartment
- MoveCompartment
IAM

- **GetWorkRequest**: Gets the work requests spawned by the DeleteCompartment operation.
- **RecoverCompartment**

You can retrieve the contents of a compartment only by resource type. There's no API call that lists all resources in the compartment. For example, to list all the instances in a compartment, call the Core Services API `ListInstances` operation and specify the compartment ID as a query parameter.

### Managing Regions

This topic describes the basics of managing your region subscriptions. For more information about regions in Oracle Cloud Infrastructure, see Regions and Availability Domains on page 180. For information about Platform Services regions, see Managing Platform Services Regions on page 2447.

### Required IAM Policy

If you're in the Administrators group, then you have the required access to manage region subscriptions.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for managing regions or other IAM components, see Details for IAM on page 2280.

### The Home Region

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your *home region*. Your home region is where your IAM resources are defined. When you subscribe to another region, your IAM resources are available in the new region, however, the master definitions reside in your home region and can only be changed there.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your home region contains your account information and identity resources. It is not changeable after your tenancy is provisioned. If you are unsure which region to select as your home region, contact your sales representative before you create your account</td>
</tr>
</tbody>
</table>

Resources that you can create and update only in the home region are:

- Users
- Groups
- Policies
- Compartments
- Dynamic groups
- Federation resources

When you use the API to update your IAM resources, you must use the endpoint for your home region. IAM automatically propagates the updates to all regions in your tenancy.

When you use the Console to update your IAM resources, the Console sends the requests to the home region for you. You don't need to switch to your home region first. IAM then automatically propagates the updates to all regions in your tenancy.

When you subscribe your tenancy to a new region, all the policies from your home region are enforced in the new region. If you want to limit access for groups of users to specific regions, you can write policies to grant access to specific regions only. For an example policy, see Restrict admin access to a specific region on page 2154.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM Updates Are Not Immediate Across All Regions</td>
</tr>
<tr>
<td>When you create or update an IAM resource, be aware that you need to allow up to several minutes for the changes in your home region to become available in all regions.</td>
</tr>
</tbody>
</table>
**Using the Console to Manage Infrastructure Regions**

To view the list of infrastructure regions

Open the Console, open the Region menu, and then click Manage Regions. A list of the regions offered by Oracle Cloud Infrastructure is displayed. Regions that you have not subscribed to provide a button to create a subscription.

**To subscribe to an infrastructure region**

1. Open the Console, open the Region menu, and then click Manage Regions. The list of regions available to your tenancy Oracle Cloud Infrastructure is displayed. Your home region is labeled.
2. Locate the region you want to subscribe to and click Subscribe.

   Note that it could take several minutes to activate your tenancy in the new region.

   Remember, your IAM resources are global, so when the subscription becomes active, all your existing policies are enforced in the new region.

   To switch to the new region, use the Region menu in the Console. See Switching Regions on page 45 for more information.

You cannot unsubscribe from a region.

**Using the API to Work with Infrastructure Regions**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage infrastructure regions:

- GetTenancy
- ListRegions: Returns a list of regions offered by Oracle Cloud Infrastructure in your selected realm.
- CreateRegionSubscription
- ListRegionSubscriptions

You cannot unsubscribe from a region.

**Region FAQs**

Can an individual user subscribe to a region?

A region subscription is at the tenancy level. An administrator can subscribe the tenancy to a region. All IAM policies are enforced in the new region, so all users in the tenancy will have the same access and permissions in the new region.

Can I see my existing resources in the new region?

When you select a region in the Console, you are shown a view of the resources in your selected region. Most cloud resources (instances, VCNs, buckets, etc.) exist only in a specific region, so you only see them when you select the region where they were created. The exception is IAM resources: compartments, users, groups, and policies are global across all regions. See also Working Across Regions on page 46.

How do my service limits apply to the new region?

Service limits can be scoped to the tenant level, the region level, or the availability domain level. When you subscribe to a new region, you get access to the region and its availability domains. Service limits apply accordingly. The service limits page lists the scope of each resource limit.

Can I restrict access to a specific region?

Yes. You can write policies that grant permissions in a specified region only. For an example policy, see Restrict admin access to a specific region on page 2154.

Can I change my home region?

No. Oracle assigns your home region and you can't change it.
Managing Platform Services Regions

This topic describes how to manage Platform Services region subscriptions.

About the Platform Services Regions

You can manage Platform Services regions in the Console.

To use Platform Services that are not natively integrated with Oracle Cloud Infrastructure, you need to subscribe to the Platform Services region as well as the Infrastructure region. For example, to create a Platform Service instance in the Germany Central (Frankfurt) region, you need to subscribe your tenancy to both the Infrastructure region: Germany Central (Frankfurt) and to the Platform Service region: Europe and Middle East.

To know which services require the Platform Service region subscription, you can view the list under More Oracle Cloud Services on the Console navigation menu. A sample of the navigation to these services is shown in the following screenshot:
Before you can view these services in the Console or access the Manage Platform Services Regions page, your tenancy must have entitlements to use the Platform Services.

**Managing Platform Services Regions**

**To view and subscribe to Platform Services regions**

1. Open the Console, open the Region menu, and then click Manage Regions.
2. On the **Manage Regions** page, click **Platform Services Regions**.

   The list of geographical regions is displayed. Regions that you have not subscribed to provide a button to create a subscription. A sample of the **Platform Services Regions** page is shown in the following screenshot:

   ![Platform Services Regions](image)

3. To subscribe to a region, locate the region in the list and click **Subscribe**.

   It might take several minutes to activate your tenancy in the new region.

### Managing the Tenancy

This topic describes options on the tenancy details page in the Console.

#### Required IAM Policy

If you're in the Administrators group, then you have the required access to manage the tenancy.

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. If you want to dig deeper into writing policies for your tenancy and other IAM components, see [Details for IAM](#) on page 2280.

#### Viewing the Tenancy Details Page

To view the tenancy details page:

Open the **Profile** menu (Ƈ) and click **Tenancy**: `<your_tenancy_name>`.

#### Details About Your Tenancy

The tenancy details page provides the following information about your tenancy:

**TENANCY OCID**

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your tenancy's OCID to use the API. You'll also need it when contacting support.
HOME REGION

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one of the available regions. This is your home region. Your home region is where your IAM resources are defined. For more information about the home region, see The Home Region on page 2445.

NAME

Your tenancy name. Your tenancy name is typically chosen when you set up your Oracle Cloud account.

CSI NUMBER

Your Customer Service Identifier for Oracle Support.

OBJECT STORAGE DESIGNATED COMPARTMENTS AND NAMESPACE

The Object Storage service provides API support for both Amazon S3 Compatibility API and Swift API. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. You can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in. For more information, see Designating Compartments for the Amazon S3 Compatibility and Swift APIs on page 3497.

For information about your Object Storage namespace, see Understanding Object Storage Namespaces on page 3395.

TAGS

Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs. If you have permissions to manage the tenancy, you also have permissions to apply free-form tags. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211.

SERVICE LIMITS

The limits allotted to your tenancy and usage against these limits. Not all service resources are included in the list shown here on the Console. For more information or to request an increase, see Service Limits on page 215.

Using the API

Many of the options set on this page are managed through the owning service. For example, the Object Storage settings are managed with the Object Storage service API, and setting the Audit log retention period is handled by the Audit service API.

To get information about your tenancy use the following operation:

- GetTenancy

To tag a tenancy, use the following operations:

- GetCompartment
- UpdateCompartment

In the above operations, use the tenancy OCID for the compartmentID parameter.

Managing Policies

This topic describes how to create, edit, and delete policies.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing policies.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies to control who else can write policies or manage other IAM components, see Let a compartment admin manage the compartment on page 2154, and also Details for IAM on page 2280.
Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Working with Policies

If you haven't already, make sure to read How Policies Work on page 2136 to understand the basics of how policies work.

When creating a policy, you must specify the compartment where it should be attached, which is either the tenancy (the root compartment) or another compartment. Where it's attached governs who can later modify or delete it. For more information, see Policy Attachment on page 2141. When creating the policy in the Console, you attach the policy to a compartment by creating the policy in that compartment. If you're using the API, you specify the identifier of the compartment in the CreatePolicy request.

When creating a policy, you must also provide a non-changeable name for it. The name must be unique across all policies in the compartment where you create it. You must also provide a description, which is a non-unique, changeable description for the policy. Oracle will also assign the policy a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

Note:
If you delete a policy and then create a new policy with the same name, they'll be considered different policies because they'll have different OCIDs.

For information about how to write a policy, see How Policies Work on page 2136 and Policy Syntax on page 2164. When using the Console to write policies, you can use the policy builder to help you construct the syntax of the policies you want to add.

When you create a policy, make changes to an existing policy, or delete a policy, your changes go into effect typically within 10 seconds.

You can view a list of your policies in the Console or with the API. In the Console, the list is automatically filtered to show only the policies attached to the compartment you're viewing. To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console or API.

For information about the number of policies you can have, see Service Limits on page 215.

Writing Policy Statements with the Policy Builder

The policy builder in the Console helps you quickly create common policies without the need to manually type the policy statements. The policy builder automatically suggests the permissions that an administrator can grant to groups of users or resources in their tenancy, as well as target resources like instances, networks, and buckets. Most of the policies suggested in the policy builder can also be found in Common Policies on page 2142, where you can learn more details about the access provided by each policy and the use cases for each. Users who don't need the suggestions offered by the policy builder or who have more complex policy requirements can bypass the builder's basic option and go straight to the advanced editor, where you can directly enter the policy statements in a free-form text box.

Features of the Policy Builder

The policy builder provides policy templates that you can complete to create policies for your tenancy. A policy template includes all the statements needed to provide the permissions to perform a task or set of related tasks in a service in OCI. To complete the template, select the group from a menu of existing groups and select the location from the list of compartments in your tenancy.

The policy templates in the policy builder are grouped by use case, such as network management, storage management, and account management, to make them easy to browse and find the permission set you need.
For example, assume you are setting up the network administrators for your tenancy. You need to grant a group of users the permissions required to work with all the resources in the Networking service. To create this policy in the policy builder:

- First, find the policy you want: From the Policy Use Cases menu, select Network Management. If you are not sure which use case a policy belongs to, you can leave this option set to All to browse all the templates.
- From the Common Policy Templates menu, select Let network admins manage a cloud network.

The policy builder displays the policy statements that will be created. In this case, there is only one statement:

```
Allow {group name} to manage virtual-network-family in {location}
```

- Now, all you need to do is select the group and location for the policy: When you select a group, the {group name} in the displayed policy statement also updates with your selection.
- Finally, select the location. You can traverse the compartment hierarchy to find and select the appropriate compartment. To create the policy in the tenancy, choose the root compartment.

### Customizing Policies

If you find that a template doesn't fit your needs exactly, then you can customize the policies provided by adding statements, removing statements, adding conditions, or other changes to create the policy you need. Click **Customize (Advanced)** to edit the statements in a free-form text box. When entering statements directly in the text box, ensure that you follow the Policy Syntax on page 2164 rules.

Examples of customizing the Network Admins policy:

- You need to include another group, GroupB to this policy. To add a group:
  
  Click **Customize (Advanced)**. In the text box, type the changes to the policy (following the required syntax).

```
Allow group GroupA, GroupB to manage virtual-network-family in
compartment CompartmentA
```

---

**Oracle Cloud Infrastructure User Guide**  
2452
• You need to add a condition to the statement. For example, you want to ensure that only users who have been verified by MFA can manage your networks. You can add that condition to the statement as follows:

```
Allow group GroupA to manage virtual-network-family in compartment CompartmentA where request.user.mfaTotpVerified='true'
```

• You want to add another statement to the policy. For example, you want GroupA to be allowed to use instances. To add another statement, enter it on the next line:

```
Allow group GroupA to manage virtual-network-family in compartment CompartmentA
Allow group GroupA to use instance-family in compartment CompartmentA
```

**Editing Policies with the Policy Builder**

After you have created the policy, you can enter any statement changes you need to make directly in the policy text. The template selector is only available when creating a new policy. The editor lets you delete, add, edit, or change the statement order.
Using the Console
To create a policy

Prerequisite: The group and compartment that you're writing the policy for must already exist.

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed.
2. Click Create Policy.
3. Enter the following:
   - **Name**: A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Compartment**: If you want to attach the policy to a compartment other than the one you're viewing, select it from list. Where the policy is attached controls who can later modify or delete it (see Policy Attachment on page 2141).
4. Enter the policy statements using the policy builder. Use the Basic option if you want to choose from common policy templates, which you can also customize. Use the Customize (Advanced) option if you already know how to write the statements you need and you want to simply type them in a text box.

   To use the policy builder Basic option:
   a. Select from the Policy Use Cases menu to filter the list of policy templates. If you're not sure which use case to choose, you can browse all the templates in the Common Policies Templates list.
   b. Select the template that best matches your requirements from the Common Policies Templates list.

      The policy builder displays the description of the chosen policy and lists the policy statements that it includes.
   c. Select the Group that this policy applies to.
   d. Select a Location. The location is the compartment that this policy grants access to. The compartment you choose here must be either the compartment you chose to attach the policy to in Step 3, or a compartment within the hierarchy of that compartment.
   e. If you need to modify the policy statements, click Customize (Advanced).

   To use the Customize (Advanced) option:
   a. Click Customize (Advanced).
   b. Enter or edit policy statements following the format described in Policy Syntax on page 2164, entering one statement per line.
5. To add tags to this policy, click Show Advanced Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
6. If you want to create another policy, select Create Another Policy.
7. Click Create.

   The new policy will go into effect typically within 10 seconds.

To get a list of your policies

Open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're currently viewing is displayed. If you want to view policies attached to a different compartment, select that compartment from the list on the left. You can't get a single list of all policies; they're always displayed by compartment.

To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console.

To update the description for an existing policy

This is available only through the API. A workaround is to create a new policy with the new description and delete the old policy.
To update the statements in an existing policy

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the policy you want to update. The policy's details and statements are displayed.
3. Click Edit Policy Statements. Use the Basic policy builder option if you want to interact with the statements using graphical controls. Use the Advanced policy builder option to edit the statements in a simple text box.

   To use the Basic option:
   • To revise a statement, enter the changes following the format in Policy Basics on page 2137 and Policy Syntax on page 2164.
   • To add a statement, click +Another Statement and enter the statement following the required format.
   • To delete a statement, click the X next to the statement.
   • To rearrange the order of the statements, use the up and down arrows to move statements to the correct order, or grab the handle to drag and drop statements to the preferred position.

   To use the Advanced option:
   • Select Advanced.
   • Revise the policy statements in the text box following the format in Policy Basics on page 2137 and Policy Syntax on page 2164.
4. Click Save Changes when you are finished editing.

Your changes will go into effect typically within 10 seconds.

To delete a policy

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. For the policy you want to delete, click Delete.
3. Confirm when prompted.

Your changes will go into effect typically within 10 seconds.

To apply tags to a policy

For instructions, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Note:

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.
Use these API operations to manage policies:

• CreatePolicy
• ListPolicies
• GetPolicy
• UpdatePolicy
• DeletePolicy

Managing User Credentials

This topic describes the basics of working with Oracle Cloud Infrastructure Identity and Access Management (IAM) user credentials. If you're not already familiar with the available credentials, see User Credentials on page 2360.

Working with Console Passwords and API Keys

Each user automatically has the ability to change or reset their own Console password, as well as manage their own API keys. An administrator does not need to create a policy to give a user those abilities.

To manage credentials for users other than yourself, you must be in the Administrators group or some other group that has permission to work with the tenancy. Having permission to work with a compartment within the tenancy is not sufficient. For more information, see The Administrators Group and Policy on page 2125.

IAM administrators (or anyone with permission to the tenancy) can use either the Console or the API to manage all aspects of both types of credentials, for themselves and all other users. This includes creating an initial one-time password for a new user, resetting a password, uploading API keys, and deleting API keys.

Users who are not administrators can manage their own credentials. In the Console, users can:

• Change or reset their own password.
• Upload an API key in the Console for their own use (and also delete their own API keys).

And with the API, users can:

• Reset their own password with CreateOrResetUIPassword.
• Upload an additional API key to the IAM service for their own use with UploadApiKey (and also delete their own API keys with DeleteApiKeyValue). Remember that a user can't use the API to change or delete their own credentials until they themselves upload a key in the Console, or an administrator uploads a key for that user in the Console or the API.

A user can have a maximum of three API keys at a time.

Working with Auth Tokens

Note:

"Auth tokens" were previously named "Swift passwords". Any Swift passwords you had created are now listed in the Console as auth tokens. You can continue to use the existing passwords.

Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. Each user created in the IAM service automatically has the ability to create, update, and delete their own auth tokens in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage auth tokens for other users.

Note that you cannot change your auth token to a string of your own choice. The token is always an Oracle-generated string.

Auth tokens do not expire. Each user can have up to two auth tokens at a time. To get an auth token in the Console, see To create an auth token on page 2463.

Oracle Cloud Infrastructure User Guide 2456
Using an Auth Token with Swift

Swift is the OpenStack object store service. If you already have an existing Swift client, you can use it with the Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage. You will need to get an auth token to use as your Swift password. When you sign in to your Swift client, you provide the following:

- Your Oracle Cloud Infrastructure Console user login
- Your Swift-specific auth token, provided by Oracle
- Your organization's Oracle tenant name

Any user of a Swift client that integrates with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work on page 2136. For basic policies that enable use of Object Storage, see Common Policies on page 2142.

Working with Customer Secret Keys

Note:

"Customer Secret keys" were previously named "Amazon S3 Compatibility API keys". Any keys you had created are now listed in the Console as Customer Secret keys. You can continue to use the existing keys.

Object Storage provides an API to enable interoperability with Amazon S3. To use this Amazon S3 Compatibility API, you need to generate the signing key required to authenticate with Amazon S3. This special signing key is an Access Key/Secret Key pair. Oracle provides the Access Key that is associated with your Console user login. You or your administrator generates the Customer Secret key to pair with the Access Key.

Each user created in the IAM service automatically has the ability to create, update, and delete their own Customer Secret keys in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage Customer Secret keys for other users.

Any user of the Amazon S3 Compatibility API with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work on page 2136. For basic policies that enable use of Object Storage, see Common Policies on page 2142.

Customer Secret keys do not expire. Each user can have up to two Customer Secret keys at a time. To create keys using the Console, see To create a Customer Secret key on page 2464.

Working with OAuth 2.0 Client Credentials

Note:

OAuth 2.0 Client Credentials are not available in the United Kingdom Government Cloud (OC4).

OAuth 2.0 client credentials are required to interact programmatically with those services that use the OAuth 2.0 authorization protocol. The credentials enable you to obtain a secure token to access those service REST API endpoints. The allowed actions and endpoints granted by the token depend on the scopes (permissions) that you select when you generate the credentials. The services that use the OAuth 2.0 protocol are:

- Oracle Analytics Cloud
- Oracle Integration

An OAuth 2.0 access token is valid for 3600 seconds (1 hour).

To create the credentials, you need to know the service resource and scope. Typically, you can select these from a drop-down list. However, if the information is not available in the list, you can manually enter the resource and scope. The scope defines the allowed permissions for the token, so ensure to set the scope at the minimum required access level.
A user can create the credentials for themselves or an Administrator can create the credentials for another user. The lists of available resources and scopes display only those resources and permission levels that the user has been granted access to.

**OAuth 2.0 Client Credential Limits**

Each user can have up to 10 OAuth 2.0 client credentials. You can increase this limit by [Requesting a Service Limit Increase](#) on page 217.

Each OAuth 2.0 client credential can have up to 10 scopes.

**Obtaining an OAuth 2.0 Access Token**

To obtain the token, use your credentials in a request against the OAuth2 token service endpoint as follows:

1. Create the OAuth 2.0 client credentials. See [To create OAuth 2.0 client credentials](#) on page 2465.

   After you create the OAuth 2.0 client credential note the following information:
   - The generated secret
   - The OCID of the OAuth 2.0 client credential
   - The scope and audience (fully-qualified scope)

2. Using the information from the previous step, make a request against the /oauth2/token endpoint to obtain a token as follows:

   ```bash
   curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded; charset=UTF-8" --user '<Oauth 2.0 client credential OCID>:<credential secret>' https://auth.<oci_region>.oraclecloud.com/oauth2/token -d 'grant_type=client_credentials&scope=<audience>-<scope>'
   ```

   Where:
   - `<Oauth 2.0 client credential OCID>:<credential secret>` is the OCID of the OAuth 2.0 client credential that you created joined by a colon (:) with the generated secret for the credential. Note that this secret is only displayed at the time you generate it and it must be copied immediately. You can retrieve the OCID from the details of the credential at any time.
   - `https://auth.<oci_region>.oraclecloud.com/oauth2/token` is the Oracle Cloud Infrastructure OAuth 2.0 authorization endpoint where `<OCI_region>` is a region your tenancy is subscribed to. For example, us-ashburn-1.
   - `<scope>-<audience>` is the fully-qualified scope, that is, the scope and audience joined by a hyphen (-). The scope and audience are available from the details page of the credential.

   **Example request:**
   ```bash
   curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded; charset=UTF-8" --user 'ocid1.credential.region1..aaaaaexamplestringaapgpedxq:{SAMplESeCreta5y' https://auth.us-ashburn-1.oraclecloud.com/oauth2/token -d 'grant_type=client_credentials&scope=https://2aexampley3uytc.analytics.ocp.oraclecloud.com:urn:opc:resource:consumer::all'
   ```

   The response will include the token. Example response:
   ```json
   {
   "access_token": "eyJraWQiOiJhcDVfwqKdi...8I7ILrzcz4cof2A",
   "token_type": "Bearer",
   "expires_in": "3600"
   }
   ```

   The token string is truncated in the example response. Copy the entire `access_token` string (within the quotation marks) as shown in your response.
Using the OAuth 2.0 Token in a Request

After you obtain an OAuth 2.0 access token, you provide the token in a bearer token header of the REST API request. For example:

```
```

What to Do When the Token Expires

The token expires after 3600 seconds (1 hour). When the token expires, request a new token following the instructions in Obtaining an OAuth 2.0 Access Token on page 2458.

Adding Scopes

You can add scopes to an existing OAuth 2.0 client credential to add access to more services with the same credential. After you add scopes, you do not need to regenerate the secret.

To request a token for multiple scopes, You can include additional scopes in a token request by appending

```
&scope=<scope>-<<audience>
```

to the final argument of the request and specifying the scope and audience for the scope you want to add.

Working with SMTP Credentials

Simple Mail Transfer Protocol (SMTP) credentials are needed in order to send email through the Email Delivery service. Each user is limited to a maximum of two SMTP credentials. If more than two are required, they must be generated on other existing users or additional users must be created.

**Note:**

You cannot change your SMTP username or password to a string of your own choice. The credentials are always Oracle-generated strings.

Each user created in the IAM service automatically has the ability to create and delete their own SMTP credentials in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage SMTP credentials for other users.

**Tip:**

Although each user can create and delete their own credentials, it is a security best practice to create a new user and generate SMTP credentials on this user rather than generating SMTP credentials on your Console user that already has permissions assigned to it.

SMTP credentials do not expire. Each user can have up to two credentials at a time. To get SMTP credentials in the Console, see To generate SMTP credentials on page 2466.

For information about using the Email Delivery service, see Overview of the Email Delivery Service on page 1738.

Using the Console

To change your Console password

You're prompted to change your initial one-time password the first time you sign in to the Console. The following procedure is for changing your password again later.

**Note:**

For Federated Users
If your company uses an identity provider (other than Oracle Identity Cloud Service) to manage user logins and passwords, you can't use the Console to update your password. You do that with your identity provider.

1. Sign in to the Console using the Oracle Cloud Infrastructure Username and Password.
2. After you sign in, go to the top-right corner of the Console, open the **Profile** menu (👤) and then click **Change Password**.

![Change Password](image)

3. Enter the current password.
4. Follow the prompts to enter the new password, and then click **Save New Password**.

**To create or reset another user's Console password**

If you're an administrator, you can use the following procedure to create or reset a user's password. The procedure generates a new one-time password that the user must change the next time they sign in to the Console.

1. View the user's details: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **Create/Reset Password**.

   The new one-time password is displayed. If you're an administrator performing the task for another user, you need to securely deliver the new password to the user. The user will be prompted to change their password the next time they sign in to the Console. If they don't change it within 7 days, the password will expire and you'll need to create a new one-time password for the user.

**To reset your password if you forgot it**

If you have an email address in your user profile, you can use the **Forgot Password** link on the sign on page to have a temporary password sent to you. If you don't have an email address in your user profile, you must ask an administrator to reset your password for you.

**To unblock a user**

If you're an administrator, you can unblock a user who has tried 10 times in a row to sign in to the Console unsuccessfully. See **To unblock a user** on page 2460.
To add an API signing key

You can use the Console to generate the private/public key pair for you. If you already have a key pair, you can choose to upload the public key. When you use the Console to add the key pair, the Console also generates a configuration file preview snippet for you.

The following procedures work for a regular user or an administrator. Administrators can manage API keys for either another user or themselves.

About the Config File Snippet

When you use the Console to add the API signing key pair, a configuration file preview snippet is generated with the following information:

- **user** - the OCID of the user for whom the key pair is being added.
- **fingerprint** - the fingerprint of the key that was just added.
- **tenancy** - your tenancy's OCID.
- **region** - the currently selected region in the Console.
- **key_file** - the path to your downloaded private key file. You must update this value to the path on your file system where you saved the private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

You can copy this snippet into your config file, to help you get started. If you don't already have a config file, see SDK and CLI Configuration File on page 4184 for details on how to create one. You can also retrieve the config file snippet later for an API signing key whenever you need it. See: To get the config file snippet for an API signing key.

To generate an API signing key pair

**Prerequisite:** Before you generate a key pair, create the .oci directory in your home directory to store the credentials. See SDK and CLI Configuration File on page 4184 for more details.

1. **View the user's details:**
   - If you're adding an API key for **yourself:**
     
     Open the Profile menu and click User Settings.
   - If you're an administrator adding an API key for **another user:** Go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. **Click Add API Key.**

3. **In the dialog, select Generate API Key Pair.**

4. **Click Download Private Key** and save the key to your .oci directory. In most cases, you do not need to download the public key.

   **Note:** If your browser downloads the private key to a different directory, be sure to move it to your .oci directory.

5. **Click Add.**

   The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text.
box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 4184 for details on how to create one.)

After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

• Replace the existing profile and its contents.
• Rename the existing profile.
• Rename this profile to a different name after pasting it into the config file.

6. Update the permissions on your downloaded private key file so that only you can view it:

a. Go to the .oci directory where you placed the private key file.

b. Use the command chmod go-rwx ~/.oci/<oci_api_keyfile>.pem to set the permissions on the file.

To upload or paste an API key

Prerequisite: You have generated a public RSA key in PEM format (minimum 2048 bits). The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
....
-----END PUBLIC KEY-----
```

1. View the user's details:

   • If you're adding an API key for yourself:

   Open the Profile menu ( ) and click User Settings.

   • If you're an administrator adding an API key for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click Add API Key.

3. In the dialog, select Choose Public Key File to upload your file, or Paste Public Key, if you prefer to paste it into a text box

4. Click Add.

   The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 4184 for details on how to create one.)

   After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:

   • Replace the existing profile and its contents.
   • Rename the existing profile.
   • Rename this profile to a different name after pasting it into the config file.

   To get the config file snippet for an API signing key

   The following procedure works for a regular user or an administrator.
1. View the user's details:
   - If you're getting an API key config file snippet for yourself:
     Open the Profile menu (🔗) and click User Settings.
     If you're an administrator getting an API key config file snippet for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.
   - If you're an administrator getting an API key config file snippet for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click API Keys. The list of API key fingerprints is displayed.
3. Click the the Actions icon (three dots) for the fingerprint, and select View configuration file.
   The Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your ~/.oci/config file. (If you have not yet created this file, see SDK and CLI Configuration File on page 4184 for details on how to create one.) After you paste the file contents, you'll need to update the key_file parameter to the location where you saved your private key file.
   If your config file already has a DEFAULT profile, you'll need to do one of the following:
   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

To delete an API signing key
The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.
1. View the user's details:
   - If you're deleting an API key for yourself:
     Open the Profile menu (🔗) and click User Settings.
   - If you're an administrator deleting an API key for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.
2. For the API key you want to delete, click Delete.
3. Confirm when prompted.
The API key is no longer valid for sending API requests.

To create an auth token
1. View the user's details:
   - If you're creating an auth token for yourself:
     Open the Profile menu (🔗) and click User Settings.
     If you're an administrator creating an auth token for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click Auth Tokens.
3. Click Generate Token.
4. Enter a description that indicates what this token is for, for example, "Swift password token".
5. Click Generate Token.
The new token string is displayed.
6. Copy the token string immediately, because you can't retrieve it again after closing the dialog box.
   If you're an administrator creating an auth token for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.
To delete an auth token

The following procedure works for a regular user or an administrator. Administrators can delete an auth token for either another user or themselves.

1. View the user's details:
   • If you're deleting an auth token for yourself:
     Open the Profile menu () and click User Settings.
   • If you're an administrator deleting an auth token for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click Auth Tokens.
3. For the auth token you want to delete, click Delete.
4. Confirm when prompted.

The auth token is no longer valid for accessing third-party APIs.

To create a Customer Secret key

1. View the user's details:
   • If you're creating a Customer Secret key for yourself:
     Open the Profile menu () and click User Settings.
   • If you're an administrator creating a Customer Secret key for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click Customer Secret Keys.

   A Customer Secret key consists of an Access Key/Secret key pair. Oracle automatically generates the Access Key when you or your administrator generates the Secret Key to create the Customer Secret key.

3. Click Generate Secret Key.
4. Enter a friendly description for the key and click Generate Secret Key.
   The generated Secret Key is displayed in the Generate Secret Key dialog box. At the same time, Oracle generates the Access Key that is paired with the Secret Key. The newly generated Customer Secret key is added to the list of Customer Secret Keys.
5. Copy the Secret Key immediately, because you can't retrieve the Secret Key again after closing the dialog box for security reasons.
   If you're an administrator creating a Secret Key for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.
6. Click Close.
7. To show or copy the Access Key, click the Show or Copy action to the left of the Name of a particular Customer Secret key.

To delete a Customer Secret key

The following procedure works for a regular user or an administrator. Administrators can delete a Customer Secret key for either another user or themselves.

1. View the user's details:
   • If you're deleting a Customer Secret key for yourself:
     Open the Profile menu () and click User Settings.
   • If you're an administrator deleting a Customer Secret key for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **Customer Secret Keys**.
3. For the Customer Secret key you want to delete, click **Delete**.
4. Confirm when prompted.

The Customer Secret key is no longer available to use with the Amazon S3 Compatibility API.

**To create OAuth 2.0 client credentials**

<table>
<thead>
<tr>
<th>Note:</th>
<th>OAuth 2.0 Client Credentials are not available in the following realms:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• the commercial realm (OC1)</td>
</tr>
<tr>
<td></td>
<td>• the United Kingdom Government Cloud (OC4)</td>
</tr>
</tbody>
</table>

1. View the user's details:
   - If you're creating an OAuth 2.0 client credential for yourself:
     a. Open the **Profile** menu and click **User Settings**.
   - If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu.
     a. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **OAuth 2.0 Client Credentials**.
3. Click **Generate OAuth 2.0 Client Credential**.
4. Enter a **Name** and **Description** for this credential.
5. Add the URI for the OAuth 2.0 services that this credential will provide access to.

   **To Select a Resource-Scope Pair**
   a. Select the **Select a Resource-Scope Pair** option.
   b. The **Resource** list displays the resources you have permission to view. Select the resource you want to add credentials for. After you select the resource, the **Audience** field is automatically populated.
   c. Next, select the **Scope** for this credential. Always select the minimum required privileges.

   **To Enter Fully Qualified Scope:**
   a. Select the **Enter Fully Qualified Scope** option.
   b. Enter the **Audience** and **Scope** for this credential.
6. To add more permissions to this credential, click **+ Another Scope** and follow the instructions in the previous step.
7. Click **Generate**. The new secret string is generated.

   Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

   If you're an administrator creating a Secret Key for another user, you need to securely deliver it to the user.

   You will need the following information from the credential for the token request:
   - The generated secret
   - The OCID of the OAuth 2.0 client credential
   - The scope and audience (fully-qualified scope)

**To add scopes to an existing OAuth 2.0 client credential**

1. View the user's details:
   - If you're creating an OAuth 2.0 client credential for yourself:
     a. Open the **Profile** menu and click **User Settings**.
   - If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu.
     a. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **OAuth 2.0 Client Credentials**.
3. Click the name of the credential that you want to add scopes to.
4. Click **Add Scopes**.
5. Add the URI for the OAuth 2.0 services that you want to add access to.

   **To Select a Resource-Scope Pair**
   
   a. Select the **Select a Resource-Scope Pair** option.
   
   b. The **Resource** list displays the resources you have permission to view. Select the resource you want to add credentials for. After you select the resource, the **Audience** field is automatically populated.
   
   c. Next, select the **Scope** for this credential. Always select the minimum required privileges.

   **To Enter Fully Qualified Scope**:
   
   a. Select the **Enter Fully Qualified Scope** option.
   
   b. Enter the **Audience** and **Scope** for this credential.

   6. To add more permissions to this credential, click **+ Another Scope** and follow the instructions in the previous step.

   7. Click **Save Changes**.

**To regenerate the OAuth 2.0 client credential secret**

**IMPORTANT:** When you regenerate the secret for a credential, requests made with the previous secret will be denied access to target scopes.

1. View the user's details:
   
   • If you're creating an OAuth 2.0 client credential for yourself:
   
      Open the **Profile** menu ( ) and click **User Settings**.
   
   • If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **OAuth 2.0 Client Credentials**.

3. Click the name of the credential that you want to regenerate the secret for.

4. Click **Add Scopes**.

5. Click **Regenerate Secret**.

6. Acknowledge the warning dialog and click **Regenerate Secret**.

7. Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

Ensure to update existing token requests with the new secret string.

**To generate SMTP credentials**

1. View the user's details:
   
   • If you're generating SMTP credentials for yourself:
   
      Open the **Profile** menu ( ) and click **User Settings**.
   
   • If you're an administrator generating SMTP credentials for another user: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **SMTP Credentials**.

3. Click **Generate SMTP Credentials**.

4. Enter a **Description** of the SMTP Credentials in the dialog box.

5. Click **Generate SMTP Credentials**. A user name and password is displayed.
6. Copy the user name and password for your records and click Close. Copy the credentials immediately, because you can't retrieve the password again after closing the dialog box for security reasons.

If you're an administrator creating the credential set for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

To delete SMTP credentials

The following procedure works for a regular user or an administrator. Administrators can delete SMTP credentials for either another user or themselves.

1. View the user's details:
   • If you're deleting SMTP credentials for yourself:
     Open the Profile menu ( ) and click User Settings.
   • If you're an administrator deleting SMTP credentials for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click SMTP Credentials.

3. For the SMTP credentials you want to delete, click Delete.

4. Confirm when prompted.

The SMTP credentials are no longer available to use with the Email Delivery service.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to manage Console passwords and access:

- CreateOrResetUIPassword: This generates a new one-time Console password for the user. The next time the user signs in to the Console, they'll be prompted to change the password.
- UpdateUserState: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.

Use these API operations to manage API signing keys:

- ListApiKeys
- UploadApiKey
- DeleteApiKey

Use these API operations to manage auth tokens:

- CreateAuthToken
- UpdateAuthToken: You can only update the auth token's description, not change the token string itself.
- ListAuthTokens
- DeleteAuthToken

Use these API operations to manage Customer Secret keys:

- CreateCustomerSecretKey
- UpdateCustomerSecretKey: You can only update the secret key's description, not change the key itself.
- ListCustomerSecretKeys
- DeleteCustomerSecretKey

Use these API operations to manage OAuth 2.0 client credentials:

- CreateOAuthClientCredential
- UpdateOAuthClientCredential
- ListOAuthClientCredentials
- DeleteOAuthClientCredential
Use these API operations to manage SMTP credentials:

- CreateSmtpCredential
- UpdateSmtpCredential: You can only update the description.
- ListSmtpCredentials
- DeleteSmtpCredential

Managing Authentication Settings

This topic describes how to set authentication rules for your tenancy. Authentication settings include policy rules for local IAM users in your tenancy and network source restrictions for all users in your tenancy.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for authentication policy and network sources.

To view authentication policy and network sources, you must be granted `inspect` access on the `authentication-policies` resource and the `network-sources` resource. For example:

```
Allow group GroupA to inspect authentication-policies in tenancy
```

```
Allow group GroupA to inspect network-sources in tenancy
```

To manage authentication policy and network sources, you must be granted `manage` permissions for both resources. For example:

```
Allow group GroupA to manage authentication-policies in tenancy
```

```
Allow group GroupA to manage network-sources in tenancy
```

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. If you want to dig deeper into writing policies for groups or other IAM components, see [Details for IAM](#) on page 2280.

**Working with Password Policy Rules**

A password policy that you set in the IAM service is applicable for all local (or non-federated) users.

When a user is created or when a user changes their password, the IAM service validates the password that is provided against the password policy to ensure that it meets the criteria for the policy. When a user logs in for the first time to change the password, or resets the password at any time, the password policy is evaluated and enforced.

**When Do Changes to Password Policy Rules Take Effect**

Changes to password policy rules take effect immediately so that the next time any user changes their password they must create a password that meets the criteria. Existing passwords will continue to work even if they would be invalid under the new rules. Users are not forced to change existing passwords to meet the new criteria. Passwords are evaluated against the rules only at the time they are created or changed.

**About the Password Policy Rules**

The following table describes the rules that you can include in your password policy:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Setting Options</th>
<th>Default IAM Service Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum password length</td>
<td>Minimum value is 8 (characters). Maximum value is 100.</td>
<td>12 characters</td>
</tr>
<tr>
<td>Rule</td>
<td>Setting Options</td>
<td>Default IAM Service Setting</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>Special characters</strong></td>
<td>Require passwords to contain at least 1 special character. Special characters allowed in passwords are: !#$%&amp;'()*+,-./:;&lt;&gt;? @{}^`{}~ Special characters not listed are not allowed.</td>
<td>Enforced</td>
</tr>
<tr>
<td><strong>Lowercase characters</strong></td>
<td>Require passwords to contain at least 1 lowercase alphabetic character a-z.</td>
<td>Enforced</td>
</tr>
<tr>
<td><strong>Uppercase characters</strong></td>
<td>Require passwords to contain at least 1 uppercase alphabetic character A-Z.</td>
<td>Enforced</td>
</tr>
<tr>
<td><strong>Numeric characters</strong></td>
<td>Require passwords to contain at least 1 number 0-9.</td>
<td>Enforced</td>
</tr>
</tbody>
</table>

Oracle recommends that you enforce all the password rules.

**Using the Console to Manage Password Policy Rules**

To edit password policy rules

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Authentication Settings. The authentication settings for your tenancy are displayed.
2. Click Edit.
3. Enter the following to set the password policy:
   - **Minimum Password Length**: Enter a number to define the minimum number of characters that a user's password must contain. Allowed values are 8 through 100.
4. Select the Password Rules you want to enforce:
   - **Must contain at least 1 numeric character**: Select the check box to require at least 1 number (0-9) in the password.
   - **Must contain at least 1 special character**: Select the check box to require at least 1 special character. Allowed special characters are: !#$%&'()\*+,-./:;<>? @\{\}^`{\}\~
   - **Must contain at least 1 lowercase character**: Select the check box to require at least 1 lowercase alphabetic character (a-z).
   - **Must contain at least 1 uppercase character**: Select the check box to require at least 1 uppercase alphabetic character (A-Z).
5. Click Save Changes.

**Working with Network Source Restrictions in Authentication Policy**

Network source restrictions let you specify an allowed set of IP ranges from which users can sign in to the Console. Users attempting to sign in from an IP address not on the allowed list will be denied access.

To enforce a network source restriction for your tenancy:

1. Set up a network source that specifies the allowed IP addresses. See Managing Network Sources on page 2427 for information on setting up the network source.
2. Select the network source in the Authentication settings page.

An administrator can set only one network source in the authentication settings, but a single network source can include multiple allowed IP addresses.
A network source restriction is applied for every user in the tenancy. If an administrator is unable to access a network with an allowed IP address to sign in from, then they must do one of the following to gain access to the tenancy:

- Use the authentication SDK to sign in and change the network source restriction setting programmatically.
- Contact Oracle Support. If you do not have an API signing key to enable access through the authentication SDK, then you must contact support to regain access to your tenancy.

**Caution:**
Before you set up a network source restriction, ensure that you have an API key set up to enable access to your tenancy in case an allowed network is not available. If you do not set up an API key and an allowed network is not available, then all users will be locked out of the tenancy until you contact Oracle Support. For information about setting up the API signing key, see Required Keys and OCIDs on page 4179.

**When Do Changes to Network Source Restrictions Take Effect**

After a network source restriction is defined, users signed in to the Console can continue with their current session, but after they sign out, the network restriction will be applied the next time they try to sign in.

**Using the Console to Manage Network Source Restrictions**

**To set up a network source restriction**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Authentication Settings. The authentication settings for your tenancy are displayed.
2. Click Edit.
3. From the Select Network Source menu, select the network source that specifies the IP range restrictions you want to apply to all Console sign-ins.
4. Click Save Changes.

**To view or edit the value of a network source**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Authentication Settings. The authentication settings for your tenancy are displayed.
2. Click the name of the network source displayed for Network Source Restrictions.

   The details page of the network source is displayed. From here, you can edit or delete the definition. See Managing Network Sources on page 2427 for information on managing network sources.

**Using the API to Work with Authentication Settings**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage authentication settings:

- GetAuthenticationPolicy
- UpdateAuthenticationPolicy

**Managing Multi-Factor Authentication**

This topic describes how users can manage multi-factor authentication (MFA) in Oracle Cloud Infrastructure.

**Required IAM Policy**

Only the user can enable multi-factor authentication (MFA) for their own account. Users can also disable MFA for their own accounts. Members of the Administrators group can disable MFA for other users, but they cannot enable MFA for another user.
About Multi-Factor Authentication

Multi-factor authentication is a method of authentication that requires the use of more than one factor to verify a user’s identity.

With MFA enabled in the IAM service, when a user signs in to Oracle Cloud Infrastructure, they are prompted for their user name and password, which is the first factor (something that they know). The user is then prompted to provide a second verification code from a registered MFA device, which is the second factor (something that they have). The two factors work together, requiring an extra layer of security to verify the user’s identity and complete the sign-in process.

In general, MFA may include any two of the following:

- Something that you know, like a password.
- Something that you have, like a device.
- Something that you are, like your fingerprint.

The IAM service supports two-factor authentication using a password (first factor) and a device that can generate a time-based one-time password (TOTP) (second factor).

General Concepts

Here's a list of the basic concepts you need to be familiar with.

MULTI-FACTOR AUTHENTICATION (MFA)

Multi-factor authentication (MFA) is a method of authentication that requires the use of more than one factor to verify a user’s identity. Examples of authentication factors are a password (something you know) and a device (something you have).

AUTHENTICATOR APP

An app you install on your mobile device that can provide software-based secure tokens for identity verification. Examples of authenticator apps are Oracle Mobile Authenticator and Google Authenticator. To enable MFA for the IAM service, you'll need a device with an authenticator app installed. You'll use the app to register your device and then you'll use the same app (on the same device) to generate a time-based one-time passcode every time you sign in.

REGISTERED MOBILE DEVICE

Multi-factor authentication is enabled for a specific user and for a specific device. The procedure to enable MFA for a user includes the registration of the mobile device. This same device must be used to generate the time-based one-time passcode every time the user signs in. If the registered mobile device becomes unavailable, an administrator must disable MFA for the user so that MFA can be re-enabled with a new device.

TIME-BASED ONE-TIME PASSWORD (TOTP)

A TOTP is a password (or passcode) that is generated by an algorithm that computes a one-time password from a shared secret key and the current time, as defined in RFC 6238. The authenticator app on your registered mobile device generates the TOTP that you need to enter every time you sign in to Oracle Cloud Infrastructure.

Supported Authenticator Apps

The following authenticator apps have been tested with the Oracle Cloud Infrastructure IAM service:

- Oracle Mobile Authenticator
- Google Authenticator

You can find these apps in your mobile device's app store. You must install one of these apps on your mobile device before you can enable MFA.
Working with MFA

Keep the following in mind when you enable MFA:

• You must install a supported authenticator app on the mobile device you intend to register for MFA.
• Each user must enable MFA for themselves using a device they will have access to every time they sign in. An administrator cannot enable MFA for another user.
• To enable MFA, you use your mobile device’s authenticator app to scan a QR code that is generated by the IAM service and displayed in the Console. The QR code shares a secret key with the app to enable the app to generate TOTPs that can be verified by the IAM service.
• A user can register only one device to use for MFA.
• After you add your Oracle Cloud Infrastructure account to your authenticator app, the account name displays in the authenticator app as Oracle <tenancy_name> - <username>.

Restricting Access to Only MFA-Verified Users

You can restrict access to resources to only users that have been authenticated through the IAM service’s time-based one-time password authentication. You set up this restriction in the policy that allows access to the resource.

To restrict the access granted through a policy to only MFA-verified users, add the following where clause to the policy:

```plaintext
where request.user.mfaTotpVerified='true'
```

For example, assume your company has this policy in place to allow GroupA to manage instances:

```plaintext
allow group GroupA to manage instance-family in tenancy
```

To enhance security, you want to ensure that only users who have been verified through MFA can manage instances. To restrict access to only these users, revise the policy statement as follows:

```plaintext
allow group GroupA to manage instance-family in tenancy where request.user.mfaTotpVerified='true'
```

With this policy in place, only the members of GroupA who have successfully signed in by entering both their password and the time-based one-time passcode generated by their registered mobile device, are allowed to access and manage instances. Users who have not enabled MFA and sign in using only their password, will not be allowed access to manage instances.

For information on writing policies, see Policy Syntax on page 2164.

Sign in Process After Enabling MFA

After you have enabled MFA, use one of the following procedures to sign in to Oracle Cloud Infrastructure:

To sign in using the Console

1. Navigate to the Console sign-in page.
2. Enter your Oracle Cloud Infrastructure **User Name** and **Password** and then click **Sign In**.

After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.

![Multi-Factor Authentication](image)

3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.

![Authenticator App Screenshot](image)

4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click **Sign In**.

**Important:** The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

**To sign in using the command line interface (CLI)**

1. To sign in with the CLI, run the following command:

   ```sh
ci session authenticate --region US East (Ashburn)
   ```

   A browser window opens, and a prompt instructs you to use the browser to sign in.

   ```
   Please switch to newly opened browser window to log in!
   ```
2. In the browser window, enter your Oracle Cloud Infrastructure **User Name** and **Password** and then click **Sign In**.

After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.

![Multi-Factor Authentication](image)

3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.

![Authenticator App Example](image)

4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click **Sign In**.

**Important:** The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

After you authenticate, prompts instruct you to return to the CLI and enter the name of a profile.

5. In the CLI, type a name for the profile.

**Tip:**

For more information about working with the CLI, see **Quickstart** on page 4195 and **Getting Started with the Command Line Interface** on page 83.
IAM

What To Do If You Lose Your Registered Mobile Device
If you lose your registered mobile device, you will not be able to authenticate to Oracle Cloud Infrastructure through the Console. Contact your administrator to disable multi-factor authentication for your account. You can then repeat the process to enable multi-factor authentication with a new mobile device.

Unblocking a User After Unsuccessful Sign-in Attempts
If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further sign-in attempts. An administrator can unblock the user in the Console (see To unblock a user on page 2418) or with the UpdateUserState API operation.

Disabling MFA
Each user can disable MFA for themselves. An administrator can also disable MFA for another user.

Caution:
Do not disable MFA unless you are instructed to by your administrator.

Using the Console
Use the following procedures to manage MFA in the Console.

To enable MFA for your user account
Prerequisite: You must install a supported authenticator app on the mobile device you intend to register for MFA.

1. In the upper-right corner of the Console, open the Profile menu and then select User Settings. Your user details are displayed.
2. Click Enable Multi-Factor Authentication.
3. Scan the QR code displayed in the dialog with your mobile device’s authenticator app.
   Note: If you close the browser, or if the browser crashes before you can enter the verification code, you must generate a new QR code and scan it again with your app. To generate a new QR code, click the Enable Multi-Factor Authentication button again.
4. In the Verification Code field, enter the code displayed on your authenticator app.
5. Click Enable.

Your mobile device is now registered with the IAM service and your account is enabled for MFA. Every time you sign in, you are prompted for your username and password first. After you provide the correct credentials, you will be prompted for a TOTP code generated by the authenticator app on your registered mobile device. You must have your registered mobile device available every time you sign in to Oracle Cloud Infrastructure.

To disable MFA for your user account

1. In the upper-right corner of the Console, open the Profile menu and then select User Settings. Your user details are displayed.
2. Click Disable Multi-Factor Authentication.
3. Confirm when prompted.

To disable MFA for another user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Click Disable Multi-Factor Authentication.
4. Confirm when prompted.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Note:

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions.

Use these API operations to manage multi-factor authentication devices:

- CreateMfaTotpDevice
- ListMfaTotpDevices
- GetMfaTotpDevice
- DeleteMfaTotpDevice
- ActivateMfaTotpDevice
- GenerateTotpSeed

Policies for Managing Resources Used with Resource Manager

This section provides example policies for managing the resources used with the Resource Manager service: stacks, jobs, private templates, and configuration source providers. For guidance using the syntax for creating policies, see Policy Syntax on page 2164.

Important:

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies on page 2142.

Stacks and jobs

The following example grants a specified group permission to manage both stacks and jobs in the tenancy, and also to manage Oracle Cloud Infrastructure resources on the tenancy stacks.

Allow group <group_name> to manage orm-stacks in tenancy
Allow group <group_name> to manage orm-jobs in tenancy

In addition to granting users permission to act on resources, you can also explicitly prevent users from running destroy jobs. The following policy modifies the policy we just created so that it prohibits members of the specified group from running destroy jobs.

Allow group <group_name> to use orm-stacks in tenancy
Allow group <group_name> to read orm-jobs in tenancy
Allow group <group_name> to manage orm-jobs in tenancy where any
{target.job.operation = 'PLAN', target.job.operation = 'APPLY'}

In this policy statement, you must include the new permission to read orm-jobs because the third statement includes a condition that uses variables that are not relevant to listing or getting jobs.
For more details about stack permissions, see `orm-stacks` on page 2338. For more details about job permissions, see `orm-jobs` on page 2338.

**Private templates**

The following example grants a specified group permission to create, update, move, and delete private templates in the tenancy.

```
Allow group <group_name> to manage orm-template in tenancy
```

The following example grants a specified group permission to create stacks from private templates, in addition to managing stacks and jobs.

```
Allow group <group_name> to manage orm-stacks in tenancy
Allow group <group_name> to manage orm-jobs in tenancy
Allow group <group_name> to read orm-templates in tenancy
```

For more details about private template permissions, see `orm-template` on page 2339.

**Configuration source providers**

The following example grants a specified group permission to create, update, move, and delete configuration source providers in the tenancy.

```
Allow group <group_name> to manage orm-config-source-providers in tenancy
```

The following example grants a specified group permission to create stacks from configuration files in source code control systems (using existing configuration source providers), in addition to managing stacks and jobs.

```
Allow group <group_name> to read orm-config-source-providers in tenancy
Allow group <group_name> to manage orm-stacks in tenancy
Allow group <group_name> to manage orm-jobs in tenancy
```

For more details about configuration source provider permissions, see `orm-config-source-providers` on page 2337.

**Deprecated IAM Service APIs**

This topic lists deprecated APIs for the IAM service.

**Federation Management APIs**

Date of Notification: October 15, 2020

**What is changing?**

The following APIs for the management of federations are deprecated. Support for these APIs will end **October 15, 2021**. The replacement solution for managing federations is to set up the federation for your tenancy between the identity provider and your tenancy’s Oracle Identity Cloud Service identity domain. See `Manage Oracle Identity Cloud Service Identity Providers` for information on managing identity providers in IDCS.

Load Balancing

This chapter explains how to set up a load balancer.

Overview of Load Balancing

The Oracle Cloud Infrastructure Load Balancing service provides automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). The service offers a load balancer with your choice of a public or private IP address, and provisioned bandwidth.

A load balancer improves resource utilization, facilitates scaling, and helps ensure high availability. You can configure multiple load balancing policies and application-specific health checks to ensure that the load balancer directs traffic only to healthy instances. The load balancer can reduce your maintenance window by draining traffic from an unhealthy application server before you remove it from service for maintenance.

How Load Balancing Works

The Load Balancing service enables you to create a public or private load balancer within your VCN. A public load balancer has a public IP address that is accessible from the internet. A private load balancer has an IP address from the hosting subnet, which is visible only within your VCN. You can configure multiple listeners for an IP address to load balance transport Layer 4 and Layer 7 (TCP and HTTP) traffic. Both public and private load balancers can route data traffic to any backend server that is reachable from the VCN.

Public Load Balancer

To accept traffic from the internet, you create a public load balancer. The service assigns it a public IP address that serves as the entry point for incoming traffic. You can associate the public IP address with a friendly DNS name through any DNS vendor.

A public load balancer is regional in scope. If your region includes multiple availability domains, a public load balancer requires either a regional subnet (recommended) or two availability domain-specific (AD-specific) subnets, each in a separate availability domain. With a regional subnet, the Load Balancing service creates a primary load balancer and a standby load balancer, each in a different availability domain, to ensure accessibility even during an availability domain outage. If you create a load balancer in two AD-specific subnets, one subnet hosts the primary load balancer and the other hosts a standby load balancer. If the primary load balancer fails, the public IP address switches to the secondary load balancer. The service treats the two load balancers as equivalent and you cannot specify which one is "primary".

Whether you use regional or AD-specific subnets, each load balancer requires one private IP address from its host subnet. The Load Balancing service supplies a floating public IP address to the primary load balancer. The floating public IP address does not come from your backend subnets.

If your region includes only one availability domain, the service requires just one subnet, either regional or AD-specific, to host both the primary and standby load balancers. The primary and standby load balancers each require
a private IP address from the host subnet, in addition to the assigned floating public IP address. If there is an availability domain outage, the load balancer has no failover.

| Caution: |
| You cannot specify a private subnet for your public load balancer. |

**Private Load Balancer**

To isolate your load balancer from the internet and simplify your security posture, you can create a private load balancer. The Load Balancing service assigns it a private IP address that serves as the entry point for incoming traffic.

When you create a private load balancer, the service requires only one subnet to host both the primary and standby load balancers. The load balancer can be regional or AD-specific, depending on the scope of the host subnet. The load balancer is accessible only from within the VCN that contains the host subnet, or as further restricted by your security rules.

The assigned floating private IP address is local to the host subnet. The primary and standby load balancers each require an extra private IP address from the host subnet.

If there is an availability domain outage, a private load balancer created in a regional subnet within a multi-AD region provides failover capability. A private load balancer created in an AD-specific subnet, or in a regional subnet within a single availability domain region, has no failover capability in response to an availability domain outage.

**All Load Balancers**

Your load balancer has a backend set to route incoming traffic to your Compute instances. The backend set is a logical entity that includes:

- A list of backend servers.
- A load balancing policy.
- A health check policy.
- Optional SSL handling.
- Optional session persistence configuration.

The backend servers (Compute instances) associated with a backend set can exist anywhere, as long as the associated network security groups (NSGs), security lists, and route tables allow the intended traffic flow.

If your VCN uses network security groups (NSGs), you can associate your load balancer with an NSG. An NSG has a set of security rules that controls allowed types of inbound and outbound traffic. The rules apply only to the resources in the group. Contrast NSGs with a security list, where the rules apply to all the resources in any subnet that uses the list. For more information about NSGs, see **Network Security Groups** on page 2841.

If you prefer to use security lists for your VCN, the Load Balancing service can suggest appropriate security list rules. You also can configure them yourself through the Networking service. See **Security Lists** on page 2850 for more information.

See **Security Rules** on page 2833 for detailed information comparing NSGs and security lists.

Oracle recommends that you create your load balancer in a regional subnet.

Oracle recommends that you distribute your backend servers across all availability domains within the region.

To create a minimal system with a functioning load balancer, you must:

- For a public load balancer, create a VCN with an internet gateway and a public regional subnet.

  | Caution: |
  | You cannot specify a private subnet for your public load balancer. |

  - For a private load balancer, create a VCN with at least one private subnet.
  - Create at least two Compute instances, each in a separate availability domain.
  - Create a load balancer.
- Create a backend set with a health check policy.
- Add backend servers (Compute instances) to the backend set.
- Create a listener, with optional SSL handling.
- Update the load balancer subnet security rules so they allow the intended traffic.

**Note:**

Private IP Address Consumption

A public load balancer created in one public subnet consumes two private IP addresses from the host subnet.

A public load balancer created in two public subnets consumes two private IP addresses, one from each host subnet.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet.

The following diagram provides a high-level view of a simple public load balancing system configuration. Far more sophisticated and complex configurations are common.
Load Balancing Concepts

The following concepts are essential to working with Load Balancing.

**BACKEND SERVER**

An application server responsible for generating content in reply to the incoming TCP or HTTP traffic. You typically identify application servers with a unique combination of overlay (private) IPv4 address and port, for example, 10.10.10.1:8080 and 10.10.10.2:8080.

For more information, see Managing Backend Servers on page 2515.

**BACKEND SET**

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy. SSL configuration is optional. The backend set determines how the load balancer directs traffic to the collection of backend servers.

For more information, see Managing Backend Sets on page 2510.

**CERTIFICATES**

If you use HTTPS or SSL for your listener, you must associate an SSL server certificate (X.509) with your load balancer. A certificate enables the load balancer to terminate the connection and decrypt incoming requests before passing them to the backend servers.

For more information, see Managing SSL Certificates on page 2551.

**health check**

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

For more information on health check configuration, see Editing Health Check Policies on page 2558.

**HEALTH STATUS**

An indicator that reports the general health of your load balancers and their components.

For more information, see the Health Status section of Editing Health Check Policies.

**LISTENER**

A logical entity that checks for incoming traffic on the load balancer's IP address. You configure a listener's protocol and port number, and the optional SSL settings. To handle TCP, HTTP, and HTTPS traffic, you must configure multiple listeners.

Supported protocols include:

- TCP
- HTTP/1.0
- HTTP/1.1

For more information, see Managing Listeners on page 2522.
LOAD BALANCING POLICY

A load balancing policy tells the load balancer how to distribute incoming traffic to the backend servers. Common load balancer policies include:

- Round robin
- Least connections
- IP hash

For more information, see How Load Balancing Policies Work on page 2488.

PATH ROUTE SET

A set of path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.

For more information, see Managing Request Routing on page 2534.

REGIONS AND availability domains

The Load Balancing service manages application traffic across availability domains within a region. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of several availability domains.

For more information, see Regions and Availability Domains on page 180.

SESSION PERSISTENCE

A method to direct all requests originating from a single logical client to a single backend web server.

For more information, see Session Persistence on page 2491.

shape

A template that determines the load balancer's total pre-provisioned maximum capacity (bandwidth) for ingress plus egress traffic. Available shapes include 10Mbps, 100 Mbps, 400 Mbps, and 8000 Mbps.

The 10Mbps shape is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

Tip:

Pre-provisioned maximum capacity applies to aggregated connections, not to a single client attempting to use the full bandwidth.

SSL

Secure Sockets Layer (SSL) is a security technology for establishing an encrypted link between a client and a server. You can apply the following SSL configurations to your load balancer:

SSL TERMINATION

The load balancer handles incoming SSL traffic and passes the unencrypted request to a backend server.

END TO END SSL

The load balancer terminates the SSL connection with an incoming traffic client, and then initiates an SSL connection to a backend server.

SSL TUNNELING

If you configure the load balancer's listener for TCP traffic, the load balancer tunnels incoming SSL connections to your application servers.

Load Balancing supports the TLS 1.2 protocol with a default setting of strong cipher strength. The default supported ciphers include:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
Load Balancing

- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

For more information, see Managing SSL Certificates on page 2551.

subnet

A subdivision you define in a VCN, such as 10.0.0.0/24 and 10.0.1.0/24. A subnet can span a region or exist within a single availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing and security rules that apply to it.

For more information on subnets, see VCNs and Subnets on page 2821 and Public IP Address Ranges on page 2754.

TAGS

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

VIRTUAL HOSTNAME

A virtual server name applied to a listener to enhance request routing.

For more information, see Managing Request Routing on page 2534.

VIRTUAL CLOUD NETWORK (VCN)

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice in the allowed IP address ranges.

You need at least one virtual cloud network before you launch a load balancer.

For information about setting up virtual cloud networks, see Networking Overview on page 2748.

VISIBILITY

Specifies whether your load balancer is public or private.

PUBLIC

A public load balancer has a public IP address that clients can access from the internet.

PRIVATE

A private load balancer has a private IP address from a VCN local subnet. Clients can access the private load balancer using methods and technology that can provide access to a private IP, such as:

- Cross-VCN (via LPG peering)
- From another region (via RPC)
- From on-prem (via FC private peering)
Load Balancing

For more information, see Managing Load Balancers on page 2494.

WORK REQUEST

An object that reports on the current state of a Load Balancing request.
The Load Balancing service handles requests asynchronously. Each request returns a work request ID (OCID) as the response. You can view the work request item to see the status of the request.
For more information, see Viewing the State of a Work Request on page 2565.

Troubleshooting an HTTP 502 Bad Gateway

Apart from proactive monitoring and management, load balancing logging will help you to identify, isolate, and troubleshoot issues with your load balancer infrastructure. In this example scenario, you are deploying a new web application, ociexample.com, with an Oracle Cloud Infrastructure public load balancer as the front end in your development environment. However, when you try to access the application, you see an HTTP 502 response on the browser. Use the following procedure to help you troubleshoot the issue by using LBaaS Access and Error Logs.

1. When you browse to a load-balanced IP address, you see 502 Bad Gateway error.
2. You can confirm this behavior by running a curl test:

   ```
curl -v http://ociexample.com
   > GET / HTTP/1.1
   > Host: 129.146.93.99
   > User-Agent: curl/7.54.0
   > Accept: */*
   >
   < HTTP/1.1 502 Bad Gateway
   < Content-Type: text/html
   < Content-Length: 161
   < Connection: keep-alive
   
   3. Use the OCI Logging Service Load Balancer Logs and check for lbStatusCode: "502".
   4. Check for

   ```

   ```
   backendStatusCode
   ```

   You will then correlate this status code with one of the following scenarios below.

502 from Backend

Possible causes

- Backend application is returning a 502
- Issue is misconfigured backend
- Backend is likely another reverse proxy or LB

504 from Backend

Possible resolutions

- Examine upstream proxy logs to determine why it is returning 502
- Resolve any issues on the ultimate backend that is causing the upstream proxy to return a 502

Possible causes

- When receiving a 504 from the Backend it typically means that the backend is another proxy or LBaaS instance. This code is typically returned when a proxy is unable to connect to an upstream server in a specified time.
- It is recommended to examine the logs of the upstream system and see what is causing that upstream proxy from connection to its backend.
Possible resolutions

- Increase the connection timeout.
- Determine why backend is taking longer time to respond than usual using a utility such as tcpdump, and built-in application tools.

**500 from Backend**

Possible causes

- Receiving a 500 from the backend is typically indicative of a server side error, commonly known as an "Internal Server Error". This typically is a result of the backend application.

Possible resolutions

- Resolve application level issue that is causing
- Common causes, inability to connect to upstream resources such as databases, APIs, services, etc.

**No Status Code from the Backend**

- You typically see no backend status code accompanied by a 502 lbStatusCode, when no Backend is available to send the connections.
- You will also notice "No healthy backends available in associated backendSet" in the OCI Logging Load Balancer Error Logs.
- It is recommended to ensure the backends are healthy, if they are healthy you will need to confirm that your health check is properly configured.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring the traffic passing through your load balancer, see Load Balancing Metrics on page 2567.
Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Load Balancing Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

• You cannot convert an AD-specific load balancer to a regional load balancer or the reverse.
• The Load Balancing services supports IPv6 addresses for load balancers in the US Government Cloud only. IPv6 support is only for the load balancer itself, and not the backend.
• The maximum number of concurrent connections is limited when you use stateful security rules for your load balancer subnets. In contrast, there is no theoretical limit on concurrent connections if you use stateless security rules. The practical limitations depend on various factors. The larger your load balancer shape, the greater the connection capacity. Other considerations include system memory, TCP timeout periods, TCP connection state, and so forth.

Tip:
To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

• Each load balancer has the following configuration limits:
  • One IP address
  • 16 backend sets
  • 512 backend servers per backend set
  • 1024 backend servers total
  • 16 listeners

How Load Balancing Policies Work

After you create a load balancer, you can apply policies to control traffic distribution to your backend servers. The Load Balancing service supports three primary policy types:

• Round Robin
• Least Connections
• IP Hash

When processing load or capacity varies among backend servers, you can refine each of these policy types with backend server weighting. Weighting affects the proportion of requests directed to each server. For example, a server weighted ‘3’ receives three times the number of connections as a server weighted ‘1’. You assign weights based on criteria of your choosing, such as each server’s traffic-handling capacity.

Load balancer policy decisions apply differently to TCP load balancers, cookie-based session persistent HTTP requests (sticky requests), and non-sticky HTTP requests.

• A TCP load balancer considers policy and weight criteria to direct an initial incoming request to a backend server. All subsequent packets on this connection go to the same endpoint.
• An HTTP load balancer configured to handle cookie-based session persistence forwards requests to the backend server specified by the cookie’s session information.
• For non-sticky HTTP requests, the load balancer applies policy and weight criteria to every incoming request and determines an appropriate backend server. Multiple requests from the same client could be directed to different servers.

**Round Robin**

Round Robin is the default load balancer policy. This policy distributes incoming traffic sequentially to each server in a backend set list. After each server has received a connection, the load balancer repeats the list in the same order.

Round Robin is a simple load balancing algorithm. It works best when all the backend servers have similar capacity and the processing load required by each request does not vary significantly.

**Least Connections**

The Least Connections policy routes incoming non-sticky request traffic to the backend server with the fewest active connections. This policy helps you maintain an equal distribution of active connections with backend servers. As with the round robin policy, you can assign a weight to each backend server and further control traffic distribution.

**Tip:**

In TCP use cases, a connection can be active but have no current traffic. Such connections do not serve as a good load metric.

**IP Hash**

The IP Hash policy uses an incoming request's source IP address as a hashing key to route non-sticky traffic to the same backend server. The load balancer routes requests from the same client to the same backend server as long as that server is available. This policy honors server weight settings when establishing the initial connection.

IP Hash ensures that requests from a particular client are always directed to the same backend server, as long as it is available.

You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

**Caution:**

Multiple clients that connect to the load balancer through a proxy or NAT router appear to have the same IP address. If you apply the IP Hash policy to your backend set, the load balancer routes traffic based on the incoming IP address and sends these proxied client requests to the same backend server. If the proxied client pool is large, the requests could flood a backend server.

**Connection Management**

Oracle Cloud Infrastructure load balancers support connection multiplexing. The load balancer can route many incoming requests from multiple clients to the destination backend server through a few (one or multiple) backend connections.

After your load balancer connects a client to a backend server, the connection can be closed due to inactivity. Also, you can configure load balancer listeners to control the maximum idle time allowed during each TCP connection or HTTP request and response pair. Oracle recommends that you do not allow your backend servers to close connections to the load balancer.

**Highlights**

Three different timeout settings affect your load balancer's behavior:

• **Keep-alive setting between the load balancer and backend server**

  The load balancer closes backend server connections that are idle for more than 300 seconds.
• **Keep-alive setting between the load balancer and the client**
  
  The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first. You cannot change the value of this setting.

• **Idle timeout**
  
  You can set the duration of the idle timeout when you create a listener. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

---

**Keep-Alive Settings**

The load balancing service does not honor keep-alive settings from backend servers. The load balancer closes backend server connections that are idle for more than 300 seconds. Oracle recommends that you do not allow your backend servers to close connections to the load balancer. To prevent possible 502 errors, ensure that your backend servers do not close idle connections in less than 310 seconds.

The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first. You cannot change the value of this setting.

---

**Connection Configuration**

When you create a TCP or HTTP listener, you can specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase. If the configured timeout has elapsed with no packets sent or received, the client's connection is closed. For HTTP and WebSocket connections, a send operation does not reset the timer for receive operations and a receive operation does not reset the timer for send operations.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>This timeout setting does not apply to idle time between a completed response and a subsequent HTTP request.</td>
</tr>
</tbody>
</table>

The default timeout values are:

• 300 seconds for TCP listeners.
• 60 seconds for HTTP listeners.

Modify the timeout parameter if either the client or the backend server requires more time to transmit data. Some examples include:

• The client sends a database query to the backend server and the database takes over 300 seconds to execute. Therefore, the backend server does not transmit any data within 300 seconds.
• The client uploads data using the HTTP protocol. During the upload, the backend does not transmit any data to the client for more than 60 seconds.
• The client downloads data using the HTTP protocol. After the initial request, it stops transmitting data to the backend server for more than 60 seconds.
• The client starts transmitting data after establishing a WebSocket connection, but the backend server does not transmit data for more than 60 seconds.
• The backend server starts transmitting data after establishing a WebSocket connection, but the client does not transmit data for more than 60 seconds.

The maximum timeout value is 7200 seconds. Contact My Oracle Support to file a service request if you want to increase this limit for your tenancy. For more information, see Service Limits on page 215.

**HTTP "X-" Headers**

HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with X-., are common. The Load Balancing service adds or modifies the following X- headers when it passes requests to your servers.
**X-Forwarded-For**

Provides a list of connection IP addresses.

The load balancer appends the last remote peer address to the X-Forwarded-For field from the incoming request. A comma and space precede the appended address. If the client request header does not include an X-Forwarded-For field, this value is equal to the X-Real-IP value. The original requesting client is the first (left-most) IP address in the list, assuming that the incoming field content is trustworthy. The last address is the last (most recent) peer, that is, the machine from which the load balancer received the request. The format is:

```
X-Forwarded-For: <original_client>, <proxy1>, <proxy2>
```

Example incoming field:

```
X-Forwarded-For: 202.1.112.187
```

Example field with appended proxy IP address:

```
X-Forwarded-For: 202.1.112.187, 192.168.0.10
```

**X-Forwarded-Host**

Identifies the original host and port requested by the client in the **Host** HTTP request header. This header helps you determine the original host, since the hostname or port of the reverse proxy (load balancer) might differ from the original server handling the request.

```
X-Forwarded-Host: www.oracle.com:8080
```

**X-Forwarded-Port**

Identifies the listener port number that the client used to connect to the load balancer. For example:

```
X-Forwarded-Port: 443
```

**X-Forwarded-Proto**

Identifies the protocol that the client used to connect to the load balancer, either http or https. For example:

```
X-Forwarded-Proto: https
```

**X-Real-IP**

Identifies the client's IP address. For the Load Balancing service, the "client" is the last remote peer.

Your load balancer intercepts traffic between the client and your server. Your server's access logs, therefore, include only the load balancer's IP address. The X-Real-IP header provides the client's IP address. For example:

```
X-Real-IP: 192.168.0.10
```

**Session Persistence**

Session persistence is a method to direct all requests originating from a single logical client to a single backend web server. Backend servers that use caching to improve performance, or to enable log-in sessions or shopping carts, can benefit from session persistence.

You enable session persistence when you create a load balancer or when you create a backend set. You can also edit an existing backend set to enable, disable, or change the session persistence configuration.
Sticky Cookies

The Load Balancing service offers two mutually exclusive cookie-based configurations for enabling session persistence:

- Application cookie stickiness
- Load balancer cookie stickiness

**Note:**

**IP Address-driven Session Persistence**

Some products offer session persistence support without cookies. These products depend on the IP address of the incoming request. ISP proxies and company exit gateways can issue many requests from a single IP address. In this case, a single backend server can be subject to high traffic volumes. Your backend fleet can become overwhelmed, one server at a time, even though effective load balancing is possible.

Another weakness of IP address-driven session persistence is that the originating IP address can change. In this case, session persistence can be lost or the request redirected to the wrong backend server.

**Application Cookie Stickiness**

To configure application cookie session persistence, you specify a cookie name and decide whether to disable fallback for unavailable servers.

The Load Balancing service activates application cookie session persistence (stickiness) when a backend server sends a `Set-Cookie` response header containing a recognized cookie name. The cookie name must match the name specified in the backend set configuration. If the configuration specifies a match-all pattern, `*`, any cookie set by the server activates session persistence. Unless a backend server activates session persistence, the service follows the load balancing policy specified when you created the load balancer.

**Requirements:**

- Your load balancer must operate in HTTP mode to support server side, cookie-driven session persistence.
- The client computer must accept cookies for Load Balancing session persistence feature to work.

**How It Works**

The Load Balancing service calculates a hash of the configured cookie and other request parameters, and sends that value to the client in a cookie. The value stored in the cookie enables the service to route subsequent client requests to the correct backend server. If your backend servers change any of the defined cookies, the service recomputes the cookie's value and resends it to the client.

**Caution:**

Oracle recommends that you treat cookie data as an opaque entity. Do not use it in your applications.

The backend server can stop application cookie persistence by deleting the session persistence cookie. If you used the match-all pattern, it must delete all cookies. You can delete cookies by sending a `Set-Cookie` response header with a past expiration date. The Load Balancing service routes subsequent requests using the configured load balancing policy.

**Load Balancer Cookie Stickiness**

When you configure load balancer cookie stickiness, the load balancer inserts a cookie into the response. The parameters configured within the cookie enable session stickiness. This method is useful when you have applications and web backend services that cannot generate their own cookies.
To configure load balancer cookie session persistence, you specify:

- **The cookie name.**
  
  If you do not specify a cookie name, the default name is X-Oracle-BMC-LBS-Route.

  Ensure that the cookie name used at the backend application servers is different from the cookie name used at the load balancer. To minimize the chance of name collision, Oracle recommends that you use a prefix such as X-Oracle-OCI-.

  If a backend server and the load balancer both insert cookies with the same name, the client or browser behavior can vary depending on the domain value associated with the cookie. If the name and domain values of the Set-cookie header generated by a backend server and the Set-cookie header generated by the load balancer are the same, the client or browser treats them as one cookie. The client returns only one of the cookie values in subsequent requests. If both Set-cookie names are the same, but the domain names are different, the client or browser treats them as two different cookies.

  **Note:**

  - RFC 6265 - HTTP State Management Mechanism describes client and browser behavior when the domain attribute is present or not present in the Set-cookie header.

  If the value of the Domain attribute is example.com in the Set-cookie header, the client includes the same cookie in the Cookie header when making HTTP requests to example.com, www.example.com, and www.abc.example.com. If the Domain attribute is not present, the client returns the cookie only for the domain to which the original request was made.

  - Ensure that this attribute specifies the correct domain value. If the Domain attribute in the Set-cookie header does not include the domain to which the original request was made, the client or browser might reject the cookie. As specified in RFC 6265, the client accepts a cookie with the Domain attribute value example.com or www.example.com sent from www.example.com. It does not accept a cookie with the Domain attribute abc.example.com or www.abc.example.com sent from www.example.com.

- **The domain in which the cookie is valid.** The Set-cookie header inserted by the load balancer contains a domain attribute with the specified value.

  This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.

- **The URI path in which the cookie is valid.** The Set-cookie header inserted by the load balancer contains a Path attribute with the specified value.

  Clients include the cookie in an HTTP request only if the path portion of the request-uri matches, or is a subdirectory of, the cookie's Path attribute.

  The default value is `/`.
Load Balancing

- **The amount of time the cookie remains valid.** The `Set-cookie` header inserted by the load balancer contains a `Max-Age` attribute with the specified value.

  The specified value must be at least one second. There is no default value for this attribute. If you do not specify a value, the load balancer does not include the `Max-Age` attribute in the `Set-cookie` header. Usually, the client or browser retains the cookie until the current session ends, as defined by the client.

- **Whether the `Set-cookie` header should contain the `Secure` attribute.** The `Secure` attribute directs the client or browser to send the cookie only using a secure protocol.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you set this field to true, you cannot associate the corresponding backend set with an HTTP listener.</td>
</tr>
</tbody>
</table>

- **Whether the `Set-cookie` header should contain the `HttpOnly` attribute.** The `HttpOnly` attribute limits the scope of the cookie to HTTP requests. This attribute directs the client or browser to omit the cookie when providing access to cookies through non-HTTP APIs. For example, it restricts the cookie from JavaScript channels.

- **Whether to disable fallback for unavailable servers.**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path route rules take precedence to determine the target backend server. The load balancer verifies that session stickiness is enabled for the backend server and that the cookie configuration is valid for the target. The system ignores invalid cookies.</td>
</tr>
</tbody>
</table>

**Fallback**

By default, the Load Balancing service directs traffic from a persistent session client to a different backend server when the original server is unavailable. You can configure the backend set to disable this fallback behavior. When you disable fallback, the load balancer fails the request and returns an HTTP 502 code. The service continues to return an HTTP 502 until the client no longer presents a persistent session cookie.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If fallback is disabled, cookies with a distant future expiration date can cause a client outage.</td>
</tr>
</tbody>
</table>

The Load Balancing service considers a server marked drain available for existing persisted sessions. New requests that are not part of an existing persisted session are not sent to that server.

**Managing Load Balancers**

This topic describes how to create or delete a load balancer on your system.

**Prerequisites**

To implement a working load balancer, you need:

- For a public load balancer in a region with multiple `availability domains`, you need a VCN with a public regional subnet or at least two public AD-specific subnets. In the latter case, each AD-specific subnet must reside in a separate availability domain. For more information on subnets, See VCNs and Subnets on page 2821 and Public IP Address Ranges on page 2754.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot specify a private subnet for your public load balancer.</td>
</tr>
</tbody>
</table>

- For a public load balancer in a region with only one availability domain, you need a VCN with at least one public subnet.

- For a private load balancer in any region, you need a VCN with at least one private subnet.
Load Balancing

- Two or more backend servers (Compute instances) running your applications. For more information on Compute instances, see Creating an Instance on page 695.

**Note:**

Private IP Address Consumption

A public load balancer created in one public regional subnet consumes two private IP addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IP address from that subnet. The Load Balancing service assigns a floating public IP address, which does not come from the host subnet.

A public load balancer created in two public AD-specific subnets consumes two private IP addresses, one from each host subnet. The primary and secondary load balancers reside within different subnets. Each load balancer requires one private IP address from its host subnet. The Load Balancing service assigns a floating public IP address, which does not come from the host subnets.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IP address from that subnet. The floating private IP address also comes from the host subnet.

**Working with Load Balancers**

For background information on Oracle Cloud Infrastructure Load Balancing, see Overview of Load Balancing on page 2480.

For the purposes of access control, you must specify the compartment where you want the load balancer to reside. Consult an administrator in your organization if you're not sure which compartment to use. For information about compartments and access control, see Managing Compartments on page 2431.

When you create a load balancer within your VCN, you get a public or private IP address, and provisioned total bandwidth. If you need another IP address, you can create another load balancer.

A public load balancer in a region with multiple availability domains requires one public regional subnet or two public AD-specific subnets to host the primary load balancer and a standby. In the latter case, each AD-specific subnet must reside in a separate availability domain. A public load balancer in a region with only one availability domain requires a single public subnet to host the primary load balancer and a standby. For more information on VCNs and subnets, see Networking Overview on page 2748. You can associate the public IPv4 address with a DNS name from any vendor. You can use the public IP address as a front end for incoming traffic. The load balancer can route data traffic to any backend server that is reachable from the VCN.

A private load balancer requires only one subnet to host the primary load balancer and a standby. The private IP address is local to the subnet. The load balancer is accessible only from within the VCN that contains the associated subnet, or as further restricted by your security list rules. The load balancer can route data traffic to any backend server that is reachable from the VCN.

The essential components for load balancing include:

- A load balancer with pre-provisioned bandwidth.
- A **backend set** with a health check policy. See Managing Backend Sets on page 2510.
- Backend servers for your backend set. See Managing Backend Servers on page 2515.
Load Balancing

- One or more listeners. See Managing Listeners on page 2522.
- Load balancer subnet security rules to allow the intended traffic. To learn more about these rules, see Security Rules on page 2833.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.</td>
</tr>
</tbody>
</table>

Optionally, you can associate your listeners with SSL server certificate bundles to manage how your system handles SSL traffic. See Managing SSL Certificates on page 2551.

For information about the number of load balancers you can have, see Service Limits on page 215.

Configuration Changes and Service Disruption

For a running load balancer, some configuration changes lead to service disruptions. The following guidelines help you understand the effect of changes to your load balancer.

- Operations that add, remove, or modify a backend server create no disruptions to the Load Balancing service.
- Operations that edit an existing health check policy create no disruptions to the Load Balancing service.
- Operations that trigger a load balancer reconfiguration can produce a brief service disruption with the possibility of some terminated connections.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console List and Details pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.

Load Balancer Health Summary

The Console list of load balancers provides health status summaries that indicate the overall health of each load balancer. Health status indicators have four levels. The meaning of each level is:

The Console list of load balancers provides health status summaries that indicate the overall health of each load balancer. Health status indicators come in four levels. The meaning of each level is:

- **OK:** All backend sets associated with the load balancer return a status of OK.
- **WARNING:** All the following conditions are true:
  - At least one backend set associated with the load balancer returns a status of WARNING or UNKNOWN.
  - No backend sets return a status of CRITICAL.
  - The load balancer life-cycle state is ACTIVE.
- **CRITICAL:** At least one backend set associated with the load balancer returns a status of CRITICAL.
- **UNKNOWN:** Any one of the following conditions is true:
  - The load balancer life-cycle state is not ACTIVE.
  - No backend sets are defined for the load balancer.
  - All the following conditions are true:
    - More than half of the backend sets associated with the load balancer return a status of UNKNOWN.
    - None of the backend sets return a status of WARNING or CRITICAL.
    - The load balancer life-cycle state is ACTIVE.
  - The system could not retrieve metrics for any reason.

For guidance on detecting and correcting common issues, see Health Status on page 2559.
Load Balancer Health Details

The load balancer Details page provides the same Overall Health status indicator found in the list of load balancers. It also includes counters for the Backend Set Health status values reported by the load balancer’s child backend sets.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Creating Load Balancers

To create a load balancer:

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose a Compartment you have permission to work in under Scope, and then click Create Load Balancer.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you select a different compartment in the Management tab under the Advanced Options, that compartment contains the load balancer you are creating instead of the compartment specified here.</td>
</tr>
</tbody>
</table>
3. Follow these workflows:

   **Step 1 - Add Details**

   Specify the attributes of the load balancer.

   - **Load Balancer Name:** Required. Accept the default name or specify a friendly name for the load balancer. It does not have to be unique, but it cannot be changed in the Console. (You can, however, change it with the API.) Avoid entering confidential information.

   - **Choose Visibility Type:** Specify whether your load balancer is public or private.
     - **Public:** Choose this option to create a public load balancer. You can use the assigned public IP address as a front end for incoming traffic and to balance that traffic across all backend servers.
     - **Private:** Choose this option to create a private load balancer. You can use the assigned private IP address as a front end for incoming internal VCN traffic and to balance that traffic across all backend servers.

   - **Choose IP Address Type:** Specify whether the public IP address is reserved or ephemeral.
     - **Ephemeral IP Address:** Choose this option to let Oracle specify an ephemeral IP address for you from the Oracle IP pool. This is the default.
     - **Reserved IP Address:** Choose this option to specify an existing reserved IP address by name, or to create a new reserved IP address by assigning a name and selecting a source IP pool for the address. If you don't select a pool you've created, the default Oracle IP pool is used.

   - **Bandwidth:** The Bandwidth shape options are the following:
     - **Flexible Shapes:** Specify Minimum Bandwidth and Maximum Bandwidth values to create an upper and lower size range for the load balancer's bandwidth shape. Possible sizes range from 10 Mbps to 8000 Mbps. You can use the slider to specify the value or enter it directly into the box to the left of each slider.

       The minimum bandwidth reflects the amount of bandwidth that is always available to provide instant readiness for the workloads.

       The maximum bandwidth is the upper amount of bandwidth the load balancer supports during time of peak workload.

       If you want to specify a fixed shape size, for example 500 Mbps, set the minimum and maximum sliders to the same value.

       If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created. You can view your service limits and quotas in the Console by navigating to Governance > Limits, Quotas and Usage. Select "LbaaS" from the Service list. Your bandwidth size options are listed. See Service Limits on page 215 for more information.

       Billing is per minute for your load balancer base instance, plus a bandwidth usage fee. If the actual usage is below or equal to your specified minimum bandwidth, you are billed for the minimum bandwidth. If actual usage exceeds the minimum bandwidth, you are billed for the actual bandwidth used for that minute.

       The Always Free option is incorporated into your paid account in your home region. The first 10 Mbps of your bandwidth is free, and is indicated as such on your bill.

       **Note:**

       Government accounts using pre-paid dynamic (fixed) shape sizes run the risk of overage charges if using flexible bandwidth shapes exceeds the predetermined size. Government accounts should be updated to the flexible load balancer SKU, with the appropriate bandwidth quantity, in their contract before using the flexible load balancer feature.
If you are using non-universal credit SKUs, ensure that your contract includes the shape you are updating to so you can prevent incurring overage charges.

- **Always Free**: If you are creating the load balancer as an Always Free user, you can only select the Always Free (10 Mbps) option. Switching away from Always Free prompts you to upgrade to a paid account. Always Free shape options are not available to Government accounts.

**Note:**

If you are creating a load balancer in an Always Free tenancy, the Always Free feature is enabled by default, and only Always Free shape options are available. Upgrading is the only way an Always Free tenancy can select a bandwidth shape option other than the default Always Free size. For more information about Always Free resources, including other capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

You can adjust the bandwidth shape to a different size after you have completed creating the load balancer. See Changing the Load Balancer Bandwidth on page 2508 for more information.

- **Enable IPv6 Address Assignment**: Available only in the US Government Cloud. Specify whether the load balancer supports IPv6 addresses for incoming requests.

**Note:**

- When you create a load balancer, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. There is no IPv6 communication between the load balancer and the backend servers.
- IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.
- **Only VCNs in the US Government Cloud currently support IPv6 addressing.** For more information about Oracle Cloud
Infrastructure's IPv6 implementation, see IPv6 Addresses on page 2889.

- **Choose Networking**

  If the current compartment contains at least one VCN, the Console provides a drop-down list of VCNs for you to choose from.

  - **Virtual Cloud Network in <compartment>:** Required. Specify a VCN for the load balancer.

    By default, the Console shows a list of VCNs in the compartment you’re currently working in. Click the Change Compartment link to select a VCN from a different compartment.

  - **Subnet in <compartment>:** Required. Select an available subnet. For a public load balancer, it must be a public subnet.

    By default, the Console shows a list of subnets in the compartment you’re currently working in. Click the Change Compartment link to select a subnet from a different compartment.

    **Tip:**

    In addition to public or private, subnets can be either regional or AD-specific. Oracle recommends using regional subnets. For more information, see Overview of VCNs and Subnets on page 2822.

  - **Subnet (2 of 2) in <compartment>:** Required for a public load balancer when you specify an AD-specific subnet for Subnet. Select a second public subnet. The second subnet must reside in a separate availability domain from the first subnet.

    **Tip:**

    - If you chose to create a private load balancer under Visibility Type, the form prompts you to select only one subnet.
If you're working in a region that includes only one availability domain, a second subnet is not required. The form prompts you to select only one subnet.

If the current compartment contains no virtual cloud networks, the Load Balancing service offers to create a VCN for you.

- **Virtual Cloud Network in `<compartment>`**: When the current compartment contains no virtual cloud networks, the drop-down list is disabled. The system offers to create a VCN for you.

  If you want to use an existing VCN in another compartment, click the Change Compartment link and choose that compartment from the drop-down list.

  **Virtual Cloud Network Name**: Optional, when the system creates a VCN for you. Specify a friendly name for the new cloud network. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

  If you do not specify a name for the new VCN, the system generates a name for you.

- **Use Network Security Groups to Control Traffic**: Check this box if you want to add your load balancer to a network security group (NSG). For more information about NSGs, see Network Security Groups on page 2841.

- **Network Security Groups in `<compartment>`**: Choose an NSG to add your load balancer to.

  By default, the Console shows a list of NSGs in the compartment you're currently working in. Click the Change Compartment link to select an NSG from a different compartment.

  (Optional) Click **+ Another Network Security Group** to add your load balancer to another NSG.

  **Tip**: You can change the NSGs that your load balancer belongs to after you create it. On the Load Balancer Details page, click the Edit link that appears beside the list of associated network security groups.

- **Show Advanced Options**: Click this link to display the following options:

  - **Management**:
    - **Create in Compartment**: Optionally, you can select a different compartment to host the load balancer. The compartment you select here overrides the compartment listed under Scope selected when first creating the load balancer.

  - **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

  **Note**: The following describes the Dynamic Shapes feature, which is only available to certain legacy customer accounts:

  **Dynamic Shapes**: Choose one of the following predefined shape sizes.
  
  - 10 Mbps
  - 100 Mbps
  - 400 Mbps
  - 8000 Mbps

  If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created. You can view your service limits and quotas in the Console by navigating to Governance > Limits, Quotas and Usage. Select "LbaaS" from the
Load Balancing

| Service list. Your bandwidth size options are listed. See Service Limits on page 215 for more information. You can also select the Always Free option if you have not used your one free tier account.  

You can adjust the bandwidth shape to a different size after you have completed creating the load balancer. See Changing the Load Balancer Bandwidth on page 2508 for more information.  

If you adjust a dynamic size value to a flexible size using the sliders, you cannot revert to a dynamic shape of any size. You can achieve the effect of having a dynamic (fixed) size by setting the minimum and maximum sliders to the same size. |

| Step 2 - Choose Backends |

A load balancer distributes traffic to backend servers within a backend set. A backend set is a logical entity defined by a load balancing policy, a list of backend servers (Compute instances), and a health check policy.  

The load balancer creation workflow creates one backend set for your load balancer. Optionally, you can add backend sets and backend servers after you create the load balancer.  

- **Specify a Load Balancing Policy:** Required. Choose the load balancer policy for the backend set. The available options are:  
  - **Weighted Round Robin:** This policy distributes incoming traffic sequentially to each server in a backend set list.  
  - **IP Hash:** This policy ensures that requests from a particular client are always directed to the same backend server.  
  - **Least Connections:** This policy routes incoming request traffic to the backend server with the fewest active connections.  
  
For more information on these policies, see How Load Balancing Policies Work on page 2488.  
- **Select Backend Servers:** Optional. Add backend servers to the backend set. Click **Add Backends** to select resources from a list of available Compute instances.  
  
| Important: |

When you add backend servers, the Load Balancing service automatically creates security list rules for you. If you prefer to create security list rules manually, click **Show Advanced Options** and choose the option to **Manually configure security list rules after the load balancer is created**.  

- **Add Backends:** Select (check) the instances you want to include in the load balancer's backend set.  
  
To select instances from a different compartment, use the **Change Compartment** link and choose a compartment from the drop-down list.  

After you select the instances you want to add from the current compartment, click **Add Selected Backends**.  

| Tip: |

- You can choose instances from one compartment at a time. After you add instances from one compartment, you can choose **Add More Backends** to add instances from another compartment. |
After you add instances to the backend set, they appear in the Select Backend Servers table. You can:

- Specify the server Port to which the load balancer must direct traffic. The default is port 80.
- Click the Actions icon for a server and choose Delete to remove it from the backend set.

**Specify Health Check Policy:** Required. Specify the test parameters that confirm the health of your backend servers.

- **Protocol:** Required. Specify the protocol to use for health check queries, either HTTP or TCP.

  **Important:**
  
  Configure your health check protocol to match your application or service.

- **Port:** Optional. Specify the backend server port against which to run the health check.

  **Tip:**
  
  You can enter the value '0' to have the health check use the backend server's traffic port.

- **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
- **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
- **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.
- **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.
- **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.
- **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.
- **Use SSL:** Optional. Check to apply SSL to the load balancer backend. If you select this option, complete the following:

  - **SSL Certificate:** Select one of these options:
    - **Choose SSL Certificate File:** Drag and drop the certificate file into the SSL Certificate field. Alternatively, click Select Files and navigate your system to where you can select the certificate file
Load Balancing

Certificate files must be in PEM format and must have the .pem, .cer, or .crt file extensions.

**Important:**
If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Paste SSL Certificate:** Copy and paste a certificate directly into this field.
- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Check this box if you want to provide a CA certificate. See Working with SSL Certificates on page 2551 for more information.
- **Specify Private Key:** Optional. (Required for SSL termination.) Check this box if you want to provide a private key for the certificate.
- **Show Advanced Options:** Click this link to access additional options. Select the tab for the corresponding functionality:
  - **Backend Set Name:** Specify a name for the backend set. It must be unique within the load balancer, and it cannot be changed. If you do not specify a name, the Load Balancing service creates one for you.
    Use only alphanumeric characters, dashes ('-'), and underscores ('_') for backend set names. Backend set names cannot contain spaces. Avoid entering confidential information.
  - **Security List:** Choose to manually configure subnet security list rules to allow the intended traffic or allow the system to create security list rules for you. To learn more about these rules, see Parts of a Security Rule on page 2837.
    - **Manually configure security list rules after the load balancer is created:** When you choose this option, you must configure security list rules after load balancer creation.
    - **Automatically add security list rules:** Default. When you choose this option, the Load Balancing service creates security list rules for you.
      The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet.
      You can choose whether to apply the proposed rules for each affected subnet.
  - **Session Persistence:** Specify how the load balancer manages session persistence.
    **Important:**
    See Session Persistence on page 2491 for important information on configuring these settings.
    - **Disable Session Persistence:** Choose this option to disable cookie-based session persistence.
    - **Enable Application Cookie Persistence:** Choose this option to enable persistent sessions from a single logical client when the backend application server response includes a Set-cookie header with the cookie name you specify.
      - **Cookie Name:** The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.
      - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
    - **Enable Load Balancer Cookie Persistence:** Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
      - **Cookie Name:** Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is X-Oracle-BMC-LBS-Route.
        Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
      - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
      - **Domain Name:** Optional. Specify the domain in which the cookie is valid.
Load Balancing

This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.

- **Path:** Optional. Specify the path in which the cookie is valid. The default value is `/`.
- **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

**Attributes**

- **Secure:** Specify whether the Set-cookie header should contain the Secure attribute. If selected, the client sends the cookie only using a secure protocol.

  If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.

- **HTTP Only:** Specify whether the Set-cookie header should contain the HttpOnly attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

- **SSL Policy:** Specify the type of cipher suite to use:

  - **TLS Version:** Required. Specify each of the Transport Layer Security (TLS) versions you want:
    - 1.0
    - 1.1
    - 1.2 (recommended)

  You can select any combination of versions.

  - **Specify the Cipher Suite:** Required. Choose one of the following options:

    - **Select Cipher Suite** - Select a set of cipher suites from the list. (default).
      
      All cipher suites listed have at least one cipher from each of the TLS versions you selected.

    - **Create Custom Cipher Suite** - Add ciphers to a new suite.

      Perform the following:

    a. Enter the name of the customer cipher suite in the Suite Name field.
    b. Click Choose Ciphers.

      The Select Ciphers page appears.
    c. Check each cipher that you want to include in the suite.

      The TLS versions associated with each cipher are listed in the Version column. Ensure that any cipher you choose is compatible with the TLS versions you previously chose.
    d. Deselect any ciphers you want to exclude.

    e. Click Select. Then select that custom cipher suite (or whatever suite you want to use) from the Select Cipher Suite list.

    - Click Show Cipher Suite Details to display the individual ciphers the selected cipher suite contains.

**Step 3 - Configure Listener**

- **Listener Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.

  If you do not specify a name, the Load Balancing service creates one for you.

- **Specify the type of traffic your listener handles:** Required. Specify the protocol to use. Choices are:

  - HTTPS
Load Balancing

- **HTTP**
- **TCP**
- **Specify the port your listener monitors for ingress traffic:** Required. Specify the port. Defaults are:
  - 443 for HTTPS
  - 80 for HTTP
  - 22 for TCP
- **If you chose the HTTPS protocol, or if you chose the TCP protocol and selected the Use SSL check box**
  - **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.
    Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.
    
    **Important:**
    If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate. See Working with SSL Certificates on page 2551 for more information.
  - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.
  
    Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.

- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
  - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.
  
    Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.

- **Use SSL:** Required for HTTPS, optional for TCP, not available for HTTP. Check to apply SSL to the load balancer listener. If you select this option, complete the following:
  - **SSL Certificate:** Select one of these options:
    - **Choose SSL Certificate File:** Drag and drop the certificate file into the **SSL Certificate** field.
  
    Alternatively, click **Select Files** and navigate your system to where you can select the certificate file.
for upload. Certificate files must be in PEM format and must have the .pem, .cer, or .crt file extensions.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.</td>
</tr>
</tbody>
</table>

- **Paste SSL Certificate:** Copy and paste a certificate directly into this field.
- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Check this box if you want to provide a CA certificate. See Working with SSL Certificates on page 2551 for more information.
- **Specify Private Key:** Optional. (Required for SSL termination.) Check this box if you want to provide a private key for the certificate.
- **Show Advanced Options:** Click this link to access additional options. Select the tab for the corresponding functionality:
  - **Timeout tab:** Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The maximum value is 7200 seconds. For more information, see Connection Management on page 2489.</td>
</tr>
</tbody>
</table>

- **SSL Policy tab:** Specify the type of cipher suite to use:
  - **TLS Version:** Required. Specify the Transport Layer Security (TLS) versions:
    - 1.0
    - 1.1
    - 1.2 (recommended)
  You can select any combination of versions. Choose the ones you want from the list.
  - **Specify the Cipher Suite:** Required. Choose one of the following options:
    - **Select Cipher Suite** - Select a predefined set of cipher suites. (default).
      Pick a choice from the Select Cipher Suite list. All cipher suites listed have at least one cipher from each of the TLS versions you selected.
    - **Create Custom Cipher Suite** - Add ciphers to a new suite.
      Perform the following:
      a. Enter the name of the customer cipher suite in the Suite Name field.
      b. Click Choose Ciphers.
         The Select Ciphers page appears.
      c. Check each cipher that you want to include in the suite.
         The TLS versions associated with each cipher are listed in the Version column. Ensure that any cipher you choose is compatible with the TLS versions you previously chose.
      d. Deselect any ciphers you want to exclude.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assign at least one cipher to a cipher suite you create. You cannot create a cipher suite that contains no ciphers.</td>
</tr>
</tbody>
</table>
  e. Click Select. Then select that custom cipher suite (or whatever suite you want to use) from the Select Cipher Suite list.
- **Click Show Cipher Suite Details** to display what ciphers the selected cipher suite contains.
Load Balancing

- **Server Order Preference**: Select Enable to give preference to the server ciphers over the client.

4. Click Create Load Balancer.

After the system provisions the load balancer, details appear in the load balancer list. To view more details, click the load balancer name.

### Note:

The following describes the Dynamic Shapes feature, which is only available to certain legacy customer accounts:

**Dynamic Shapes**: Choose one of the following predefined shape sizes.

- 10 Mbps
- 100 Mbps
- 400 Mbps
- 8000 Mbps

If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created. You can view your service limits and quotas in the Console by navigating to Governance > Limits, Quotas and Usage. Select "LbaaS" from the Service list. Your bandwidth size options are listed. See Service Limits on page 215 for more information. You can also select the Always Free option if you have not used your one free tier account.

You can adjust the bandwidth shape to a different size after you have completed creating the load balancer. See Changing the Load Balancer Bandwidth on page 2508 for more information.

If you adjust a dynamic size value to a flexible size using the sliders, you cannot revert to a dynamic shape of any size. You can achieve the effect of having a dynamic (fixed) size by setting the minimum and maximum sliders to the same size.

**Editing Load Balancers**

To edit a load balancer

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to edit.
3. Click the load balancer you want to edit under the Name column.
   - The Details page for that load balancer appears.
4. Click the various links under Resources to edit different aspects of the load balancer as wanted.
   - See Creating Load Balancers on page 2497 for details on specific configurations.

**Changing the Load Balancer Bandwidth**

If you are not an Always Free user, you can adjust the size of the bandwidth to one of the other predefined sizes.

### Note:

Always Free users cannot change the bandwidth of a load balancer. Upgrade to a different account if you want to increase your bandwidth size.

**To change a load balancer's bandwidth**

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
   - The Load Balancer page appears listing the load balancers associated with the selected compartment.
2. Choose the **Compartment** that contains the load balancer you want to change.
3. Click the load balancer whose bandwidth you want to change.
   The selected load balancer's Details page appears.
4. Click **Update Shape**.
   The Update Shape dialog box appears. The options displayed vary on what type of existing bandwidth size option you are using.
   - Changing a flexible shape: Enter the values for the **Minimum Bandwidth** and **Maximum Bandwidth** shape sizes you want changed.
     
     **Note:**
     Using flexible bandwidth shapes for Government accounts can result in overages if the pre-paid shape sizes are exceeded.
     
     If you want to specify a dynamic shape size, for example 500 Mbps, set the minimum and maximum sliders to the same value.
   - Changing a dynamic shape: Select the new bandwidth of the load balancer from the **Choose Shape Size** list. The existing bandwidth size of the load balancer is unavailable to select.
     
     You can switch from a dynamic shape size to a flexible shape by checking the **Use a Flexible Load Balancer** option and specifying your shape size using the minimum and maximum sliders (see **Changing a flexible shape**).
     
     **Note:**
     Once you have switched to a flexible shape, you cannot revert to a dynamic shape.

5. Click **Save Changes**.
   Changing the bandwidth size of the load balancer requires resetting all existing sessions of the load balancer.
6. Click **Confirm** to continue.
   The Details page reappears.

**Terminating Load Balancers**

**To terminate a load balancer**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to delete.
3. Find the load balancer you want to terminate.
4. Click the **Actions** icon ( ) associated with the load balancer you want to delete and then click **Terminate**.
   Alternatively, you can click the load balancer link to display the Details page and click **Terminate**.
   You are prompted to confirm you want to terminate the load balancer.
5. Click **Terminate** to confirm the termination.

**Moving a Load Balancer to a Different Compartment**

You can move your load balancer from its current compartment into a different compartment. For information about compartments and access control, see **Managing Compartments** on page 2431.

**To move a load balancer to a different compartment**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Select a compartment under the **List Scope** section.
3. Click the **Actions** icon (ISTRIBUTION) associated with the load balancer you want to move, then click **Move Resource**. The Move Resource dialog box appears.

4. Choose the destination compartment from the list.

5. Click **Move Resource**.

### Managing Tags for a Load Balancer

You can apply tags to your resources, such as load balancers, to help you organize them according to your business needs. You can apply tags at the time you create a load balancer, or you can update the load balancer later with the wanted tags. For general information about applying tags, see [Resource Tags](#) on page 211.

**To manage tags for a load balancer**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to tag, and then click the load balancer's name.
3. Click the **Tags** tab to view or edit existing tags, or click **Apply Tag(s)** to add new ones.

For more information, see [Resource Tags](#) on page 211.

### Logging

You can view logging on a variety of load balancer areas, including access and errors. See [Details for Load Balancer Logs](#) on page 2605 for more information.

### Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see [Monitoring Overview](#) on page 2660 and [Notifications Overview](#) on page 3350.

For information about monitoring the traffic passing through your load balancer, see [Load Balancing Metrics](#) on page 2567.

### Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these API operations to manage load balancers:

- ChangeLoadBalancerCompartment
- CreateLoadBalancer
- DeleteLoadBalancer
- GetLoadBalancer
- GetLoadBalancerHealth
- ListLoadBalancers
- ListLoadBalancerHealths
- UpdateLoadBalancer: You can update the load balancer's display name.
- UpdateNetworkSecurityGroups
- UpdateLoadBalancerShape

### Managing Backend Sets

This topic describes how to create and delete backend sets for use with a load balancer. For information about managing load balancers, see [Managing Load Balancers](#) on page 2494.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Backend Sets

A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers. To create a backend set, you must specify a load balancing policy and health check script, and then add a list of backend servers (Compute instances). SSL and session persistence configuration is optional. A backend set must be associated with one or more listeners for the load balancer to work.

You cannot delete a backend set used by an active listener.

Changing the load balancing policy of a backend set temporarily interrupts traffic and can drop active connections.

For background information on the Oracle Cloud Infrastructure Load Balancing, see Overview of Load Balancing on page 2480.

Click Backend Sets under Resources in the Load Balancer Details page to display the Backend Sets page. This page contains a button for creating new backend sets.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console List and Details pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.

Backend Set Health Summary

The Console list of a load balancer's backend sets provides health status summaries that indicate the overall health of each backend set. Health status indicators have four levels. The meaning of each level is:

- **OK**: All backend servers in the backend set return a status of OK.
- **WARNING**: Both of the following conditions are true:
  - Half or more of the backend set's backend servers return a status of OK.
  - At least one backend server returns a status of WARNING, CRITICAL, or UNKNOWN.
- **CRITICAL**: Fewer than half of the backend set's backend servers return a status of OK.
- **UNKNOWN**: At least one of the following conditions is true:
  - More than half of the backend set's backend servers return a status of UNKNOWN.
  - The system could not retrieve metrics for any reason.
  - The backend set does not have a listener attached.

For guidance on detecting and correcting common issues, see Health Status on page 2559.
**Backend Set Health Details**

The backend set *Details* page provides the same *Overall Health* status indicator found in the load balancer's list of backend sets. It also includes counters for the *Backend Health* status values reported by the backend set's child backend servers.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

**Creating Backend Sets**

**To create a backend set**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click **Backend Sets** under the **Resources** menu, then click **Create Backend Set**.

   The **Create Backend Set** dialog box appears.
4. Enter the following:
   
   - **Name**: Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.
     
     Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.
   
   - **Traffic Distribution Policy**: Required. Choose the load balancer policy for the backend set. The available options are:
     
     - **IP Hash**
     - **Least Connections**
     - **Weighted Round Robin**
     
     For more information on these policies, see How Load Balancing Policies Work on page 2488.
     
     **Tip:**
     
     You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.
   
   - **Use SSL**: Optional. Check this box to associate an SSL certificate bundle with the backend set.
     
     If there are no certificate bundles attached to the load balancer, this option is disabled.
     
     **Note:**
     
     If you check **Use SSL**, the **SSL Policies** fields appear at the bottom of the page.
     
     - **Certificate Name**: Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See Managing SSL Certificates on page 2551 for more information.
     
     - **Verify Peer Certificate**: Optional. Select this option to enable peer certificate verification.
     
     - **Verify Depth**: Optional. Specify the maximum depth for certificate chain verification.
     
     - **Session Persistence**: Optional. Specify how the load balancer manages session persistence.
     
     **Important:**
     
     See Session Persistence on page 2491 for important information on configuring these settings.
     
     - **Disable Session Persistence**: Choose this option to disable cookie-based session persistence.
     
     - **Enable Application Cookie Persistence**: Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a Set-cookie header with the cookie name you specify.
       
       - **Cookie Name**: The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.
       
       - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
       
       - **Enable Load Balancer Cookie Persistence**: Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
         
         - **Cookie Name**: Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is X-Oracle-BMC-LBS-Route.
           
           Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
         
         - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
         
         - **Domain Name**: Optional. Specify the domain in which the cookie is valid.
           
           This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.
• **Path:** Optional. Specify the path in which the cookie is valid. The default value is /.

• **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

• **Attributes**
  - **Secure:** Specify whether the Set-cookie header should contain the Secure attribute. If selected, the client sends the cookie only using a secure protocol.
    
    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.
  - **HTTP Only:** Specify whether the Set-cookie header should contain the HttpOnly attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

• **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.

  • **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

    __Important:__

    Configure your health check protocol to match your application or service.

  • **Port:** Optional. Specify the backend server port against which to run the health check.

    __Tip:__

    You can enter the value '0' to have the health check use the backend server's traffic port.

  • **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.

  • **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

  • **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

  • **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. The default is '3'.

  • **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.

  • **Response Body Regexp:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

• **SSL Policy:** Optional. Specify the type of cipher suite to use:

  __Note:__

  You must check Use SSL for the SSL Policy features to be displayed.

  • **TLS Version:** Optional. Specify the Transport Layer Security (TLS) version(s):
    - 1.0
    - 1.1
    - 1.2 (recommended)

    You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

    • **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

      All choices present in the list have at least one cipher associated with each TLS version you selected.

    • Click Show Cipher Suite Details to display the individual ciphers the selected cipher suite contains.

5. Click Create.
After your backend set is provisioned, you must specify backend servers for the set. See Managing Backend Servers on page 2515 for more information.

**Editing Backend Sets**

**To edit a backend set**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Updating the backend set temporarily interrupts traffic and can drop active connections.</td>
</tr>
</tbody>
</table>

When you edit a backed set, you can choose a new load balancing policy and modify the SSL configuration.

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click **Backend Sets** under the **Resources** menu, then click the name of the backend set you want to edit.
4. Click **Edit Backend Set**.
5. Edit the backend set configuration changes as wanted.
   
   See Creating Backend Sets on page 2512 for details on specific configurations.
6. Click **Submit**.

If you want to modify the backend set's health check policy, see Editing Health Check Policies on page 2558.

If you want to add or remove backend servers from the backend set, see Managing Backend Servers on page 2515.

**Deleting Backend Sets**

**To delete a backend set**

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot delete a backend set used by an active listener. First, remove any backend sets you want to delete from the associated listeners.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click **Backend Sets** under the **Resources** menu.
4. Click the the Actions icon (three dots) associated with the backend set you want to delete, then click **Delete**.
5. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage load balancer backend sets:

- CreateBackendSet
- DeleteBackendSet
- GetBackendSet
- GetBackendSetHealth
- ListBackendSets
- UpdateBackendSet

**Managing Backend Servers**

This topic describes how to manage backend servers for use with a load balancer. For information about managing load balancers, see Managing Load Balancers on page 2494.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Backend Servers

When you implement a load balancer, you must specify the backend servers (Compute instances) to include in each backend set. The load balancer routes incoming traffic to these backend servers based on the policies you specified for the backend set. You can use the Console to add and remove backend servers in a backend set.

To route traffic to a backend server, the Load Balancing service requires the IP address of the compute instance and the relevant application port. If the backend server resides within the same VCN as the load balancer, Oracle recommends that you specify the compute instance's private IP address. If the backend server resides within a different VCN, you must specify the public IP address of the compute instance. You also must ensure that the VCN's security rules allow Internet traffic.

Caution:

When you add backend servers to a backend set, you specify either the instance OCID or an IP address for the server to add. An instance with multiple VNICs attached can have multiple IP addresses pointing to it.

- If you identify a backend server by OCID, Load Balancing uses the primary VNIC's primary private IP address.
- If you identify the backend servers to add to a backend set by their IP addresses, it is possible to point to the same instance more than once.

To enable backend traffic, your backend server subnets must have appropriate ingress and egress security rules. When you add backend servers to a backend set, you can specify the applicable network security groups (NSGs). If you prefer to use security lists for your VCN, the Load Balancing service Console can suggest security list rules for you. You also can configure them yourself through the Networking service. See Security Lists on page 2850 for more information.

Tip:

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

You can add and remove backend servers without disrupting traffic.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console List and Details pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.
**Backend Server Health Summary**

The Console list of a backend set's backend servers provides health status summaries that indicate the overall health of each backend server. The primary and standby load balancers both provide health check results that contribute to the health status. Health status indicators have four levels. The meaning of each level is:

- **OK**: The primary and standby load balancer health checks both return a status of OK.
- **WARNING**: One health check returned a status of OK and one did not.
- **CRITICAL**: Neither health check returned a status of OK.
- **UNKNOWN**: One or both health checks returned a status of UNKNOWN or the system was unable to retrieve metrics.

To view the health status details for a specific backend server, click its **IP Address**.

For guidance on detecting and correcting common issues, see **Health Status** on page 2559.

**Backend Server Health Details**

The **Details** page for a backend set provides the same **Overall Health** status indicator found in the backend set's list of backend servers. It also reports the following data for the two health checks performed against each backend server:

**IP ADDRESS**

The IP address of the health check status report provider, which is a Compute instance managed by the Load Balancing service. This identifier helps you differentiate same-subnet load balancers that report health check status.

The Load Balancing service ensures high availability by providing one primary and one standby load balancer. To diagnose a backend server issue, you must know the source of the health check report. For example, a misconfigured security rule might cause one load balancer instance to report that a backend server is healthy. The other load balancer instance might return an unhealthy status. In this case, one of the two load balancer instances cannot communicate with the backend server. Reconfigure the security rules to restore the backend server's health status.

**STATUS**

The status returned by the health check. Possible values include:
• **OK**
  The backend server's response satisfied the health check policy requirements.
• **INVALID_STATUS_CODE**
  The HTTP response status code did not match the expected status code specified by the health policy.
• **TIMED_OUT**
  The backend server did not respond within the timeout interval specified by the health policy.
• **REGEX_MISMATCH**
  The backend server response did not satisfy the regular expression specified by the health policy.
• **CONNECT_FAILED**
  The health check server could not connect to the backend server.
• **IO_ERROR**
  An input or output communication error occurred while reading or writing a response or request to the backend server.
• **OFFLINE**
  The backend server is set to offline, so health checks are not run.
• **UNKNOWN**
  Health check status is not available.

**LAST CHECKED**

The date and time of the most recent health check.

Health status is updated every three minutes. No finer granularity is available.

**How to debug backend timeout**

Backend timeout or a 504 means that a backend server is either down or not responding to the request forwarded by the load balancer. The client application receives the following response code: HTTP/1.1 504 Gateway Timeout.

**Causes**

• The load balancer failed to establish a connection to the backend server before the connection timeout expired.
• The load balancer established a connection to the backend server but the backend did not respond before the idle timeout period elapsed.
• The security lists/NSGs for the subnet/VNIC did not allow traffic from the backends to the load balancer.
• Backend server/application crash.

**Troubleshooting Steps**

1. Run a curl test directly to the backend from a host in the same network.
   a. `curl -i http://10.0.0.5`
   b. If this test takes longer than one second but the test still responded, then it is likely an application level issue causing latency. We recommend checking any upstream dependency that may cause latency, common components include the following:
      • Network attached storage such as ISCSI or NFS
      • Database latency
      • An off-premise API
      • An application tier
2. Check the application by accessing it directly from the backend and access logs. Can it be addressed? Is it working as intended?
3. If the load balancer and the backend are in different subnets, check the security lists rules to allow traffic else the traffic will be dropped.

4. Check if there are no firewall rules on the backend servers that is blocking the traffic.
   a. `iptables -L` will list all firewall rules enforced by iptables
   b. `sudo firewall-cmd --list-all` will list all firewall rules enforced by firewalld

5. Enable logging on the load balancer that will help determine if the latency is caused due to load balancer or the backend server.

How to test TCP and HTTP backends

The following section describes how to troubleshoot a load balancer connection. The topology used has a public load balancer in a public subnet and the back-ends are in the same subnet.

Oracle recommends using primarily the OCI logging service to troubleshoot in this scenario. Details for Load Balancer Logs on page 2605. However, in addition to using OCI logging you can also use some additional tools to troubleshoot the traffic processed by the load balancer and sent to a backend. To perform these tests we recommend creating an instance in the same network as your load balancer and allowing the traffic in the same network security groups and security lists. Use the following tools to troubleshoot.

• `ping <ip address of backend>`

Using the Console

To add one or more servers to a backend set

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer’s name.
3. In the Resources menu, click Backend Sets, and then click the name of the backend set to which you want to add one or more backend servers.

   Tip:
   If the load balancer has no backend sets, you must create one before you can specify a backend server.

4. In the Resources menu, click Backends, and then click Add Backends.

   Tip:
   You cannot add a backend server marked as Backup to a backend set that uses the IP Hash policy.
5. **Choose how to add backend servers:** Specify how you want to add backend servers to the backend set:

- **Compute Instances:** Choose this option to select from a list of available Compute instances.
- **Instances in <compartment>:** Select (check) the instances you want to include in the backend set.
  
  To select instances from a different compartment, use the Change Compartment link and choose a compartment from the drop-down list.

  **Tip:**

  You can choose instances from one compartment at a time. After you add instances from one compartment, you must repeat the Add Backends process to add instances from another compartment.

Once you select an instance to add to the backend set, you can specify:

- **Port:** Required. The backend server port to which the load balancer must direct traffic.
- **Weight:** The load balancing weight assigned to the server. For more information, see [How Load Balancing Policies Work](#) on page 2488.
- Choose to manually configure subnet security list rules that allow the intended traffic or let the Load Balancing service create security list rules for you. To learn more about these rules, see [Parts of a Security Rule](#) on page 2837.

  - **Manually configure security list rules after the load balancer is created:** When you choose this option, you must create your own rules after adding the backend servers.
  
  - **Automatically add security list rules:** When you choose this option, the Load Balancing service creates security list rules for you.

    The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet. You can then choose whether to apply the proposed rules for each affected subnet.

- **IP Addresses:** Choose this option to enter the IP addresses of the backend servers (Compute instances) to add.

  - **IP Address:** Required. Specify the IP address of a backend server you want to add to the backend set.
  
  - **Port:** Required. Specify the server port to which the load balancer must direct traffic.
  
  - **Weight:** Required. Specify the load balancing weight to apply to this server. For more information, see [How Load Balancing Policies Work](#) on page 2488.

  You can click the plus + icon to add another server to the list or click the X icon to remove a list item.

6. **Click Add.**

**To edit backend server settings**

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Backend Sets, and then click the name of the backend set that includes the backend servers you want to edit.
4. In the Resources menu, click Backend. A list of servers in the backend set appears.
5. Select (check) the row corresponding to the backend server you want to edit.
6. Choose an action from the **Actions** button drop-down list. The available actions include:

   a. **Edit**: Opens a single dialog box in which you can edit the port, weight, drain, offline, and backup settings.
   b. **Edit Port**: Opens a dialog box in which you can change the application port setting.
   c. **Edit Weight**: Opens a dialog box in which you can change the load balancing weight.
   d. **Edit Drain State**: Opens a dialog box in which you can change the drain state.

   If you set the server's drain status to `true`, the load balancer stops forwarding new TCP connections and new non-sticky HTTP requests to this backend server. This setting allows an administrator to take the server out of rotation for maintenance purposes.
   e. **Edit Offline State**: Opens a dialog box in which you can change the offline status.

   If you set the server's offline status to `true`, the load balance forwards no ingress traffic to this backend server.
   f. **Edit Backup State**: Opens a dialog box in which you can change the backup status.

   If you set the server's backup status to `true`, the load balancer forwards ingress traffic to this backend server only when all other backend servers not marked as backup fail the health check policy. This configuration is useful for handling disaster recovery scenarios.

   **Caution:**
   Backend servers marked as **Backup** are not compatible with a load balancer that uses the IP Hash policy.

   g. **Delete**: Removes the server from the backend set.

   **Tip:**
   You can select multiple servers to apply the same action to each one.

7. Click **Save Changes**.

**To remove a server from a backend set**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set from which you want to remove a server.
4. In the **Resources** menu, click **Backends**. A list of servers in the backend set appears.
5. Select (check) the row corresponding to the backend server you want to edit.
6. Choose the **Delete** action from the **Actions** button drop-down list.
7. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage the backend servers in a backend set:

- **CreateBackend**
- **DeleteBackend**
- **GetBackend**
- **GetBackendHealth**
- **ListBackends**
- **UpdateBackend**
Managing Listeners

This topic describes how to create and manage listeners. This topic is part of the setup and maintenance of a load balancer. For more Load Balancing information about managing load balancers, see Managing Load Balancers on page 2494.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with *inspect load-balancers* gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Listeners

A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.

To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.

When you create a listener, you must ensure that your VCN's *security rules* allow the listener to accept traffic.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To accommodate high-volume traffic, Oracle strongly recommends that you use <em>stateless security rules</em> for your load balancer subnets.</td>
</tr>
</tbody>
</table>

You can have one SSL certificate bundle per listener. You can configure two listeners, one each for ports 443 and 8443, and associate SSL certificate bundles with each listener. For more information about SSL certificates for load balancers, see Managing SSL Certificates on page 2551.

Click **Listeners** under **Resources** in the Load Balancer Details page to display the Listeners page. This page contains a button for creating listeners.

Creating Listeners

To create a listener

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click **Listeners** under the **Resources** menu, then click **Create Listener**.

   The Create Listener dialog box appears.
4. Enter the following:

- **Name**: Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.

- **Hostname**: Optional. Select up to 16 virtual hostnames for this listener.

  **Important:**

  To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated hostnames, you can create one on the **Hostnames** page.

- **Protocol**: Required. Specify the protocol to use, either HTTP or TCP.

- **Port**: Required. Specify the port on which to listen for incoming traffic.

- **Use SSL**: Optional. Check this box to associate an SSL certificate bundle with the listener. The following settings are required to enable SSL handling. See Managing SSL Certificates on page 2551 for more information.

  - **Certificate Name**: The friendly name of the SSL certificate bundle to use.
  
  - **Verify Peer Certificate**: Optional. Select this option to enable peer certificate verification.
  
  - **Verify Depth**: Optional. Specify the maximum depth for certificate chain verification.

- **Backend Set**: Required. Specify the default backend set to which the listener routes traffic.

- **Idle Timeout in Seconds**: Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

  **Tip:**

  The maximum value is 7200 seconds. For more information, see Connection Management on page 2489.

- **Path Route Set**: Optional. Specify the name of the set of path-based routing rules that applies to this listener's traffic.

  **Important:**

  - To apply a path route set to a listener, the set must be part of the load balancer's configuration.
  
  - To remove a path route set from an existing listener, choose None as the **Path Route Set** option. The path route set remains available for use by other listeners on this load balancer.

- **Show Advanced Options**: Click to display the following options:

  - **TLS Version**: Specify the Transport Layer Security (TLS) version(s):
    
    - 1.0
    - 1.1
    - 1.2 (recommended)
    
    You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

  - **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

    All choices present in the list have at least one cipher associated with each TLS version you selected.

  - **Server Order Preference**: Select Enable to give preference to the server ciphers over the client.

5. Click **Create**.

When you create a listener, you must also update your VCN's security rules to allow traffic to that listener.
Editing Listeners

To edit a listener

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click Listeners under the Resources menu.
4. Click the the Actions icon (three dots) associated with the listener you want to edit, then click Edit.
5. Edit the listener configuration as wanted.

   See Creating Listeners on page 2522 for details on specific configurations.
6. Click Save Changes.

Deleting Listeners

To delete a listener

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click Listeners under the Resources menu.
4. Click the the Actions icon (three dots) associated with the listener you want to delete, then click Delete.
5. Confirm when prompted.

Enabling Listeners to Accept Traffic

To enable a listener to accept traffic, you must update your VCN’s security rules:

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.

   The list of VCNs in the current compartment appears.
2. Click the name of the VCN containing your load balancer, and then click Security Groups or Security Lists.

   A list of the security groups or lists in the cloud network appears.
3. Click the name of the NSG or security list that applies to your load balancer.
4. Add or edit the existing rules to allow access from the appropriate resources.

   An NSG’s security rules appear on the Network Security Group Details page. From there you can add, edit, or remove rules.

   The Security List Details page provides access to separate tables in which you can add or edit Ingress Rules or Egress Rules.

   For details on rule configuration, see Security Rules on page 2833.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage listeners:

- CreateListener
- DeleteListener
- UpdateListener
Managing Cipher Suites

This topic describes how to create and manage cipher suites. Cipher suites are part of the setup and maintenance of a load balancer. For more Load Balancing information about managing load balancers, see Managing Load Balancers on page 2494.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you are new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Cipher Suites

A cipher suite is a logical entity for a set of algorithms, or ciphers, using Transport Layer Security (TLS) to determine the security, compatibility, and speed of HTTPS traffic. All ciphers are associated with at least one version of Transport Layer Security (TLS) 1.0, 1.1, and 1.2.

Note:

Any cipher suite you use or create must contain individual ciphers that match the TLS version supported in your environment. Some ciphers can work with multiple TLS versions. If your environment supports at least one of the TLS versions associated with a given cipher, you can use it.

When you create or edit a listener, you add or can change the associated cipher suite. See Managing Listeners on page 2522 for more information.

Click Cipher Suites under Resources in the Load Balancer Details page to display the Cipher Suites page. This page contains a button for creating cipher suites.

This page also contains a list of all the currently available cipher suites, both ones that came originally preconfigured from Oracle Cloud Infrastructure (Predefined=Yes), and ones that you created yourself (Predefined=No). You can modify or delete those cipher suites you created yourself (Predefined=No). You cannot modify predefined cipher suites.

Creating Cipher Suites

You can create cipher suites as a resource within the Load Balancer service in the Console. The cipher suites you create are available to use when configuring the load balancer's listener and backend set.

To create a cipher suite

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer for which you want to create cipher suites.
3. Click the load balancer you want from the list.
   The Load Balancer Details page for that load balancer appears.
4. Click Cipher Suites under Resources.
   The Cipher Suites page appears.
5. Click Create Cipher Suite.
   The Create Cipher Suite page appears.
6. Enter a name for the cipher suite you are creating in the **Suite Name** field. Avoid entering confidential information.

7. Check those TLS versions under **Filters** from which you want to select.

   Ciphers associated with the TLS versions you checked (displaying which TLS versions they support) appear. Only select TLS versions that are supported in your environment.

   **Note:**
   
   Assign at least one cipher to a cipher suite you create. You cannot create a cipher suite that contains no ciphers.

8. Check those ciphers that you want to include in your cipher suite.

   The total number of ciphers available can span multiple pages. Use the **Search Ciphers** field to find a specific cipher.

   Uncheck a cipher to deselect it from the cipher suite.

9. Click **Create Suite**.

   **Note:**

   Note the following related to creating cipher suites:

   - Ensure compatibility between specified SSL protocols and configured ciphers in the cipher suite, or else the SSL handshake will not be successful.
   - Ensure compatibility between configured ciphers in the cipher suite and configured certificates (for example, RSA-based ciphers require an RSA certificate whereas ECDSA based ciphers require ECDSA certificates).
   - For all load balancer and listener resources that were created before the cipher suites feature was available, the following apply:
     - When running a GET operation, the cipher suite value returned is by default "oci-default-ssl-cipher-suite-v1" inside the listener's SSL configuration. You can update this value by editing the load balancer or listener.
     - When running a GET operation, the cipher suite value returned is displayed as "oci-customized-ssl-cipher-suite" inside the listener's SSL configuration if the cipher configuration of those load balancers was customized after the load balancer creation via Oracle operations.
   - For all existing load balancer backendsets that were created before the cipher suites feature was available, running a GET operation displays the cipher suite value as "oci-wider-compatible-ssl-cipher-suite-v1" inside the backendset's SSL configuration.
   - If running a GET operation on a load balancer listener displays the cipher suite value as "oci-customized-ssl-cipher-suite", then choose the appropriate cipher suite name (either pre-defined or custom defined cipher suites) when updating these load balancers.
   - The cipher suite name "oci-customized-ssl-cipher-suite" is reserved for use by Oracle and is not acceptable as an available name for a custom cipher suite.

**Viewing Cipher Suite Details**

The Cipher Suite Details page is where you can view the ciphers contained in the cipher suite. When you first create a cipher suite, the Details page appears. After that, you can view the Details page using the following method.

From the Details page, you can also modify or delete custom cipher suites. You cannot modify or delete preconfigured cipher suites.
To view the details of a cipher suite

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer whose cipher suite you want to modify, and then click the load balancer's name.
3. Click Cipher Suites under Resources.

   The Cipher Suites page appears.
4. Click the link under Name for the cipher suite whose details you want to view.

   Alternatively, you can click the Actions icon (three dots), and then click View Details.

   The Details page for that cipher suite appears. The Details page displays those ciphers currently included in the cipher suite.

Editing Cipher Suites

Edit a cipher suite to change the ciphers it contains.

To edit a cipher suite

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer whose cipher suite you want to modify, and then click the load balancer's name.
3. Click Cipher Suites under Resources.

   The Cipher Suites page appears.
4. Click the Actions icon (three dots), and then click Edit for the cipher suite you want to edit.

   Alternatively, you can open the Details page for the cipher suite you want to edit. See Viewing Cipher Suite Details on page 2526 for more information.
5. Modify the ciphers contained in the cipher suite as wanted:

   • To add ciphers, click Manage Cipher(s).

     The Select Ciphers page appears. Check the ciphers that you want to add. The ciphers you add must be compatible with the TLS version you are using. Use the Filters to limit the available ciphers by the TLS versions they support. Click Select Ciphers. You are returned to the Details page.

   • To remove ciphers, check those ciphers listed in the Details page and click Remove. All the check ciphers are removed.

     You can remove individual ciphers by clicking the Actions icon (⋮) for the associated cipher, then click Delete.

     | Note: |
     |-------|
     | You cannot delete all ciphers from a cipher suite. The cipher suite must contain at least one cipher after editing. |

Any updates you make are automatically saved.

Deleting Cipher Suites

You cannot delete a cipher suite that is in use. Ensure all listeners and backend sets using the cipher suite you want to delete are managed to a different suite first. You may not have access to all compartments containing associated resources.

To delete a cipher suite

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only delete a custom (Predefined=No) cipher suite.</td>
</tr>
</tbody>
</table>
1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Cipher Suites.
   The Cipher Suite page appears.
4. Click the Actions icon (three dots) associated with the cipher suite you want to delete, and then click Delete.
   Alternatively, you can open the Details page for the cipher suite you want to delete. The Details page for that cipher suite appears. Click Delete. See Viewing Cipher Suite Details on page 2526 for more information.
5. Confirm when prompted. The deleted cipher suite disappears from the list.

**Supported Ciphers**

Here is a list of supported ciphers by TLS version.

**TLS version 1.2**

- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- AES128-GCM-SHA256
- AES128-SHA256
- AES256-GCM-SHA384
- AES256-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256
- DH-DSS-AES256-GCM-SHA384
- DH-DSS-AES256-GCM-SHA384
- DH-RSA-AES256-GCM-SHA384
- DH-DSS-AES256-SHA256
- DH-RSA-AES256-SHA256
- DH-DSS-AES256-SHA256
- ECDH-RSA-AES256-GCM-SHA384
- ECDH-ECDSA-AES256-GCM-SHA384
- ECDH-RSA-AES256-SHA384
- ECDH-ECDSA-AES256-SHA384
- DH-DSS-AES128-GCM-SHA256
- DH-RSA-AES128-GCM-SHA256
- DH-DSS-AES128-SHA256
- DH-RSA-AES128-SHA256
- DH-DSS-AES128-SHA256
- ECDH-RSA-AES128-GCM-SHA256
- ECDH-ECDSA-AES128-GCM-SHA256
- ECDH-RSA-AES128-SHA256
- ECDH-ECDSA-AES128-SHA256

**TLS version 1.0/1.1 ciphers supported by TLS version 1.2**

- ECDHE-ECDSA-AES128-SHA
- ECDHE-RSA-AES128-SHA
- ECDHE-RSA-AES256-SHA
- ECDHE-ECDSA-AES256-SHA
- AES128-SHA

- ECDHE-ECDSA-DES-CBC3-SHA
- DHE-RSA-DES-CBC3-SHA
- DHE-DSS-DES-CBC3-SHA
- DH-RSA-DES-CBC3-SHA
- DH-DSS-DES-CBC3-SHA
- ECDH-RSA-DES-CBC3-SHA
- ECDHE-ECDSA-DES-CBC3-SHA
- PSK-3DES-EDE-CBC-SHA
- KRB5-IDEA-CBC-SHA
• KRB5-DES-CBC3-SHA
• KRB5-IDEA-CBC-MD5
• KRB5-DES-CBC3-MD5
• ECDHE-RSA-RC4-SHA
• ECDHE-ECDSA-RC4-SHA
• ECDH-RSA-RC4-SHA
• ECDH-ECDSA-RC4-SHA
• RC4-SHA
• RC4-MD5
• PSK-RC4-SHA
• KRB5-RC4-SHA
• KRB5-RC4-MD5

**Predefined Cipher Suites**

Here is a list of the cipher suites that are available for use with Load Balancing, along with the individual ciphers they include.

**oci-default-ssl-cipher-suite-v1**

This cipher suite contains a restricted set of ciphers that are only supported in TLS version 1.2, and meets stricter compliance requirements.

• ECDHE-RSA-AES128-GCM-SHA256
• ECDHE-RSA-AES128-SHA256
• ECDHE-RSA-AES256-GCM-SHA384
• ECDHE-RSA-AES256-SHA384
• DHE-RSA-AES256-GCM-SHA384
• DHE-RSA-AES256-SHA256
• DHE-RSA-AES128-GCM-SHA256
• DHE-RSA-AES128-SHA256

**oci-modern-ssl-cipher-suite-v1**

This cipher suite offers a wider set of ciphers, but still only supported in TLS version 1.2.

• ECDHE-ECDSA-AES128-GCM-SHA256
• ECDHE-RSA-AES128-GCM-SHA256
• ECDHE-ECDSA-AES128-SHA256
• ECDHE-RSA-AES128-SHA256
• ECDHE-ECDSA-AES256-GCM-SHA384
• ECDHE-RSA-AES256-GCM-SHA384
• ECDHE-ECDSA-AES256-SHA384
• ECDHE-RSA-AES256-SHA384
• AES128-GCM-SHA256
• AES128-SHA256
• AES256-GCM-SHA384
• AES256-SHA256
• DHE-RSA-AES256-GCM-SHA384
• DHE-RSA-AES256-SHA256
• DHE-RSA-AES128-GCM-SHA256
• DHE-RSA-AES128-SHA256

**oci-compatible-ssl-cipher-suite-v1**

This cipher suite supports the broadest set of ciphers. It contains ciphers supported by TLS versions 1.1 and 1.2.
Load Balancing

- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- ECDHE-ECDSA-AES128-SHA
- ECDHE-RSA-AES128-SHA

`oci-customized-ssl-cipher-suite`

This cipher suite reflects customized cipher tasks performed by Oracle on a client-specific basis prior to the general release of the cipher suite feature.

**Managing Cipher Suites in Listeners and Backend Sets**

When you create a load balancer, specifying the cipher suite is part of configuring the listener and the backend set. See *Creating Load Balancers* on page 2497 for more information.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage cipher suites:

- CreateSSLCipherSuite
- UpdateSSLCipherSuite
- DeleteSSLCipherSuite
- GetSSLCipherSuite
- ListSSLCipherSuites

Managing Request Routing

This topic describes how to manage your load balancer's request routing. For information about managing load balancers, see Managing Load Balancers on page 2494.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Routing Incoming Requests

The Load Balancing service enables you to route incoming requests to various backend sets. You can:

- Assign virtual hostnames to a listener.
- Create path route rules.
- Combine these techniques.

Virtual Hostnames

When used in concert with A records you create in your DNS system, you can assign virtual hostnames to any listener you create for your load balancer. Each hostname can correspond to a backend set, that backend set can route traffic to specific backends which will host different applications. Some advantages of virtual hostnames include:

- A single associated IP address. Multiple hostnames, backed by DNS entries that you create in your nameservers, can point to the same load balancer IP address.
- A single load balancer. You do not need a separate load balancer for each application.
- A single load balancer shape. Running multiple applications behind a single load balancer helps you manage aggregate bandwidth demands and optimize utilization.
- Simpler backend set management. Managing a set of backend servers under a single resource simplifies network configuration and administration.

You can define exact virtual hostnames, such as "app.example.com", or you can use wildcard names. Wildcard names include an asterisk (*) in place of the first or last part of the name. When searching for a virtual hostname, the service chooses the first matching variant in the following priority order:

1. Exact name match (no asterisk), such as app.example.com.
2. Longest wildcard name that begins with an asterisk, such as *.example.com.

   **Tip:**
   Prefix wildcard names might require a wildcard certificate for HTTPS sites.

3. Longest wildcard name that ends with an asterisk, such as app.example.*.

   **Tip:**
   Suffix wildcard names might require a multi-domain Subject Alternative Name (SAN) certificate for HTTPS sites.

   You do not need to specify the matching pattern to apply. The pattern is inherent in the asterisk position, that is, starting, ending, or none.

The following considerations apply to virtual hostnames:

- You cannot use regular expressions.
- To apply virtual hostnames to a listener, you first create one or more virtual hostnames associated with a load balancer.
- Virtual hostname selection priority is not related to the listener's configuration order.
- You can apply a maximum of 16 virtual hostnames to a listener.
- You can associate a maximum of 16 virtual hostnames with a load balancer.

   **Tip:**
   The virtual hostnames feature supports HTTP and HTTPS listeners only, but does not support TCP listeners.

**Note:**

**Default Listener**

If a listener has no virtual hostname specified, that listener is the default for the assigned port.

If all listeners on a port have virtual hostnames, the first virtual hostname configured for that port serves as the default listener.

**Path Route Rules**

Some applications have multiple endpoints or content types, each distinguished by a unique URI path. For example, /admin/, /data/, /video/, or /cgi/. You can use path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.

A *path route* is a string that the Load Balancing service matches against an incoming URI to determine the appropriate destination backend set.

- You cannot use asterisks in path route strings.
- You cannot use regular expressions.
- Path route string matching is case-insensitive.

   **Important:**
   Browsers often add an ending slash to the path in a request. If you specify a path such as /admin, you might want to configure the path both with and without the trailing slash. For example, /admin and /admin/.

A *path route rule* consists of a path route string and a pattern match type.
Load Balancing

- Pattern match types include:
  - **EXACT_MATCH**
    Looks for a path string that exactly matches the incoming URI path.
    Applies case-insensitive regex:
    ```
    ^<path_string>$
    ```
  - **FORCE_LONGEST_PREFIX_MATCH**
    Looks for the path string with the best, longest match of the beginning portion of the incoming URI path.
    Applies case-insensitive regex:
    ```
    <path_string>.*
    ```
  - **PREFIX_MATCH**
    Looks for a path string that matches the beginning portion of the incoming URI path.
    Applies case-insensitive regex:
    ```
    ^<path_string>.*
    ```
  - **SUFFIX_MATCH**
    Looks for a path string that matches the ending portion of the incoming URI path.
    Applies case-insensitive regex:
    ```
    .*<path_string>$
    ```
- Path route rules apply only to HTTP and HTTPS requests and have no effect on TCP requests.
  - A path route set includes all path route rules that define the data routing for a particular listener.
  - You can specify up to 20 path route rules per path route set.
  - You can have one path route set per listener. The maximum number of listeners limits the number of path route sets you can specify for a load balancer.

**Rule Priority**

The system applies the following priorities, based on match type, to the path route rules within a set:
- For one path route rule that specifies the EXACT_MATCH type, there is no cascade of priorities. The listener looks for an exact match only.
- For two path route rules, one that specifies the EXACT_MATCH type and one that specifies any other match type, the exact match rule is evaluated first. If no match is found, then the system looks for the second match type.
- For multiple path route rules specifying various match types, the system applies the following priority cascade:
  1. EXACT_MATCH
  2. FORCE_LONGEST_PREFIX_MATCH
  3. PREFIX_MATCH or SUFFIX_MATCH
- The order of the rules within the path route set does not matter for EXACT_MATCH and FORCE_LONGEST_PREFIX_MATCH. The system applies the priority cascade no matter where these match types appear in the path route set.
- If matching cascades down to prefix or suffix matching, the order of the rules within the path route set DOES matter. The system chooses the first prefix or suffix rule that matches the incoming URI path.
Virtual Hostname and Path Route Rules Combinations

Virtual hostnames and path route rules route requests to backend sets. Listeners with a virtual hostname receive priority over the default (no hostname) listener. The following example shows the results of a simple routing interaction.

The example system includes three listeners and one path route set:

Listener 1

- Virtual hostname: none
- Default backend set: A
- Path route set: PathRouteSet1

Listener 2

- Virtual hostname: captive.com
- Default backend set: B
- Path route set: PathRouteSet1

Listener 3

- Virtual hostname: wild.com
- Default backend set: C
- Path route set: PathRouteSet1

Path Route Set

- Path route set name: PathRouteSet1
  - Exact match on path string /tame/ routes to backend set B.
  - Exact match on path string /feral/ routes to backend set C.

The example configuration routes incoming URLs as follows:

http://animals.com/ is routed to backend set A

- Virtual hostname animals.com matches Listener 1.
- Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.

http://animals.com/tame/ is routed to backend set B

- Virtual hostname animals.com matches Listener 1.
- Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.

http://animals.com/feral/ is routed to backend set C

- Virtual hostname animals.com matches Listener 1.
- Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.

http://captive.com/ is routed to backend set B

- Virtual hostname captive.com matches Listener 2.
- Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.

http://captive.com/tame/ is routed to backend set B

- Virtual hostname captive.com matches Listener 2.
- Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.

http://captive.com/feral/ is routed to backend set C

- Virtual hostname captive.com matches Listener 2.
- Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.

http://wild.com/ is routed to backend set C
Load Balancing

- Virtual hostname wild.com matches **Listener 3**.
- Path / is not an EXACT_MATCH for any path route string in PathRouteSet1.

http://wild.com/tame/ is routed to backend set B

- Virtual hostname wild.com matches **Listener 3**.
- Path /tame/ is an EXACT_MATCH for path route string /tame/ in PathRouteSet1.

http://wild.com/feral/ is routed to backend set C

- Virtual hostname wild.com matches **Listener 3**.
- Path /feral/ is an EXACT_MATCH for path route string /feral/ in PathRouteSet1.

**Using the Console**

You can specify virtual hostnames and path route sets when you create or update a listener.

**Creating Virtual Hostnames**

To apply virtual hostnames to a listener, you first create one or more virtual hostnames. The virtual hostnames become a part of the load balancer's configuration. You then specify one or more virtual hostnames to use when you create or update a listener for the load balancer.

**To create a virtual hostname**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Hostnames**, and then click **Create Hostname**.
4. In the **Create Hostname** dialog box, enter the following:
   - **Name**: Required. Specify a friendly name for the hostname. The name must be unique, and cannot be changed. Avoid entering confidential information.
   - **Hostname**: Required. Specify the virtual hostname. See **Virtual Hostnames** for a description of valid hostname construction and behavior.
5. Click **Create**. The **Work Request Submitted** dialog box opens.
6. To close the dialog box, click **Close**. To open the **Work Requests** page and view the status of the work request, click **View All Work Requests**.

After you create a virtual hostname, the name becomes available for use with the associated load balance. To apply the hostname, create or update a listener.

**To update a virtual hostname**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Hostnames**.
4. For the hostname you want to edit, click the Actions icon (three dots), and then click **Edit**.
5. In the **Edit Hostname** dialog box, enter your updates to the **Hostname** field.
   - You cannot edit the **Name** field of an existing virtual hostname.
6. Click **Update**. The **Work Request Submitted** dialog box opens.
7. To close the dialog box, click **Close**. To open the **Work Requests** page and view the status of the work request, click **View All Work Requests**.

**To delete a virtual hostname**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Hostnames.
4. For the hostname you want to edit, click the Actions icon (three dots), and then click Delete. The Work Request Submitted dialog box opens.
5. To close the dialog box, click Close. To open the Work Requests page and view the status of the work request, click View All Work Requests.

Creating Path Route Sets

To apply path route rules to a listener, you first create a path route set that contains the rules. The path route set becomes a part of the load balancer's configuration. You then specify the path route set to use when you create or update a listener for the load balancer. To remove a path route set from a listener, edit the listener and choose None as the Path Route Set option.

To create a path route set

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Path Route Sets, and then click Create Path Route Set.
4. In the Create Path Route Set dialog box, enter the following:
   - Name: Required. Specify a friendly name for the path route set. The name must be unique, and cannot be changed.
     The path route set name cannot begin with a period and cannot contain the characters ;, ?, #, %, /, \, [, or ]. Avoid entering confidential information.
   - Path Route Rules
     - Order: Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.
   - Match Style: Required. The type of matching to apply to incoming URIs.
   - URL String: Required. The path string to match against the incoming URI path, for example /admin/.
   - Backend Set Name: Required. The name of the target backend set for requests where the incoming URI matches the specified path.
5. (Optional) Click + Additional Rule to create another path route rule or click the red box to delete an existing rule. You can have up to 20 path route rules in a set.
6. Click Create.

After you create a path route set, the set becomes available for use with the associated load balance. Create or update a listener to apply the path route set.

To update a path route set

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Path Route Sets.
4. Click the name of the path route set you want to update, and then click Edit Path Route Rules.
5. In the **Edit Path Route Rules** dialog box, edit the following as needed for each rule you want to change:

- **Order**: Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

  Tip:

  The *order of the rules within the path route set* does not matter in most cases. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

- **Match Style**: Required. The *type of matching* to apply to incoming URIs.

- **URL String**: Required. The path string to match against the incoming URI path, for example `/admin/`.

- **Backend Set Name**: Required. The name of the target backend set for requests where the incoming URI matches the specified path.

6. (Optional) Click **+ Additional Rule** to create another path route rule or click the red box to delete an existing rule. You can have up to 20 path route rules in a set.

7. Click **Save Changes**.

### To update a single path route rule

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

3. In the **Resources** menu, click **Path Route Sets**, and then click the name of the path route set you want to update.

4. For the path route rule you want to edit, click the Actions icon (three dots), and then click **Edit Path Route**.

5. In the **Edit Path Route Rule** dialog box, edit the following as needed for each rule you want to change:

- **Order**: Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

  Tip:

  The *order of the rules within the path route set* does not matter in most cases. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

- **Match Style**: Required. The *type of matching* to apply to incoming URIs.

- **URL String**: Required. The path string to match against the incoming URI path, for example `/admin/`.

- **Backend Set Name**: Required. The name of the target backend set for requests where the incoming URI matches the specified path.

6. Click **Save Changes**.

### Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these API operations to manage request routing:

- `CreateListener`
- `CreatePathRouteSet`
- `DeleteListener`
- `DeletePathRouteSet`
- `GetPathRouteSet`
- `ListPathRouteSets`
- `UpdateListener`
- `UpdatePathRouteSet`
Managing Rule Sets

This topic describes how you can create rule sets composed of actions to apply to traffic at an HTTP listener. For more information about managing load balancer listeners, see Managing Listeners on page 2522.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Rule Sets

A rule set is a named set of rules associated with a load balancer and applied to one or more listeners on that load balancer. Rules are objects that represent actions applied to traffic at a load balancer listener.

You can include the following types of rules in a rule set:

- Access control rules, which restrict access to application resources based on the source of the request.
- Access method rules, which specify the permitted HTTP methods.
- URL redirect rules, which route incoming HTTP requests to a different destination URL.
- Request and response header rules, which add, alter, or remove HTTP request or response headers.
- HTTP header rules, which specify the size of the HTTP header and whether period and underscore characters are permitted within the headers.

Rule sets apply only to HTTP listeners.

You can apply an existing rule set when you edit a listener. You can apply the same rule set to multiple listeners on the same load balancer.

Rule sets are not shared between load balancers. To use the same set of rules on another load balancer, you must create a new, identical rule set under that load balancer.

You can have up to 20 rules in a rule set. You can associate a maximum of 50 rules with a load balancer.

Access Control Rules

Access control rules permit access to application resources based on user-specified IP address or address range match conditions. If you do not specify any access control rules, the default rule is to allow all traffic. If you add access control rules, the load balancer denies any traffic that does not match the rules.

The service accepts only classless inter-domain routing (CIDR) format (x.x.x.x/y or x:x::x/y) strings for the match condition.

Specify 0.0.0.0/0 or ::/0 to match all incoming traffic.

Note:

Only US Government Cloud regions currently permit IPv6 values.
Access Method Rules

Access method rules specify the HTTP methods allowed at the associated listener. The load balancer does not forward a disallowed request to the backend servers and returns a 405 Method Not Allowed response with a list of the allowed methods. You can associate only one list of allowed methods with a given listener.

By default, you can specify only the standard HTTP methods defined in the HTTP Method Registry. The list of HTTP methods is extensible. If you need to configure custom HTTP methods, contact My Oracle Support to remove the restriction from your tenancy. Your backend application must be able to handle the specified methods.

Default HTTP Methods

ACL

ROPPATCH
PUT
REBIND
REPORT
SEARCH
URL Redirect Rules

URL redirect rules specify how to route incoming HTTP requests to a different destination URL. URL redirect rules apply only to HTTP listeners. You configure each redirect rule for a particular listener and a designated path. A listener can have only one redirect rule for a given incoming URL path.

When you create a URL redirect rule, you specify the path string and match condition the service uses to evaluate an incoming URL for redirection. You also define the redirect URL and response code.

Incoming path string evaluation

You specify the path string, or pattern, to evaluate in the incoming URL. For example:

```
/video
```

You also specify the match condition to apply when evaluating the incoming URL for redirection. The available match types are:

- **FORCE_LONGEST_PREFIX_MATCH**
  The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
- **EXACT_MATCH**
  The incoming URL path must exactly and completely match the specified path string.
- **PREFIX_MATCH**
  The beginning portion of the incoming URL path must exactly match the specified path string.
- **SUFFIX_MATCH**
  The ending portion of the incoming URL path must exactly match the specified path string.

Redirection URL construction

You define the redirect URL applied to the original request. URL redirect rules recognize the following URL components:

```
<protocol>://<host>:<port>/<path>?<query>
```

You can specify a literal string or provide a token for any component. Tokens extract values from the incoming HTTP request URL. Tokens are case-sensitive. For example, `{host}` is a valid token, but `{HOST}` is not.

- **Protocol**
  The HTTP protocol to use in the redirect URL. Valid values are HTTP and HTTPS.
  The `{protocol}` token extracts the protocol from the incoming HTTP request URL. It is the only valid token for this property.
• **Host**
  
The valid domain name or IP address to use in the redirect URL.
  
The `{host}` token extracts the host from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.
  
Curly braces {} are valid in this property only to surround tokens.

• **Port**
  
The communication port to use in the redirect URL. Valid values include integers from 1 to 65535.
  
The `{port}` token extracts the port from the incoming HTTP request URL. It is the only valid token for this property.

• **Path**
  
The HTTP URL path to use in the redirect URL. To omit the path from the redirect URL, set this value to an empty string.
  
The `{path}` token extracts the path string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

If the path string does not begin with the `{path}` token, it must begin with a forward slash /.

• **Query**
  
The query string to use in the redirect URL. To omit all incoming query parameters from the redirect URL, set this value to an empty string.
  
The `{query}` token extracts the query string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

If the query string does not begin with the `{query}` token, it must begin with a question mark ?.

You can specify multiple query parameters as a single string. Separate each query parameter with an ampersand &.

If the specified query string results in a redirect URL ending with ? or &; the last character is truncated. For example, if the incoming URL is `http://host.com:8080/documents` and the query property value is `?lang=en&{query}`, the redirect URL is `http://host.com:8080/documents?lang=en`. The system truncates the final ampersand & because the incoming URL included no value to replace the `{query}` token.

**Caution:**

Failure to specify a value for at least one URL component field can result in a redirect loop.

---

**Manual Redirect URL construction**

The Console provides text entry fields for each URL component. Alternatively, you can manually specify the full redirect URL.

You can retain the literal characters of a token when you specify values for the path and query properties of the redirect URL. Use a backslash \ as the escape character for the \, \, and } characters. For example, if the incoming HTTP request URL is `/video`, the path property value `/example{path}123\{path\}` appears in the constructed redirect URL as `/example/video123{path}`.

Some path and query string examples:

- `/example/video/123` appears as `/example/video/123` in the redirect URL.
- `/example{path}` appears as `/example/video/123` in the redirect URL when `/video/123` is the path in the incoming HTTP request URL.
- `{path}/123` appears as `/example/video/123` in the redirect URL when `/example/video` is the path in the incoming HTTP request URL.
• {path}123 appears as /example/video123 in the redirect URL when /example/video is the path in the incoming HTTP request URL.

• /{host}/123 appears as /example.com/123 in the redirect URL when example.com is the hostname in the incoming HTTP request URL.

• /{host}/{port} appears as /example.com:123 in the redirect URL when example.com is the hostname and 123 is the port in the incoming HTTP request URL.

• {query} appears as /lang=en in the redirect URL when the query is lang=en in the incoming HTTP request URL.

• lang=en&time_zone=PST appears as lang=en&time_zone=PST in the redirect URL.

• {query} appears as lang=en&time_zone=PST in the redirect URL when lang=en&time_zone=PST is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, the {query} token renders as an empty string.

• lang=en&{query}&time_zone=PST appears as lang=en&country=us&time_zone=PST in the redirect URL when country=us is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, this value renders as lang=en&time_zone=PST.

• protocol={protocol}&hostname={host} appears as protocol=http&hostname=example.com in the redirect URL when the protocol is http and the hostname is example.com in the incoming HTTP request.

• port={port}&hostname={host} appears as port=8080&hostname=example.com in the redirect URL when the port is 8080 and the hostname is example.com in the incoming HTTP request URL.

**Response Code**

You can specify the HTTP status code to return when the incoming request is redirected. Valid response codes for redirection from the standard HTTP specification are:

- 301 Moved Permanently
- 302 Found
- 303 See Other
- 307 Temporary Redirect
- 308 Permanent Redirect

The default value is 302 Found.

**Request and Response Header Rules**

Request and response header rules add, alter, or remove HTTP request or response headers. These rules can help you pass metadata to your backend servers to do things like:

- Identify which listener sent a request.
- Notify a backend server about SSL termination.

Examples of how rule sets can help you enhance site security include:

- Adding headers to prevent external domains from iframing your site.
- Removing debug headers, such as "Server," sent by backend servers. This action helps you hide the implementation details of your backend.
- Adding the "strict-transport-security" header, with a proper value, to responses. This header helps guarantee that access to your site is HTTPS only.
- Adding the "x-xss-protection" header with a proper value. This header helps you enforce the cross-site scripting (XSS) protection built into modern browsers.
- Adding the "x-content-type" header with a proper value. This header helps you prevent attacks based on content type shifting.

**Note:**

Adding or removing the built-in Host header or one of the X-Headers as described in HTTP "X-" Headers does not remove or override the header
value. Instead, performing these actions can append additional values or duplicate the header.

**Example: Notify WebLogic that the Load Balancer Terminated SSL**

You can configure your load balancer to perform SSL termination. Often, your backend applications require notification of this action. For example, HTTPS WebLogic e-commerce online transaction processing looks for the WL-Proxy-SSL header to confirm that a request came in over SSL. You can use rule sets to add this header at the load balancer listener.

**Tip:**

For security reasons, WebLogic ignores this header unless you check the WebLogic Plugin Enabled box in WebLogic's Administration Console.

1. Follow the instructions to create a rule set and:
   a. Choose the Add Request Header option from the Action drop-down list.
   b. Enter WL-Proxy-SSL as the Header name.
   c. Set the header Value:
      1. If your load balancer is configured to perform SSL termination, set this value to "true."
      2. If the SSL termination point is in the web server where the plug-in operates, set this value to "false."

2. Create a listener, or edit an existing listener, and add the new rule set.

**HTTP Header Rules**

HTTP header rules specify the size of the HTTP header and the kinds of characters that are permitted within the header. Because some applications require a URL header size greater than the default 8k to support their features, HTTP header rules allow you to set header buffers of up to 64k to avoid "414" (large URI requests) errors.

HTTP header rules allow periods ("."), underscores ("_"), providing you more flexibility in your naming structures.

**Creating Rule Sets**

To apply a rule set to a listener, you first create the rule set that contains the rules. The rule set becomes a part of the load balancer's configuration. You can specify the rule set to use when you create or update a listener for the load balancer.

**To create a rule set**

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Rule Sets, and then click Create Rule Set.
4. In the Create Rule Set dialog box, enter the following:
   • **Name**: Required. Specify a friendly name for the rule set. The name must be unique, and cannot be changed. Avoid entering confidential information.
   • **Specify Access Control Rules**: Optional. Check this box to add access control rules.
     • **IP Address CIDR**: Enter the IP address CIDR block from which access is allowed.
     • **+ Another Access Control Rule**: Optional. Click this button to enter another IP address CIDR or click the corresponding X to remove an existing entry.
   • **Specify Access Method Rules**: Optional. Check this box to add access method rules.
     • **Allowed Methods**: From the drop-down list, select the HTTP methods to allow. You can select multiple methods. Click the label's X to remove an existing method.
   • **Specify URL Redirect Rules**: Optional. Check this box to add URL redirect rules.
     • **Source Path**: Specify the incoming path string that triggers the redirect rule. For example, /video.
     • **Match Type**: Choose the match condition to apply when evaluating an incoming path string. The available match types are:
       • **FORCE_LONGEST_PREFIX_MATCH**
         The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
       • **EXACT_MATCH**
         The incoming URL path must exactly and completely match the specified path string.
       • **PREFIX_MATCH**
         The beginning portion of the incoming URL path must exactly match the specified path string.
       • **SUFFIX_MATCH**
         The ending portion of the incoming URL path must exactly match the specified path string.
     • **Redirect to**: Specify a value for at least one URL component field. Any component fields that you do not modify retain the incoming URL’s values.
       Optionally, click the **Switch to full URL** link to enter the redirect URL manually.

       **Caution:**
       Failure to specify a value for at least one URL component field can result in a redirect loop.

       • **Protocol**: Specify the HTTP protocol to use in the redirect URL. Valid values are:
         • {protocol}
         • HTTPS
         • HTTP
       • **Host**: Specify a valid domain name (hostname) or IP address for the redirect URL. All redirect URL tokens are valid for this property.
       • **Port**: Specify the communication port to use in the redirect URL. Valid values include integers from 1 to 65535.
       • **Path**: The HTTP URL path to use in the redirect URL. All redirect URL tokens are valid for this property.

       **Important:**
       If the path string does not begin with the {path} token, it must begin with the forward slash character /.

       • **Query**: Specify the query string to use in the redirect URL. All redirect URL tokens are valid for this property.
Important:
If the query string does not begin with the \{query\} token, it must begin with the question mark \? character.

- **Response Code**: Specify the HTTP status code to return when the incoming request is redirected. The default response code is **302 Found**.

  Valid response codes for redirection from the standard HTTP specification are:
  - 301 Moved Permanently
  - 302 Found
  - 303 See Other
  - 307 Temporary Redirect
  - 308 Permanent Redirect

- **Another URL Redirect Rule**: Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.

- **Specify Request Header Rules**: Optional. Check this box to add request header rules.

- **Order**: Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.

- **Action**: Select the action that the rule applies. Available actions include:
  - **Add Request Header**
    Adds the specified header and value to the incoming request.
    If the specified header is already present, the system replaces it.
    If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.
  - **Extend Request Header**
    Adds the specified prefix or suffix to the incoming request.
    Provide a prefix value, a suffix value, or both when you choose this action.
    The system does not support this rule for headers with multiple values.
  - **Remove Request Header**
    Removes the specified header.
    If the same header appears more than once in the request, the load balancer removes all occurrences of the specified header.

  **Note**:
  These rules apply only to HTTP or HTTP2 headers.

- **Header**: A header name that conforms to RFC 7230.

  **Caution**:
  The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do
not rely on underscore or dash characters to uniquely distinguish header names.

- **Value:** (Add rules only.) A header value that conforms to RFC 7230.
- **Prefix:** (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
- **Suffix:** (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
- **+ Another Request Header Rule** Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.
- **Specify Response Header Rules:** Optional. Check this box to add response header rules.
- **Order:** Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.
- **Action:** Select the action that the rule applies. Available actions include:
  - **Add Response Header**
    Adds the specified header and value to the outgoing response.
    If the specified header is already present, the system replaces it.
    If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.
  - **Extend Response Header**
    Adds the specified prefix or suffix to the incoming request.
    Provide a prefix value, a suffix value, or both when you choose this action.
    The system does not support this rule for headers with multiple values.
  - **Remove Response Header**
    Removes the specified header.
    If the same header appears more than once in the response, the load balancer removes all occurrences of the specified header.

**Note:**
These rules apply only to HTTP or HTTP2 headers.

- **Header:** A header name that conforms to RFC 7230.

**Caution:**
The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do
Load Balancing

not rely on underscore or dash characters to uniquely distinguish header names.

- **Value**: (Add rules only.) A header value that conforms to RFC 7230.
- **Prefix**: (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
- **Suffix**: (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
- **Another Response Header Rule**: Optional. Click this button to create another rule or click the corresponding X to delete an existing rule.
- **Specify HTTP Rules**: Optional. Check this box to specify HTTP header options for a listener.
  - **HTTP Header Buffer Size**: Select one of the following buffer sizes for the HTTP header from the list: None, 8k, 16k, 32k, 64k.
  - **Allow Invalid Characters in HTTP Header**: Check this box to allow periods ("." ) and underscores ("_" ) in the HTTP header.
- **Specify HTTP Header Options**: Optional. Check this box to specify HTTP header options for a listener.
  - **HTTP Header Buffer Size**: Select one of the following buffer sizes for the HTTP header from the list: None, 8k, 16k, 32k, 64k.
  - **Allow Invalid Characters in HTTP Header**: Optional. Check this box to allow invalid characters in the HTTP header.

5. Click Create.

After you create a rule set, the set becomes available for use with the associated load balancer. Update a listener to apply the rule set.

### Editing Rule Sets

**To update a rule set**

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer associated with the rule set you want to modify, and then click the load balancer's name.
3. In the Resources menu, click Rule Sets.
4. Click the name of the rule set you want to edit, and then click Edit Rules.
5. Edit the rules as needed.
   
   You cannot edit the Name field of an existing rule set.
6. Click Save Changes.

### Deleting Rule Sets

**To delete a rule set from a listener**

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Choose the Compartment that contains the load balancer associated with the rule set you want to delete, and then click the load balancer's name.
3. In the Resources menu, click Listeners.
4. For the listener you want to edit, click the the Actions icon (three dots), and then click Edit Listener.
5. In the Rule Sets section of the dialog box, click the corresponding X to remove an existing rule set.

**Tip:**

This action removes the rule set from the current listener, but the rule set remains available for application to other listeners on the load balancer.

6. Click Save Changes.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage rule sets:

- CreateRuleSet
- DeleteRuleSet
- GetRuleSet
- ListRuleSets
- UpdateRuleSet

Use this API to route incoming HTTP requests to a different destination URL:

- RedirectRule

Use this API to allow the setting of HTTP header size and allow or disallow invalid characters in the HTTP headers:

- HttpHeadersRule

Managing SSL Certificates

This topic is part of the setup and maintenance of a load balancer. For more information about managing load balancers, see Managing Load Balancers on page 2494.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with SSL Certificates

To use SSL with your load balancer, you must add one or more certificate bundles to your system. The certificate bundle you upload includes the public certificate, the corresponding private key, and any associated Certificate Authority (CA) certificates. For the easiest workflow, upload the certificate bundles you want to use before you create the listeners or backend sets you want to associate them with.

Load balancers commonly use single domain certificates. However, load balancers with listeners that include request routing configuration might require a subject alternative name (SAN) certificate (also called multi-domain certificate) or a wildcard certificate. The Load Balancing service supports each of these certificate types.

Important:

- The Load Balancing service does not generate SSL certificates. It can only import an existing certificate that you already own. The certificate can be one issued by a vendor, such as Verisign or GoDaddy. You can also use a self-signed certificate that you generate with an open source tool, such as OpenSSL or Let’s Encrypt. Refer to the corresponding tool's documentation for instructions on how to generate a self-signed certificate.
Oracle Cloud Infrastructure accepts x.509 type certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Converting to PEM format

If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format. The following example commands provide guidance.

**Certificate or certificate chain from DER to PEM**

```
openssl x509 -inform DER -in <certificate_name>.der -outform PEM -out <certificate_name>.pem
```

**Private key from DER to PEM**

```
openssl rsa -inform DER -in <private_key_name>.der -outform PEM -out <private_key_name>.pem
```

**Certificate bundle from PKCS#12 (PFX) to PEM**

```
openssl pkcs12 -in <certificate_bundle_name>.p12 -out <certificate_bundle_name>.pem -nodes
```

**Certificate bundle from PKCS#7 to PEM**

```
openssl pkcs7 -in <certificate_bundle_name>.p7b -print_certs -out <certificate_bundle_name>.pem
```

**How to configure and troubleshoot Peer Cert Verify**

The Verify Peer Certificate is used for client authentication. Peer Cert Verify Depth is the number of certificates in the chain that need to be verified for client authentication.

The following are expected values to be set:

- One Intermediate Cert, Client Cert, Root Cert - 2
- Client Cert, Root Cert - 1

To determine if your Peer Cert Verification is misconfigured, note the following:

- Your Client will indicate that it is unable to verify the certificate and will result in a Client SSL handshake failure. This error message will vary based on the client type.
- In your Load Balancer Logs, you will witness the error: `Client %s has SSL certificate verify error`
• Using the OpenSSL tool, run the following command: `openssl verify -verbose -CAfile RootCert.pem Intermediate.pem`

  You will see an error that shows you at what depth the validation failure is occurring: `error 20 at 0 depth lookup:unable to get local issuer certificate`

• To resolve this situation, you will need to provide the correct certificate depth, and confirm the client certificate and CA certificate match and are provided in the correct order.

### Uploading Certificate Chains

If you have multiple certificates that form a single certification chain (for example, any Intermediate CA certificates), include all relevant certificates in one file in the correct order before you upload them to the system. The correct order begins with the certificate directly signed by the Trusted Root CA at the bottom. Any additional certificates are pasted directly on top of the authority who signed it.

You need to combine the Server certificate (`SSL_Certificate.crt`) and the Intermediate CA certificate (`intermediateCA.crt`) files into a single concatenated file.

To get a single concatenated file out of the Intermediate CA and the SSL Certificate, open a command prompt and run the following command:

```
cat ssl_certificate.crt IntermediateCA.crt >> certbundle.pem
```

The following example of a concatenated certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

### Submitting Private Keys

**Tip:**

Oracle recommends a minimum length of 2048 bits for your RSA private key.

If your private key submission returns an error, the three most common reasons are:

• You provided an incorrect passphrase.
• Your private key is malformed.
• The system does not recognize the encryption method used for your key.

### Key Pair Mismatch

If you receive an error related to the private key and public key being mismatched, prior to uploading use these OpenSSL commands to confirm they are part of the same pair.

```
openssl x509 -in <certificate_name>.crt -noout -modulus | openssl sha1
openssl rsa -in <private_key>.key -noout -modulus | openssl sha1
```
Confirm that the returned sha1 hash values match exactly. If they are different the Private Key provided is not used to sign the public certificate and can not be used.

**Private key consistency**

If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```bash
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

**Decrypting a private key**

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```bash
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

**Updating an Expiring Certificate**

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

   **Note:**
   The steps to update your client or backend server are unique to your system.
2. Upload the new SSL certificate bundle to the load balancer
   
   a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
   
   b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
   
   c. Click the load balancer you want to configure.
   
   d. In the **Resources** menu, click **Certificates**, and then click **Add Certificate**.
   
   e. In the **Add Certificate** dialog box, enter the following:
      
      • **Certificate Name**: Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
      
      • **Choose SSL Certificate File**: Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.

      Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.
3. **Edit listeners or backend sets (as needed) so they use the new certificate bundle**

**Editing a listener:**

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

b. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

c. In the **Resources** menu, click **Listeners**.

d. For the listener you want to edit, click the Actions icon (three dots), and then click **Edit Listener**.

e. In the **Certificate Name** drop-down list, choose the new certificate bundle.

f. Click **Submit**.

**Editing a backend set:**

> **Caution:**
> Updating the backend set temporarily interrupts traffic and can drop active connections.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

c. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to edit.

d. Click **Edit Backend Set**.

e. In the **Edit Backend Set** dialog box, select (check) **Use SSL**.

f. In the **Certificate Name** drop-down list, choose the new certificate bundle.

g. Click **Save Changes**.

4. **(Optional) Remove the expiring SSL certificate bundle**

> **Important:**
> You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

c. Click the load balancer you want to configure.

d. In the **Resources** menu, click **Certificates**.

e. For the certificate you want to delete, click the Actions icon (three dots), and then click **Delete**.

f. Confirm when prompted.

**Configuring SSL Handling**

With Oracle Cloud Infrastructure Load Balancing, you can:

- Terminate SSL at the load balancer. This configuration is **frontend SSL**. Your load balancer can accept encrypted traffic from a client. There is no encryption of traffic between the load balancer and the backend servers.

- Implement SSL between the load balancer and your backend servers. This configuration is **backend SSL**. Your load balancer does not accept encrypted traffic from client servers. Traffic between the load balancer and the backend servers is encrypted.

- Implement end to end SSL. Your load balancer can accept SSL encrypted traffic from clients and encrypts traffic to the backend servers.
**Terminating SSL at the Load Balancer**

To terminate SSL at the load balancer, you must create a listener at a port such as 443, and then associate an uploaded certificate bundle with the listener.

**Implementing Backend SSL**

To implement SSL between the load balancer and your backend servers, you must associate an uploaded certificate bundle with the backend set.

***Tip:***

- If you want to have more than one backend server in the backend set, sign your backend servers with an intermediate CA certificate. The intermediate CA certificate must be included as part of the certificate bundle.
- Your backend services must be able to accept and terminate SSL.

**Implementing End to End SSL**

To implement end to end SSL, you must associate uploaded certificate bundles with both the listener and the backend set.

**Using the Console**

To upload an SSL certificate bundle to your load balancing system

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer’s name.
3. Click the load balancer you want to configure.
4. In the Resources menu, click Certificates, and then click Add Certificate.
5. In the Add Certificate dialog box, enter the following:

   - **Certificate Name:** Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
   - **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the SSL Certificate field.
     Alternatively, you can choose the Paste SSL Certificate option to paste a certificate directly into this field.

     **Important:**
     
     If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

   - **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
     - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the CA Certificate field.
       Alternatively, you can choose the Paste CA Certificate option to paste a certificate directly into this field.

   - **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
     - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the Private Key field.
     - **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

6. Click Add Certificate.
To delete an SSL certificate bundle from your load balancing system

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any listeners or backend sets before deleting.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click the load balancer you want to configure.
4. In the Resources menu, click Certificates.
5. For the certificate you want to delete, click the Actions icon (three dots), and then click Delete.
6. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage load balancer certificates:

- CreateCertificate
- DeleteCertificate
- ListCertificates

Editing Health Check Policies

This topic describes how to modify health check policies for a backend set.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Working with Health Check Policies

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
• HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

**Important:**

Configure your health check protocol to match your application or service.

If you run an HTTP service, be sure to configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, customers might experience transaction failures. For example:

- The backend HTTP service has issues when talking to the health check URL and the health check URL returns 5XX messages. An HTTP health check catches the message from the health check URL and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service is may not be usable.
- The backend HTTP service responds with 4XX messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

**Health Status**

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console List and Details pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

Health status indicators have four levels. The following table provides the general meaning of each level:

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
<td>Green</td>
<td>No attention required. The resource is functioning as expected.</td>
</tr>
<tr>
<td>Warning</td>
<td>Yellow</td>
<td>Some reporting entities require attention. The resource is not functioning at peak efficiency or the resource is incomplete and requires further work.</td>
</tr>
<tr>
<td>Critical</td>
<td>Red</td>
<td>Some or all reporting entities require immediate attention. The resource is not functioning or unexpected failure is imminent.</td>
</tr>
<tr>
<td>Level</td>
<td>Color</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Unknown</td>
<td>Gray</td>
<td>Health status cannot be determined. The resource is not responding or is in transition and might resolve to another status over time.</td>
</tr>
</tbody>
</table>

The precise meaning of each level differs among the following components:

- **Load balancers**
- **Backend sets**
- **Backend servers**

### Using Health Status

At the highest level, load balancer health reflects the health of its components. The health status indicators provide information you might need to drill down and investigate an existing issue. Some common issues that the health status indicators can help you detect and correct include:

**A health check is misconfigured.**

In this case, all the backend servers for one or more of the affected listeners report as unhealthy. If your investigation finds that the backend servers do not have problems, then a backend set probably includes a misconfigured health check.

**A listener is misconfigured.**

All the backend server health status indicators report **OK**, but the load balancer does not pass traffic on a listener.

The listener might be configured to:

- Listen on the wrong port.
- Use the wrong protocol.
- Use the wrong policy.

If your investigation shows that the listener is not at fault, check the security list configuration.

**A security rule is misconfigured.**

Health status indicators help you diagnose two cases of misconfigured security rules:

- All entity health status indicators report **OK**, but traffic does not flow (as with misconfigured listeners). If the listener is not at fault, check the security rule configuration.
- All entity health statuses report as unhealthy. You have checked your health check configuration and your services run properly on your backend servers.

In this case, your security rules might not include the IP range for the source of the health check requests. You can find the health check source IP on the **Details** page for each backend server. You can also use the API to find the IP in the **sourceIpAddress** field of the **HealthCheckResult** object.

**Note:**

Source IP

The source IP for health check requests comes from a Compute instance managed by the Load Balancing service.

**One or more of the backend servers reports as unhealthy.**

A backend server might be unhealthy or the health check might be misconfigured. To see the corresponding error code, check the **status** field on the backend server's **Details** page. You can also use the API to find the error code in the **healthCheckStatus** field of the **HealthCheckResult** object.
Other cases in which health status might prove helpful include:

- VCN network security groups or security lists block traffic.
- Compute instances have misconfigured route tables.

Health status is updated every three minutes. No finer granularity is available.

Health status does not provide historical health data.

**Health Check Best Practices**

Configure your health check protocol to match your application or service. If you run an HTTP service, be sure to configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, customers might experience transaction failures. For example:

- The backend HTTP service has issues when talking to the health check URL and the health check URL returns 5XX messages. An HTTP health check catches the message from the health check URL and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service may not be usable.
- The backend HTTP service responds with 4XX messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

**Configure the Health Check**

To configure the health check, use the following procedure.

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the Compartment that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the Resources menu, click **Backend Sets** and then click the name of the backend set you want to modify.
4. Click **Update Health Check**.
5. In the Health Check section, specify the test parameters to confirm the health of backend servers. All parameters are required when updating an existing health check policy.

- **Protocol**: Required. Specify the protocol to use, either HTTP or TCP.

  **Note:**
  Configure your health check protocol to match your application or service.

- **Port**: Required. Specify the backend server port against which to run the health check.

  **Note:**
  You can enter the value '0' to have the health check use the backend server's traffic port.

- **URL Path (URI)**: (HTTP only) Required. Specify a URL endpoint against which to run the health check. Example:

  /health
  (This is a commonly used path for a health check application).

- **Interval in ms**: Required. Specify how frequently to run the health check, in milliseconds. Default is 10000 (10 seconds).

- **Timeout in ms**: Required. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. Default is 3000 (3 seconds).

  **Note:**
  Enter a timeout value that is smaller than the interval value to ensure the health check works correctly.

- **Number of retries**: Required. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.

- **Status Code**: (HTTP only) Required. Specify the status code a healthy backend server must return.

- **Response Body Regex**: (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server. The system treats a blank entry here as the value ".*".

  **Note:**
  Health checks require all fields to match. Your status code and response body both must match, as specified.

6. Click **Save**.

**Common Side effects of health check misconfiguration**

The following are common side effects of health check misconfiguration, and can be used to troubleshoot issues.

- **Wrong Port**
  In this scenario, all of the backend servers report as unhealthy. If the backend servers do not have any problems, you may have made a mistake setting the port it needs to be a port that matches a port that is listening and has allowed traffic on the backend.

  OCI Logging Error: \texttt{errno}="EHOSTUNREACH", \texttt{syscall}="connect".

- **Wrong Path**
  In this scenario, all of the backend servers report as unhealthy. If the backend servers do not have any problems, you may have made a mistake setting the path for the HTTP health check it needs to match a an actual application
on the backend. In this scenario you can use a curl test from a system in the same network. ex: $ curl -i http://10.0.0.5/health

You will receive the configured status code in the response OCI Logging Error: "msg":"invalid statusCode","statusCode":404,"expected":"200".

• Wrong Protocol

In this scenario, all of the backend servers report as unhealthy. If the backend servers do not have any problems, you may have made a mistake setting the protocol it needs to match the protocol that is listening on the backend. For example: We only support TCP and HTTP health checks. If your backend is using HTTPS then you would need to use TCP as the protocol.

OCI Logging Error: "code":"EPROTO","errno":"EPROTO".

• Wrong Status Code

In this scenario, all of the backend servers report as unhealthy. If the backend servers do not have any problems, for a HTTP health check you may have made a mistake setting the status code to match the actual status code being returned from the backend. A common scenario is when a backend is returning a 302 and you are expecting a 200. This is likely the backend sending you to a login page or another location on the server. In this scenario you can either fix the backend to return the expected code or use 302 in your health check config.

OCI Logging Error: "msg":"invalid statusCode","statusCode":XX,"expected":"200" where XX to be the status code that is returned.

• Wrong Regex Pattern

All the backend servers report as unhealthy. If the backend servers do not have any problems, you may have made a mistake setting an incorrect regex pattern consistent with the body, or the backend is not returning the expected body. In this scenario you can either change the backend to match the pattern or correct the pattern to match the backend. The following are some specific pattern examples.

• Any Content - ".*"
• A page returning the value "Status:OK:" - "Status:OK:.*"
• OCI Logging Error: "response match result: failed"

• Misconfigured Network Security Groups, Security Lists or Local Firewall

All or some of the backend servers report as unhealthy. If the backend servers do not have any problems, you may have made a mistake configuring either the NSGs, Security Lists, or local firewalls such as firewalld, iptables, or SELinux. In this scenario you can use a curl or netcat test from a system that belongs to the same subnet and NSG as your LBaaS instance HTTP: ex: $ curl -i http://10.0.0.5/health TCP: ex: nc -zvw3 10.0.05 443.

You can check your local firewall by using the following command: firewall-cmd --list-all --zone=public. If your firewall is missing the expected rules you can use a command set like this to add the service: (this example is for HTTP port 80):

• firewall-cmd --zone=public --add-service=http
• firewall-cmd --zone=public --permanent --add-service=http

Creating a custom health check page

In many scenarios you may want to expose your own custom health check page to do a more thorough check. One example scenario is to use the flask application as in the example below rather than relying on your existing application.https://pypi.org/project/py-healthcheck/

import tornado.web
from healthcheck import TornadoHandler, HealthCheck, EnvironmentDump

# add your own check function to the healthcheck

def redis_available():
  client = _redis_client()
info = client.info()
return True, "Redis Test Pass"

health = HealthCheck(checkers=[redis_available])
app = tornado.web.Application([
    ("/healthcheck", TornadoHandler, dict(checker=health)),
])

In the above example the test page is doing more than just making sure the HTTP application is listening. This example checks for a redis client and waits for a response to make sure the full application is healthy before returning a 200 OK. Some other command examples would be to check for disk space or the availability of an upstream dependency. In your health check configuration you would specify the following:

- /healthcheck as your path
- flask default 5000 as port
- 200 as status code

**Editing Health Check Policies**

You create your health check tests when you [create a backend set](#).

**To edit an existing health check policy**

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer’s name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to modify.
4. Click **Update Health Check**.
5. In the **Health Check** section, specify the test parameters to confirm the health of backend servers.

   **Tip:**
   
   All parameters are required when updating an existing health check policy.

   - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

     **Important:**
     
     Configure your health check protocol to match your application or service.

   - **Port:** Required. Specify the backend server port against which to run the health check.

     **Tip:**
     
     You can enter the value '0' to have the health check use the backend server's traffic port.

   - **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.

     **Important:**
     
     Enter a timeout value that is smaller than the interval value to ensure the health check works correctly.

   - **Interval in ms:** Required. Specify how frequently to run the health check, in milliseconds. Default is 10000 (10 seconds).

   - **Timeout in ms:** Required. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. Default is 3000 (3 seconds).

   **Important:**
   
   Enter a timeout value that is smaller than the interval value to ensure the health check works correctly.

   - **Number of retries:** Required. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. Default is 3.

   - **Status Code:** (HTTP only) Required. Specify the status code a healthy backend server must return.

   - **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server. The system treats a blank entry here as the value ".*".

   **Tip:**
   
   Health checks require all fields to match. Your status code and response body both must match, as specified.

6. Click **Save**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to edit a backend set's health check policy:

   UpdateBackendSet

Use these API operations to retrieve health status information:

- GetBackendHealth
- GetBackendSetHealth
- GetLoadBalancerHealth
- ListLoadBalancerHealths

**Viewing the State of a Work Request**

This topic describes how to view the state of work requests associated with a given load balancer.
Load Balancing

**Note:**

The Load Balancing service does not use the common Work Requests API to support work request operations. Instead, Load Balancing work requests are supported by the Load Balancing API. See Using the Console to View Work Requests on page 260 for information on viewing work requests for other services.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2143.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2292.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Monitoring Work Requests**

Many of the Oracle Cloud Infrastructure Load Balancing service requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment. To provide visibility for in-progress workflows, the Load Balancing service creates a work request object. Because some operations depend on the completion of other operations, you must monitor each operation’s work request and confirm it has succeeded before proceeding to the next operation. For example, if you want to create a backend set and add a backend server to the new set, you first must create the backend set. After that operation completes, you can add the backend server. If you try to add a backend server before the backend set creation completes, the system cannot ensure that the request to add the server succeeds. You can monitor the request to add a backend set to determine when that workflow is complete, and then add the backend server.

The work request states are:

- **ACCEPTED**
  
  The request is in the work request queue to be processed.

- **IN PROGRESS**
  
  A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.

- **SUCCEEDED**
  
  A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.

- **FAILED**
  
  A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

**Using the Console**

The Oracle Cloud Infrastructure Console consumes the REST API and is subject to the same considerations as any Oracle Cloud Infrastructure client. You can view the state of a load balancing work request in the Console:

1. Open the navigation menu. Under the Core Infrastructure group, go to Networking and click Load Balancers.
2. Click the name of the **Compartment** that contains the load balancer you want to review, and then click the load balancer's name.

3. In the **Resources** menu, click **Work Requests**. The status of all work requests appears on the page.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these operations to monitor the state of work requests:

- **ListWorkRequests**
- **GetWorkRequest**

**Load Balancing Metrics**

You can monitor the health, capacity, and performance of your load balancers by using **metrics**, **alarms**, and **notifications**.

This topic describes the metrics emitted by the Load Balancing service in the **oci_lbaas** metric namespace.

Resources: Load balancers, listeners, and backend sets.

**Overview of the Load Balancing Service Metrics**

Your load balancer acts as an intermediary for data traffic between clients and your application servers. Clients send requests to your load balancer and the load balancer distributes the requests to your backend servers according to rules you establish. See the diagram in **Overview of Load Balancing** on page 2480 for a high-level view of a simple public load balancing system configuration.

The Load Balancing service metrics help you measure the number and type of connections, and quantity of data managed by your load balancer. You can use metrics data to diagnose and troubleshoot load balancer and client issues. The metrics also help you analyze the HTTP responses returned by the servers in your backend set.

To view a default set of metrics charts in the Console, navigate to the load balancer or backend set you're interested in, and then click **Metrics**. You also can use the Monitoring service to create **custom queries**.

**Prerequisites**

- **IAM policies**: To monitor resources, you must be given the required type of access in a **policy** written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which **compartment** you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or **Notifications**.
- The metrics listed on this page are automatically available for any load balancer, listener, and backend set you create. You do not need to enable monitoring on the resource to get these metrics.

**Available Metrics: oci_lbaas**

Load Balancing service metrics include the following **dimensions**:

**AVAILABILITYDOMAIN**

The **availability domain** in which the load balancer resides.

**BACKENDSETNAME**

The name of the backend set to which the metrics apply.
**LBCOMPONENT**

The load balancer component to which the metrics apply.

Valid metrics for the Load Balancing service vary among the three `lbComponent` dimension values:

- **Backendset**
- **Listener**
- **Loadbalancer**

The tables on this page describe which data is valid for each of these dimension values. If you choose a metric that does not apply to the specified dimension value, the metric returns no data.

**LBHOSTID**

A unique ID that represents the current load balancer host. This ID is subject to change.

**LISTENERNAME**

The name of the listener to which the metrics apply.

**REGION**

The `region` in which the load balancer resides.

**RESOURCEID**

The `OCID` of the resource to which the metrics apply.

### Metrics for the `lbComponent` Dimension Value "Backendset"

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveConnections</td>
<td>Active Connections</td>
<td>count</td>
<td>The number of active connections from the load balancer to all backend servers.</td>
<td>availabilityDomain backendSetName lbComponent lbHostId region resourceId</td>
</tr>
<tr>
<td>BackendServers</td>
<td>Backend Servers</td>
<td>count</td>
<td>The number of backend servers in the backend set.</td>
<td></td>
</tr>
<tr>
<td>BackendTimeouts</td>
<td>Backend Timeouts</td>
<td>count</td>
<td>The number of timeouts across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>BytesReceived</td>
<td>Bytes Received</td>
<td>bytes</td>
<td>The number of bytes received across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>BytesSent</td>
<td>Bytes Sent</td>
<td>bytes</td>
<td>The number of bytes sent across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>ClosedConnections</td>
<td>Closed Connections</td>
<td>count</td>
<td>The number of connections closed between the load balancer and backend servers.</td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Dimensions</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------</td>
<td>------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>HttpRequests</td>
<td>Inbound Requests</td>
<td>count</td>
<td>The number of incoming client requests to the backend set.</td>
<td></td>
</tr>
<tr>
<td>HttpResponses</td>
<td>Responses</td>
<td>count</td>
<td>The number of HTTP responses across all backend servers.</td>
<td></td>
</tr>
<tr>
<td>HttpResponses200 Responses</td>
<td>HTTP 200 Responses</td>
<td>count</td>
<td>The number of HTTP 200 responses received from backend servers.</td>
<td></td>
</tr>
<tr>
<td>HttpResponses2xx Responses</td>
<td>HTTP 2xx Responses</td>
<td>count</td>
<td>The number of HTTP 2xx responses received from backend servers.</td>
<td></td>
</tr>
<tr>
<td>HttpResponses3xx Responses</td>
<td>HTTP 3xx Responses</td>
<td>count</td>
<td>The number of HTTP 3xx responses received from backend servers.</td>
<td></td>
</tr>
<tr>
<td>HttpResponses4xx Responses</td>
<td>HTTP 4xx Responses</td>
<td>count</td>
<td>The number of HTTP 4xx responses received from backend servers.</td>

</tr>
</tbody>
</table>

Using the Console

To view default metric charts for a single load balancer

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to view, and then click the load balancer's name.
3. In the **Resources** menu, click **Metrics** (if necessary).

   The **Metrics** page displays a default set of charts for the current load balancer.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

To view default metric charts for multiple load balancers

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Metric Namespace**, select **oci_lbaas**.

   The **Service Metrics** page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the **Monitoring service** to create **custom queries**.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

Using the API

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
Chapter 23

Logging

This chapter explains how to use Oracle Cloud Infrastructure Logging.

Logging Overview

The Oracle Cloud Infrastructure Logging service is a highly scalable and fully managed single pane of glass for all the logs in your tenancy. Logging provides access to logs from Oracle Cloud Infrastructure resources. These logs include critical diagnostic information that describes how resources are performing and being accessed.

How Logging Works

Use Logging to enable, manage, and search logs. The three kinds of logs are the following:

- **Audit logs**: Logs related to events emitted by the Oracle Cloud Infrastructure Audit service. These logs are available from the Logging Audit page, or are searchable on the Search page alongside the rest of your logs.
- **Service logs**: Emitted by OCI native services, such as API Gateway, Events, Functions, Load Balancing, Object Storage, and VCN Flow Logs. Each of these supported services has pre-defined logging categories that you can enable or disable on your respective resources.
- **Custom logs**: Logs that contain diagnostic information from custom applications, other cloud providers, or an on-premise environment. Custom logs can be ingested through the API, or by configuring the Unified Monitoring Agent. You can configure an OCI Compute instance/resource to directly upload Custom Logs through the Unified Monitoring Agent. Custom logs are supported in both a virtual machine and bare metal scenario.

A log is a first-class Oracle Cloud Infrastructure resource that stores and captures log events collected in a given context. For example, if you enable Flow Logs on a subnet, it has its own dedicated log. Each log has an OCID and is stored in a log group. A log group is a collection of logs stored in a compartment. Logs and log groups are searchable, actionable, and transportable.

To get started, enable a log for a resource. Services provide log categories for the different types of logs available for resources. For example, the Object Storage service supports the following log categories for storage buckets: read and write access events. Read access events capture download events, while write access events capture write events. Each service can have different log categories for resources. The log categories for one service have no relationship to the log categories of another service. As a result, the Functions service uses different log categories than the Object Storage service.

When you enable a log, you must add it to a log group that you create. Log groups are logical containers for logs. Use log groups to organize and streamline management of logs by applying IAM policy or grouping logs for analysis. For more information, see Managing Logs and Log Groups on page 2577.

Logs are indexed in the system, and searchable through the Console, API, and CLI. You can view and search logs on the Logging Search page. When searching logs, you can correlate across many logs simultaneously. For example, you can view results from multiple logs, multiple log groups, or even an entire compartment with one query. You can filter, aggregate, and visualize your logs. For more information, see Searching Logs on page 2634.
Note:
Logs are encrypted in the OCI system during storage, but they are not encrypted when returned to the customer.

After you enable a log, log entries begin to appear on the detail page for the log (see Enabling Logging for a Resource on page 2591 for more information). If you need more archiving support, you can use Service Connector Hub (archiving to object storage, write to stream, and so on). For more information on service logs, see Service Log Reference on page 2593, and Service Connector Hub Overview on page 3750.

Note:
You can view usage report detail for Logging by accessing Cost and Usage Reports.

Logging APIs

Oracle Cloud Infrastructure Logging has the following APIs available:

- Logging Management API
- Logging Ingestion API
- Logging Search API

Also see Using the (Logging Management) API, Using the (Logging Ingestion) API for custom logs, and Using the (Logging Search) API for more information on logging operations specific to each API.

Logging Concepts

The following concepts are essential to working with Logging.

Service Logs

Critical diagnostic information from supported Oracle Cloud Infrastructure services. See Supported Services on page 2591.

Custom Logs

Diagnostic information from custom applications, other cloud providers, or an on-premise environment. To ingest custom logs, call the API directly or configure the unified monitoring agent.

Audit Logs

Read-only logs from the Audit service, provided for you to analyze and search. Audit logs capture the information about API calls made to public endpoints throughout your tenancy. These include API calls made by the Console, Command Line Interface (CLI), Software Development Kits (SDK), your own custom clients, or other Oracle Cloud Infrastructure services.

Log Groups

Log groups are logical containers for logs. Use log groups to streamline log management, including applying IAM policy or searching sets of logs. You can move log groups from one compartment to another and all the logs contained in the log group moves with it.

Service Log Category

Services provide log categories for the different types of logs available for resources. For example, the Object Storage service supports the following log categories for storage buckets: read and write access events. Read access events capture download events, while write access events capture write events. Each service can have different log categories for resources. The log categories for one service have no relationship to the log categories of another service.
**Service Connector Hub**

Service Connector Hub moves logging data to other services in Oracle Cloud Infrastructure. For example, use Service Connector Hub to alarm on log data, send log data to databases, and archive log data to Object Storage. For more information, see Service Connector Hub Overview on page 3750.

**Unified Monitoring Agent**

The fluentd-based agent that runs on customer machines (OCI instances), to help customers ingest custom logs.

**Agent Configuration**

A configuration of the Unified Monitoring Agent that specifies how custom logs are ingested.

**Limits on Logging**

In your tenancy, you can create a maximum of:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logs</td>
<td>500 logs per tenancy</td>
</tr>
<tr>
<td>Log groups</td>
<td>100 log groups per tenancy</td>
</tr>
</tbody>
</table>

For more information on extra Logging resource limits, see Logging Limits on page 226. See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators: Use the following topics to find examples of IAM policy for Logging:
Managing Logs and Log Groups

This topic describes how to manage logs and log groups.

Overview of Logs and Log Groups

Logs contain critical diagnostic information that tells you how your resources are performing and being accessed. You can enable logging on supported resources. To see a list of supported resources grouped by service, see Supported Services on page 2591.

Log groups are logical containers for organizing logs. Logs must always be inside log groups. You must create a log group to enable a log.

Use log groups to limit access to sensitive logs with IAM policy. With log groups, you don't have to rely on complex compartment hierarchies to secure your logs. For example, say the default log group in a single compartment is where you store logs for the entire tenancy. You grant access to the compartment for log administrators with IAM policy as you normally would. However, let's say some projects contain personally identifiable information (PII) and those logs can only be viewed by a select group of log administrators. Log groups allow you to put logs that contain PII into a separate log group, and then use IAM policy to restrict access to all but a few log administrators.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Administrators: for policy samples specific to logs and log groups, see Required Permissions for Working with Logs and Log Groups on page 2577.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to know more about writing policies for Logging, see Details for Logging on page 2294.

Required Permissions for Working with Logs and Log Groups

To enable service logs in a resource, a user must be granted manage access on the log group and access to the resource. In general, inspect access on the resource is enough, but check for specific resources. Inspect access provides permission to update the resource and permission for the log group that contains the log.

Logs and log groups use the log-group resource-type, but to search the contents of logs you must use a different resource-type.
Managing log groups and log objects

To manage groups or objects, use verbs for log-groups:

- Allow group A to use log-groups in compartment C
- Allow group B to manage log-groups in compartment C
- Allow group D to read log-groups in compartment C

This allows users in group A to create, update, or delete log groups and log objects in compartment C.

To provision agent configurations

Three different types of access are needed:

1. Access to operate on configurations.
2. Access to operate on log groups.
3. Inspect capabilities on dynamic groups or groups.

To have access to configurations, the policy must be:

- Allow group B to use unified-configuration in compartment X

To create, update, or delete custom logs used as a destination in a configuration

This policy allows users in compartment B to create, update, or delete configurations in compartment X.

To provide a destination for the logs incoming from the configuration, you need log-groups access:

- Allow group B to use log-groups in compartment X

To assign a configuration to a set of instances

To assign a configuration to a set of instances, you need inspect access to the dynamic group or group that identifies the instances:

- Allow group B (IDENTITY_DYNAMIC_GROUP_INSPECT) in tenancy
- Allow group B (IDENTITY_GROUP_INSPECT) in tenancy

Enable instances to push logs into the Logging service

To allow instances to push logs, the instances need to have access to get a configuration and push the logs. log-content controls this permission (where X is the compartment where the configurations are located):

- Allow dynamic-group production-fleet to use log-content in compartment X

To view logs

To view logs in the Console (Search), the following is required:

- Allow group Searchers to read log-content in compartment X

Example log search policy

To allow a group to read the contents of indexed logs:

- allow group GroupA to read log-groups in tenancy
- allow group GroupA to read log-content in tenancy

Example policies for logs and log groups

In these examples, policy statements use GroupA as the name of the group.
Logging

To allow a group to view the log groups in the tenancy (or in a compartment), requires `inspect` access:

```
allow group GroupA to inspect log-groups in tenancy
```

To allow a group to read metadata for logs or log groups, requires `read` access:

```
allow group GroupA to read log-groups in tenancy
```

To allow a group to update log groups, or the logs in them, requires `use` access:

```
allow group GroupA to use log-groups in tenancy
```

To enable a log on a resource (or to create and delete log groups and the logs in them), requires `manage` access:

```
allow group GroupA to manage log-groups in tenancy
```

To allow usage of a specific log group or groups, use a `where` clause with the `target.loggroup.id` variable. For example:

```
Allow group GroupA to manage loggroups in tenancy where target.loggroup.id='ocid1.loggroup.oc1.phx.<uniqueID>'
```

To specify multiple log groups:

```
Allow group GroupA to manage log-groups in tenancy where any {target.loggroup.id='ocid1.loggroup'}
```

**Custom logs**

For **custom logs** the following is required. This policy is needed to allow the user to search logs through the Console **Search** page:

```
allow group userGroup1 to read log-content in compartment c
```

**Note:**

Even though this policy is described for usage with custom logs, the policy is also true for all logs. `LOG_CONTENT_READ` allows reading logs from both custom and OCI service logs. It is identical in behavior to this policy:

```
allow group GroupA to read log-content in tenancy
```

The following is needed for the agent that uses the instance principal on the virtual machine to send logs:

```
allow dynamicGroup1 to use log-content in compartment c
```

**Note:**

If a user group is being used instead of a dynamic group for pushing custom logs, replace the dynamic group name with the user group name in these policies.

For custom logs, if you use `allow group dynamicGroup1 to use log-content in compartment c`, the instances in that dynamic group get permission to download the configuration, send logs, and can search logs.

**IAM Policy Requirements for Resources**

In addition to the permissions to work with the log group, to add service logs to a resource you must have the `update` permission for the resource. For many resources, the update permission is granted with the `use` verb. For example, users who can `use` buckets in CompartmentA, can also enable logging on a bucket in CompartmentA.
However, some resources don’t include permission to update a resource with the `use` verb. For example, to update a rule for the Events service, you must have the full `manage` permission. To enable a log on an Events rule (or any other resource that doesn't include the update permission with the `use` verb), you must have the `manage` permission.

To allow a group to enable logging for these resources, without granting the full permissions of `manage`, you can add a policy statement to grant only the `<RESOURCE>_UPDATE` permission (or, in the case of the Events service, `<RESOURCE>_MODIFY`) from the `manage` verb. For example, to allow a group EventUsers to enable logs on Events rules in CompartmentA, you could write a policy like the following:

```
Allow group EventUsers to read cloudevents-rules in compartment CompartmentA
Allow group EventUsers to manage cloudevents-rules in compartment CompartmentA
  where request.permission='EVENTRULE_MODIFY'
```

For information about resource permissions, see Policy Reference on page 2167.

**VCN Flow Logs IAM Policy**

In addition to Required Permissions for Working with Logs and Log Groups on page 2577, subnet read and update permissions are required for managing VCN Flow Logs.

To provide subnet permissions, use one of the following policies, listed in order from broader to narrowed privileges:

```
Allow group FlowLogsEnablers to manage virtual-network-family in tenancy
```

Or:

```
Allow group FlowLogsEnablers to manage subnets in tenancy
```

Or:

```
Allow group FlowLogsEnablers to {SUBNET_READ, SUBNET_UPDATE} in tenancy
```

This group is similar to what is described for EventUsers in IAM Policy Requirements for Resources on page 2579.

**Example Scenario**

Your company has an Operations department. Within the Operations department are several costs centers. You want to be able to tag resources that belong to the Operations department with the appropriate cost center.

1. Create a log group called "confidential". Avoid entering confidential information.
2. Add logs with sensitive data to the "confidential" log group.

An employee named Alice already belongs to the group BucketManagers. Alice can manage buckets in CompartmentA. You want Alice and other members of BucketManagers group to be able to enable logs on buckets in CompartmentA.

To grant the BucketManagers group access to the sensitive data log group (and only the sensitive data log group), add the following statements to the BucketManagers policy:

```
Allow group BucketManagers to manage log-groups in compartment CompartmentA
  where target.loggroups.id='ocid1.lumloggroup.oc1.phx.<uniqueID>'
```

Alice can now enable logs to bucket resources in CompartmentA.

**Move Log Groups to a Different Compartment**

You can move log groups from one compartment to another. When you move a log group to a new compartment, all the logs in the log group move with the log group to the new compartment. After you move the log group to the new compartment, the policies in the new compartment apply immediately, and affect access to the log group and any logs the log group contains.
Logging

For more information, see Moving Resources to a Different Compartment on page 2433.

Log and Log Group Names

For log group names, the first character must start with a letter. Otherwise, the following guidelines apply to both log and log group names:

• Use from 1 to 256 characters.
• Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.
• Log and log group names are case-sensitive. Logging handles write-log and WRITE-log as separate logs.
• Avoid entering confidential information.

Legacy Archival

Legacy automatic log archival was previously available before general release. This is a toggle configurable for every log. If enabled, it automatically creates a bucket in your compartment, and places a copy of your log there. New and improved functionality is now available in Service Connector Hub.

Using the Console

The Logs table lists both custom logs and service logs (indicated by the Log type field). The table is organized in terms of the following fields:

• Log name
• Log type
• Status
• Details
• Created

From this page you can click the Log name entry to go to the Log details page, or click the linked resource in Details to go directly to the resource. For example, if the log is for the Load Balancer service, clicking the link opens the Load Balancer Details page. From the action menu, you can edit the log, disable logging, change the log group, view tags, or delete the log.

To view the contents of logs

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens. This page displays the following on the **Log Information** tab:

- **OCID**
- **Compartment**
- **Log Group** (click to view the log group contents)
- **Created** date and time in UTC format
- **Retention Period**

  **Note:**
  
  Retention period can be set in 30-day increments, up to a maximum of 180 days.

- **Legacy Archival** mode
- **Status** (Creating, Active, Updating, Inactive, Deleting, Deleted)
- The **Tags** tab shows associated tags for this log.
- Under **Log Details**, following is displayed: the **Log Type** (whether Service or Custom), **Service** (for service logs), **Log Category**, and **Resource** (click to view the linked resource).

  In the Explore Log resource, log data is displayed in a similar manner as the **Log Data** on the **Search** page. You can apply some simple filters, such as sorting by newest or oldest from the **Sort** field, or filtering by time from the corresponding **Filter by Time** field.

4. Click **Explore with Log Search**, which allows you to view this log on the **Search** page directly. After clicking this link, the Search page opens with the **Select Logs to Search** field populated with the log in the filter settings. At this point, you can perform more analysis and investigation related to this log directly on the **Search** page. For more information, see Searching Logs on page 2634.

  In addition to these functions in the Explore Log resource, you can also click the Metrics resource to view interactive charts for either a chosen time period (**Start Time** and **End Time**), or pre-selected ranges from **Quick Selects**. The charts display the **Bytes Ingested** (total bytes of log entries ingested) and the **Search Success** (number of successful search queries issued by the user).

  Clicking anywhere in a chart displays a larger version of the chart. You can perform several chart actions from the Options menu (both in the Metrics resource and in the zoomed-in view):

  - **View Query in Metrics Explorer**: Opens the chart in the Monitoring Metrics Explorer. See Metrics Explorer page on page 2684 for more information.
  - **Copy Chart URL**
  - **Copy Query (MQL)**
  - **Create an Alarm on this Query**: Opens the Monitoring Create Alarm page. See To create an alarm on page 2719 for more information.
  - **Table View**: Displays a tabular summary of the chart data. Select **Chart View** to switch back to the chart.

**To edit the name of a log**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Logs**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.
3. Under **Log name**, click the name of the log you want to view. The log detail page opens.
4. Click **Edit**. The **Edit Log** panel is displayed. This panel indicates the resource, and allows you to change the log name in the associated field under **Configure Log**. You can also enable or disable the **Enable Legacy Archival Logs** setting (see Legacy Archival on page 2581). Avoid entering confidential information.

  From the main **Logs** page, for the log you want to edit, you can also click the the Actions icon (three dots), and then click **Edit** to access the **Edit Log** panel.
5. Make your changes and click **Save Changes**.
To delete a log

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Under Log name, click the name of the log you want to view. The log detail page opens.
4. Click Delete. A confirmation dialog is displayed regarding the delete operation.
5. Confirm by clicking Delete.

From the main Logs page, for the log you want to delete, you can also click the the Actions icon (three dots), and then click Delete.

To move a log to a new log group

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Under Log name, click the name of the log you want to view. The log detail page opens.
4. Click Change Log Group. The Move to a Different Log Group dialog is displayed.
5. From the Choose New Group list, select the new group from the list, and click Change Log Group. The new log group membership is reflected on the Log Information tab's Log Group field.

From the main Logs page, for the log you want to move to a new group, you can also click the the Actions icon (three dots), and then click Change Log Group.

To enable or disable an existing log

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Under Log name, click the name of the log you want to view. The log detail page opens.
4. Click Disable Log/Enable Log. A confirmation dialog is displayed regarding the disabling or enabling of the log.
5. Confirm by clicking Disable Log/Enable Log. The log detail page changes its status and displays Inactive (for a disabled log) or Active (for an enabled log) in the status field, both on the log detail page and the Logs page.

From the main Logs page, for the log you want to enable or disable, you can also click the the Actions icon (three dots), and then click Disable Logging/Enable Logging.

To create a log group

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Log Groups.
2. Choose a compartment you have permission to work in and click Create Log Group. The Create Log Group panel is displayed.
3. Enter the following:
   - Compartment: The compartment in which you want to create the log group. This field is pre-filled based on your compartment choice.
   - Name: A name for this log group. The first character of a log group name must be a letter. For more, see Log and Log Group Names on page 2581. Avoid entering confidential information.
   - Description: A friendly description.
   - Optionally, enter tagging information.
4. Click **Create**. The log group detail page is then displayed. From this page you can:

- Edit the group
- Move resources
- Add tags
- Delete the log group
- View log group information and tags
- View log group resources (explore the log group, view the logs included in the log group, create custom or service logs, and view metrics)

The **Metrics** resource in a log group detail page functions the same as in a log detail page. See **To view the contents of logs** on page 2581 for more information.

**To edit a log group**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.
3. Click **Edit**. The **Edit Log Group** panel is displayed. From here, you can change the log group name and its description in the associated fields. Avoid entering confidential information. See **Log and Log Group Names** on page 2581 for more information on naming.

   From the main **Log Groups** page, for the log group you want to edit, you can also click the the Actions icon (three dots), and then click **Edit**.

4. Make your changes and click **Update**.

   **Note:**

   You cannot move, edit, or delete the default log group.

**To delete a log group**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.

   **Tip:**

   You cannot delete a log group that contains logs.

3. Click **Delete**. A confirmation dialog is displayed regarding the delete operation.
4. Confirm by clicking **Delete**. The log group is removed from the **Log Groups** page.

   From the main **Log Groups** page, for the log group you want to delete, you can also click the the Actions icon (three dots), and then click **Delete**.

   **Note:**

   You cannot move, edit, or delete the default log group.

**To move a log group to a different compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Log Groups**.
2. Choose a compartment you have permission to work in and click the linked log group name under **Log Group** in the table. The log group detail page is displayed.

3. Click **Move Resource**. The **Move Resource to a Different Compartment** dialog is displayed.
4. Choose the new compartment and then click **Move Resource**.

   From the main **Log Groups** page, for the log group you want to move to a new compartment, you can also click the the Actions icon (three dots), and then click **Move Resource**.
To list the logs in a log group

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Log Groups.
2. Choose a compartment you have permission to work in.
3. For the log group you want to inspect for logs, click the name of the log group under Log Group in the table. The log group detail page is displayed.
4. In Resources, click Logs to display a list of all the logs contained in the log group. This resource table of logs functions in the same manner as the main Logs page.

Create a log group and configure LBaaS access and error logs

This procedure describes how to create a log group and how to configure LBaaS access and error logs.

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Log Groups.
2. Click Create Log Group. Choose the compartment where you want to create the log group. Choose a Name and Description that can properly identify your log group.
3. Click Create.
4. Next, click Logs. The Logs page is displayed.
5. Click Enable Service Log. The Enable Resource Log panel is displayed.
6. Next, enable access logs. Under Select Resource, Resource Compartment, choose a compartment you have permission to work in.
7. Select a service from the Service - Select Load Balancers.
8. Select a resource: in Resource, select a load balancer that you need to troubleshoot.
9. Configure the log: in Log Category, select a log category to specify the type of log to create. For this procedure, select Access Logs In Log Name, and then type a name for the log. In this procedural example, we will name it loadbalancer-access.
10. Click Enable Log.
11. Click Enable Service Log. The Enable Resource Log panel is displayed. Next, we will enable error logs.
12. Under Select Resource, Resource Compartment, choose a compartment you have permission to work in.
13. Select a service from the Service - Select Load Balancers.
14. Select a resource: in Resource, select the load balancer that you need to troubleshoot.
15. Configure the log: in Log Category, select a log category to specify the type of log to create. For this example, select Error Logs In Log Name, and then type a name for the log. For this example, we will name it loadbalancer-error.
16. Click Enable Log.

Using the Command Line Interface (CLI)

For more information on installing the CLI, see Quickstart on page 4195, and logging-ingestion, logging, and logging-search for command documentation.

Agent Configuration Commands

The following are agent configuration-related commands:

To create a unified agent configuration registration

Open a command prompt and run:

```
oci logging agent-configuration create --compartment-id | --compartment_OCID>, --is-enabled <boolean>, --service-configuration <service_configure>
```
To create a unified agent log configuration registration
Open a command prompt and run:

```
oci logging agent-configuration create-log-configuration --compartment-id | -c <compartment_OCID>, --is-enabled <boolean>
```

To get a unified agent configuration for an ID
Open a command prompt and run:

```
oci logging agent-configuration get --config-id <agent_configuration_OCID>
```

To list all agent configurations in the specified compartment
Open a command prompt and run:

```
oci logging agent-configuration list --compartment-id | -c <compartment_OCID>
```

To update an existing unified agent configuration
Open a command prompt and run:

```
oci logging agent-configuration update --config-id <agent_configuration_OCI>, --display-name <configuration_name>, --is-enabled <Boolean>, --service-configuration <service_configure>
```

This call fails if the log group does not exist.

To update an existing unified agent log configuration
Open a command prompt and run:

```
oci logging agent-configuration update-log-configuration --config-id <agent_configuration_OCI>, --display-name <configuration_name>, --is-enabled <Boolean>
```

This call fails if the log group does not exist.

To move a unified agent configuration into a different compartment within the same tenancy
Open a command prompt and run:

```
oci logging agent-configuration change-compartment --config-id <agent_configuration_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource. For information about moving resources between compartments, see Moving Resources to a Different Compartment on page 2433.

To delete a unified agent configuration
Open a command prompt and run:

```
oci logging agent-configuration delete --config-id <agent_configuration_OCID>
```

Log Commands
The following are log commands:
Create a log within a specified log group

Open a command prompt and run:

```
oci logging log create --display-name <log_name>, --log-group-id <log_group_OCID>, --log-type <SERVICE_or_CUSTOM>
```

This call fails if the log group has already been created with the same displayName or (service, resource, category) triplet.

Get the log object configuration for the log object OCID

Open a command prompt and run:

```
oci logging log get --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

List the specified log group’s log objects

Open a command prompt and run:

```
oci logging log list --log-group-id <log_group_OCID>
```

Move a log into a different log group within the same tenancy

Open a command prompt and run:

```
oci logging log change-log-group --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource.

To delete a log object in a log group

If you have an issue with deleting a log object, open a command prompt and run the following command to delete it:

```
oci logging log delete --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

To ingest logs associated with a logId

Open a command prompt and run:

```
oci logging-ingestion put-logs --log-entry-batches, --log-id, --specversion
```

List all services supporting logging

Open a command prompt and run:

```
oci logging service list
```

Update an existing log object with the associated configuration

Open a command prompt and run:

```
oci logging log update --log-group-id <log_group_OCID>, --log-id <log_OCID>
```

This call fails if the log object does not exist.

**Log Group Commands**

The following are log group-related commands:

Create a new log group with a unique display name
Logging

Open a command prompt and run:

```
oci logging log-group create --compartment-id | -c <compartment_OCID>, --display-name <log_group_name>
```

This call fails if the log group is already created with same displayName in the compartment.

**Get a specified log group's information**

Open a command prompt and run:

```
oci logging log-group get --log-group-id <log_group_OCID>
```

**List all log groups for the specified compartment or tenancy**

Open a command prompt and run:

```
oci logging log-group list --compartment-id | -c <compartment_OCID>
```

**Updates an existing log group with the associated configuration**

Open a command prompt and run:

```
oci logging log-group update --log-group-id <log_group_OCID>
```

This call fails if the log group does not exist.

**Move a log group into a different compartment within the same tenancy**

Open a command prompt and run:

```
oci logging log-group change-compartment --log-group-id <log_group_OCID>
```

When provided, the If-Match is checked against the ETag values of the resource. For information about moving resources between compartments, see Moving Resources to a Different Compartment on page 2433.

**To delete a specified log group**

Open a command prompt and run:

```
oci logging log-group delete --log-group-id <log_group_OCID>
```

**Work Request Commands**

The following are work request-related commands:

**Get the details of a work request with a given ID**

Open a command prompt and run:

```
oci logging work-request get --work-request-id <work_request_OCID>
```

**List the work requests in a compartment**

Open a command prompt and run:

```
oci logging work-request list --compartment-id | -c <compartment_OCID>
```

**List the errors for a given work request**
Open a command prompt and run:

```
oci logging work-request-error list --work-request-id <work_request_OCID>
```

**List the logs for a given work request**

Open a command prompt and run:

```
oci logging work-request-log list --work-request-id <work_request_OCID>
```

**Delete a work request that has not yet started**

Open a command prompt and run:

```
oci logging work-request delete --work-request-id <work_request_OCID>
```

---

**Object Storage Example**

The following is an Object Storage example:

**To create a log group and create a log in Object Storage**

Open a command prompt and run:

```
oci logging log-group create --compartment-id <compartment_OCID> --display-name CLITestLogGroup
oci logging log create --display-name object_log_write --log-group-id <log_group_OCID> --log-type SERVICE --is-enabled true --configuration file://~/.oci/objectstorage_configuration.json
```

`objectstorage_configuration.json`:

```json
{
  "archiving": {
    "isEnabled": true
  },
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "source": [
    {
      "category": "write",
      "parameters": null,
      "resource": "bucket-cli-sample",
      "service": "objectstorage",
      "sourceType": "OCISERVICE"
    }
  ]
}
```

**VCN Flow Logs Example**

The following are sample commands related to VCN Flow Logs:

**To create a log group**

Open a command prompt and run:

```
oci logging log-group create --compartment-id <compartment_OCID> --display-name <log_group_name> --description <description>
```

**To create a flowlogs log object (enable Flow Logs)**
Open a command prompt and run:

```
oci logging log create --display-name <log_display_name> --log-group-id <log_group_OCID>
--description <description> --log-type SERVICE --is-enabled <Boolean>
--configuration file://input.json
```

Sample configuration file:

```json
{
   "compartment-id":"...", # CompartmentId of where the subnet resource is present.
   "source": {
      "resource": "ocid1.subnet.....", # OCID of subnet for which flowlogs is enabled.
      "service": "flowlogs", # "flowlogs" is the official service name and it should be all lowercase.
      "source-type": "OCISERVICE", # OCISERVICE is the name of the Logging source-type.
      "category": "all"
   }
}
```

To disable a flowlogs log object (disable Flow Logs)

Open a command prompt and run:

```
oci logging log update --log-group-id <log_group_OCID> --log-id <log_OCID>
--is-enabled false
```

To delete the log object

Open a command prompt and run:

```
oci logging log delete --log-id <log_OCID>
```

Functions Example

To enable Functions logging

To enable Functions logging, open a command prompt and run:

```
oci logging log create --display-name cli_test --log-group-id ocid1.loggroup.oc1.phx.<log_group_OCID>
--log-type SERVICE --is-enabled true --configuration file://fnconfig.json
```

Sample fnconfig.json configuration file:

```json
{
   "compartment-id":"ocid1.compartment.oc1..<compartment_OCID>" # OCID of the compartment
   "source": {
      "resource": "ocid1.fnapp.oc1.phx.<unique_ID>", # OCID of the function
      "service": "functions",
      "source-type": "OCISERVICE",
      "category": "invoke"
   }
}
```
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage logs:

- ListLogs
- GetLog
- CreateLog
- UpdateLog
- ChangeLogLogGroup
- DeleteLog

Use the following operations to manage log groups:

- ListLogGroups
- GetLogGroup
- CreateLogGroup
- UpdateLogGroup
- ChangeLogGroupCompartment
- DeleteLogGroup

Service Logs

Oracle Cloud Infrastructure services, such as API Gateway, Events, Functions, Load Balancing, Object Storage, and VCN Flow Logs emit service logs. Each of these supported services has a Logs resource that allows you to enable or disable logging for that service.

Supported Services

You can enable service logs for the following Oracle Cloud Infrastructure services:

- API Gateway
- Events
- Functions
- Load Balancers
- Object Storage
- VCN Flow Logs
- VPN Connect

**Note:**

VPN Connect logs are only supported with v2 VPN connections. v1 connections are not supported.

**Note:**

This list of Oracle Cloud Infrastructure services is updated as supported services are added.

Enabling Logging for a Resource

Logs can be enabled in two places: directly on the resource itself, or on the central Logs page. When you enable a log on a specific resource, you specify the category. Different resources can have different categories. For example, rules in the Events Service have the Logs resource available for logging management. The rule can issue a log according to the category listed in the corresponding Category field. On this page, the logs are listed that the resource can create.
Enabling Logging from the Resource page

For Oracle Cloud Infrastructure services that are compatible with Logging, the Logs resource allows you to manage the logs issued by the resource. You can view the following information:

- Category
- Status
- Log name
- Log group

In addition, you can enable or disable logging, edit the log, or delete it (the last two options are available in the action menu). When enabling logging, you also create the log object itself.

For a newly created resource, logging is automatically enabled. For a resource you want to enable logging on, under Resources click Logs, and then toggle Enable Logging. The Create Log panel is displayed, and the entry fields are pre-populated:

- **Compartment** (the same as your resource)
- **Log Group**: The first log group in your compartment. You can select another log group, or create a new group by clicking Create New Group.
- **Log Name**: Pre-populated as the name of your resource and the category, which are combined with an underscore (\<resource\>_\<category\>). For example, if the resource is named "resource" and the category is "ruleexecutionlog", the log name is "resource_ruleexecutionlog".

After logging is enabled, you can click the link under Log name or Log group to view the log details or log group details pages, respectively.

To disable logging, toggle the Enable log control, which displays a disable logging confirmation dialog. Click Disable Log to confirm. The Status field is set to INACTIVE to indicate the inactive status.

When creating a log, a log object is established. To delete the log, select Delete from the action menu. A confirmation is displayed confirming whether you want to delete the log. After clicking Delete, this removes the log object, as opposed to disabling it (which means the log object still exists but does not record new data into it).

Enabling Logging on the Logs page

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs. The Logs page is displayed.
2. Click Enable Service Log. The Enable Resource Log panel is displayed.
3. Under Select Resource, Resource Compartment, choose a compartment you have permission to work in.
4. Select a service from the Service list (see Supported Services on page 2591 for the available services).
5. Select a resource:
   - In **Service**, select the service of the resource for which you want to enable the log.
   - In **Resource Compartment**, select the compartment of the resource.

   **Tip:**
   You can type in the list box to perform a filtered search of all compartments in the tenancy.
   - In **Resource** select a resource.

6. Configure the log:
   - In **Log Category** select a log category to specify the type of log to create. For example, Object Storage buckets have categories for read and write. Select read to enable a log with only read events. Select write for a log with only write events.

   You can only have one log for any combination of service, resource, and log category. For example, Object Storage buckets have two categories: read and write. Therefore:
   - You can enable a single read log and a single write log for every bucket in your tenancy.
   - You cannot enable more than two logs (one read and one write) for any one bucket.
   - In **Log Name**, type a name for the log. See Log and Log Group Names on page 2581 for more information. Avoid entering confidential information. Select **Enable Legacy Archival Logs** to automatically create a bucket in your compartment, and place a copy of your log there. See Legacy Archival on page 2581 for more information.

7. To specify the log location (click **Show Advanced Options** if necessary):
   - In **Compartment**, select the compartment for the log.

   **Tip:**
   You can type in the list box to perform a filtered search of all compartments in the tenancy.
   - In **Log Group**, select a log group for the log.

8. In **Log Retention**, select a value from the list:
   - 1 month (the default)
   - 2 months
   - 3 months
   - 4 months
   - 5 months
   - 6 months

9. Apply any tagging-related information in the **Tag Namespace**, **Tag Key**, and **Value** fields.

10. Click **Enable Log**.

    The Log detail page is displayed, and the log is in the process of being created (a "Creating log" message is displayed). See Using the Console on page 2581 for more information on viewing and using this page.

**Service Log Reference**

The overarching logging schema is described in Logging Format Overview on page 2594, while each service that enables logging has its own specific logging details. This reference includes:

- Details for API Gateway on page 2597
- Details for Events
- Details for Functions
Logging Format Overview

Every log line is normalized into a common event format for ease of correlation. This format is based on the JSON implementation of CloudEvents v1.0 specification. A log line has three key sections:

- Unified envelope
- Oracle-specific metadata (oracle.*)
- Contents of the log line (data)

Outer Envelope Format

All messages sent to the ingestion front end use the outer envelope format, and only change the message body based on the log type. The outer envelope format conforms to the CloudEvents v1.0 spec, with extension fields defined for logging purposes. The following table describes this format.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Position</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specification Version</td>
<td>Yes</td>
<td>Body: specversion</td>
<td>String</td>
<td>The version of the CloudEvents specification this message conforms to.</td>
</tr>
<tr>
<td>Id</td>
<td>Yes</td>
<td>Body: id</td>
<td>String</td>
<td>A source-unique identifier for this message. Duplicate messages can have the same ID. Consumers can assume events with the same IDs are unique.</td>
</tr>
</tbody>
</table>
| Type             | Yes      | Body: type     | String  | The type of the message. Consumers use the type and specversion to determine how to interpret the body. Pattern: com.oraclecloud. 
{service}. 
{resource-type}. 
{category}. For example: com.oraclecloud.compute.instance.terminated.  |
<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Position</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Yes</td>
<td>Body: source</td>
<td>URI-reference</td>
<td>The message source. When emitted by a service, refers to the name of the resource that generated the message, for example, the Object Storage bucket name, Instance Name. When emitted by an agent, based on the source/input used to read events. For example, the instance name (not the OCID) or the hostname of the asset in an on-premise environment.</td>
</tr>
<tr>
<td>Subject</td>
<td>No</td>
<td>Body: subject</td>
<td>String</td>
<td>A specific subresource that generated the event, if applicable to the source. This is useful for sources with subresources. Examples:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Object Storage example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Source: my-bucket</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Subject: image.png</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Custom Logging example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Source: hostname</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>- Subject: /var/log/some.log</td>
</tr>
<tr>
<td>Name</td>
<td>Required</td>
<td>Position</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------</td>
<td>--------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Time</td>
<td>No</td>
<td>Body: time</td>
<td>Timestamp</td>
<td>The time the message was generated. If present, must adhere to the format specified in RFC 3339. If not provided, the wall clock of the ingestion host that receives the request is used.</td>
</tr>
<tr>
<td>Data Schema</td>
<td>No</td>
<td>Body: dataschema</td>
<td>String</td>
<td>The schema version for the data field. This is not required, and if not provided, is assumed to be the initial version.</td>
</tr>
<tr>
<td>Data Content Type</td>
<td>No</td>
<td>Body: datacontenttype</td>
<td>String</td>
<td>The format in which the message body is encoded. If not provided, the default is JSON (equivalent to datacontenttype: application/json).</td>
</tr>
<tr>
<td>Message Body</td>
<td>Yes</td>
<td>Body: data</td>
<td>Object</td>
<td>The message body encoded in the format defined by datacontenttype. If datacontenttype is not specified, this is expected to be JSON (equivalent to datacontenttype: application/json).</td>
</tr>
<tr>
<td>Oracle Cloud Metadata</td>
<td>Yes</td>
<td>Body: oracle</td>
<td>Object</td>
<td>More Oracle-specific metadata is provided in a map of attributes at the top level of the envelope. This conforms to CloudEvents v1 Attribute Extensions specification. See the following table for supported Oracle Cloud Infrastructure metadata attributes.</td>
</tr>
</tbody>
</table>
Oracle Metadata Attributes

The following attributes are supported in the **oci** extension field of the message format. Naming for these attributes conforms to the CloudEvents v1 Attribute Naming Convention, that is, they are lowercase alpha-numeric identifiers fewer than 20 characters long.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required for Ingestion</th>
<th>Enriched for Retrieval</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logid</td>
<td>Yes</td>
<td>-</td>
<td>String</td>
<td>The OCID of the log object the message was sent to.</td>
</tr>
<tr>
<td>loggroupid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the log group the object resides in.</td>
</tr>
<tr>
<td>tenantid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the tenant that owns the log object.</td>
</tr>
<tr>
<td>compartmentid</td>
<td>No</td>
<td>Yes</td>
<td>String</td>
<td>The OCID of the compartment the log object resided in at the time the message was ingested.</td>
</tr>
</tbody>
</table>

Details for API Gateway

This topic provides details for API Gateway logs.

</tr>
<tr>
<td>Execution</td>
<td>Execution Logs</td>
<td>Execution logs for an API deployment.</td>
</tr>
</tbody>
</table>

Availability

API Gateway Access/Execution logging is available in all the regions of the commercial realm.

API Deployment Access Log

API deployment access logs record a summary of every request and response that goes through the API gateway, matching a route on the API deployment. Each access log entry contains information about the request and response (time the request was received, server protocol, response status, and so on). For the complete list of fields, see Contents of an Access Log on page 2597.

Contents of an Access Log

Access logs appear as a value in the **Log Data** field. This value is JSON-formatted data with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpMethod</td>
<td>GET</td>
<td>HTTP method derived from the request line.</td>
</tr>
<tr>
<td>requestUri</td>
<td>/example/</td>
<td>Request URI derived from the request line.</td>
</tr>
<tr>
<td>serverProtocol</td>
<td>HTTP/1.1</td>
<td>HTTP protocol derived from the request line.</td>
</tr>
</tbody>
</table>
### Field | Example | Description
--- | --- | ---
bodyBytesSent | 45 | Total size of the response (in bytes) sent to the client.
gatewayId | ocid1.apigateway.oc1.iad.<unique_ID> | OCID of the API Gateway for the API deployment servicing the request.
httpUserAgent | Apache-HttpClient/4.5.9 (Java/1.8.0_252) | HTTP user agent for the request.
message | GET /example/ HTTP/1.1 | Request line received from the client.
opcRequestId | FF7F0B8A32246FC7526AE45A2FA8D5CE/A408784281BF81B0EE23596CE57CA93C/C06F7DDDFC7C505FAA0566D8F2FE0BB2 | Value of the opc-request-id HTTP header, or an internally generated request ID if none was specified in the request.
remoteAddr | 138.1.55.172 | IP address of the requesting client.
httpReferrer | https://www.example.com | The URL of the referral, if present.
requestDuration | 0.016 | Total time taken (in seconds, with millisecond precision), from when the gateway starts receiving request from the client, until it completes sending a response to the client.
status | 404 | Status code of the response from the gateway.

### Sample Access Log

```json
{
    "httpMethod": "GET",
    "requestUri": "/example/",
    "serverProtocol": "HTTP/1.1",
    "bodyBytesSent": 45,
    "gatewayId": "ocid1.apigateway.oc1.iad.<unique_ID>",
    "httpUserAgent": "Apache-HttpClient/4.5.9 (Java/1.8.0_252)",
    "message": "GET /example/ HTTP/1.1",
    "opcRequestId": "FF7F0B8A32246FC7526AE45A2FA8D5CE/A408784281BF81B0EE23596CE57CA93C/C06F7DDDFC7C505FAA0566D8F2FE0BB2",
    "remoteAddr": "138.2.05.172",
    "requestDuration": 0.016,
    "status": 404
}
```

### API Deployment Execution Log

API deployment execution logs record information about processing within the API gateway for an individual route, to help with troubleshooting and monitoring. Each execution log entry contains information (time the request was received, level to denote the severity of the log message, a message code, and so on). For the complete list of fields, see Contents of an Execution Log on page 2598.

### Contents of an Execution Log

By default Log Level info is enabled. This value is JSON-formatted data with the following fields:
<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>code</td>
<td>request.loopDetected</td>
<td>Short code for the logging event encountered while running the request. For the complete list of message codes, see the &quot;Log Codes&quot; table Log Codes on page 2599.</td>
</tr>
<tr>
<td>gatewayId</td>
<td>ocid1.apigateway.oc1.iad. <code>&lt;unique_ID&gt;</code></td>
<td>API gateway OCID for the API deployment servicing the request.</td>
</tr>
<tr>
<td>functionId</td>
<td>ocid1.fnfunc.oc1.iad. <code>&lt;unique_ID&gt;</code></td>
<td>OCID of function that the API gateway invoked. This field is only present for function backends.</td>
</tr>
<tr>
<td>level</td>
<td>WARN</td>
<td>Log level for the execution log entry, whether INFO, WARN, or ERROR.</td>
</tr>
<tr>
<td>message</td>
<td>A request loop has been detected - requests for this gateway are being directed back to this gateway.</td>
<td>Execution message emitted while processing the request.</td>
</tr>
<tr>
<td>opcRequestId</td>
<td>FF7F0B8A32246FC7526AE45A2FA8A408784281BF81B0EE23596CE57C02CF/ A408784281BF81B0EE23596CE57C02CF/ C06F7DDDFC7C505FAA0566D8F2F8B83</td>
<td>Value of the opc-request-id HTTP header, or an internally generated request ID if none was specified in the request.</td>
</tr>
</tbody>
</table>

**Log Codes**

<table>
<thead>
<tr>
<th>Log Code</th>
<th>Description</th>
<th>Related Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpBackend.timeout</td>
<td>Request to the HTTP backend timed out.</td>
<td>HTTP Backend</td>
</tr>
<tr>
<td>httpBackend.dnsResolutionFailed</td>
<td>Failed to resolve the HTTP backend URL.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.sslHandshakeFailed</td>
<td>SSL Handshake failed with the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.successfulRequest</td>
<td>Successful request to the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.responseReceived</td>
<td>Response received from the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>httpBackend.requestSent</td>
<td>Request sent to the HTTP backend.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.successfulRequest</td>
<td>Successful invocation of the Oracle Function.</td>
<td>Oracle Functions Backend</td>
</tr>
<tr>
<td>functionBackend.notFoundOrNotAuthorized</td>
<td>Failed to invoke the Oracle Function due to 404 from Oracle Functions service.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.rateLimited</td>
<td>Rate limited when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.serviceUnavailable</td>
<td>Oracle Functions service unavailable.</td>
<td></td>

<td>--------------------------------</td>
</tr>
<tr>
<td>functionBackend.badGateway</td>
<td>Received &quot;Bad Gateway&quot; when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.timeout</td>
<td>Oracle Function invocation timed out.</td>
<td></td>
</tr>
<tr>
<td>functionBackend.internalServiceError</td>
<td>Internal service error when invoking the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>specification.badVariableReference</td>
<td>The context variable couldn't be resolved.</td>
<td>Incorrect Specification at run-time</td>
</tr>
<tr>
<td>specification.invalidAuthenticationPolicy</td>
<td>Invalid authentication policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badTransformationPolicy</td>
<td>Bad transformation policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badHeaderTransformationPolicy</td>
<td>Bad Header Transformation policy.</td>
<td></td>
</tr>
<tr>
<td>specification.badQueryParameterTransformationPolicy</td>
<td>Bad Query Parameter Transformation policy.</td>
<td></td>
</tr>
<tr>
<td>request.internalServiceError</td>
<td>Internal service error.</td>
<td>Request processing</td>
</tr>
<tr>
<td>request.loopDetected</td>
<td>A request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.</td>
<td></td>
</tr>
<tr>
<td>request.possibleLoopDetected</td>
<td>A possible request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.</td>
<td></td>
</tr>
<tr>
<td>request.headersTruncated</td>
<td>Request headers were truncated.</td>
<td></td>
</tr>
<tr>
<td>request.queryParametersTruncated</td>
<td>Request query parameters were truncated.</td>
<td></td>
</tr>
<tr>
<td>authorization.unauthorizedRequest</td>
<td>Authorization failed for the request.</td>
<td>Request Authorization</td>
</tr>
<tr>
<td>authorization.scopeCheckFailed</td>
<td>Failed to check the scope for the request.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.successfulFunctionInvocation</td>
<td>Successfully invoked the Oracle Function.</td>
<td>Custom Authentication</td>
</tr>
<tr>
<td>customAuthentication.failedFunctionInvocation</td>
<td>Failed to invoke the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.successfulAuthenticationSuccessful</td>
<td>Authentication successful.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.authenticationFailed</td>
<td>Custom Authentication failed.</td>
<td></td>
</tr>
<tr>
<td>customAuthentication.unexpectedResponse</td>
<td>Unexpected response from the Oracle Function.</td>
<td></td>
</tr>
<tr>
<td>jwtAuthentication.successfulAuthenticationSuccessful</td>
<td>Authentication successful.</td>
<td>JWT Authentication</td>
</tr>
<tr>
<td>jwtAuthentication.authenticationFailed</td>
<td>JWT Authentication failed.</td>
<td></td>
</tr>
<tr>
<td>jwtAuthentication.badJsonWebKeySet</td>
<td>JSON Web Key Set is not valid.</td>
<td></td>
</tr>
<tr>
<td>jwtAuthentication.loadingJsonWebKeySet</td>
<td>Loading the JSON Web Key Set.</td>
<td></td>
</tr>
<tr>
<td>headerTransformation.badHeaderValue</td>
<td>Bad value for request header.</td>
<td>Header Transformation</td>
</tr>
</tbody>
</table>
Logging

<table>
<thead>
<tr>
<th>Log Code</th>
<th>Description</th>
<th>Related Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>headerTransformation.protectedHeaderTransformed</td>
<td>The policy tried to transform a protected header.</td>
<td></td>
</tr>
<tr>
<td>headerTransformation.protectedElementTransformed</td>
<td>The policy tried to transform a protected element.</td>
<td></td>
</tr>
<tr>
<td>headerTransformation.missingSetValue</td>
<td>Missing value for the set transform policy.</td>
<td></td>
</tr>
<tr>
<td>queryParameterTransformation.badParameterValue</td>
<td>Bad value for request query parameter.</td>
<td>Query Parameter Transformation</td>
</tr>
<tr>
<td>queryParameterTransformation.protectedElementTransformed</td>
<td>The policy tried to transform a protected element.</td>
<td></td>
</tr>
<tr>
<td>queryParameterTransformation.missingSetValue</td>
<td>Missing value for the set transform policy.</td>
<td></td>
</tr>
</tbody>
</table>

Sample Execution Logs

- Type: Request
- Scenario: Request Loop Detected
- Description: A request loop condition has been detected, whereby requests for the gateway are being redirected to itself creating a cycle.
- Example:

```json
{  "code": "request.loopDetected",  "gatewayId": "ocid1.apigateway.oc1.iad.<unique_ID>",  "level": "WARN",  "message": "A request loop has been detected - requests for this gateway are being directed back to this gateway.",  "opcRequestId": "FF7F0B8A32246FC7526AE45A2FA8D5CE/A408784281BF81B0EE23596CE57CA93C/C06F7DDDFC7C505FAA0566D8F2FE0BB2",}
```

Events logging is available in all the regions of the commercial realm. Events logging is not available in regions within the Government Cloud realm.
## Contents of an Events Log

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logTime</td>
<td>The time of the event, expressed in RFC 3339 timestamp format.</td>
</tr>
<tr>
<td>ruleId</td>
<td>The events rule ID.</td>
</tr>
<tr>
<td>eventId</td>
<td>The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.</td>
</tr>
<tr>
<td>message</td>
<td>The event message.</td>
</tr>
</tbody>
</table>
| target   | The rule action. For example:  
  - For streaming, it means that the event was delivered to the stream.  
  - For a notification, it means it was delivered to the email subscribed to the topic.  
  - For a function, it means it triggered the function with the event data. |

### An Example Events Log

For events there are two types of messages:

```json
{
  "specversion": "1.0",
  "type": "com.oraclecloud.eventsservice.eventrule.ruleexecutionlog",
  "source": "Flowlogs",
  "id": "6e6dbfd3-4bce-4484-848d-af53f19bd6c9",
  "time": "2020-08-24T23:31:44Z",
  "oracle": {
    "logid": "ocid1.log.oc1.iad.<unique_ID>",
    "loggroupid": "ocid1.loggroup.oc1.iad.<unique_ID>",
    "compartmentid": "ocid1.compartment.oc1..<unique_ID>",
    "tenantid": "ocid1.tenancy.oc1..<unique_ID>",
    "ingestedtime": "2020-08-19T15:33:30.832Z"
  },
  "data": {
    "ruleId": "ocid1.eventrule.oc1.iad.<unique_ID>",
    "eventId": "24bc7219-efec-4ccd-350b-be2d833439d2",
    "message": "Event failed to deliver to FAAS. Exception from FAAS endpoint  
      https://ptktjbkp22a.us-ashburn-1.functions.oci.oraclecloud.com,  
      exception message:  
      (502, FunctionInvokeImageNotAvailable, false) Failed to pull function image (opc-request-id:  
      AA3D3CEE50107C103AA662B8646A0EEE/01EGHCZXNW1BT0750ZJ0058HCQ/01EGHCZXNW1BT0750ZJ0058HCQ,

      statuscode 502", "target": "ocid1.fnfunc.oc1.iad.<unique_ID>"
  }
}
```
Logging

```
"tenantid": "ocid1.tenancy.oc1..<unique_ID>",
"ingestedtime": "2020-08-19T15:33:30.832Z"
},
"data": {
  "ruleId": "ocid1.eventrule.oc1.phx.<unique_ID>",
  "eventId": "30bde0fa-af8a-f50c-aa01-4fc42f28acb9",
  "message": "Rule has matched event"
}
```

**Events Log Object Name**

Objects that store Events log data use the following naming format:

```
Rule_Execution_Log/<event_rule_OCID>/<YYYY-MM-DDTHH_MMZ>[_<seqNum>].log.gz
```

For example:

```
Rule_Execution_Log/
ocid1.eventrule.oc1.phx.<unique_ID>/2019-03-21T00_00Z.log.gz
Rule_Execution_Log/

**Details for Functions**

This topic provides details for Functions logs.

**Resources**

- applications

**Log Categories**

<table>
<thead>
<tr>
<th>API value (ID)</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>invoke</td>
<td>Function Invocation Logs</td>
<td>Logs entries each time a function in an application is invoked.</td>
</tr>
</tbody>
</table>

**Availability**

Functions logging is available in all the regions of the [commercial realm](#).

**Comments**

To use Functions logging, you must add a print statement to your function.

**Examples:**

For node js:

```javascript
console.log('Entering Hello Node.js function');
```

For java:

```java
System.out.println("Entering Java Hello World Function");
```

For go:

```go
fmt.Println("Entering Hello Go function")
```

    "requestId": "/01EG3NN3C11BT19PGZJ00000VZ/01EG3NN3C11BT19PGZJ00000W0",
    "src": "STDOUT"
  }
}```
Functions Log Object Name

Objects that store Functions log data use the following naming format:

\[ \text{log/}<\text{function-OCID}>/\text{<YYYY-MM-DDTHH_MMZ>[_<seqNum>].log.gz} \]

For example:

\[ \text{log/ocid1.function.oc1.phx.<unique_ID>/2019-03-21T00_00Z.log.gz} \]
\[ \text{log/ocid1.function.oc1.phx.<unique_ID>/2019-03-21T00_00Z_2.log.gz} \]

Using the Command Line Interface (CLI)

See Functions Example on page 2590 for an example command to enable Functions logging.

Details for Load Balancer Logs

This topic provides details for load balancer access logs. See these instructions to create a log group and configure LBaaS access and error logs.

Resources

- load balancer

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Access Logs</td>
<td>Load balancer access logs.</td>
</tr>
<tr>
<td>Error</td>
<td>Error Logs</td>
<td>Load balancer error logs.</td>
</tr>
</tbody>
</table>

Availability

LBaaS access logs are available in all the regions of the commercial realm.

Load Balancer Access Log

Load balancer access logs capture detailed information about requests sent to the load balancer. Each access log entry contains:

- The time the request was received.
- Client and intermediate HTTP proxy IP addresses.
- Time taken at the load balancer and backend to process the request.

Limitations and Considerations

Some traffic might not be logged during a capture window because of capacity issues or system errors. In such cases, the following error log message is logged.

\[ \{ "timestamp": "2020-08-05T00:12:39+00:00", "errorLog": \{ "type": "General", "errorDetails": "Missed 100 access logs" \} \} \]

For traffic destined to the public IP of a load balancer, access logs record the corresponding private IP.
Contents of an Access Log

Access logs appear as a value in the Log Data field. This value is a JSON-formatted data with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>2020-04-20T00:56:18+00:00</td>
<td>Log entry generation time in ISO-8601 format.</td>
</tr>
<tr>
<td>clientAdd</td>
<td>192.168.0.33:7870</td>
<td>IP address and port number of the requesting client.</td>
</tr>
<tr>
<td>forwardedForAddr</td>
<td>192.168.0.33</td>
<td>IP address of the client and http proxies between client and load balancer.</td>
</tr>
<tr>
<td>host</td>
<td>a.com</td>
<td>Domain name which resolves to VIP address assigned to the load balancer.</td>
</tr>
<tr>
<td>backendAddr</td>
<td>192.168.0.34:8080</td>
<td>IP address and port number of the backend server, which processed the client request.</td>
</tr>
<tr>
<td>requestProcessingTime</td>
<td>0.003</td>
<td>Total time taken (in seconds, with millisecond precision), from when the load balancer starts receiving request from the client, until it completes sending responses to the client.</td>
</tr>
<tr>
<td>backendConnectTime</td>
<td>0.00</td>
<td>Time spent (in seconds, with millisecond precision), to establish backend server connection.</td>
</tr>
<tr>
<td>backendProcessingTime</td>
<td>0.002</td>
<td>Total time taken from the load balancer establishing a connection to a backend, until it completes receiving the response from the backend.</td>
</tr>
<tr>
<td>lbStatusCode</td>
<td>200</td>
<td>Status code of the response from the load balancer.</td>
</tr>
<tr>
<td>backendStatusCode</td>
<td>200</td>
<td>Status code of the response from the target.</td>
</tr>
<tr>
<td>receivedBytes</td>
<td>150</td>
<td>Total size of the request (in bytes), received from the client.</td>
</tr>
<tr>
<td>sentBytes</td>
<td>450</td>
<td>Total size of the response (in bytes), sent to the client from the load balancer.</td>
</tr>
<tr>
<td>request</td>
<td>&quot;GET / HTTP/1.1&quot;</td>
<td>Request line received from the client.</td>
</tr>
<tr>
<td>sslCipher</td>
<td>ECDHE-RSA-AES256-GCM-SHA384</td>
<td>Negotiated SSL cipher between the client and the load balancer.</td>
</tr>
<tr>
<td>sslProtocol</td>
<td>TLSv1.2</td>
<td>Negotiated SSL protocol between the client and the load balancer.</td>
</tr>
<tr>
<td>userAgent</td>
<td>curl/7.29.0</td>
<td>User Agent, which sent the request to the load balancer.</td>
</tr>
</tbody>
</table>

Load Balancer Error Log

Load balancer error logs capture detailed information about requests related to troubleshooting and monitoring. Each Error Log entry contains information such as the time the request was received, error type, and extra details related to the specific error.

Contents of an Error Log

This value is JSON-formatted data with the following fields.
<table>
<thead>
<tr>
<th>Field</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>2020-08-04T21:25:27+00:00</td>
<td>Log entry generation time in ISO-8601 format.</td>
</tr>
<tr>
<td>type</td>
<td>frontDoor</td>
<td>Error log Category.</td>
</tr>
<tr>
<td>errorDetails</td>
<td>Access for client 160.34.88.6 forbidden by ACL rule</td>
<td>Detailed description of the error message.</td>
</tr>
</tbody>
</table>

Sample Error Logs

**Type: healthChecker**

timestamp: 2020-08-05T00:12:39+00:00, "errorLog": {"type": "healthChecker", "errorDetails":

- check failure because of connection timeout.

**Type: healthChecker**

timestamp: 2020-08-04T23:28:52+00:00, "errorLog": {"type": "healthChecker", "errorDetails":

- check failure because of RegEx mismatch.

**Type: healthChecker**

timestamp: 2020-08-04T19:53:29+00:00, "errorLog": {"type": "healthChecker", "errorDetails":

- check failure because of connection RST.
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HealthChecker</td>
<td>Example:</td>
</tr>
<tr>
<td>healthChecker</td>
<td>Unreachable host. Back-end health check failure because of unreachable host.</td>
</tr>
<tr>
<td>healthChecker</td>
<td>Success (Unhealthy to healthy). Unhealthy backend became healthy.</td>
</tr>
<tr>
<td>healthChecker</td>
<td>SSL Backend, with some SSL error.</td>
</tr>
<tr>
<td>frontDoor</td>
<td>Drop (TCP) Client connection drop to ACL rules.</td>
</tr>
<tr>
<td>sslClient</td>
<td>SSL error as client did not send certificate.</td>
</tr>
<tr>
<td>backEnd</td>
<td>Connection failure when all backends are unhealthy.</td>
</tr>
</tbody>
</table>
Details for Object Storage

This topic provides details for Object Storage logs.

Resources

- buckets

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>write</td>
<td>Write Access Events</td>
<td>Includes logs for write events.</td>
</tr>
<tr>
<td>read</td>
<td>Read Access Events</td>
<td>Includes logs for read events.</td>
</tr>
</tbody>
</table>

Availability

Object Storage logging is available in all the regions of the commercial realm.

Comments

Choose the log category for the type of information that you want to log. For example, if you enable a write log, the requestAction property would contain values of PUT, POST, or DELETE. If you enable a read log, requestAction would contain values of GET, LIST, or HEAD.

Contents of an Object Storage Log

<table>
<thead>

        "tenantName": "MyTenancy",
        "userAgent": "Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/85.0.4183.83 Safari/537.36"
    },
    "oracle": {
        "logid": "ocid1.log.oc1.phx.<unique_ID>"
    }
}
```

Object Storage Log Object Name

Objects that store Object Storage data use the following naming format:

```
public_log/<bucket_name>/YYYY-MM-DDTHH_MMZ[<seqNum>].log.gz
```

For example:

```
public_log/example_bucket/2019-03-21T00_00Z.log.gz
public_log/example_bucket/2019-03-21T00_00Z_2.log.gz
```

Using the Command Line Interface (CLI)

See Object Storage Example on page 2589 for example commands.
Details for VCN Flow Logs

This topic provides details for VCN Flow logs.

Resources

• subnet

Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>
<th>Console (Display Name)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>Flow Logs (All records)</td>
<td>Includes both accept and reject records in VCN flow logs.</td>
</tr>
</tbody>
</table>

Availability

VCN Flow Logs are available in all the regions of the commercial realm.

Comments

Each instance in a VCN has one or more virtual network interface cards (VNICs). The Networking service uses security rules to determine what traffic is allowed through a given VNIC. Security rules can be defined using Security lists or Network security groups.

To help troubleshoot the traffic in and out of your VNICs, you can set up VCN flow logs. Flow logs record details about traffic that has been accepted or rejected based on the security rules set up for your VCN.

You can enable flow logs for a given subnet, which means traffic is logged for all existing and future VNICs in that subnet. Each flow log contains information about traffic for a single VNIC.

Note:

Certain traffic to core Oracle infrastructure services hosted on link-local (169.254.0.0/16) IP addresses do not appear in flow logs. This includes items such as VCN DNS, DHCP, and block storage. Also excluded is network management traffic, such as ARP.

Contents of a VCN Flow Log

A flow log record contains the following fields:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.action</td>
<td>Type of record. Possible values:</td>
<td>ACCEPT</td>
</tr>
<tr>
<td></td>
<td>• ACCEPT: This record's traffic was accepted by the security lists.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REJECT: This record's traffic was rejected by the security lists.</td>
<td></td>
</tr>
<tr>
<td>data.bytesOut</td>
<td>Number of bytes recorded in the capture window.</td>
<td>17114</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Sample Value</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>data.destinationAddress</td>
<td>IP address of the destination, either in IPv4 dot, or IPv6 colon notation.</td>
<td>10.0.99.4 8222:91f5:88bb:2bf0:94a:e71b:65d3:4bd7</td>
</tr>
<tr>
<td></td>
<td>Note:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When IPv6 traffic is encountered in a customer’s virtual cloud network, a</td>
<td></td>
</tr>
<tr>
<td></td>
<td>flow log entry with IPv6 address values is generated, in place of the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>current location of IPv4 values. The source and destination addresses</td>
<td></td>
</tr>
<tr>
<td></td>
<td>could be either IPv4 or IPv6, based on the configuration and traffic present</td>
<td></td>
</tr>
<tr>
<td></td>
<td>in the customer’s VCN. This data is only available in regions where</td>
<td></td>
</tr>
<tr>
<td></td>
<td>IPv6 support is generally available, and configured by the customer.</td>
<td></td>
</tr>
<tr>
<td>data.destinationPort</td>
<td>IANA port number of the destination.</td>
<td>36266</td>
</tr>
<tr>
<td>data.endTime</td>
<td>End time of the capture window in UNIX epoch seconds.</td>
<td>1598917970</td>
</tr>
<tr>
<td>data.flowid</td>
<td>Hash of key fields (source and destination addresses, ports, and protocol).</td>
<td>a6a737770</td>
</tr>
<tr>
<td>data.packets</td>
<td>Number of packets recorded in the capture window.</td>
<td>250</td>
</tr>
<tr>
<td>data.protocol</td>
<td>IANA protocol number.</td>
<td>6</td>
</tr>
<tr>
<td>data.protocolName</td>
<td>IANA name for protocol.</td>
<td>TCP</td>
</tr>
<tr>
<td>data.sourceAddress</td>
<td>IP address of the source, either in IPv4 dot, or IPv6 colon notation.</td>
<td>123.0.0.1 1fde:9f1c:2433:4038:68fc:e0b:73f3:32f5</td>
</tr>
<tr>
<td>data.sourcePort</td>
<td>IANA port number of the source.</td>
<td>443</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Sample Value</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>data.startTime</td>
<td>Start time of the capture window in Unix epoch seconds.</td>
<td>1598917969</td>
</tr>
<tr>
<td></td>
<td>UNIX epoch time uses a fixed point in the past to reference the current time. That means that every second of the current time can be expressed as a number, such as 1576090259 (which is Wednesday, December 11, 2019 6:50:59 PM GMT). Each flow log record records a one-minute interval (0 to 59 seconds) of data flow, using epoch start and end times to indicate the time that data appears during the 60-second interval for that record. Let's consider the epoch time entries that would appear for data flow during a fixed interval of 140 seconds. At five seconds past a particular minute, you open a connection to your host and begin to continuously send data over that connection for the next 140 seconds (&lt; three minutes, three records). Epoch start and end times would appear in the log according to the following: • The first record would show an epoch start time at the five seconds past the minute mark and an epoch end time at the end of that minute (54 seconds later). • The next record would show an epoch start time at the zero-seconds mark, and epoch end time at the end of that minute (59 seconds later). This assumes you sent the data continuously. If your transmission had been intermittent, the epoch times would reflect the first and last second data flow that occurred during that 60-second interval (the absolute time). • The final record would show an epoch start time at the zero-seconds mark, and an epoch end time for 20 seconds later (since the total flow life was only 140 seconds, or 20 seconds into the third one-minute logging interval recorded by each record).</td>
<td></td>
</tr>
<tr>
<td>data.status</td>
<td>Status of data capture window. Possible values:</td>
<td>OK</td>
</tr>
<tr>
<td></td>
<td>• OK: Normal packet log.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• NODATA: No traffic was recorded during the capture window, in which case, only the following data fields are set: endTime, startTime, status, and version. The remaining data fields are set to null: action, bytesOut, destinationAddress, destinationPort, flowid, packets, protocol, protocolName, sourceAddress, and sourcePort. • SKIPDATA: Some traffic was not logged during the capture window because of system errors or capacity issues, in which case, only data fields endTime, startTime, status, and version are set, and the remaining data fields are set to null. The flow log can contain other records for accepted or rejected traffic in the capture window.</td>
<td></td>
</tr>
<tr>
<td>data.version</td>
<td>Version of the flow log record schema.</td>
<td>2</td>
</tr>
<tr>
<td>datatime</td>
<td>Timestamp in milliseconds. Same as the oracle.ingestedtime field but in milliseconds.</td>
<td>1598917955000</td>
</tr>
<tr>
<td>id</td>
<td>Random UUID, unique to each log entry.</td>
<td>abcdabcd-abed-abedabcdabcdabcd</td>
</tr>
</tbody>
</table>

<td>2020-08-31T23:52:35Z</td>
</tr>
<tr>
<td>type</td>
<td>Category of log: DataEvent, QualityEvent.NoData, or QualityEvent.SkipData.</td>
<td>com.oraclecloud.vcn.flownlogs.DataEvent</td>
</tr>
</tbody>
</table>

### Limitations and Considerations

- Some traffic might not be logged during a capture window because of capacity issues or system errors. In such cases, NODATA, or SKIPDATA log status is recorded.
- Some services manage VNICS. For example, the Load Balancing service manages VNICS attached to load balancers. Flow logs for managed VNICS are captured, and identified by VNIC ID. Flow logs, however, currently do not include a field to indicate what service such VNICS belong to.
- For traffic over the public IP of a Compute instance, flow logs records the corresponding private IP.

### Using the Command Line Interface (CLI)

See VCN Flow Logs Example on page 2589 for example commands.

### Details for VPN Connect

This topic provides details for VPN Connect logs.

### Resources

- IPSecConnection

### Log Categories

<table>
<thead>
<tr>
<th>API value (ID):</th>

</tbody>
</table>
Availability
See VPN Connect v2 availability on page 3156 for up-to-date information on VPN Connect logging availability.

Comments
VPN Connect logs contain all status-related information of the IPSec tunnels associated with the site-to-site type of IPSec connections. This includes bringing of tunnels up or down, and accompanying negotiation information. Each IPSec connection has two IPSec tunnels created, thus the VPN Connect logs will contain status on both tunnels. Amongst other types of filtering, IPSec tunnels can be distinguished and thus filtered on their data.TunnelId (see Contents of a VPN Connect Log on page 2616 below for details).

Most VPN Connect log messages begin with a connection name. The connection name is unique for each IPSec tunnel. Its base form is comprised of ten numeric digits (see the sample value for the data.message property in the table below). In total, a connection name has three additional variants, and which variant(s) are used is based on the following:

1. Each IPSec tunnel has a unique ten-digit key assigned to (for example, 9123456789) which is contained in the beginning of many of the IPSec log messages. This is the form for IPv4 tunnels.
2. If the given IPSec tunnel is also configured for IPv6, IPSec log messages can also contain the same ten-digit key with a _v6 appended to it (for example, 9123456789_v6).
3. If the tunnel is policy-based (that is, MED is enabled) there can be multiple SAs depending on the configuration. The form of the ten-digit key for IPv4 tunnels with multiple SAs is a sequence of _1, _2, _3, and accordingly depending on the number of SAs (for example, 9123456789_1, 9123456789_2, 9123456789_3).
4. If the given policy-based tunnel is also configured for IPv6, IPSec log messages can also contain the same ten-digit key and SA index, along with v6 (for example, 9123456789_v6_1).

Contents of a VPN Connect Log
A VPN Connect log contains the following fields:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Sample Value</th>
</tr>

An Example VPN Connect Log

```json
{
  "data": {
    "message": "2062988354": terminating SAs using this connection",
    "tunnelId": "ocid1.ipsectunnel.region1.sea.uniqueId"
  },
  "id": "e3002eaa-d717-472e-8474-d024943a0f27",
  "oracle": {
    "compartmentId": "ocid1.tenancy.region1..uniqueId",
    "ingestedTime": "2021-02-18T18:22:01.453Z",
    "logGroupId": "ocid1.loggroup.region1.sea.uniqueId",
    "logId": "ocid1.log.region1.sea.uniqueId",
    "tenantId": "ocid1.tenancy.region1..uniqueId"
  },
  "source": "ocid1.ipsecconnection.region1.sea.uniqueId",
  "specversion": "1.0",
  "time": "2021-02-18T18:21:52.024Z",
  "type": "com.oraclecloud.vpn.ipseclog.read"
}
```

Troubleshooting

An error is displayed on the log details page if you attempt to enable logs for a v1 VPN connection. Only v2 connections are supported.

Audit Logs

On the Audit page, you can explore audit logs. Audit logs are also searchable on the Search page, and you can view Audit logs in every compartment by selecting the `_Audit` log group on the Search page. For an overview of Audit, see Overview of Audit on page 488.

Note:

This page replaces the classic Audit page features found in the Governance and Administration portion of the Console, which will eventually be deprecated. As a result, a new and improved Audit experience is now part of Oracle Cloud Infrastructure Logging, and we recommend you use this latest version of Audit instead.

Required Permissions for Audit Logs

To view and search Audit logs, you must have the corresponding Audit-related permissions. See Details for the Audit Service on page 2177 and Required Permissions for Searching Logs on page 2635 for more information.

Filtering Audit Logs

To filter Audit logs:

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Audit. The list of audit logs in the current compartment is displayed.
2. Choose a compartment you have permission to work in.
3. In **User**, add user filters. Multiple users can be added.
4. In **Resource**, add resource filters. Multiple resources can be filtered on.
5. In **Request Action Types**, select an action operation:
   - GET
   - POST
   - PUT
   - PATCH
   - DELETE
   Multiple request action types can be filtered on.
6. In **Event Type**, add event filters. Multiple event filters can be added.
7. In **Custom Filters**, start typing to automatically display filter settings, along with operators. For example, entering `d` displays filters starting with that letter. Use the up or down arrow keys to select from the list, or continue typing to enter what you want to filter on. This functions the same as this field on the Logging **Search** page.

   **Note:**
   If you want to find log events with a specific status code, include quotes ("') around the code to avoid results that have those numbers embedded in a longer string.

8. In **Filter by Time**, select from one of the preset time periods:
   - Past 5 Minutes (the default)
   - Past 15 Minutes
   - Past Hour
   - Past 3 Hours
   - Today
   - Custom (choose your own using the **Start Date** and **End Date** fields)
9. After entering your search text or filters, click **Apply**.

   **Note:**
   Since the **Audit** page automatically refreshes after applying filters, you do not need to click the **Apply** button as you select different filters. You will, however, need to click **Apply** again after some time has passed and new logs have appeared.

The **Convert to search** option allows viewing your Audit Log results in the **Search** page, to further search and perform analysis across other logs in the system. When you use this option, the **Advanced Search** version of the **Search** page is filled with the chosen filter parameters (available in the **Query** field).

Click **View query syntax** to view the actual syntax query statement(s) associated with your filter settings. If you have applied multiple filters for a field, you can view how the query is constructed in terms of the combined OR and AND statements.

**Exploring the Details of Events**

On the **Explore Events** tab, each log entry is organized in terms of the **Event Time**, **User**, **Resource**, **Type**, **Action**, and **Status**. Click and expand an audit log entry. Each entry displays the log data in a JSON field view, similar to the **Search** page, where you can collapse and expand nodes, or click the copy icon to copy the log entry to the clipboard.

**To export log data**

At the top right portion of **Explore Events**, click **Export Log Data (JSON)**. This feature allows you to export the log data to a JSON file that you can save to your system.
Viewing the Activity Stream

Click the **Activity Stream** tab to view the audit logs as a visual sequential list (by date, from newest to oldest log event). You click and expand an event to display the event in JSON format, and you can click the copy icon to copy the audit event to the clipboard.

Exporting Audit Events

Audit events can be exported using Service Connector Hub.

Audit Schema

See [Version 2 Audit Log Schema](#) on page 488 for more information on the audit logging schema.

Custom Logs

Custom logs are logs that contain diagnostic information from custom applications, other cloud providers, or an on-premise environment. Custom logs can be ingested in the following ways:

- By using PutLogs to ingest custom logs directly. See the Logging Ingestion API and REST APIs on page 4368 for more information. Also see [Using the API](#) on page 2634 for an example log entry payload that can be used with PutLogs.
- By configuring the Unified Monitoring Agent. See [Installing the Agent](#) on page 2621 for instructions.

**Note:**

When managing Oracle Cloud Agent plugins, the Unified Monitoring Agent is referred to as "Custom Logs Monitoring".

Custom logs can be viewed in the Oracle Cloud Infrastructure Compute instance page, and have an associated **Logs** resource. They can also be viewed on the Logging **Search** page, **Logs** page, or within an associated **Log Groups** detail page. Custom logs are also supported in bare metal instances.

The agent can be installed on many machines, and it pulls logs from local directories, where your apps or systems emit logs. The agent can also parse your logs for you. All of this is configured in **Agent Configurations**. You can create an agent configuration separately, and then associate a custom log with it, or create a custom log and then later create its agent configuration.

An agent configuration is the central mechanism for defining:

- What hosts you want logs from.
- What specific logs you want from the hosts.
- Additional parsers.
- The custom log destination.

Creating a custom log is a two-step process, in that you create the custom log object first, and then second, create its associated agent configuration. See [Creating Custom Logs](#) on page 2619 for more information on creating custom logs and agent configurations, and **Agent Management** on page 2621 for more information on setting up and managing the agent.

**Note:**

For the agent to run correctly, ensure that your firewall settings allow the following URI endpoints:

- https://auth.<your region>.oraclecloud.com

Creating Custom Logs

To create custom logs:
1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Logs.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. In Custom Log Name, enter a name for the custom log. Avoid entering confidential information.
4. From Compartment, choose a compartment you have permission to work in.
5. From Log Group, select a log group to place the custom log into.
6. Optionally, select a log retention value from Log Retention, and add any applicable tags in Add Tags.
7. Click Create Log Object. The Create Agent Configuration panel is displayed. You can next create a new configuration, to define the parameters for the associated log data (the default), or add it later.
8. In Name and compartment, enter a Configuration Name in the corresponding field, and select a Compartment you have permissions to work in.
9. In Choose Host Groups, which allows you to define which VMs apply to this configuration, select a Group Type from the list, whether Dynamic Group or User Group.

For the Dynamic Group case, Dynamic Group refers to a group of instances, which you can create in the IAM feature of the Console. See About Dynamic Groups on page 2422 for more information. These Dynamic Groups can be selected from the Groups field when setting up Dynamic Group settings.

For the User Group case, select the group from the Groups field. User Groups also refer to the IAM Groups feature of the Console. See Managing Groups on page 2419 for more information.

Click Add Host Group to add more groups. You can add a combination of Group Types for the agent configuration, that is, both Dynamic Groups and User Groups can be set up in the configuration.

Note:
A maximum of five groups per configuration are allowed, and a host can be in a maximum of five different groups.

10. Next, in the configuration, you need to define the format of the logs (that is, what logs do you want to watch for) in Configure Log Inputs. Select an Input Type from the list, whether Windows Event Log or Log Directory.

- For Windows Event Log, enter an Input Name and select an Event Channels option from the list.
- For Log Directory, enter an Input Name and a Path in the corresponding fields. For example, /<log_path>/<log_name>. Multiple paths can be entered.

Click Advanced Parser Options, which opens the Advanced Parser Options panel. This allows you to specify how to parse the log, according to the following parsers. Some of the parsers require further input and have more options, depending on the type chosen.

- AUDITD
- JSON
- TSV
- CSV
- NONE (the default)
- SYSLOG
- APACHE2
- APACHE_ERROR
- MSGPACK
- REGEXP
- multiline

For example for JSON, you must select a Time Type value from the list, while optionally, you can specify event time and null field settings. Meanwhile for REGEXP, you specify the regular expression for matching logs, along with the time format. See Log Inputs and Parsers on page 2626 for more information.

11. After configuring the log inputs and the parser, you can optionally specify any tag settings. Click Submit to save your changes, and create the custom log and its associated agent configuration.

In summary, the agent configuration defines what instances the configuration applies to (Choose Host Groups), which log files are obtained and what parser (if any) is used (Configure Log Inputs), and to what log object in the
Oracle Cloud Infrastructure system that the records are pushed to (Select log destination). The latter is already set up since this was set during the custom log creation step.

The custom log object is now created, as well as the agent configuration, which pulls data from instances, and pushes into the custom log object.

Agent Management

To ingest events from your applications into your custom log, you can install the Oracle fluentd-based agent. This agent allows you to control exactly which logs you want to collect, how to parse them, and more.

Note:
The Unified Monitoring Agent is a fully managed agent, and custom client configuration is not officially supported. For example, gathering logs from remote sources is not recommended, since doing so can have serious security implications (because the log source cannot be verified).

Oracle Cloud Infrastructure Logging provides an easy mechanism (Agent Configurations) to enable and manage the agent for a set of supported operating systems. Agent Configurations give you a central experience to easily configure what custom logs you want to ingest across your fleet of hosts. The following are the supported operating systems for agent configurations:

- Oracle Linux 7, Oracle Linux 8
- CentOS 7, CentOS 8

Note:
For Linux, only register Linux-specific input types, such as "Log Path", for a dynamic group that includes only a Linux instance. For Windows, only register Windows-specific input types, such as "Windows event log", for a dynamic group that includes only a Windows instance. Otherwise, the Unified Monitoring Agent malfunctions if you register a Windows input type for a Linux instance, and vice versa.

Installing the Agent

New Oracle Cloud Infrastructure Instances

For supported operating systems, you can enable the agent directly during creation time. The Custom Logs Monitoring plugin must be enabled, and all plugins must be running. See Managing Plugins with Oracle Cloud Agent on page 740 for more information.

Existing Oracle Cloud Infrastructure Instances

For existing instances with supported operating systems, the Custom Logs Monitoring plugin must be enabled, and all plugins must be running. See Managing Plugins with Oracle Cloud Agent on page 740 for more information.

If you already have the monitoring plugin enabled, then your instance will be automatically patched to install the agent by September 18, 2020. Otherwise, you can follow the manual installation instructions:

Linux:
1. Connect to the instance.
2. You can obtain the agent by using this script, and then run the script to download the agent. For example:

   ```bash
   ./downloadAgent.sh centos7
   ./downloadAgent.sh centos8
   ./downloadAgent.sh oel7
   ./downloadAgent.sh oel8
   ```
Logging

./downloadAgent.sh windows

Otherwise, you can download the agent for the following individual operating systems:

- Oracle Linux 7 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ol7-repo/o/unified-monitoring-agent-0.0.5.rpm
- Oracle Linux 8 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-ol8-repo/o/unified-monitoring-agent-0.0.5.rpm
- CentOS 7 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-centos7-repo/o/unified-monitoring-agent-0.0.5.rpm
- CentOS 8 RPM: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-centos8-repo/o/unified-monitoring-agent-0.0.5.rpm

For the FIPS-enabled agent:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance is impacted when using the FIPS-enabled agent.</td>
</tr>
</tbody>
</table>

3. Run the following command to install the RPM:

```
yum install -y <rpm-name>
```

Windows:

1. Connect to the instance.
2. Download the agent from: https://objectstorage.us-phoenix-1.oraclecloud.com/n/axmjwnk4dzjv/b/unified-monitoring-agent-windows-repo/o/unified-monitoring-agent-0.0.5.msi
3. Open an elevated command prompt (running as Administrator), and run the MSI command (installation can take up to five minutes to complete):

```
C:\path\to\file\unified-monitoring-agent-0.0.2.msi
```
4. For a more advanced version of the preceding command (to debug MSI installation issues), run:

```
msiexec /i "C:\path\to\file\unified-monitoring-agent-0.0.2.msi" /l*v "C:\unified-monitoring-agent_msi.log"
```

Instances Created from Custom Images and Non-Oracle Cloud Infrastructure Instances

1. Install the agent according to the same steps in Existing Oracle Cloud Infrastructure Instances on page 2621.
2. Configure User API keys for the instance you are running on. To generate the user API key, follow the instructions described in How to Generate an API Signing Key on page 4180.
   - (Linux) Step 2a. Place the ".oci" directory and its contents under /etc/unified-monitoring-agent.
   - (Windows) Step 2a. For Windows, there are a few steps that differ, so ensure to follow the appropriate steps. Create the ".oci" folder and its contents in the directory C:\oracle_unified_agent.
3. Follow the instructions described in 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049, to create the configuration file with the modifications in the next step.
4. After following the steps in 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2049, ensure to name the profile (<profile-name>) for this section as "UNIFIED_MONITORING_AGENT".

The following is an example of what the configuration looks like for the Unified Monitoring Agent to use for authentication with the service:

```
[UNIFIED_MONITORING_AGENT]
user=ocid1.user.region..aaa...
fingerprint=<cert fingerprint>
key_file=/path/to/ocifolder/.oci/private.pem
tenancy=ocid1.tenancy.region..aaa...
region=<instances region>
pass_phrase="pashphrase1234"
```

Verify Agent Installation

**Windows:**

1. Connect to the instance.
2. Open Services.msc (Start menu and type services.msc). Scroll until you see the "Oracle Unified Monitoring Agent" and that the agent is in a "Running" state.
3. In the Task Scheduler under Task Scheduler Library, verify that the UnifiedAgentConfigUpdater exists, and has (or will) run successfully. After the initial install, it can take up to 20 minutes for the first run. If preferred, this can be run manually.
4. After the UnifiedAgentConfigUpdater task has run, verify that a "unified-monitoring-agent.conf" file in exists in C:\oracle_unified_agent.
5. After a few minutes, supervisor (unified-monitoring-agent-supervisor-0.log) logs and worker (unified-monitoring-agent-0.log) logs appear in the C:\oracle_unified_agent directory.
6. The preceding logs contain the Fluentd parser and plugin output.

**Oracle Linux 7, Oracle Linux 8, CentOS 7, and CentOS 8:**

1. Connect to the instance.
2. Check that the agent is running by running the following command:

   ```
   systemctl status unified-monitoring-agent
   ```
3. The status looks like the following:

   ```
   Loaded: loaded (/usr/lib/systemd/system/unified-monitoring-agent.service; enabled; vendor preset: disabled)
   Active: active (running) since Thu 2020-09-10 18:11:45 GMT; 2h 14min ago
   Docs: https://docs.cloud.oracle.com/
   ```

Managing Agent Configurations

To use agent configurations, you must be running an Oracle Cloud Infrastructure instance with the supported operating system (see Agent Management on page 2621). Agent configurations give you a central experience to easily configure what custom logs you want to ingest across your fleet of hosts. A configuration allows you to select:

- Which hosts you want to collect logs from.
- Exactly which logs you want to ingest from those hosts.
- A log group/log destination.

Configurations are managed through the Console and Logging API. In addition, since you can choose to create an agent configuration later after creating a custom log, you can use the Agent Configurations page to set up the agent configuration and point it to your custom log.

The Agent Configurations page is organized in terms of the following:

- Name
- Config OCID
To create a new agent configuration

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click Create Agent Config. The Agent Configurations panel is displayed.
4. In Name and compartment, enter a Configuration Name in the corresponding field, and select a Compartment you have permissions to work in. Avoid entering confidential information.
5. In Choose Host Groups, select a Group Type from the list, whether Dynamic Group or User Group. Click Add Host Group to add more groups.
6. In Configure Log Inputs, select an Input Type form the list, whether Windows Event Log or Log Directory.
   - For Windows Event Log, enter an Input Name and select an Event Channels option from the list.
   - For Log Directory, enter an Input Name and a Path in the corresponding fields.
7. In Select log destination, the User Group or Dynamic Group in the configuration that you select in Compartment needs to have permission to work in the compartment. Select the Log Group, and the Log Name from the corresponding drop-down lists. The Log Name can only point to a custom log and the custom log must exist in the chosen log group for the configuration to work.
8. Optionally, after clicking Show Additional Options, specify any preferred tag settings.
9. Click Create. The agent configuration is created and appears in the Agent Configurations page.

To view an agent configuration

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Agent Configurations. The Agent Configurations page is displayed.
2. Under List Scope, Compartment, choose a compartment you have permission to work in.
3. Click the linked agent configuration name under Name in the table. The agent configuration detail page is displayed. This page displays the following on the Log Information tab:
   - OCID
   - Compartment
   - Created date and time in UTC format
   - Status (Creating, Active, Updating, Inactive, Deleting, Deleted)
   - The Tags tab shows associated tags for this log.
   - Under Log Details the following is displayed: the compartment, the linked log group and log name.

In the Configuration resource, the Host Group and Log Input configuration settings are listed in corresponding tables. Under Host Group you can view the Group Type, Group Name, and the OCID. Click the linked Group Type (whether a User Group or Dynamic Group), which opens the IAM Groups or Dynamic Groups section of the Console, respectively. See Managing Groups on page 2419 and About Dynamic Groups on page 2422 for more information.

Under Log Input you can view the Input Type, Input Name, File Paths, Parser, and Parser Parameters (if applicable for the chosen parser).

In the Explore Log resource, log data is displayed in a similar manner as the Log Data on the Search page. You can apply some simple filters, such as sorting by newest or oldest from the Sort field, or filtering by time from the corresponding Filter by Time field.

Clicking Explore with Log Search allows you to view this log on the Search page directly. After clicking this link, the Search page opens with the Select Logs to Search field populated with the log in the filter settings. At this point, you can perform more analysis and investigation related to this log directly on the Search page. For more information, see Searching Logs on page 2634.

To edit an agent configuration
Logging

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Agent Configurations**. The **Agent Configurations** page is displayed.

2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.

3. Click the linked agent configuration name under **Name** in the table. The agent configuration detail page is displayed.

4. Click **Edit**. The **Agent Configurations** panel is displayed.

   From the main **Agent Configurations** page, for the agent configuration you want to edit, you can also click the the Actions icon (three dots), and then click **Edit** to access the **Agent Configurations** panel.

5. Make your changes and click **Update**.

**To enable or disable an existing agent configuration**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Agent Configurations**. The **Agent Configurations** page is displayed.

2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.

3. Click the linked agent configuration name under **Name** in the table. The agent configuration detail page is displayed.

4. Click **Disable/Enable**. A confirmation dialog is displayed regarding the disabling or enabling of the agent configuration.

5. Confirm by clicking **Disable/Enable**. The agent configuration detail page changes its status and displays **Inactive** (for a disabled configuration), or **Active** (for an enabled configuration) in the status field, both on the agent configuration detail page and the **Agent Configurations** page.

   From the main **Agent Configurations** page, for the agent configuration you want to disable/enable, you can also click the the Actions icon (three dots), and then click **Disable/Enable**.

**To delete an agent configuration**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Agent Configurations**. The **Agent Configurations** page is displayed.

2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.

3. Click the linked agent configuration name under **Name** in the table. The agent configuration detail page is displayed.

4. Click **Delete**. A confirmation dialog is displayed regarding the delete operation.

5. Confirm by clicking **Delete**. The agent configuration is removed from the **Agent Configurations** page.

   From the main **Agent Configurations** page, for the agent configuration you want to delete, you can also click the the Actions icon (three dots), and then click **Delete**.

**To move an agent configuration to a different compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Agent Configurations**. The **Agent Configurations** page is displayed.

2. Under **List Scope, Compartment**, choose a compartment you have permission to work in.

3. Click the linked agent configuration name under **Name** in the table. The agent configuration detail page is displayed.

4. Click **Move Resource**. The **Move Resource to a Different Compartment** dialog is displayed.

5. Choose the new compartment and then click **Move Resource**.

   From the main **Agent Configurations** page, for the agent configuration you want to move to a new compartment, you can also click the the Actions icon (three dots), and then click **Move Resource**.

**Selecting Target Hosts with Dynamic Groups**

To set up a configuration for multiple hosts, you can use the **Dynamic Group** feature from IAM. The overall process first involves creating a compartment, then placing all the instances in the compartment you want to collect logs from. Next, you can create the Dynamic Group. The Dynamic Group policy statement would then point to the compartment that contains the instances. Lastly, create a log group, custom log, and its associated agent configuration.
Logging

Set the following policy statement:

```
allow dynamic-group <dynamic_group_name> to use log-content in tenancy
```

This policy statement allows the agent configuration to push logs to the Logging service backend, which you can later see in the Logging Service's Search page.

In the Dynamic Groups configuration, set up your Dynamic Group to have a rule that includes all the agents that you want to use to send logs to the Logging service. For example, in a Rule inside the Dynamic Group it can state:

```
ANY {instance.id = 'ocid1.instance.<region>.<location>.<unique_ID>',
     instance.compartment.id = 'ocid1.compartment.<region>..<unique_ID>'}
```

If you remove `instance.id = 'ocid1.instance.<region>.<location>.<unique_ID>'` and just have:

```
ANY {instance.compartment.id = 'ocid1.compartment.<region>..<unique_ID>'}
```

this means use all the instances under this compartment to send logs. For more information on Dynamic Groups, see About Dynamic Groups on page 2422.

Next, create the log group (see To create a log group on page 2583). After the log group is created, you can then create the custom log and the agent configuration (see Creating Custom Logs on page 2619 for steps to create the custom log and agent configuration). During the agent configuration, you can use the Dynamic Group you created earlier and select it in the Choose Host Groups section of the Agent Configurations panel. This links the log configuration with the instance you want to send logs to. Once the agent configuration is active, the logs you see are sent by the instance, inside the Dynamic Group you earlier set up. You can later click Explore with Log Search in the agent configuration to view the logs through the Search page (see Searching Logs on page 2634).

Log Inputs and Parsers

Agent configurations allow you to easily select which types of logs you want to ingest, and how to parse them. The following are the supported log inputs in agent configurations:

- Windows Event Logs
- Log Directory (Tail)

For Log Directory inputs, you can specify parsers to structure your logs. The following are the list of supported parsers:

- None
- Auditd (https://github.com/linux-audit/audit-documentation/wiki)
- JSON (https://docs.fluentd.org/parser/json)
- CSV (https://docs.fluentd.org/parser/csv)
- TSV (https://docs.fluentd.org/parser/tsv)
- Syslog (https://docs.fluentd.org/parser/syslog)
- Apache2 (https://docs.fluentd.org/parser/apache2)
- Apache_Error (https://docs.fluentd.org/parser/apache_error)
- Msgpack (https://docs.fluentd.org/parser/msgpack)
- Regexp (https://docs.fluentd.org/parser/regexp)
- Multiline (https://docs.fluentd.org/parser/multiline)

Log Destination

You can choose the exact log group and log object where you want your log events to be indexed. All incoming log events from your hosts are ingested and indexed in your selected log object. After they are ingested, you can view and search your log events on the Search page (see Searching Logs on page 2634). All existing Oracle Cloud Infrastructure Identity and Access Management policies in both the log group and compartment apply both during ingestion and search. So, only authorized users can view and ingest logs in your tenancy.
Logging

Viewing Custom Logs in a Compute Instance

The Logs resource on a Compute Instance page allows you to view logging details for the instance in the selected compartment. Logging Search APIs are called and any available logs are pulled for the instance. Instances can have a customer application running on them (for example, a gaming server), and they can configure logs from the gaming server to be collected by the Unified Monitoring Agent, and then be pushed into the Logging service and be indexed there. Logs are pulled and displayed on the Logs resource. As such, when a customer views their Compute instance, they can see that their application is pushing logs to the Logging service. Logs, however, cannot be enabled or created from this interface.

Under Explore Logs, you can sort log entries (Newest, the default or Oldest), or filter by time (the default Past 5 minutes, Past 15 minutes, Past hour, Past 24 hours, Today, Custom). Otherwise the functionality is the same as when you are viewing logs under Log Data in the central logging Search page (see Using the Console on page 2635).

Click Explore with Log Search to open the central logging Search page, where you can add or remove filters and so on. The Search page loads with instanceid of the instance already set as a filter under Filters.

Click Create Custom Log to open the central Logs page, where you can create custom logs for the instance. Custom logs are sent from Oracle Cloud Infrastructure Compute VM instances.

For the Logs resource to be available on such an instance, the following is required:

- The Custom Logs Monitoring plugin must be enabled, and all plugins must be running. For more information, see Managing Plugins with Oracle Cloud Agent on page 740.
- The instance must have one of the supported operating systems:
  - Oracle Linux 7, Oracle Linux 8
  - CentOS 7, CentOS 8

If the operating system is not supported, then this Logs resource is not displayed. If the operating system is supported by the Oracle Cloud Agent and is not enabled, a warning is displayed that you must enable the agent to create logs.

Agent Troubleshooting

The following topics describe troubleshooting tips related to the Unified Monitoring Agent, for both Linux and Windows.

Hardware Requirements

Depending on your logging requirements and configuration (number of logs, type of buffering, and so on), the hardware requirements and performance of the Unified Monitoring Agent can vary widely. When no operational pressure is present (less than 1,000 log events per minute), the agent should not consume more than 200 MB of RAM, and 20% of a CPU core. The Unified Monitoring Agent service hard-coded limits are 5 GB RAM, and 40% of a core. 1 GB of RAM is also recommended.

Enabling Monitoring

Monitoring can aid with troubleshooting. See Enabling Monitoring for Compute Instances on page 783 for more information on how you can enable monitoring (metrics and logging) in your Oracle Cloud Infrastructure Compute instances.

Linux

systemd Units

The Unified Monitoring Agent is based on systemd units, and is composed of the following components:

1. unified-monitoring-agent.service: The main Unified Monitoring Agent service.
2. unified-monitoring-agent_config_downloader.service: The configuration automatic updater service.
3. **unified-monitoring-agent_config_downloader.timer**: The timer unit, which triggers the automatic downloader service on specified, randomized, intervals.

4. **unified-monitoring-agent_restarter.path**: The path unit, which triggers the reload of the configuration by the Unified Monitoring Agent, if a change is detected (because of a new configuration being downloaded by the automatic updater service).

**Note:**
Remember that most of the `systemctl` or `journalctl` commands must be run with super user privileges (either as `root`, or through `sudo`).

To verify the correct operation of these systemd units, you can use the `systemctl` command like the following:

```bash
systemctl status <unit_name>
```

Where `<unit_name>` must be replaced with one of the following values:

1. **unified-monitoring-agent.service**
2. **unified-monitoring-agent_config_downloader.service**
3. **unified-monitoring-agent_config_downloader.timer**
4. **unified-monitoring-agent_restarter.path**

Typically these `systemctl` commands show output similar to the following:

```bash
systemctl status unified-monitoring-agent.service
# unified-monitoring-agent.service - unified-monitoring-agent: Fluentd based data collector for Oracle Cloud Infrastructure
    Loaded: loaded (/usr/lib/systemd/system/unified-monitoring-agent.service; enabled; vendor preset: disabled)
    Active: active (running) since Tue 2020-09-29 13:54:03 UTC; 1min 37s ago
      Docs: https://docs.cloud.oracle.com/
      Process: 2337 ExecReload=/bin/kill -USR2 ${MAINPID} (code=exited, status=0/SUCCESS)
      Main PID: 2327 (fluentd)
      Memory: 66.3M (limit: 5.0G)
      CGroup: /system.slice/unified-monitoring-agent.service
```

```bash
systemctl status unified-monitoring-agent_config_downloader.timer
# unified-monitoring-agent_config_downloader.timer - Run unified-monitoring-agent configuration automatic updater.
```

```bash
systemctl status unified-monitoring-agent_config_downloader.service
# unified-monitoring-agent_config_downloader.service - unified-monitoring-agent_config_downloader.service
    Loaded: loaded (/usr/lib/systemd/system/unified-monitoring-agent_config_downloader.service; enabled; vendor preset: disabled)
    Active: inactive (dead) since Tue 2020-09-29 13:54:38 UTC; 1min 30s ago
      Main PID: 2333 (code=exited, status=0/SUCCESS)
```
Logging

The most important parts of the systemctl command output are the Loaded and Active fields. The Loaded field has the value loaded for all system units. The Active field has the following values:

- active (running) for the unified-monitoring-agent.service unit.
- active (waiting) or active (running) for the unified-monitoring-agent_restarter.path and the unified-monitoring-agent_config_downloader.timer units.
- active (running) or inactive (dead) for the unified-monitoring-agent_config_downloader.service unit. For the latter value, the field Main PID includes the value code=exited, status=0/SUCCESS).

Processes

Another way to further verify the correct operation of the Unified Monitoring Agent, is to check the system’s running processes. When operating correctly, the Unified Monitoring Agent runs two processes: one supervisor process, and one worker process. You can verify their existence by running the following command in a terminal (sample output included):

```
ps aux | grep unified-monitoring-agen[t]
```

As shown in the preceding sample, there are two processes running, with the same arguments, except for the extra –under-supervisor added to the second one. This denotes the worker process, thus making the process without this parameter the supervisor.

Logs

**Note:**

Remember that most of the systemctl or journalctl commands must be run with super user privileges (either as root, or through sudo).

The Unified Monitoring Agent logs are available at /var/log/unified-monitoring-agent/unified-monitoring-agent.log. This file includes logs from the Unified Monitoring Agent itself.

Besides the agent’s logs, which do not contain system-related events (for example, service start, service stop, and so on), you can also view the logs from journald, systemd's system logging service. To view the system logs specific to a unit, you can use the journalctl command like the following:

```
journalctl -u <unit_name>
```

Where <unit_name> must be replaced with one of the following values:
1. `unified-monitoring-agent.service`
2. `unified-monitoring-agent_config_downloader.service`
3. `unified-monitoring-agent_config_downloader.timer`
4. `unified-monitoring-agent_restarter.path`

When querying `journald` logs through `journalctl`, you can also define specific time ranges:

```
journalctl --since "2020-12-30 00:00:01" --until "2020-12-31 23:59:59"
```

The date format used is `YYYY-MM-DD HH:MM:SS`.

You can also tail the journal logs, by adding the `-f` parameter:

```
journalctl -f
```

**Troubleshooting Scenarios**

**Problem:** The Unified Monitoring Agent is not installed.

**Solution:** For newly created instances, it can take up to 25 minutes for the automatic installation of the agent. If it is not installed after this time period, check the following:

1. The network connectivity of the instance.
2. Whether monitoring is enabled in the Console.

You can also check the log file `/var/log/oracle-cloud-agent/plugins/unifiedmonitoring/unifiedmonitoring.log` for information regarding the installation of the Unified Monitoring Agent by the Oracle Cloud Agent.

**Problem:** The Unified Monitoring Agent is not running. Its status is not loaded/active, nor are both supervisor and worker processes running.

**Solution:** Restart the Unified Monitoring Agent and check the logs for any problems:

```
systemctl restart unified-monitoring-agent
```

**Problem:** Configuration is not automatically downloaded.

**Solution:** Ensure you have followed the steps in Installing the Agent on page 2621 and Verify Agent Installation on page 2623. Consult the journal of the automatic configuration updater service by running:

```
journalctl -u unified-monitoring-agent_config_downloader.service
```

**Problem:** Configuration is not automatically reloaded.

**Solution:** Ensure you have followed the steps in Installing the Agent on page 2621 and Verify Agent Installation on page 2623. Consult the journal of all the units:

1. The timer unit must have run at least one time.
2. The automatic configuration download service must have run after the relevant time unit has triggered it. You can verify from its logs that the configuration has been downloaded and extracted to the Unified Monitoring Agent's configuration directory. You can also verify this by listing the files in that directory:

   ```
   ls -lhatR /etc/unified-monitoring-agent
   ```

3. Verify that the path unit is active by checking its status:

   ```
   systemctl status unified-monitoring-agent_restarter.path
   ```

4. Verify that a reload signal has been received by the Unified Monitoring Agent, by inspecting its journal:

   ```
   journalctl -u unified-monitoring-agent_config_downloader.service "Reloading unified-monitoring-agent" appears in the output of this command.
   ```

**Problem:** You are testing your parsing pattern and need to force the agent to download the configuration right away.
**Solution**: Run the following command:

```
systemctl restart unified-monitoring-agent_config_downloader
```

**Note:**
Automatic update of the configuration on the agent side can take up to 30 minutes.

**Data Collection**

If you want to open a ticket so an engineer can help you with your problem regarding the Unified Monitoring Agent, include the output of the following commands. Super user privileges might be required for some of them.

```
yum info unified-monitoring-agent
rpm -ql unified-monitoring-agent | xargs sha512sum
systemctl status --full unified-monitoring-agent.service
systemctl status --full unified-monitoring-agent_config_downloader.service
systemctl status --full unified-monitoring-agent_config_downloader.timer
systemctl status --full unified-monitoring-agent_restarter.path
journalctl -a --no-pager -u unified-monitoring-agent.service
journalctl -a --no-pager -u unified-monitoring-agent_config_downloader.service
journalctl -a --no-pager -u unified-monitoring-agent_config_downloader.timer
journalctl -a --no-pager -u unified-monitoring-agent_restarter.path
```

Also include an archive of the files under `/var/log/unified-monitoring-agent/` and `/var/log/oracle-cloud-agent/`. You can create a gzipped tar archive of these directories with the command:

```
tar cvzf agent_logs_${(date +%s)}.tar.gz /var/log/unified-monitoring-agent/ /var/log/oracle-cloud-agent/
```

If the Unified Monitoring Agent is running but has erratic behavior, you can also include backtrace and memory profile information, by running the following command and including the files `/tmp/sigdump-<integer>.log` in your report (where `<integer>` is an integer with 1–6 digits, even though in rare cases it might have more than that).

```
ps aux | grep unified-monitoring-agent[t] | grep ruby | awk '{print $2}' | xargs kill -SIGCONT
```

What this command does is to find the Unified Monitoring Agent process PIDs, and send them the SIGCONT signal, which causes a dump to be generated in `/tmp/sigdump-<integer>.log`.

**Uninstall and Reinstall**

You can remove the Unified Monitoring Agent, without removing the agent's configuration, by running the following command:

```
yum -y remove unified-monitoring-agent
```

The agent's configuration remains under the `/etc/unified-monitoring-agent/` directory. If you do not want to keep the configuration for a future (re)installation of the Unified Monitoring Agent package, you need to remove it manually:

```
# use the following command to print the contents of the agent's configuration directory
find /etc/unified-monitoring-agent/
# use the following command to remove the directory and all of its contents
# (this step cannot be undone)
```
The agent is automatically reinstalled by the Oracle Cloud Agent, at most 25 minutes. You need to have monitoring enabled for your instance in the Console for this to occur. See Managing Plugins with Oracle Cloud Agent on page 740 for more information.

**Windows**

**Unified Monitoring Agent Troubleshooting Steps**

**Check the service status:**

1. The agent runs as part of a Windows service, to see its status, open the start menu and type Services.msc and open it. Go to the service Oracle Cloud Unified Monitoring Service to see the status.
2. Right-click the service and select Properties for more information. Start/stop/restart are available here.
3. From the Start menu type cmd, right-click on Command Prompt and select Run as Administrator. Run the following commands:
   - To view Unified Monitoring Agent service status:
     ```bash
     sc query unified-monitoring-agent
     ```
   - Restart the Unified Monitoring Agent service:
     ```bash
     sc stop unified-monitoring-agent
     sc start unified-monitoring-agent
     ```

   **Note:**
   The preceding commands do not work in PowerShell, so you must instead use the Windows Command Prompt.

**Find Windows Service errors:**

1. From the Start menu, type Event Viewer and select it.
2. Open Windows Logs, then System. Every time a service starts or stops, fails to do either, or crashes suddenly, it is recorded here.

   **Note:**
   On most Windows machines, there is a cap on how many events can be in the event viewer. As a result, if an event happened a long time ago, the logs might not be available.

**Fluentd logs:**

1. Open explorer.exe (file icon on the task bar)
2. Go to C:\oracle_unified_agent.
3. If there is only one file, it means that there isn’t a valid configuration file on the machine.
4. If there are two files, then there is a supervisor log that will have all the setup/start-up logs, and a worker log with all the parsing/output logs. unified-monitoring-agent.conf is the name of the configuration file if it has been downloaded properly.
5. Run Fluentd manually. Try the preceding steps to identify the issue, but if needed, you can debug an issue by manually running Fluentd.

   **Note:**
   Running Fluentd manually runs it in the Windows service, which stops the service from running as normally, which is different behavior than on Linux.
6. Use the following command to run Fluentd manually. This can be run in PowerShell or Command Prompt, but it needs to be run as Administrator:

```
C:\oracle_unified_agent\unified-monitoring-agent\embedded\bin\fluentd -c C:\oracle_unified_agent\unified-monitoring-agent.conf -vv
```

**Automatic Configuration Updater Troubleshooting Steps**

1. Verify Task Scheduler is running as expected.
2. From the Start menu, and type Task Scheduler.
3. Go to Task Scheduler (Local), then Task Scheduler Library. Find the task named UnifiedAgentConfigUpdater.
4. Verify the Last Run Time. If it was at an invalid date, or it says not run, then the Next Run time will be when it should run for the first time. For debugging, select the task and select Run if you need it to run immediately.
5. Last Run Result specifies the outcome of downloading the configuration from the control plane. If there is an error result, you need to run it manually to determine what happened. Task Scheduler does not keep output logs.
6. Run the configuration updater manually.

**Note:** Run the updater in PowerShell as an Administrator for the best experience.

```
C:\oracle_unified_agent\unified-monitoring-agent\embedded\bin\ruby.exe C:\oracle_unified_agent\unified-monitoring-agent\embedded\lib\ruby\gems\2.6.0\gems\fluent-public-config-updater-0.0.1\lib\fluent_config_updater.rb -c C:\oracle_unified_agent -b 10
```

**Oracle Cloud Agent Troubleshooting Steps**

Check the Oracle Cloud Agent logs. For Windows Server 2012r2 or 2016, the log file locations are:

- C:\Users\OCA\AppData\Local\Local\OracleCloudAgent\agent.log
- C:\Users\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring \unifiedmonitoring.log (runtime logs)
- C:\Users\OCAUM\AppData\Local\OracleCloudAgent\plugins\unifiedmonitoring \unifiedmonitoring_msi.log (install logs)
- C:\oracle_unified_agent\unified-monitoring-agent-0.log (agent worker log, which might not exist depending on state)
- C:\oracle_unified_agent\unified-monitoring-agent-supervisor-0.log (agent supervisor log, which might not exist depending on state)

Windows Server 2019 log file locations:

- C:\Windows\ServiceProfiles\OCA\AppData\Local\OracleCloudAgent\agent.log
- C:\Windows\ServiceProfiles\OCAUM\AppData\Local\OracleCloudAgent\plugins \unifiedmonitoring\unifiedmonitoring.log (runtime logs)
- C:\Windows\ServiceProfiles\OCAUM\AppData\Local\OracleCloudAgent\plugins \unifiedmonitoring\unifiedmonitoring_msi.log (install logs)
- C:\oracle_unified_agent\unified-monitoring-agent-0.log (agent worker log, which might not exist depending on state)
- C:\oracle_unified_agent\unified-monitoring-agent-supervisor-0.log (agent supervisor log, which may not exist depending on state)

**Intermittent Failed MSI Install**

An intermittent failed MSI install can occur for one of two reasons:
1. An MSI installation was interrupted (system reboot, process stop, and so on), and on the second run, the msiexec.exe process is still holding a file handle to a folder that it created.
2. During an upgrade where the MSI fails to get access to the main agent folder, because Ruby.exe doesn’t end like it should (a Fluentd issue). This causes the MSI to fail and to clean up the system, removing much of the agent (not the position or buffer files though).

In both instances, a second install or letting Oracle Cloud Agent run through the install a second time resolves this issue. If it still is stuck in this state do the following:

1. Stop all msiexec and ruby processes in Task Manager, Details.
2. Rename C:\oracle_unified_agent to C:\oracle_unified_agent_old.
3. Install the agent again, or wait for Oracle Cloud Agent to install it.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operation to ingest custom logs directly:

- **PutLogs**

The following is a sample log entry payload that can be used with PutLogs:

```json
{
   "specversion": "1.0",
   "logEntryBatches": [
      {
         "entries": [
            {
               "data": "Random test",
               "id": "sha123",
               "time": "2020-11-25T21:10:29.600Z"
            }
         ],
         "source": "hostname",
         "type": "sampleType",
         "subject": "/var/application.log",
         "defaultlogentrytime": "2020-11-25T21:10:29.600Z"
      }
   ]
}
```

**Searching Logs**

This topic describes how to search your logs using the **Search** page.

**Overview of Log Search**

Logging provides a powerful tool to search indexed logs. Use the Console to perform any of the following tasks:

- Search logs, whether in a basic user interface mode, or by typing custom queries in an advanced mode.
- Filter on values in logs, whether by log fields, text search, or time intervals, all in terms of chosen compartments or log groups.
- Visualize log data in a bar chart view, along with accompanying tabular data.
- Explore each log line in more detail. View the raw JSON payload, and view before/after information.
- Export search results to a JSON file.

Logs are indexed by default, which allows them to be searched using the Console.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Administrators: For specific examples of policy, see Required Permissions for Searching Logs on page 2635.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to know more about writing policies for Logging, see Details for Logging on page 2294.

Required Permissions for Searching Logs

To search indexed logs, a user must have the read permission on the log content and read access to the log group.

allow group GroupA to read log-groups in tenancy
allow group GroupA to read log-content in tenancy

To search indexed logs, you must have access to the log group that contains the indexed logs. For more information, see Required Permissions for Working with Logs and Log Groups on page 2577.

To view and search Audit Logs on page 2617, you must also have the corresponding Audit-related permissions. See Details for the Audit Service on page 2177 for more information. For example:

- search "compartment" requires AUDIT_EVENT_READ, and if there are any log objects, it would also require LOG_CONTENT_READ
- search "compartment/_Audit" requires just AUDITEVENT_READ.
- search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid" requires LOG_CONTENT_READ only.
- search "compartmentOcid1/_Audit" "compartmentOcid2/logGroupNameOrOcid/logNameOrOcid" requires LOG_CONTENT_READ on compartmentOcid2 and AUDIT_EVENT_READ on compartmentOcid1.

Using the Console

You can perform log searches by using either the Basic mode filter controls in the interface, or the Advanced mode custom query language interface. See Basic Search Queries on page 2635 and Advanced Search Queries on page 2636 for more information.

Basic Search Queries

To search and filter logs:

1. Open the navigation menu. Under Solutions and Platform, go to Logging, and then click Search.
2. In Select Logs to Search, the root compartment is already selected by default for filtering. Click this field to open the Select Logs to Search panel, where you can filter by compartments you have permission to work in, in addition to filtering by Log Groups and Logs. You can filter by multiple compartments and log groups. For any filters you create in this panel that you want to remove, click the filter X icon in the Select Logs to Search field.
3. In Filter By Field or Text Search, you can start typing to automatically display filter settings, along with operators. For example, entering d displays filters starting with that letter. Use the up or down
Logging

arrow keys to select from the list, or continue typing to enter what you want to filter on. For example, `data.compartmentName='<tenancy_name>'`.

4. In Logs, select one or more logs.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To limit the logs available to choose from, select one or more log groups from Log Groups.</td>
</tr>
</tbody>
</table>

5. Click Continue to apply the filter. The log data in the Explore and Visualize tab is reloaded according to the new filter settings.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Since the Search page automatically refreshes after applying filters and selecting logs, you do not need to click the Click Enter to search button as you select different filters. You will, however, need to click Click Enter to search again after some time has passed and new logs have appeared. When performing Advanced Mode queries however, you do need to always click this button to submit a query.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter settings are maintained when switching to Advanced Mode.</td>
</tr>
</tbody>
</table>

To remove a filter(s) from the Search page, under Filters, click the X icon next to the filter.

To search with Quick Start Queries

You can quickly search according to several predetermined queries. From Quick Start Queries, select a query from the list. The Search page displays the results for the chosen query.

To limit results to a specific time range

In Filter By Time, select a time range from the list, or select Custom to specify a date range in the calendar Start Date and End Date. You can also specify a time value in the box next to the calendar. Use an end time to refine the time window.

Didn't get the result you expected?

Try specifying a time range:

- Under Filter By Time, select a predetermined time range or specify a custom date range. Use an end time to refine the time window, then click Click Enter to search.

Advanced Search Queries

When performing a search on the Logging Search page, you can click Show Advanced Mode to enter your own custom log search queries. In addition, Advanced Mode searching provides more comprehensive search options that are not available in Basic Mode.

Be default, the following is displayed in the Query field after clicking Show Advanced Mode:

```
search "ocid1.tenancy.oc1..<unique_id>" | sort by datetime desc
```

For example, you can modify this default search by entering:

```
search "ocid1.tenancy.oc1..<unique_id>" | sort by datetime desc | summarize count() as cnt by rounddown(datetime, '15m') as interval
```

This returns `{"interval": 1600364700000,"cnt": 31}` and `{"interval": 1600365600000,"cnt": 220}` under Log Data in the Explore tab.

When entering search queries, auto-complete hints are providing as you type (which you can select from a pop-up menu as you type), and syntax validation is performed in real time in the background as you type a query.
When you switch from **Advanced Mode** to **Basic Mode**, the query is lost and is not available in **Basic Mode**. A warning is displayed for this scenario to confirm your preference.

The **Advanced Mode** search uses a specific syntax, using the Logging query language, which is described in **Logging Query Language Specification** on page 2639.

**To search with Quick Start Queries**

You can quickly search according to several predetermined queries. From **Quick Start Queries**, select a query from the list. The **Search** page displays the results for the chosen query.

**Saved Searches**

You can save the search parameters that you use for any searches performed in both **Basic Mode** and **Advanced Mode**.

To save a search:

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Saved Searches**.
2. Under **List Scope, Compartment**, choose a compartment you have permission to work in. The **Saved Searches** page is displayed.
3. You can start the save operation using one of these two methods:
   - From the **Saved Searches** page, click **New Search**, which opens the Logging **Search** page, where you can begin a search.
   - From the **Search** page directly, whether in **Basic Mode** and **Advanced Mode**.
4. Click **Save Search**. The **New Saved Search** panel is displayed.
5. In **Search Name**, enter a name to associate with your saved search. Avoid entering confidential information.
6. In **Compartment**, select a compartment you have permissions to work in.
7. In **Description**, enter a description for the saved search.
8. Click **Save Search** to save your search.

   **Note:**
   
   The **Search Query** field cannot be edited and is view-only. It only displays the contents of your search parameters.

The search is saved and a message appears with the linked name of your saved search. Clicking the linked saved search name opens the details page for the saved search, where you can view more information about it. This page displays the following on the **Saved Search Information** tab:

- OCID
- Region
- Compartment
- Description
- **Created** date and time in UTC format.
- **Last Modified** date and time in UTC format.
- **Search Query** view-only description of the search parameters in the saved search.
- The **Tags** tab shows associated tags for this log.
- Under **Latest Results**, log data is displayed under **Saved Search Data**, in a similar manner as the **Log Data** on the **Search** page. You can apply some simple filters, such as sorting by newest or oldest from the **Sort** field, or filtering by time from the corresponding **Filter by Time** field.

11. **Click Explore with Log Search**, which allows you to view this saved search on the **Search** page directly. After clicking this link, the **Search** page opens with the saved search loaded, whether it is a basic or advanced mode.
search. At this point, you can perform more analysis and investigation related to this search directly on the **Search** page. For more information, see **Searching Logs** on page 2634.

While on the **Search** page, you can also switch between any of the saved searches by selecting them from the **Saved Searches** list.

### Note:

When editing a saved search from the **Saved Searches** page, you can only change the **Search Name**, **Compartment**, and **Description** fields in the **Edit Saved Search** panel. If you need to change the search parameters, create a new saved search.

---

**Viewing and Working with Search Results**

After you get an initial set of results, you can view more details, whether in terms of the log fields, JSON, or before and after states, and visually as a chart. On the **Explore** tab under **Log Data**, a **Number of Log Events Per Minute** bar graph displays the number of log events, according to your filter settings.

### Note:

You will need to click **Click Enter to search** after time has passed, to see the latest logs.

### Note:

For any actions taken on the **Explore** and **Visualize** tabs, you can define how often to refresh the data on the **Search** page, by selecting a value from the **Autorefresh Interval** list (choose from **OFF**, **5 Minutes**, or **15 Minutes**). The default is **OFF**.

---

**To examine a single log entry**

- In the **Explore** tab under **Log Data**, click the down arrow (▼) to expand the log entry in **JSON** view.

  The **JSON** view is displayed. In JSON view you can view the log data fields and values, collapse and expand nodes, or click the copy icon to copy the log entry to the clipboard.

**To switch between JSON and Before & After view**

- In the **Explore** tab under **Log Data**, click the down arrow (▼) to expand the log entry and click **JSON**.

  The JSON view is displayed. Click the **Before & After** tab to switch to its view.

**To examine Before & After view**

- In the **Explore** tab under **Log Data**, click the down arrow (▼) to expand the log entry and click **Before & After**.

  The **Before & After** view is displayed. In contrast to the entry labeled as **Current**, this view displays the exact preceding and successive logging lines in the log object.

**Right-click to view more log options**
In the **Explore** tab, each entry has three interactive header columns, which correspond to: the log timestamp, the plugin where the log occurred, and the log message.

Right-click one of the log entry columns to open a context-sensitive menu for that entry and the column header. These options are available whether the log entry is collapsed or expanded. The following right-click options are available:

- **Copy value**

**Note:**
This is the only option available for the third column’s right-click menu.

- **Filter matching**
- **Filter not matching**
- **Remove from summary view**

**To export log data**

At the top-left portion of **Log Data**, click **Export Log Data (JSON)**. This feature allows you to export the log data to a JSON file that you can save to your system.

**To visualize log data as a chart**

You can view log data graphically as a chart, along with accompanying tabular data.

Select from the following chart settings:

- **Visualization Type**: Select Bar. The Bar charts are organized in terms of time (UTC) on the X-axis, with time on the Y-axis. You can hover the mouse over bars when stacked bars appear, which displays the number of log records in a tool tip.
- **Interval**: Select from 1 minute (the default), 5 minutes, 15 minutes, 30 minutes, or 1 hour.
- **Group By**: Select a logging field to group the results by.

For any chart type being viewed, you can click to expand the `<number of> records found` list below the chart, which lists the total record sum, and the number of records at each time interval.

**Using the Command Line Interface (CLI)**

For more information on installing the CLI, see Quickstart on page 4195, and logging-search for command documentation.

**Submit a query to search logs**

Open a command prompt and run:

```
oci logging-search search-logs --search-query, --time-end, --time-start
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operation to search logs:

- **SearchLogs**

Use the following for saved searches:

- **LogSavedSearch**

**Logging Query Language Specification**

This topic describes the query syntax components that can be used with Advanced Search Queries on page 2636 and Saved Searches on page 2637.
Query Components

The logging query language processing is based on a data flow model. Each query can reference one or more logs, and produces a table dataset as a result. The query language provides several operators for searching, filtering, and aggregating structured and unstructured logs.

A logging query includes the following components:

- Log streams
- Fields
- Data types
- Stream expressions
- Pipe expressions
- Operators

Log Streams

To begin your search, you must first define the set of logs you want to search. You can choose to search specific log objects, log groups, or compartments. You can mix and match as many logs as you need. The search scope is defined using the following pattern:

```
search <log_stream> (,? <log_stream>)*
```

The query language fetches log entries from the scope you provide, and constructs a log stream that you can filter, aggregate, and visualize.

Log stream:

```
<log_stream> := "<compartment_ocid> ( /<log_group_ocid> ( /<log_object_ocid> )? )?"
```

Examples:

- `search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid"`
- `search "compartmentOcid/logGroupNameOrOcid"
- `search "compartmentOcid"
- `search "compartmentOcid/logGroupNameOrOcid/logNameOrOcid", "compartmentOcid_2/logGroupNameOrOcid_2", "compartmentOcid_3"

Fields

All fields in log streams are case-sensitive. Although actual logs have indexed fields in lower case only, you can also create new fields in the query with mixed case:

```
search "." | select event as EventName
```

Fields are in JSON notation, therefore, special characters must be in quotes.

```
Fields: <field_name> := <identifier> (DOT <identifier>)*
```

For Identifier:

```
<identifier> := a-zA-Z_[a-zA-Z_0-9]* | ("" ("" | "") | "")
```
Logging

Examples:
- type
- data.message
- data.request.URL
- "type"
- "data"."message"
- "data.message" (not the same as "data"."message")
- data."$event"
- data."first name"
- data."an example of escaped ("\") double quotes"

Data Types

The following key data types are supported by the query language. These are (long and double) 8 bytes.
For details about the representation of the values of the corresponding types, see Literals on page 2647.

- Strings
- Numbers (integer, float-point)
- Arrays
- Booleans
- Timestamps
- Intervals

Stream Expressions

All expressions which produce a stream are stream expressions. Stream expressions can be formed using the following operators:

- Tabular operators
- Aggregate operators

Pipe Expressions

A pipe (|) applies an operator on the left side to a stream expression on the right side. The pipe expression is a stream expression.

The operator on the right side of a pipe must consume only one stream (for example, aggregate operations, filters).

The left side becomes the "current stream" for the right side expression, making all fields in the current stream available according to short names. For example:

```
search "application"
  | where level = 'ERROR'

>>
  {"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1", "message":"download failed...", "impact":2}
  {"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2", "message":"reached 90% file size limit...", "impact":4}
  {"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host":"host2", "message":"reached 95% file size limit...", "impact":5}
```

Operators

The following are supported when performing advanced queries:

- Tabular operators
Logging

- Scalar operators
- Aggregate operators

Tabular Operators

A tabular operator creates or modifies a log stream by filtering out or changing log entries. Also refer to BNF syntax notation. The following are tabular operators:

- **search**
- **where**
- **top**
- **sort**
- **dedup**
- **select**
- **extend**

**search**

Constructs a log stream from actual log objects. Also see Log Streams on page 2640 for details.

```
search "compartmentOCID/loggroup1/logname1" "compartmentOCID/loggroup2/logname2" "compartmentOCID/loggroup3/logname3"
```

**where**

Filters the current log stream using a Boolean expression.

```
search "application" | where level = 'ERROR'
```

where is optional:

```
search "application"  
  | where level = 'ERROR'
```

Some example comparisons with numbers and Boolean field comparisons are the following:

```
| data.statusCode = 200

| data.isPar
```

You can perform a full text search by specifying a filter on the entire content of the log. A search on logContent returns any log line where a value matches your string. This functionality supports wildcards. For example:

```
search "application"  
  | where logContent = 'ERROR' -- returns log lines with a value matching "ERROR"
```

```
search "application"  
  | where logContent = '*ERROR*' -- returns log lines with a value containing "ERROR"
```
**top**

Fetches only a specified number of rows from the current log stream, sorted based on some expression.

\[
\text{<top>} := \text{top } [0-9]+ \text{ by } \text{<expr>}
\]

Examples:

- `top 3 by datetime`
- `top 3 by *`
- `top 3 by (a + b)`

A number of rows must be a constant positive integer, and a sorting expression must be provided.

```
search "application" | top 3 by impact
```

```
>>
[{"timestamp": "2019-01-03T00:06:59", "level": "ERROR", "host": "host2", "message": "reached 95% file size limit...", "impact": 5},
{"timestamp": "2019-01-03T00:06:39", "level": "ERROR", "host": "host2", "message": "reached 90% file size limit...", "impact": 4},
{"timestamp": "2019-01-03T00:04:01", "level": "ERROR", "host": "host1", "message": "download failed...", "impact": 2}]
```

**sort**

Sorts the current log stream by the specified columns, in either ascending (default) or descending order. The operator uses the "DESC" and "ASC" keywords to specify the type of the order. The default sort order is asc.

\[
\text{<sort>} := \text{sort by } \text{<sort_expr>} (, \text{<sort_expr>})*
\]

\[
\text{<sort_expr>} := \text{<expr> (asc | desc) ?}
\]

Example:

```
search "application" | sort by impact desc
```

```
>>
[{"timestamp": "2019-01-03T00:06:59", "level": "ERROR", "host": "host2", "message": "reached 95% file size limit...", "impact": 5},
{"timestamp": "2019-01-03T00:06:39", "level": "ERROR", "host": "host2", "message": "reached 90% file size limit...", "impact": 4},
{"timestamp": "2019-01-03T00:04:01", "level": "ERROR", "host": "host1", "message": "download failed...", "impact": 2},
{"timestamp": "2019-01-03T00:05:33", "level": "WARNING", "host": "host2", "message": "reached 70% file size limit...", "impact": 1},
{"timestamp": "2019-01-03T00:04:05", "level": "INFO", "host": "host1", "message": "host list updated..."},
{"timestamp": "2019-01-03T00:06:59", "level": "INFO", "host": "host2", "message": "fs clean up started..."}
```

More than one column can be used to specify the order:

```
search "application" | sort by host, impact desc
```

```
>>
[{"timestamp": "2019-01-03T00:06:59", "level": "ERROR", "host": "host2", "message": "reached 95% file size limit...", "impact": 5},
{"timestamp": "2019-01-03T00:06:39", "level": "ERROR", "host": "host2", "message": "reached 90% file size limit...", "impact": 4},
{"timestamp": "2019-01-03T00:05:33", "level": "WARNING", "host": "host2", "message": "reached 70% file size limit...", "impact": 1}]
```
Logging

{"timestamp": "2019-01-03T00:06:59", "level":"INFO", "host":" host2",
"message":"fs clean up started..."}
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:04:05", "level":"INFO", "host":" host1",
"message":"host list updated..."}
dedup
Processes the current log stream by filtering out all duplicates by specified columns. If more than one column is
specified, all columns have to be delimited by commas.
<dedup> := dedup <expr> (, <expr>)
Examples:
search "application"
| dedup host
>>
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1}
search "application"
| dedup host, impact
{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
"message":"download failed...", "impact":2}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host":"host2",
"message":"reached 70% file size limit... ", "impact":1}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host":"host2",
"message":"reached 90% file size limit... ", "impact":4}
{"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host":"host2",
"message":"reached 95% file size limit... ", "impact":5}
select
Applies a series of named scalar expressions to the current log stream. See summarize for an aggregation version of
select.
<select> := select <select_expr> (, <select_expr>)*
<select_expr> := ( * | <expr> (as <identifier>)? )
Example:
search "application"
| select level, host, impact+10 as impact, timestamp
>>
{"level":"ERROR", "host":"host1", "impact": 12, "timestamp":
"2019-01-03T00:04:01"}
{"level":"INFO", "host":" host1", "timestamp": "2019-01-03T00:04:05"}
{"level":"WARNING", "host":"host2", "impact": 11, "timestamp":
"2019-01-03T00:05:33"}
{"level":"ERROR", "host":"host2", "impact": 14, "timestamp":
"2019-01-03T00:06:39"}
{"level":"ERROR", "host":"host2", "impact": 15, "timestamp":
"2019-01-03T00:06:59"}
{"level":"INFO", "host":" host2", "timestamp": "2019-01-03T00:06:59"}
extend

Oracle Cloud Infrastructure User Guide

2644


Logging

Extends the current log stream with a computed column.

\[ \text{<extend>} \ := \ \text{extend} \ \text{<expr>} \ \text{as} \ \text{<identifier>})? \]

Example:

```
search "application"
    | extend concat(host, 'us.oracle.com') as fqn

{"timestamp": "2019-01-03T00:04:01", "level":"ERROR", "host":"host1",
  "message":"download failed...", "impact":2, "fqn": "host1.us.oracle.com"
{"timestamp": "2019-01-03T00:04:05", "level":"INFO", "host": "host1",
  "message":"host list updated...", "fqn": "host1.us.oracle.com"}
{"timestamp": "2019-01-03T00:05:33", "level":"WARNING", "host": "host2",
  "message":"reached 70% file size limit...", "impact":1, "fqn":
  "host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:39", "level":"ERROR", "host": "host2",
  "message":"reached 90% file size limit...", "impact":4, "fqn":
  "host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:59", "level":"ERROR", "host": "host2",
  "message":"reached 95% file size limit...", "impact":5, "fqn":
  "host2.us.oracle.com"}
{"timestamp": "2019-01-03T00:06:59", "level":"INFO", "host": "host2",
  "message":"fs clean up started...", "fqn": "host2.us.oracle.com"}
```

Scalar Operators

Scalar operators are applicable to individual values.

Arithmetic operations are the following:

- +
- -
- *
- /

Boolean operators are the following:

- and
- or

Unary operator:

- \(- (<\text{expr}>))\)

Comparison operators are the following (numeric expressions only):

- \(<\text{expr}> < <\text{expr}>\)
- \(<\text{expr}> > <\text{expr}>\)
- \(<\text{expr}> <= <\text{expr}>\)
- \(<\text{expr}> >= <\text{expr}>\)
- \(<\text{expr}> = <\text{expr}>\)
- \(<\text{expr}> != <\text{expr}>\)

String comparison:

- \(<\text{expr}> = <\text{expr}>\)

Functions:

- \(\text{not} \ (<\text{expr}>))\)
• `contains_ci/contains_cs (<expr>, <expr>, (true | false))`

  The last parameter is case-sensitive.

• `rounddown (<expr>, '[0-9]+(d | h | m | s)')`

  The last parameter is the time interval in days, hours, minutes, or seconds.

• `concat (<axpr>, <expr>)`

• `upper (<expr>)`

• `lower (<expr>)`

• `substr (<expr>, [0-9]+, ([0-9]+)?)`

  The second argument is the start index, while the third argument is optional, namely, how many characters to take.

• `isnull (<expr>)`

• `isnotnull (<expr>)`

### Aggregate Operators

#### count

Calculates a number of rows in the current log stream:

```
search "application"
  | count
>>
{"count": 6}
```

#### summarize

Groups the current log stream by the specified columns and time interval, and aggregates using named expressions. If grouping columns are not specified, `summarize` aggregates over the whole stream.

```
search "application"
  | summarize count(impact) as impact by level interval 1m
>>
{"timestamp": "2019-01-03T00:04:00", "level":"ERROR", "impact": 2}
{"timestamp": "2019-01-03T00:04:00", "level":"INFO", "impact": 0}
{"timestamp": "2019-01-03T00:05:00", "level":"WARNING", "impact":1}
{"timestamp": "2019-01-03T00:06:00", "level":"ERROR", "impact":5}
{"timestamp": "2019-01-03T00:06:00", "level":"INFO", "impact": 0}
```

**interval** is optional:

```
search "application"
  | summarize max(impact)
>>
{"impact": 5}
```

### Special Columns

#### logContent

`logContent` is a special column which represents the text of the whole original message. For example:

```
search "application"
  | where logContent = '*ERROR*' -- returns log lines with a value containing "ERROR"
```
**Comments**
Both single line and multi-line comments are supported, for example:

```plaintext
search "application"
  | count -- this is a single line comment

/** this is a
  multi-line
  comment */
```

**Identifiers**
Identifiers are the names of all available entities in the query. An identifier can reference a field in the current log stream, or a parameter defined in the beginning of the query. Identifiers have the following format:

```
name: \$?[a-zA-Z_]\[a-zA-Z_0-9]*
```

For example: `level`, `app_severity`, `$level`.

The quoted form allows special symbols in the names (except double quotes):

```
name: "\^[^"]*"
```

For example: "opc-request-id", "-level".

All parameter references start with a dollar sign ($), for example: `$level`.

**Literals**

<table>
<thead>
<tr>
<th>Type</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>'hello', 'world!'</td>
</tr>
<tr>
<td>wildcard pattern</td>
<td>&quot;acc-*&quot;</td>
</tr>
<tr>
<td>integer</td>
<td>-1, 0, +200</td>
</tr>
<tr>
<td>float</td>
<td>1.2, 0.0001, 1.2e10</td>
</tr>
<tr>
<td>array</td>
<td>[1,2,3,4], []</td>
</tr>
<tr>
<td>interval</td>
<td>3h, 2m</td>
</tr>
<tr>
<td>nullable</td>
<td>null</td>
</tr>
</tbody>
</table>

**Functions**
Scalar functions are the following:

- `isnull(expr1)`
- `concat(expr1, ...)`

Aggregate functions are the following:

- `sum(expr1)`
- `min(expr1)`
- `max(expr1)`
- `count()`: Counts a number of rows.
- `count(expr)`: Counts a number of non-null expr values.
System parameters

All parameters with the prefix "query." are reserved. The following parameters are supported:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query.from</td>
<td>String with date time in ISO 8601 format.</td>
<td>'2007-04-05T14:30'</td>
<td>Specifies starting time of the query window.</td>
</tr>
<tr>
<td>query.to</td>
<td>String with date time in ISO 8601.</td>
<td>'2007-04-05T14:30+05:00'</td>
<td>Specifies end time of the query window.</td>
</tr>
</tbody>
</table>
Chapter 24

Marketplace

This chapter explains how to work with listings in the Oracle Cloud Infrastructure Marketplace.

Overview of Marketplace

Oracle Cloud Infrastructure Marketplace is an online store that offers solutions specifically for customers of Oracle Cloud Infrastructure. In the Oracle Cloud Infrastructure Marketplace catalog, you can find listings for two types of solutions from Oracle and trusted partners: images and stacks. These listing types include different categories of applications. Also, some listings are free and others require payment.

Images are templates of virtual hard drives that determine the operating system and software to run on an instance. You can deploy image listings on an Oracle Cloud Infrastructure Compute instance. Marketplace also offers stack listings. Stacks represent definitions of groups of Oracle Cloud Infrastructure resources that you can act on as a group. Each stack has a configuration consisting of one or more declarative configuration files. With an image or a stack, you have a customized, more streamlined way of getting started with a publisher's software.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

While the resources created from Marketplace images and stacks have an OCID to identify them, the listings themselves have a listing ID and a package version ID for every package version in the listing. Listing IDs are numeric values. Package version IDs are string values. These identifiers are unique to Marketplace and unrelated to OCIDs.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create
new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For the actual policy statements required to perform tasks related to Marketplace, see the topic specific to the task.

**Working with Listings**

This topic describes how to work with listings in the Oracle Cloud Infrastructure Marketplace catalog. You can do the following:

- Search for listings to find what you want to deploy
- Filter listings to refine application results
- View a listing to learn about the product that it offers
- Launch an instance from an image listing
- Launch stack resources from a stack listing
- Download Terraform configuration files from stack listings to update deployed applications

By default, Marketplace displays all listings in its catalog. However, an individual's ability to see or launch particular listings varies by tenancy, according to what permissions the individual has, and the pricing model for the listing.

Listings are either image listings or stack listings. Image listings have a **Launch Instance** button. Stack listings have a **Launch Stack** button.

For information about pricing and how it affects whether you can see a listing, see Pricing for Listings on page 2653.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators, the policies you need to create to provide users with access to Marketplace depend on whether the tenancy is in a commercial region, the United Kingdom Government Cloud region, or the United States Government Cloud realm.

**Note:**

In commercial regions and the United Kingdom Government Cloud region, administrators do not need to write policies to grant users the ability to list or read listings. In these regions, you can see individual listings and lists of listings by default. Furthermore, to reduce the scope of access to a particular compartment, specify the specific compartment instead of the tenancy in the policy statement.

**For a Tenancy in a Commercial Region or the United Kingdom Government Cloud**

- The following policy gives the specified example group, MarketplaceUsers, the ability to list accepted terms of use agreements. However, it does not include the ability to accept a terms of use agreement. The terms of use agreement for a given listing must be viewed and accepted prior to launch. For a policy that includes the ability
to use listings, see the policy statements later in this section that grant access to the type of listing you want to launch, whether an image listing or a stack listing.

- The following policy gives the specified example group, MarketplaceUsers, the ability to not only list and read, but also use Marketplace listings. It does not include the ability to create instances using images from listings. (For that, see the next set of policy statements.)

- The policies described in Policies for Managing Resources Used with Resource Manager on page 2476 grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

If you need to write more restrictive policies, see the policy references on which these policies were based, Details for the Core Services on page 2181 and Details for Resource Manager on page 2336, as needed.

**For a Tenancy in the US Government Cloud Realm**

- The following policy gives the specified example group, MarketplaceUsers, the ability to view all listings in the specified example compartment:

- The following policy gives the specified example group, MarketplaceUsers, the ability to work with all listings in the specified example compartment in any way possible. The statements include the ability to accept terms of use agreements, view listings, and create images and stacks from listings:
Marketplace

Allow group MarketplaceUsers to manage virtual-network-family in compartment ABC
Allow group MarketplaceUsers to manage orm-stack in compartment ABC
Allow group MarketplaceUsers to manage orm-job in compartment ABC

• The following policy gives the specified example group, MarketplaceUsers, the ability to work with specific listings in the specified example compartment in any way possible. The statements include the ability to list and subscribe to images and the ability to create images and stacks from listings:

Allow group MarketplaceUsers to manage app-catalog-listings in compartment ABC
Allow group MarketplaceUsers to use marketplace-listings in compartment ABC where any {listing.id='123456', listing.id='987654'}
Allow group MarketplaceUsers to manage instance-family in compartment ABC
Allow group MarketplaceUsers to use volume-family in compartment ABC
Allow group MarketplaceUsers to manage virtual-network-family in compartment ABC
Allow group MarketplaceUsers to manage orm-stack in compartment ABC
Allow group MarketplaceUsers to manage orm-job in compartment ABC

• The following policy gives the specified example group, AgreementAcceptors, the ability to accept the terms of use agreement for any listing in the specified example compartment. The statements make it possible for anyone with the appropriate permissions to launch an image or stack from a listing without having the permission to accept the terms of use agreement themselves:

Allow group AgreementAcceptors to read marketplace-listings in compartment ABC
Allow group AgreementAcceptors to manage app-catalog-listings in compartment ABC

If you need to write more restrictive policies, see the policy reference on which policies for tenancies in the US Government Cloud realm were based, Details for the Marketplace Service on page 2319.

Pricing for Listings

Marketplace listings belong to one of several pricing models available to and set by the publisher when the publisher creates the listing. Pricing models include:

• **Free**: usage incurs no charge
• **BYOL**: usage relies on software licenses that you already own
• **Paid**: usage incurs charges based on hourly rates, either according to OCPU hours consumed or according to the number of instances (irrespective of OCPU hours consumed by each)

The listing price does not include any additional fees that you might incur for the use of infrastructure resources.

For a cloud account to access paid listings, it must have a United States mailing address and the form of payment provided when the account was created must support payment in United States dollars. United States-based customers can deploy most paid listings in any commercial region data center, but some paid listings can only be deployed in United States commercial regions. These listings have a region restriction label that marks them as **US-only**.

Customers in US Government Cloud realms can see all paid listings from Oracle and third-party publishers. Users in United Kingdom government tenancies do not have access to any paid listings.

Using the Console

To find a listing

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.
2. Under **Scope**, in the **Compartment** list, click the name of the compartment where you want to look for listings.
3. Click the **Search for listings by entering a name, ID, category, or publisher name** text box.
4. Provide a search string, and then press ENTER. (If you provide a listing ID, it must contain the full, exact listing ID to match. Marketplace supports partial matching for other listing search types.)
Marketplace displays all current listings that contain the search string in either the name, listing ID, application category, or publisher name. To refine the results, you can filter them.

To filter listings

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.
2. Under Scope, in the Compartment list, click the name of the compartment where you want to look for listings.
3. Under Filters, do one or more of the following:
   - To display listings of a certain deployment type, click Type, and then click either Image or Stack.
   - To display listings from a specific publisher, click Publisher, and then click a publisher name.
   - To display listings from a particular product category, click Category, and then click a category name.
   - To display listings according to price, click Price, and then click a pricing model.

You can combine multiple filters to further narrow down listings. You can also clear filters to expand the list of listings that you see.

To view a listing's details

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.
2. Under Scope, in the Compartment list, click the name of the compartment where you want to view a listing.
3. Click the listing that you're interested in.
4. Marketplace displays the listing overview by default. To view other details, do the following:
   - To view information about the publisher, click Provider.
   - To view other listings from the same publisher, click More Apps.
   - To view instructions for using the instance that you create from the listing, click Usage Information.

To launch an instance based on an image

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you create an instance, several other resources are involved (for example, an image, a cloud network, or a subnet). Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they’re not, you need the required level of access to each of the compartments.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.
2. Under Scope, in the Compartment list, click the name of the compartment where you want to find the listing to launch.
3. Click the listing that you're interested in.
4. Review the Usage Instructions tab to ensure you understand what you will need to deploy and to access the instance after you launch it. Both Linux and Windows instances require a cloud network to launch the instance into. For more information, see Networking Overview on page 2748. Depending on the type of instance, to access it, you might need an SSH key pair or a security list that enables Remote Desktop Protocol. For more information, see Managing Key Pairs on Linux Instances on page 693 and Creating a Windows Instance on page 702.
5. Under Version, click the package version of the image that you want to install. By default, the menu displays the latest version.
6. Under Compartment, click the name of the compartment where you want to launch the instance. (If you don't have permissions to launch the instance in the selected compartment, it will be launched in the root compartment instead.)
7. Select the check box to accept the terms of use, and then click Launch Instance.
8. To finish launching the instance, follow the instructions in Creating an Instance.

The information you need to connect to an instance after you create it might be in the Usage Information or the Related Documents sections of the listing.
To launch a stack

Tip:

When you create a stack, potentially many other resources are involved (for example, an instance, a cloud network, or a subnet), aside from the stacks and jobs resources. You must have the required access to all involved resources to create a stack. Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.

2. Under Scope, in the Compartment list, click the name of the compartment where you want to find the listing to launch.

3. Click the listing that you're interested in.

4. Click the listing that you're interested in.

5. Review the Usage Instructions tab and ensure you understand what you will need to deploy and to access the instance after the stack finishes deployment.

6. Under Version, click the package version of the stack that you want to install. By default, the menu displays the latest version.

7. Under Compartment, click the name of the compartment where you want to launch the instance. (If you don't have permissions to launch the instance in the selected compartment, it will be launched in the root compartment instead.)

8. Select the check box to accept the terms of use, and then click Launch Stack.

9. On the Stack Information page, configure the following:

   • Name. Optionally, provide a name by which you can refer to the stack after it's deployed. Avoid entering confidential information.

   • Description. Optionally, provide a description of the stack. For example, you can specify the name of the application that will run on the instance after the stack is deployed.

   • Create in Compartment. This is the compartment where the stack will be created in the tenancy. (Stacks are attached to a specific region. However, where necessary, the resources on a given stack can be deployed across multiple regions.)

   • Tags. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

   When you are ready, click Next.

10. On the Configure Variables page, verify that the values for variables extracted from the Terraform configuration file are as you want them. Some variables might be required, but don't have a default value and must be configured before you can proceed. These vary from listing to listing, but often include the following: availability domain and compartment. Optionally, you can change default values, such as any display names automatically given to resources, to help differentiate them. For some stacks, you can customize additional variables by selecting the Additional Customization or WLS Instance Advanced Configuration check box. The variables in these sections otherwise use default values. When you are ready, click Next.

11. On the Review page, confirm that variables have been configured properly. (Marketplace does not display variables that have default values or variables that you didn't change.) Then, click Create.

Resource Manager runs the plan job and the apply job to create stack resources accordingly. The information you need to connect to the instance created as part of the stack can appear in the Application Information tab or in the Usage Information or Related Documents sections of the listing.

To download a Terraform configuration file

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.
2. Click the listing that you're interested in.
3. Under **Version**, click the package version of the stack that you want. By default, the menu displays the latest version.
4. Under **Compartment**, click the name of any compartment. (You must select a compartment in order to accept the terms of use in the next step.)
5. Select the check box to accept the terms of use, and then click **Download**.
6. Follow the prompts to save the configuration file locally.

For information about how to use the file to edit a stack or create a stack, see Managing Stacks and Jobs on page 3557.

### Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

#### To filter listings

Open a command prompt and run `oci marketplace listing list` to view listings that meet specified filter criteria:

```
oci marketplace listing list --package-type <package_type> --publisher-id <unique_publisher_ID> --category <product_category> --pricing <pricing_model>
```

For example, the following command lists only image listings:

```
oci marketplace listing list --package-type image
```

The following command lists only listings from the specified publisher:

```
oci marketplace listing list --publisher-id 29367738
```

The following command lists only listings from the specified product category:

```
oci marketplace listing list --category "database management"
```

The following command lists only listings that have the specified pricing model:

```
oci marketplace listing list --pricing byol
```

#### To view a listing's details

Open a command prompt and run `oci marketplace listing get` to view detailed information about a listing:

```
oci marketplace listing get --listing-id <listing_ID>
```

For example:

```
oci marketplace listing get --listing-id 29367738
```

#### To launch an instance

Open a command prompt and run `oci compute instance launch` to launch an instance:

```
oci compute instance launch --availability-domain <availability_domain> --compartment-id <compartment_OCID> --shape <instance_shape> --subnet-id <subnet_OCID> --image-id <image_OCID>
```
For example:

```
oci compute instance launch --availability-domain Uocm:PHX-AD-1 --compartment-id ocid1.compartment.oc1..example1example25qr1po4agcmothkbqgmuz2zzum45ibplooqtawbk3zz --shape VM.Standard1.2 --subnet-id ocid1.subnet.oc1.phx.exampleahetdvobxd5cvbgfcmjw2ddryahoqrp4ot2fauxvbdeteirpa2gpt2a --image-id ocid1.image.oc1.phx.exampleae44ah3b5xyet6t1vli23cvbtetyugfckfwgg6fywrk3fauuxscyq
```

**Using the API**

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with listings:

- GetListing
- GetPackage
- ListCategories
- ListListings
- ListPackages
- ListPublishers

**Publishing Listings**

Applications listed in Oracle Cloud Infrastructure Marketplace are provided by publishers. Publishers belong to the Oracle PartnerNetwork. Oracle reviews and approves the applications submitted by publishers. If you would like to become a publisher, see How do I become a marketplace publisher? in the Oracle Cloud Marketplace Partner Portal documentation.

**Viewing Accepted Terms of Use Agreements**

Before you can launch an image or a stack from a Marketplace listing, you must first read and accept all software terms of use agreements associated with the package version that you choose. This topic describes how to see what terms of use agreements you have accepted through Oracle Cloud Infrastructure Marketplace. Your organization might need or want to review the specific terms of use associated with a particular package version after you deploy one or more Marketplace listings.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For administrators, the following policies provide access to Marketplace.

- The following policy gives the specified group the ability to list accepted terms of use agreements. The terms of use agreement for a given listing must be viewed and accepted prior to launch. The policy does not include the ability to list, read, or use listings themselves. For that, see the policy statements that grant access to the type of listing you want to launch, whether an image listing or a stack listing.

```
Allow group <IAM_group_name> to inspect compartments in tenancy
```

- The following policy gives the specified group the ability to list, read, and use Marketplace image listings. It does not include the ability to create instances using images from listings. (For that, see the next policy.) Furthermore,
to reduce the scope of access to just creating subscriptions in a particular compartment, specify that compartment instead of the tenancy.

Allow group <IAM_group_name> to manage app-catalog-listing in tenancy

- The following policy gives the specified group general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. Use this policy in conjunction with the preceding policy for users who need to launch instances from image listings. For users who need to launch stacks from stack listings, use this policy in conjunction with the next set of policies.

Allow group <IAM_group_name> to manage instance-family in compartment ABC
Allow group <IAM_group_name> to read app-catalog-listing in tenancy
Allow group <IAM_group_name> to use volume-family in compartment ABC
Allow group <IAM_group_name> to use virtual-network-family in compartment XYZ

- The policies described in Policies for Managing Resources Used with Resource Manager on page 2476 grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

If you need to write more restrictive policies, see the policy references on which these policies were based, Details for the Core Services on page 2181 and Details for Resource Manager on page 2336, as needed.

Using the Console
To view the accepted terms of use agreements for a given compartment

1. Open the navigation menu. Under the Solutions and Platform group, go to Marketplace.
2. Click Accepted Agreements.
3. Under Scope, click Compartment, and then click the name of the compartment where you accepted a terms of use agreement that you now want to view.
4. In the list, next to the listing that you're interested in, click the Actions menu ( ). (Marketplace independently lists package versions with their distinct terms of use agreements. Also, Marketplace tracks what agreements you accept regardless of whether you actually complete the software deployment. Therefore, the list might show the names of listings that you didn't actually finish deploying in your tenancy.)
5. To review any of the terms of use agreements you accepted for the specified listing and package version, click its name.

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

To view the accepted terms of use agreements for a given compartment

Open a command prompt and run oci marketplace accepted-agreement list to view a list of terms of use agreements that you previously accepted:

oci marketplace accepted-agreement list --compartment-id <compartment_id>

For example:
Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with a listing's terms of use agreements:

- CreateAcceptedAgreement
- DeleteAcceptedAgreement
- GetAcceptedAgreement
- GetAgreement
- ListAcceptedAgreements
- ListAgreements
- UpdateAcceptedAgreement
Chapter 25

Monitoring

This chapter explains how to actively and passively monitor performance and usage metrics for your resources.

Monitoring Overview

The Oracle Cloud Infrastructure Monitoring service enables you to actively and passively monitor your cloud resources using the Metrics and Alarms features.

How Monitoring Works

The Monitoring service uses metrics to monitor resources and alarms to notify you when these metrics meet alarm-specified triggers.

Metrics are emitted to the Monitoring service as raw data points, or timestamp-value pairs, along with dimensions and metadata. Metrics come from a variety of sources:

- Resource metrics automatically posted by Oracle Cloud Infrastructure resources. For example, the Compute service posts metrics for monitoring-enabled Compute instances through the oci_computeagent namespace. One such metric is CpuUtilization. See Supported Services on page 2669 and Viewing Default Metric Charts on page 2671.
- Custom metrics published using the Monitoring API.
- Data sent to new or existing metrics using Service Connector Hub.

Metric data posted to the Monitoring service is only presented to you or consumed by the Oracle Cloud Infrastructure features that you enable to use metric data.
When you query a metric, the Monitoring service returns aggregated data according to the specified parameters. You can specify a range (such as the last 24 hours), statistic, and interval. The Console displays one monitoring chart per metric for selected resources. The aggregated data in each chart reflects your selected statistic and interval. API requests can optionally filter by dimension and specify a resolution. API responses include the metric name along with its source compartment and metric namespace. You can feed the aggregated data into a visualization or graphing library.

Metric and alarm data is accessible via the Console, CLI, and API. For retention periods, see Storage Limits on page 2671.

The Alarms feature of the Monitoring service publishes alarm messages to configured destinations managed by the Notifications service. Each destination is a topic with a set of subscribers. For more information about the Notifications service, see Notifications Overview on page 3350.

## Message types

The message type indicates the reason that the message was sent.

- **OK_TO_FIRING**: The alarm changed from OK status to FIRING status.
- **FIRING_TO_OK**: The alarm changed from FIRING status to OK status.
- **REPEAT**: The alarm is maintaining a FIRING status and repeat notifications are configured.
- **RESET**: The alarm is not detecting the metric firing; the metric is no longer being emitted. The resource that was emitting the metric might have been moved or terminated.

### Important:
When a RESET status change occurs, determine the health of the resource.

## Message format and examples

Alarm message format:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dedupekey</td>
<td>string</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>Unique identifier for all the alarm messages of the alarm. Use for de-duplication.</td>
</tr>
<tr>
<td>title</td>
<td>string</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>The alarm's configured display name.</td>
</tr>
<tr>
<td>body</td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>The alarm's configured message body.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>The reason for sending the notification message. Valid values: See Message types on page 2661.</td>
</tr>
<tr>
<td>severity</td>
<td>string</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>The highest severity level of the listed alarms. Valid values: CRITICAL, ERROR, WARNING, and INFO</td>
</tr>
<tr>
<td>timestampEpochMillis</td>
<td>long</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>The time when the alarm was triggered, in milliseconds since epoch time.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>timestamp</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The time when the alarm was triggered, in ISO-8601 format. Same information as in timestampEpochMillis.</td>
</tr>
<tr>
<td>alarmMetadata</td>
<td>array of objects</td>
</tr>
<tr>
<td>Required</td>
<td>List of alarms related to this notification message.</td>
</tr>
<tr>
<td>version</td>
<td>int</td>
</tr>
<tr>
<td>Required</td>
<td>The version of the alarm message format.</td>
</tr>
</tbody>
</table>

**alarmMetadata format:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm OCID.</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm state. Valid values: OK, FIRING</td>
</tr>
<tr>
<td>severity</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm severity level. Valid values: CRITICAL, ERROR, WARNING, INFO</td>
</tr>
<tr>
<td>query</td>
<td>string</td>
</tr>
<tr>
<td>Required</td>
<td>The alarm's configured query.</td>
</tr>
<tr>
<td>totalMetricsFiring</td>
<td>int</td>
</tr>
<tr>
<td>Required</td>
<td>The number of metric streams represented in this notification message.</td>
</tr>
<tr>
<td>dimensions</td>
<td>array of objects</td>
</tr>
<tr>
<td></td>
<td>List of dimension key-value pairs that identify each metric stream. The list is limited to a hundred entries. Empty for an alarm with a status of OK.</td>
</tr>
</tbody>
</table>

Example messages, by subscription protocol, for an alarm titled "High CPU Utilization" that is continuing to be in the FIRING state. In this example, the message includes two metric streams: one for "myinstance1" and another for "myinstance2."

**Email and Slack**

```json
{"dedupeKey":"exampleuniqueID","title":"High CPU Utilization","body":"Follow runbook at http://example.com/runbooks","type":"REPEAT","severity":"CRITICAL","timestampEpochMillis":1542406320000,"alarmMetaData":[]}
```
SMS

119L3T: [CRITICAL] "High CPU Utilization" has transitioned to OK_TO_FIRING at 2021-02-10T05:52:00Z

https://cloud.oracle.com/monitoring/alarms/status

Metrics Feature Overview

The Metrics feature relays metric data about the health, capacity, and performance of your cloud resources. A metric is a measurement related to health, capacity, or performance of a given resource. Resources, services, and applications emit metrics to the Monitoring service. Common metrics reflect data related to:

- Availability and latency
- Application uptime and downtime
- Completed transactions
- Failed and successful operations
- Key performance indicators (KPIs), such as sales and engagement quantifiers

By querying Monitoring for this data, you can understand how well the systems and processes are working to achieve the service levels you commit to your customers. For example, you can monitor the CPU utilization and disk reads of your Compute instances. You can then use this data to determine when to launch more instances to handle increased load, troubleshoot issues with your instance, or better understand system behavior.

Example Metric: Failure Rate

For application health, one of the common KPIs is failure rate, for which a common definition is the number of failed transactions divided by total transactions. This KPI is usually delivered through application monitoring and management software.

As a developer, you can capture this KPI from your applications using custom metrics. Simply record observations every time an application transaction takes place and then post that data to the Monitoring service. In this case, set up metrics to capture failed transactions, successful transactions, and transaction latency (time spent per completed transaction).
The Alarms feature of the Monitoring service works with the Notifications service to notify you when metrics meet alarm-specified triggers. The previous illustration depicts the flow, starting with resources emitting metric data points to Monitoring. When triggered, an alarm sends an alarm message to the configured topic (in Notifications), which then sends the message on to all of the topic's subscriptions. (This illustration does not cover raw and aggregated metric data. For these details, see the "Monitoring Overview" illustration.)

When configured, repeat notifications remind you of a continued firing state at the configured repeat interval. You are also notified when an alarm transitions back to the OK state, or when an alarm is reset.

You can search for alarms using Search-supported attributes. For more information about Search, see Overview of Search on page 3626.

**Search-Supported Attributes for Alarms**

For attribute descriptions, see Alarm Reference.

- id
- displayName
- compartmentId
- metricCompartmentId
- namespace
- query
- severity
- destinations
- suppression
- isEnabled
- lifecycleState
- timeCreated
Monitoring Concepts

The following concepts are essential to working with Monitoring.

aggregated data

The result of applying a statistic and interval to a selection of raw data points for a given metric. For example, you can apply the statistic max and interval 1h (one hour) to the last 24 hours of raw data points for the metric CpuUtilization. Aggregated data is displayed in default metric charts in the Console. You can also build metric queries for specific sets of aggregated data. For instructions, see Viewing Default Metric Charts on page 2671 and Building Metric Queries on page 2700.

alarm

The alarm query to evaluate and the notification destination to use when the alarm is in the firing state, along with other alarm properties. For instructions on managing alarms, see Managing Alarms on page 2719.

alarm query

The Monitoring Query Language (MQL) expression to evaluate for the alarm. An alarm query must specify a metric, statistic, interval, and a trigger rule (threshold or absence). The Alarms feature of the Monitoring service interprets results for each returned time series as a Boolean value, where zero represents false and a non-zero value represents true. A true value means that the trigger rule condition has been met. For more information, see Building Metric Queries on page 2700 and the query attribute description in the Alarm API reference.

data point

A timestamp-value pair for the specified metric. Example: 2018-05-10T22:19:00Z, 10.4

A data point is either raw or aggregated. Raw data points are posted by the metric namespace to the Monitoring service using the PostMetricData operation. The frequency of the data points posted varies by metric namespace. For example, your custom namespace might send data points for a given metric at a 20-second frequency.

Aggregated data points are the result of applying a statistic and interval to raw data points. The interval of the aggregated data points is determined by the SummarizeMetricsData request. For example, a request specifying the statistic sum and interval 1h (one hour) returns a sum value for each hour of available raw data points for the given metric.

dimension

A qualifier provided in a metric definition. Example: Resource identifier (resourceId), provided in the definitions of oci_computeagent metrics. Use dimensions to filter or group metric data. Example dimension name-value pair for filtering by availability domain: availabilityDomain = "VeBZ:PHX-AD-1"

frequency

The time period between each posted raw data point for a given metric. (Raw data points are posted by the metric namespace to the Monitoring service.) While frequency varies by metric, default service metrics typically have a frequency of 60 seconds (that is, one data point posted per minute). See also resolution.

interval

The time window used to convert the given set of raw data points.

The timestamp of the aggregated data point corresponds to the end of the time window during which raw data points are assessed. For example, for a five-minute interval, the timestamp "2:05" corresponds to the five-minute time window from 2:00 to 2:05:00.
The following example query specifies a 5-minute interval. \texttt{CpuUtilization[5m].max()} For supported values, see Monitoring Query Language (MQL) Reference on page 2741.

\begin{itemize}
  \item \textbf{Note:}
  \begin{itemize}
    \item Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the \texttt{1h} or \texttt{1d} interval values are supported.
  \end{itemize}
\end{itemize}

To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

See also \textit{resolution}.

\textbf{message}

The content that the Alarms feature of the Monitoring service publishes to topics in the \textit{alarm}'s configured notification destinations. A message is sent when the \textit{alarm} transitions to another state, such as from "OK" to "FIRING." For more information about messages, see How Monitoring Works on page 2660.

\textbf{metadata}

A reference provided in a \textit{metric definition}. Example: unit (bytes), provided in the definition of the \texttt{oci_computeagent metricDiskBytesRead}. Use metadata to determine additional information about a given metric. For metric definitions, see \textit{Supported Services} on page 2669.

\textbf{metric}

A measurement related to health, capacity, or performance of a given resource. Example: The \texttt{oci_computeagent metricCpuUtilization}, which measures usage of a Compute instance. For metric definitions, see \textit{Supported Services} on page 2669.

\begin{itemize}
  \item \textbf{Note:}
  \begin{itemize}
    \item Metric resources do not have \textit{OCIDs}.
  \end{itemize}
\end{itemize}

\textbf{metric definition}

A set of references, qualifiers, and other information provided by a \textit{metric namespace} for a given \textit{metric}. For example, the \texttt{oci_computeagent metricDiskBytesRead} is defined by \textit{dimensions} (such as resource identifier) and \textit{metadata} (specifying bytes for unit) as well as identification of its \textit{metric namespace} (\texttt{oci_computeagent}). Each posted set of \textit{data points} carries this information. Use the \texttt{ListMetricData} API operation to get metric definitions. For metric definitions, see \textit{Supported Services} on page 2669.

\textbf{metric namespace}

Indicator of the \textit{resource}, service, or application that emits the \textit{metric}. Provided in the \textit{metric definition}. For example, the \texttt{CpuUtilization metric definition} emitted by the Oracle Cloud Agent software on Compute \textit{instances} lists the \textit{metric namespace} \texttt{oci_computeagent} as the source of the \texttt{CpuUtilization metric}. For metric definitions, see \textit{Supported Services} on page 2669.
**Monitoring**

**metric stream**
An individual set of *aggregated data for a metric*. A stream can be either specific to a single *resource* or aggregated across all resources in the compartment. Within a *metric chart* in the Console, each metric stream is represented as a line. By default, metric streams are resource-specific, so the chart displays a line for each resource. If you choose to *aggregate all metric streams*, then the chart displays one line for all resources.

**notification destination**
Protocol and other details for sending *messages* when the *alarm* transitions to another state, such as from "OK" to "FIRING." The details and setup may vary by destination service. For the Notifications service, each destination includes a topic and subscription protocol (such as PagerDuty). For more information about messages, topics, and subscriptions, see *Notifications Overview* on page 3350.

**Oracle Cloud Agent software**
Software that allows a Compute instance to post raw *data points* to the Monitoring service. Automatically installed with the latest versions of supported images. See *Enabling Monitoring for Compute Instances* on page 783.

**query**
The Monitoring Query Language (MQL) expression to evaluate for returning *aggregated data*. The query must specify a *metric*, *statistic*, and *interval*. For more information, see *Building Metric Queries* on page 2700.

**resolution**
The period between time windows, or the regularity at which time windows shift. For example, use a resolution of *1m* to retrieve aggregations every minute.
To specify a non-default resolution that differs from the interval, use the *SummarizeMetricsData* operation.

**Note:**
For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.
For more information about the resolution parameter as used in metric queries, see *SummarizeMetricsData*.

**Maximum time range returned for a query**
The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>
To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

For alarm queries, the specified `interval` has no effect on the `resolution` of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the `resolution` parameter as used in alarm queries, see `Alarm`.

As shown in the following illustration, `resolution` controls the start time of each aggregation window relative to the previous window while `interval` controls the length of the windows. Both requests apply the statistic max to the data within each five-minute window (from the interval), resulting in a single aggregated `data point` representing the highest `CPUUtilization` counter for that window. Only the resolution value differs. This resolution changes the regularity at which the aggregation windows shift, or the start times of successive aggregation windows. Request A does not specify a resolution and thus uses the default value equal to the `interval` (5 minutes). This request's five-minute aggregation windows are thus taken from the sets of data points emitted from 0:n to 5:00, 5:n to 10:00, and so forth. Request B specifies a 1-minute resolution, so its five-minute aggregation windows are taken from the set of data points emitted every minute from 0:n to 5:00, 1:n to 6:00, and so forth.

A custom string provided with a custom metric that can be used as a filter or to aggregate results. The `resource group` must exist in the definition of the posted metric. Only one `resource group` can be applied per metric.
**statistic**

The aggregation function applied to the given set of raw data points. For supported statistics, see Monitoring Query Language (MQL) Reference on page 2741.

**suppression**

A configuration to avoid publishing messages during the specified time range. Useful for suspending alarm notifications during system maintenance. Each suppression applies to a single alarm. In the Console, you can apply one definition of a suppression to multiple alarms. The result is an individual suppression for each alarm. For instructions on suppressing alarms, see To suppress alarms on page 2738.

**trigger rule**

The condition that must be met for the alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

**Availability**

The Monitoring service is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains on page 180 for the list of available regions, along with associated locations, region identifiers, region keys, and availability domains.

**Supported Services**

The following services have resources or components that can emit metrics to Monitoring:

- API Gateway - see API Gateway Metrics on page 478
- Big Data - see View Cluster Metrics
- Block Storage - see Block Volume Metrics on page 585
- Blockchain Platform - see Blockchain Platform Metrics
- Compute - see these topics:
  - Compute Instance Metrics on page 788
  - Instance Pool Metrics on page 793
  - Infrastructure Health Metrics on page 795
  - Compute Management Metrics on page 798
- Container Engine for Kubernetes - see Container Engine for Kubernetes Metrics on page 963
- Data Catalog - see Data Catalog Metrics
- Data Integration - see Data Integration Metrics
- Database - see Database Metrics on page 1578
- Digital Assistant - see Digital Assistant Metrics
- DNS - see DNS Metrics on page 1704
- Events - see Events Metrics on page 1917
- Email Delivery - see Email Delivery Metrics on page 1756
- File Storage - see File System Metrics on page 1997
- Functions - see Function Metrics on page 2107
- Health Checks - see Health Checks Metrics on page 2121
- Integration - see Viewing Message Metrics
- Load Balancing - see Load Balancing Metrics on page 2567
- Management Agent - see Management Agent Metrics
- MySQL Database - see MySQL Database Metrics
• Networking - see these topics:
  • VNIC Metrics on page 3321
  • FastConnect Metrics on page 3236
  • VPN Connect Metrics on page 3164
  • Service Gateway Metrics on page 3325
• NoSQL Database Cloud - see Service Metrics
• Notifications - see Notifications Metrics on page 3389
• Object Storage - see Object Storage Metrics on page 3499
• OS Management - see OS Management Metrics
• Streaming - see Streaming Metrics on page 3896
• Vault - see Vault Metrics on page 4020
• WAF - see WAF Metrics on page 4170

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Note:
Metric resources do not have OCIDs.

Ways to Access Monitoring

You can access the Monitoring service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

Console: To access Monitoring using the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the following browsers and versions:
• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

Open the navigation menu. Under Solutions and Platform, go to Monitoring.

API: To access Monitoring through APIs, use Monitoring API for metrics and alarms and Notifications API for notifications (used with alarms).

Moving Alarms to a Different Compartment

You can move alarms from one compartment to another. When you move an alarm to a new compartment, its associated metrics remain where they are. After you move the alarm to the new compartment, inherent policies apply immediately and affect access to the alarm through the Console. For more information on moving resources to other compartments, see To move a resource to a different compartment on page 2444.

Important:
To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see Details for Monitoring on page 2320.
Monitoring

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2155 and Restrict user access to a specific metric namespace on page 2156. For a common alarms policy, see Let users view alarms on page 2156. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group. Use the dynamic group's matching rules to add the resources, and then create a policy that allows that dynamic group access to metrics. See Let instances make API calls to access monitoring metrics in the tenancy on page 2156.

Limits on Monitoring

See Monitoring Limits on page 227 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include the following.

Storage Limits

<table>
<thead>
<tr>
<th>Item</th>
<th>Time range stored</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric definitions</td>
<td>14 days</td>
</tr>
<tr>
<td>Alarm history entries</td>
<td>90 days</td>
</tr>
</tbody>
</table>

Returned Data Limits (Metrics)

When you query metrics and view metric charts, the returned data is subject to certain limits. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

Troubleshooting Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Viewing Default Metric Charts

This topic describes how to view metric charts for selected resources or a single resource and create alarms based on queries used for charts. Charts are available using the Console.

Prerequisites

- IAM policies: Viewing metric charts is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized,
confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2155 and Restrict user access to a specific metric namespace on page 2156.

- **Metrics exist in Monitoring:** The resources that you want to monitor must emit metrics to the Monitoring service.
- **Compute instances:** To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.

### Working with Default Metric Charts

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview on page 2663. For default metrics by service, see Supported Services on page 2669.

Default metric charts use predefined service *queries*. You can select *resources* of interest and update the *interval*, *statistic*, and time range.

**Note:**
Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

**Using the Console**

**To view default metric charts for all resources**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Choose the Metric Namespace for the resource types of interest in the selected compartment.
   
   For example, choose `oci_lbaas` to see metrics for load balancers.

Default charts are displayed for all resources in the selected **Metric Namespace** and **Compartment**. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

**Don't see all expected resources or metrics?**

- Try a different time range.
- Make sure the correct **Compartment** is selected.

Metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.

- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances on page 783.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

**To investigate missing resources or metrics**

- Try a different time range.
- Make sure the correct **Compartment** is selected.

Metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.

- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances on page 783.
• Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To filter results

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or region of interest.

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Choose a Compartment and Metric Namespace to view the default charts for the resources of interest.
3. To the right of Dimensions, click Add.
4. In the Edit dimensions dialog box, select a Dimension Name and Dimension Value.

   Dimension fields

   • Dimension Name: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

   Note:

   Long lists of dimensions are trimmed.
   • To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
   • To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

   • Dimension Value: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
   • + Additional dimension: Adds another name-value pair for a dimension.

5. Click Done.

The default charts show the filtered results of your query.

To select different resources

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Choose a Compartment and Metric Namespace to view the default charts for the resources of interest.
3. To select resources on a different compartment, select the Compartment.

   The default charts update to show results for the selected compartment.

4. To select a specific resource within the selected compartment, filter results by a resource-specific dimension, such as resourceDisplayName:
   a. To the right of Dimensions, click Add.
   b. For Dimension Name, select resourceDisplayName or other resource-specific dimension.

   Note:

   Long lists of dimensions are trimmed.
   • To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
   • To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

   c. For Dimension Value, select the value corresponding to the resource you want.
   d. Click Done.

   The default charts update to show filtered results.

To aggregate data from all metric streams

Aggregate all metric streams to view the average. For example, aggregate all metric streams for CPU Utilization to view the average data across all resources. By default, a chart represents each metric stream with a line, which results
Monitoring in multiple lines per chart. When you aggregate metric streams, a chart represents all metric streams with a single line, which results in just one line per chart.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Choose a **Compartment** and **Metric Namespace** to view the default charts for the resources of interest.
3. Select **Aggregate Metric Streams**.

**To change the time range**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see [SummarizeMetricsData](#).

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the [SummarizeMetricsData](#) operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of **1m**, and the end time defaults to the current time (**2019-01-08T10:00:00.789Z**). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (**2019-01-01T10:00:00.789Z**).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (**2019-01-06T10:00:00.789Z**), the earliest data point possible within this seven-day period would be 10:00 on January 1st (**2019-01-01T10:00:00.789Z**). Therefore, only 5 days of metric data points can be returned in this example.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Choose a **Compartment** and **Metric Namespace** to view the default charts for the resources of interest.
3. To select a period of time, such as **Last hour**, click **Start Time** or **End Time**.
4. To enter a time value, click in **Start Time** or **End Time** and then type a value.

**To change a chart interval or statistic**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range,
then all interval values are supported. If you select 90 days for the time range, then only the \textbf{1h} or \textbf{1d} interval values are supported.

For metric queries, the \textit{interval} you select drives the default \textit{resolution} of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see \texttt{SummarizeMetricsData}.

\textbf{Maximum time range returned for a query}

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the \texttt{SummarizeMetricsData} operation.

\textbf{See examples of returned data}

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of \texttt{1m}, and the end time defaults to the current time \texttt{(2019-01-08T10:00:00.789Z)}. This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st \texttt{(2019-01-01T10:00:00.789Z)}.

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th \texttt{(2019-01-06T10:00:00.789Z)}, the earliest data point possible within this seven-day period would be 10:00 on January 1st \texttt{(2019-01-01T10:00:00.789Z)}. Therefore, only 5 days of metric data points can be returned in this example.

1. Open the navigation menu. Under \texttt{Solutions and Platform}, go to \texttt{Monitoring} and click \texttt{Service Metrics}.
2. Choose a \texttt{Compartment} and \texttt{Metric Namespace} to view the default charts for the resources of interest.
3. At the top of the chart you want, select an \texttt{Interval} or \texttt{Statistic}.

For supported values, see \texttt{Monitoring Query Language (MQL) Reference} on page 2741.

\textbf{To go back to the default charts}

On the upper right of the \texttt{Service Metrics} page, click \texttt{Reset charts}.

\textbf{To view chart details}

Chart details include the \texttt{query} as a Monitoring Query Language (MQL) expression and the names and OCIDs of represented \texttt{resources}.

1. Open the navigation menu. Under \texttt{Solutions and Platform}, go to \texttt{Monitoring} and click \texttt{Service Metrics}.
2. Choose a \texttt{Compartment} and \texttt{Metric Namespace} to view the default charts for the resources of interest.
3. Click the chart you want.
4. To view a list of resources represented in the chart, click the arrow to the left of the query displayed under the chart.

You can copy the OCID for a resource by clicking **Copy** to the right of the resource OCID.

**To share a chart**

**Note:**

The person you share the chart with must have the required IAM policies for access to metrics.

On the **Service Metrics** page, on the upper right of the chart you want, go to **Options**, and then click **Copy Chart URL**.

**To view a query in Metrics Explorer**

On the **Service Metrics** page, on the upper right of the chart you want, go to **Options**, and then click **View Query in Metrics Explorer**.

**To copy a query (MQL expression)**

On the **Service Metrics** page, on the upper right of the chart you want, go to **Options**, and then click **Copy Query (MQL)**.

**To view default metric charts for a single resource**

On the page for the resource of interest, under **Resources**, click **Metrics**.

For example, to view metric data for a Compute instance:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.
3. On the instance details page, under **Resources**, click **Metrics**.

   A chart is shown for each metric. For a list of metrics related to Compute instances, see **Compute Instance Metrics** on page 788.

The Console displays the last hour of metric data for the selected resource. A chart is shown for each metric emitted by the selected resource.

For a list of metrics emitted by your resource, see **Supported Services** on page 2669.

**To create an alarm from a chart query**

Follow the instructions for the page on which the query appears: Service Metrics or Metrics Explorer.

**Service Metrics page**

To create an alarm from a chart query (Service Metrics)

1. View the **Service Metrics** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Choose a **Compartment** and **Metric Namespace** to view the default charts for the resources of interest.
3. At the top of the chart you're interested in, go to Options, and then select **Create an Alarm on this Query**.
4. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

**Alarm settings**

**Basic Mode (default)**

By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name:**
  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

- **Alarm Severity:** The perceived type of response required when the alarm is in the firing state.

- **Alarm Body:** The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional):** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description:** The metric to evaluate for the alarm condition.
  - **Compartment:** The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace:** The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group (optional):** The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric Name:** The name of the metric. Only one metric can be specified. Example: CpuUtilization
  - **Interval:** The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Note:**
  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**

For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is **1m**. For more information about the resolution parameter as used in alarm queries, see *Alarm*.

**Statistic:** The aggregation function.

Statistic values:

- **COUNT** - The number of observations received in the specified time period.
- **MAX** - The highest value observed during the specified time period.
- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

**Metric dimensions:** Optional filters to narrow the metric data evaluated.

**Dimension fields**

- **Dimension Name:** A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

• **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.

• **Additional dimension**: Adds another name-value pair for a dimension.

• **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

• **Operator**: The operator used in the condition threshold.

  **Operator values**
  • greater than
  • greater than or equal to
  • equal to
  • less than
  • less than or equal to
  • **between** (inclusive of specified values)
  • **outside** (inclusive of specified values)
  • **absent**

• **Value**: The value to use for the condition threshold.

• **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See **Monitoring Query Language (MQL) Reference** on page 2741.

• **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

• **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.

• **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

• **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  
  - **Query Code Editor box**: The alarm query as a Monitoring Query Language (MQL) expression.

```
Note:

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.
```

Example alarm query:

```
CpuUtilization[1m]
{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    
    - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    
    - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
    
    - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.

      - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team" for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
      
      - **Topic Description**: Description of the new topic.
      
      - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

        **Email subscription**

        Sends an email message when you publish a *message* to the subscription's parent *topic*.

        Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

        Some message types allow friendly formatting.

        - **Subscription Protocol**: Select Email.
        
        - **Subscription Email**: Type an email address.

        **HTTPS (Custom URL) subscription**

        Sends specified information when you publish a *message* to the subscription's parent *topic*.

        Endpoint format (URL using HTTPS protocol):

        ```
        https://<anyvalidURL>
        ```

        Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```plaintext
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the [PagerDuty documentation](https://developer.pagerduty.com/docs/).

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```plaintext
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the [Slack documentation](https://developer.slack.com/docs).

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a message to the subscription's parent topic. Supported endpoint formats: **E.164 format**.

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>
<td>BR</td>

</tbody>
</table>
### Metrics Explorer page

To create an alarm from a chart query (Metrics Explorer)

1. View the Metrics Explorer page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. If necessary, open the query for editing: Click the Edit query icon.
3. Click Create Alarm.
4. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

   **Alarm settings**

   **Basic Mode (default)**

   By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

   **Alarm Name:**

   User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

   **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>

</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.

- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.
  
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  
  - **Metric Name**: The name of the metric. Only one metric can be specified. Example: `CpuUtilization`
  
- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  **Interval values**

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour
  - **1d** - 1 day

  **Note:**

  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour
  - **1d** - 1 day

  **Note:**

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm
Monitoring query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.
  
  Statistic values
  
  - **COUNT**: The number of observations received in the specified time period.
  - **MAX**: The highest value observed during the specified time period.
  - **MEAN**: The value of Sum divided by Count during the specified time period.
  - **MIN**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **RATE**: The per-interval average rate of change.
  - **SUM**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

  **Note:**

  Long lists of dimensions are trimmed.
  
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
  - **Operator**: The operator used in the condition threshold.
    - **Operator values**
      - greater than
      - greater than or equal to
      - equal to
      - less than
      - less than or equal to
      - between (inclusive of specified values)
      - outside (inclusive of specified values)
      - absent
    - **Value**: The value to use for the condition threshold.
    - **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click Advanced Mode or Switch to Advanced Mode to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 2741.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>

Example alarm query:

```
CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    
    - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    
    - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
    
    - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
      
      - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
      
      - **Topic Description**: Description of the new topic.
      
      - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
        
        **Email subscription**
        
        Sends an email message when you publish a *message* to the subscription's parent *topic*.
        
        Message contents and appearance vary by message type. See *alarm messages*, *event messages*, and *service connector messages*.
        
        Some message types allow friendly formatting.
        
        - **Subscription Protocol**: Select Email.
        
        - **Subscription Email**: Type an email address.
        
        **HTTPS (Custom URL) subscription**
        
        Sends specified information when you publish a *message* to the subscription's parent *topic*.
        
        Endpoint format (URL using HTTPS protocol):
        
        ```
        https://<anyvalidURL>
        ```
        
        Basic access authentication is supported, allowing you to specify a username and password in the URL, as in https://user:password@domain.com or https://user@domain.com. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Monitoring Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>

</tbody>
</table>

- **Additional destination service**: Adds another destination service and topic to use for notifications.

  **Note:**
  
  Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  
  - **Suppression Description**
  - **Start Time**
  - **End Time**

6. If you want to disable the new alarm, clear **Enable This Alarm?**.
7. Click **Save alarm**.

   The new alarm is listed on the **Alarm Definitions** page.

   For more information about alarms, see **Alarms Feature Overview** on page 2664.

**resource page**

Examples of resource pages are Compute instance detail pages and Block Volume volume detail pages. Alarms are available from these pages for resources that emit metrics.

To create an alarm from a chart query (resource page)

1. To view charts: On the resource page, under **Resources**, click **Metrics**.
2. At the top of the chart you're interested in, go to **Options**, and then select **Create an Alarm on this Query**.
3. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

   **Alarm settings**
   
   **Basic Mode (default)**
   
   By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.
   
   - **Alarm Name**:
     
     User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

   **Rendering of the title by protocol**
   
<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Rendering of the title</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: “High CPU usage alert. Follow runbook instructions for resolution.”
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**
  - **Interval**: The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

**Note:**

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm
monitoring query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.
  - **COUNT**: The number of observations received in the specified time period.
  - **MAX**: The highest value observed during the specified time period.
  - **MEAN**: The value of Sum divided by Count during the specified time period.
  - **MIN**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **RATE**: The per-interval average rate of change.
  - **SUM**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

**Dimension fields**

- **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.
  
  **Operator values**
  
  - greater than
  - greater than or equal to
  - equal to
  - less than
  - less than or equal to
  - between (inclusive of specified values)
  - outside (inclusive of specified values)
  - absent

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See **Monitoring Query Language (MQL) Reference** on page 2741.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.</td>
</tr>
</tbody>
</table>

Example alarm query:

```
CpuUtilization[1m]
{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
4. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    
    - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    
    - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
    
    - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
      
      - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
      
      - **Topic Description**: Description of the new topic.
      
      - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

        **Email subscription**
        
        Sends an email message when you publish a *message* to the subscription's parent *topic*.
        
        Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        
        Some message types allow friendly formatting.
        
        - **Subscription Protocol**: Select Email.
        
        - **Subscription Email**: Type an email address.

        **HTTPS (Custom URL) subscription**
        
        Sends specified information when you publish a *message* to the subscription's parent *topic*.
        
        Endpoint format (URL using HTTPS protocol):
        
        ```
        https://<anyvalidURL>
        ```
        
        Basic access authentication is supported, allowing you to specify a username and password in the URL, as in https://user:password@domain.com or https://user@domain.com. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Connector Hub. SMS messages sent by unsupported services are dropped. **Troubleshoot dropped messages.**

Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).

### Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>

</table>
### Building Metric Queries

This topic describes how to query metrics for resources of interest, create alarms from a given query, and share Console charts.

#### Prerequisites

- **IAM policies**: Querying metrics is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For common policies that give groups access to metrics, see Let users view metric definitions in a compartment on page 2155 and Restrict user access to a specific metric namespace on page 2156.

- **Metrics exist in Monitoring**: The resources that you want to monitor must emit metrics to the Monitoring service.

- **Compute instances**: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.

#### Working with Metric Queries

This section shows MQL syntax of metric and alarm queries.
Use metric **queries** to actively and passively monitor your cloud resources. Actively monitor with metric queries that you generate spontaneously, on demand. In the Console, update a chart to show data from multiple queries. Store queries you want to reuse. Passively monitor with alarms that add a condition, or trigger rule, to a metric query.

Metric query syntax (boldface elements are required):

```
metric[interval]{dimensionname=dimensionvalue}.groupingfunction.statistic
```

Threshold Alarm query syntax (boldface elements are required):

```
metric[interval]{dimensionname=dimensionvalue}.groupingfunction.statistic
alarmoperator alarmvalue
```

For supported parameter values, see Monitoring Query Language (MQL) Reference on page 2741.

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview on page 2663.

**Example queries**

**Simple metric query**

 Maximum CPU Utilization at a one-minute interval.

 Number of lines displayed in the metric chart (Console): 1 per resource.

```
CpuUtilization[1m].max()
```

**Filtered metric query**

 Maximum CPU Utilization at a one-minute interval, filtered to a single resource.

 Number of lines displayed in the metric chart (Console): 1.

```
CpuUtilization[1m]{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
```

**Aggregated metric query**

 All IopsRead at a one-minute interval, filtered to a compartment, aggregated for the maximum.

 Number of lines displayed in the metric chart (Console): 1.

```
IopsRead[1m]
{compartmentId="ocid1.compartment.oc1.phx..exampleuniqueID"}.grouping().max()
```

**Group-aggregated metric query**

 Aggregated average of CPU Utilization by availability domain and pool ID, filtered to Compute instances that use the specified shape.

 Number of lines displayed in the metric chart (Console): 1 per pool and 1 per availability domain.

```
CPUUtilization[1m]
{shape="VM.Standard2.8"}.groupBy(availabilityDomain,poolId).mean()
```

**Alarm query (threshold)**

 Triggered when the 90th percentile of CPU Utilization, aggregated by pool ID, and filtered to the specified availability domain, exceeds 85.

 Number of lines displayed in the metric chart (Console): 1 per pool.

```
CpuUtilization[1m]{availabilityDomain="VeBZ:PHX-AD-1"}.groupBy(poolId).percentile(0.9) > 85
```
**Monitoring**

**Grouped count of resources (alarm query or metric query)**

**Note:**

Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.

An example of a nested query is a grouped count of hosts with up time greater than zero, where the alarm query to identify these hosts is defined within parentheses:

```
(metric[1h].groupBy(host).min() > 0).grouping().count()
```

You can use such a query to either define an alarm or query a metric.

**Using the Console**

**To create a query**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.

   The **Metrics Explorer** page displays an empty chart with fields to build a query.

2. Fill in the fields for a new query.

   - **Compartment**: The compartment containing the resources that you want to monitor. By default, the first accessible compartment is selected.
   - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
   - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
   - **Metric Name**: The name of the metric. Only one metric can be specified. Metric selections depend on the selected compartment and metric namespace. Example: **CpuUtilization**
   - **Interval**: The aggregation window.

   **Interval values**

   Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

   - **1m** - 1 minute
   - **5m** - 5 minutes
   - **1h** - 1 hour
   - **1d** - 1 day

   **Note:**

   For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

   For more information about the resolution parameter as used in metric queries, see **SummarizeMetricsData**.

   **Maximum time range returned for a query**

   The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

   The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.
<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

- **Statistic**: The aggregation function.

  **Statistic values**
  - **COUNT**: The number of observations received in the specified time period.
  - **MAX**: The highest value observed during the specified time period.
  - **MEAN**: The value of Sum divided by Count during the specified time period.
  - **MIN**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **RATE**: The per-interval average rate of change.
  - **SUM**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.
- **Aggregate Metric Streams**: Aggregates all results to plot a single aggregated average for all metric streams. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

3. Click **Update Chart**.

The chart shows the results of your new query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

4. To customize the y-axis label or range, type the label you want into **Y-Axis Label** or type the minimum and maximum values you want into **Y-Axis Min Value** and **Y-Axis Max Value**.

Only numeric characters are allowed for custom ranges. Custom labels and ranges are not persisted in shared queries (MQL).

5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.

**Advanced Mode** is located on the right, under the chart.

Use Advanced Mode to edit your query using MQL syntax to aggregate results by group. The MQL syntax also supports additional parameter values. For more information about query parameters in Basic Mode and Advanced Mode, see Monitoring Query Language (MQL) Reference on page 2741.

6. To create another query, click **Add Query** below the chart.

**To change the time range**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
</tbody>
</table>
Monitoring

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the SummarizeMetricsData operation.

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

1. View the Metrics Explorer page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. To select a period of time, such as Last hour, click Start Time or End Time.
3. To enter a time value, click in Start Time or End Time and then type a value.

To filter results

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or pool of interest. Filtering is done through selected dimensions; available dimensions vary by metric.

You can also match resource groups provided with the metric. Blank (null) for resource group returns metric data that does not have a resource group.

To filter by dimensions

1. View the Metrics Explorer page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. If necessary, open the query for editing: Click the Edit query icon.
3. Under Metric dimensions, select a Dimension Name and Dimension Value.

Dimension fields

- Dimension Name: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Long lists of dimensions are trimmed.</td>
</tr>
<tr>
<td>• To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.</td>
</tr>
<tr>
<td>• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics</td>
</tr>
</tbody>
</table>

- Dimension Value: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- + Additional dimension: Adds another name-value pair for a dimension.
4. To add a dimension name-value pair, click + Additional dimension.
5. Click **Update Chart**.
   The chart shows the filtered results of your query.

   **Troubleshooting Errors and Query Limits**

   If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

   Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

6. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.

   The dimension name-value fragment appears after the metric-interval fragment.

   In the following example query, the dimension name-value fragment is `{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}`, which filters results by the specified resource identifier.

   ```
   CpuUtilization[1m]
   {resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
   ```

   The **MQL** syntax supports more parameter values. See Monitoring Query Language (MQL) Reference on page 2741.

   **To match resource group**

   You can match *resource groups* provided with the metric.

   ```
   Note:
   Blank (null) for resource group returns metric data that does not have a resource group.
   ```

   1. View the **Metrics Explorer** page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click **Metrics Explorer**.
   2. If necessary, open the query for editing: Click the **Edit query** icon.
   3. Select the **Resource Group** you want to use as a filter.
   4. Click **Update Chart**.

      The chart shows query results that match the resource group.

   **Troubleshooting Errors and Query Limits**

   If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

   Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

   **To aggregate all results**

   Aggregate all results to plot a single aggregated average for all *metric streams*. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

   1. View the **Metrics Explorer** page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click **Metrics Explorer**.
   2. If necessary, open the query for editing: Click the **Edit query** icon.
   3. Click **Aggregate Metric Streams**.
4. Click **Update Chart**.

The chart shows the results of your query.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See **MetricData Reference**.

5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.

The *grouping()* function appears before the statistic. For example, the following query returns the maximum (\(\text{max}()\)) IopsRead metric data at a one-minute interval, filtered to a compartment, with all results aggregated.

\[ \text{IopsRead}[1m](\text{compartmentID} = "<\text{compartment\_OCID}>\}).\text{grouping()}.\text{max}() \]

Edit your query in **MQL** to **aggregate results by group**. The MQL syntax also supports more parameter values. See **Monitoring Query Language (MQL) Reference** on page 2741.

To aggregate results by group

<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregating query results by group requires the <em>groupBy()</em> function, which is available in <strong>Advanced Mode</strong> only.</td>
</tr>
</tbody>
</table>

Aggregate query results by group to plot group-specific aggregated averages. Each group's average is plotted as a single line on the metric chart. This operation is helpful when you want to identify trends by group rather than individual resource.

For example, the following query returns the average (\(\text{mean}()\)) CPU Utilization metric data at a one-minute interval. Results are filtered to the specified *shape* and grouped by *availability domain*. If you have Compute instances of this shape sending metrics across three availability domains, then three lines are plotted on the metric chart.

\[ \text{CPUUtilization}[1m]\{\text{shape}="\text{VM.Standard1.1}"\}.\text{groupBy}(\text{availabilityDomain}).\text{mean}() \]

You can also aggregate by resource groups when provided with the metric (*groupBy*(resourceGroup)).

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Select **Advanced Mode** below the chart on the right.
4. In the **Query Code Editor** box, insert the *groupBy*({dimension}) function between the metric-interval fragment and the statistic, where {dimension} is the name of a dimension provided in the definition of the indicated metric.

For example, insert the following fragment to group by availability domain, assuming that the dimension is available for the selected metric.

\[ \text{groupBy}(\text{availabilityDomain}) \]

The **MQL** syntax supports more parameter values. See **Monitoring Query Language (MQL) Reference** on page 2741.

5. Click **Update Chart**.

The chart is updated to show a single line for each grouped result.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of *metric streams*, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams
by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To edit a query using MQL syntax

Edit your query using MQL syntax to aggregate results by group or for more parameter values. See Monitoring Query Language (MQL) Reference on page 2741.

1. View the Metrics Explorer page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. If necessary, open the query for editing: Click the Edit Query icon.
3. Click Advanced Mode.

   The query is displayed as a Monitoring Query Language (MQL) expression.
4. In the Query Code Editor box, edit the query as needed.
5. Click Update Chart.

   The chart is updated.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To create an alarm from a query

Create an alarm to passively monitor for a condition in results from metric queries. Creating an alarm from a query involves adding a trigger rule to the query and setting up notifications.

1. View the Metrics Explorer page: Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Metrics Explorer.
2. If necessary, open the query for editing: Click the Edit Query icon.
3. Click Create Alarm.
4. On the Create Alarm page, under Define alarm, add the trigger, and fill in or update other alarm settings as needed:

   Alarm settings
   
   Basic Mode (default)
   
   By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

   • Alarm Name:
     
     User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

   Rendering of the title by protocol

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>
• **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.

• **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

• **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

• **Metric description**: The metric to evaluate for the alarm condition.
  
  • **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  
  • **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  
  • **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  
  • **Metric Name** (optional): The name of the metric. Only one metric can be specified. Example: `CpuUtilization`
  
  • **Interval**: The aggregation window, or the frequency at which data points are aggregated.

**Interval values**

<table>
<thead>
<tr>
<th>Interval</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1m</td>
<td>1 minute</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
</tr>
<tr>
<td>1d</td>
<td>1 day</td>
</tr>
</tbody>
</table>

**Note:**

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm
query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  Statistic values
  - **COUNT**: The number of observations received in the specified time period.
  - **MAX**: The highest value observed during the specified time period.
  - **MEAN**: The value of Sum divided by Count during the specified time period.
  - **MIN**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **RATE**: The per-interval average rate of change.
  - **SUM**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

  **Note:**

  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
  - **Operator**: The operator used in the condition threshold.
    - **Operator values**
      - greater than
      - greater than or equal to
      - equal to
      - less than
      - less than or equal to
      - between (inclusive of specified values)
      - outside (inclusive of specified values)
      - absent
    - **Value**: The value to use for the condition threshold.
  - **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See [Monitoring Query Language (MQL) Reference](#) on page 2741.

- **Alarm Name**
  - User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.
  - **Rendering of the title by protocol**
    - **Protocol** | **Rendering of the title**
      - Email | Subject line of the email message.
      - HTTPS (Custom URL) | Not rendered.
      - PagerDuty | Title field of the published message.
      - Slack | Not rendered.
      - SMS | Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  **Note:**

  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

Example alarm query:

```
CpuUtilization[1m] {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, select or create at least one notification destination:

**Notifications settings**

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
    
    - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
    
    - **Topic**: The *topic* to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
    
    - **Create a topic**: Sets up a *topic* and subscription protocol in the selected compartment, using the specified destination service.
      
      - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
      
      - **Topic Description**: Description of the new topic.
      
      - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
        
        **Email subscription**
        
        Sends an email message when you publish a *message* to the subscription's parent *topic*.
        
        Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        
        Some message types allow friendly formatting.
        
        - **Subscription Protocol**: Select Email.
        
        - **Subscription Email**: Type an email address.
        
        **HTTPS (Custom URL) subscription**
        
        Sends specified information when you publish a *message* to the subscription's parent *topic*.
        
        Endpoint format (URL using HTTPS protocol):
        
        ```
        https://<anyvalidURL>
        ```
        
        Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

• **Subscription Protocol**: Select HTTPS (Custom URL).
• **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

• **Subscription Protocol**: Select PagerDuty.
• **Subscription URL**: Type (or copy and paste) the integration key portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/). Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

• **Subscription Protocol**: Select Slack.
• **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Connector Hub. SMS messages sent by unsupported services are dropped. **Troubleshoot dropped messages.**

Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).

### Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>

</tbody>
</table>

• **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**
Each alarm is limited to one destination per supported destination service.

• **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
• **Notification Interval**: The period of time to wait before resending the notification.
• **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  • **Suppression Description**
  • **Start Time**
  • **End Time**

6. If you want to disable the new alarm, clear **Enable This Alarm?**.
7. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

For more information about alarms, see **Alarms Feature Overview** on page 2664.

**To hide a query from the chart**

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. Click the **Toggle query on chart** icon for the query that you want to hide.

**To share a query**

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Click **Advanced Mode**.
4. In the **Query Code Editor** box, copy the query.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use this API operation to find metric names and dimensions (view **metric definitions**):

`ListMetrics`

Use this API operation to query metrics by name (and optionally filter by **dimension**):

`SummarizeMetricsData`
Publishing Custom Metrics

This topic describes how to publish your own custom metrics to the Monitoring service.

You can publish your own metrics to Monitoring using the API. You can view charts of your published metrics using the Console, query metrics using the API, and set up alarms using the Console or API.

Prerequisites

IAM policies: To publish custom metrics, you must be given the required type of access in a policy written by an administrator. This requirement applies whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. Administrators: For a related common policy, see Let users publish custom metrics on page 2156.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Note:

When defining your custom metrics, note the following:

- Ensure that your custom metrics do not exceed limits. For example, note the valid range of dimensions and maximum number of streams for custom metrics. See PostMetricData.
- Define your metrics with aggregation in mind. While custom metrics can be posted as frequently as every second (minimum frequency of one second), the minimum aggregation interval is one minute.
- Define your metrics with return limits in mind. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.
- When retrieving custom metrics, you can match to a resource group. Blank (null) for resource group returns metric data that does not have a resource group.

Use this API operation to publish custom metrics:

PostMetricData

Note:

Oracle recommends the following:

- Send batched requests to maximize metric streams per request. A batched request contains multiple metrics or metric namespaces. Note limits. See PostMetricData.
- Publish metrics only when relevant contexts require monitoring; that is, when data points need to be collected. If you want to publish metrics during inactive periods when no observations exist, then you can manually create "0" values for publishing.

You can access your published custom metrics the same way you access any other metrics stored by the Monitoring service. View charts from queries using the Console, query metrics using the CLI or API, and set up alarms using the Console, CLI, or API.
Example of a batched request

This example shows a single request containing data points for metrics across two metric namespaces.

```json
[
  {
    "namespace":"myFirstNamespace",
    "compartmentId":"ocid1.compartment.oc1..exampleuniqueID",
    "resourceGroup":"myFirstResourceGroup",
    "name":"successRate",
    "dimensions":{
      "resourceId":"ocid1.exampleresource.region1.phx.exampleuniqueID",
      "appName":"myAppA"
    },
    "metadata":{
      "unit":"percent",
      "displayName":"MyAppA Success Rate"
    },
    "datapoints":[
      {
        "timestamp":"2019-03-10T22:19:20Z",
        "value":83.0
      },
      {
        "timestamp":"2019-03-10T22:19:40Z",
        "value":90.1
      }
    ]
  },
  {
    "namespace":"myFirstNamespace",
    "compartmentId":"ocid1.compartment.oc1..exampleuniqueID",
    "resourceGroup":"mySecondResourceGroup",
    "name":"successRate",
    "dimensions":{
      "resourceId":"ocid1.exampleresource.region1.phx.differentuniqId",
      "appName":"myAppA"
    },
    "metadata":{
      "unit":"percent",
      "displayName":"MyAppA Success Rate"
    },
    "datapoints":[
      {

Managing Alarms

This topic describes how to create, update, suppress, and delete alarms, as well as how to retrieve alarm history. See also Best Practices for Your Alarms on page 2739.

Prerequisites

- IAM policies: Managing alarms is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications. For a common alarms policy, see Let users view alarms on page 2156.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Using the Console

To see all firing alarms

Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Status. You can suppress alarms during a given time range. You can also disable and delete alarms.

To create an alarm

This section includes steps to create example alarms as well as any kind of alarm.

To create an example threshold alarm

This procedure walks through creation of an example threshold alarm to detect Compute instances operating at non-optimal thresholds. A threshold alarm is an alarm that checks for metric values outside a given range or value. The procedure uses options as displayed in Basic Mode.

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. Click **Create alarm**.

3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:
   - **Alarm Name**: Non-Optimal Alarm
   - **Alarm Severity**: Warning
   - **Alarm Body**: Non-optimal utilization detected. An application or process may be consuming more CPU than usual.
   - **Metric description**:
     - **Compartment**: (select your compartment)
     - **Metric Namespace**: oci_computeagent
     - **Metric Name**: CpuUtilization
     - **Interval**: 1m
   
   **Note:**
   Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.
   - **Statistic**: Count
   - **Trigger rule**:
     - **Operator**: between
     - **Value**: 60
     - **Value**: 80
     - **Trigger Delay Minutes**: 10

4. Set up an email notification under **Notifications, Destinations**:
   - **Destination Service**: Notifications Service
   - **Compartment**: (select your compartment)
   - **Topic**: Click **Create a topic**
     - **Topic Name**: Operations Team
     - **Topic Description**: Resource Monitoring Channel
     - **Subscription Protocol**: Email
     - **Email Addresses**: (type an email address for the operations team here)

5. Repeat notifications every day:
   - **Repeat Notification?**: (select this option)
   - **Notification Interval**: 24 hours

6. Click **Save alarm**.

**To create an example absence alarm**

This procedure walks through creation of an example absence alarm to detect resources that may be down or unreachable. An absence alarm is an alarm that checks for absent metrics (using the absent operator). The procedure uses options as displayed in Basic Mode.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.
3. On the Create Alarm page, under Define alarm, fill in or update the alarm settings:

- Alarm Name: Up/Down Resource Alarm
- Alarm Severity: Critical
- Alarm Body: Resource may be down. Please investigate. Move workloads to another available resource.
- Metric description:
  - Compartment: (select your compartment)
  - Metric Namespace: oci_computeagent
  - Metric Name: CpuUtilization
  - Interval: 1m

  **Note:**
  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.

  - Statistic: Count
  - Trigger rule:
    - Operator: absent
    - Trigger Delay Minutes: 5

4. Set up an email notification under Notifications, Destinations:

- Destination Service: Notifications Service
- Compartment: (select your compartment)
- Topic: Click Create a topic
  - Topic Name: Operations Team
  - Topic Description: Resource Up/Down Channel
  - Subscription Protocol: Email
  - Email Addresses: (type an email address for the operations team here)

  **Note:**
  To add a notification (subscription) for another protocol, such as PagerDuty, create a copy of this alarm and choose the corresponding protocol. For more information about subscription protocols, see To create a subscription on page 3358.

5. Repeat notifications every minute:

- Repeat Notification?: (select this option)
- Notification Interval: 1 minute

6. Click Save alarm.

**To create an alarm (any kind)**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. Click Create alarm.

  **Note:**
  You can also create an alarm from a predefined query on the Service Metrics page. Expand Options and click Create an Alarm on this Query. For more information about service metrics, see Viewing Default Metric Charts on page 2671.
3. On the Create Alarm page, under Define alarm, fill in or update the alarm settings:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To toggle between Basic Mode and Advanced Mode, click Switch to Advanced Mode or Switch to Basic Mode (to the right of Define Alarm).</td>
</tr>
</tbody>
</table>

**Basic Mode (default)**

By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric Name**: The name of the metric. Only one metric can be specified. Example: `CpuUtilization`
- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  **Interval values**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To</td>
</tr>
</tbody>
</table>
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**
For alarm queries, the specified *interval* has no effect on the *resolution* of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic:** The aggregation function.

  **Statistic values**
  - **COUNT** - The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.
  - **MEAN** - The value of Sum divided by Count during the specified time period.
  - **MIN** - The lowest value observed during the specified time period.
  - **P50** - The value of the 50th percentile.
  - **P90** - The value of the 90th percentile.
  - **P95** - The value of the 95th percentile.
  - **P99** - The value of the 99th percentile.
  - **P99.5** - The value of the 99.5th percentile.
  - **RATE** - The per-interval average rate of change.
  - **SUM** - All values added together.

- **Metric dimensions:** Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension Name:** A qualifier specified in the metric definition. For example, the dimension *resourceId* is specified in the metric definition for *CpuUtilization*.

  **Note:**
  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
  - **Operator**: The operator used in the condition threshold.
    - **Operator values**
      - greater than
      - greater than or equal to
      - equal to
      - less than
      - less than or equal to
      - between (inclusive of specified values)
      - outside (inclusive of specified values)
      - absent
    - **Value**: The value to use for the condition threshold.
    - **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click Advanced Mode or Switch to Advanced Mode to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 2741.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.

- **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.

- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  **Note:**

  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

  Example alarm query:

  ```
  CpuUtilization[1m]
  {availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    - Available options:
      - **Notifications Service**.
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
  - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
    - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic Description**: Description of the new topic.
    - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      - **Email subscription**
        - Sends an email message when you publish a *message* to the subscription’s parent *topic*.
        - Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        - Some message types allow friendly formatting.
      - **Subscription Protocol**: Select Email.
      - **Subscription Email**: Type an email address.
    - **HTTPS (Custom URL) subscription**
      - Sends specified information when you publish a *message* to the subscription’s parent *topic*.
      - Endpoint format (URL using HTTPS protocol):
        - `https://<anyvalidURL>`
        - Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the [PagerDuty documentation](#).

- **Subscription Protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the [Slack documentation](#).

- **Subscription Protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: [E.164 format](#).

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Monitoring

Connector Hub. SMS messages sent by unsupported services are dropped. Troubleshoot dropped messages.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Available Countries and Regions

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>
<td>Brazil</td>

</table>
## Additional destination service

Adds another destination service and topic to use for notifications.

### Note

Each alarm is limited to one destination per supported destination service.

### Repeat Notification?

While the alarm is in the firing state, resends notifications at the specified interval.

### Notification Interval

The period of time to wait before resending the notification.

### Suppress Notifications

Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.

- **Suppression Description**
- **Start Time**
- **End Time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.

The new alarm is listed on the **Alarm Definitions** page.

### To disable or enable an alarm

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click the alarm that you want to disable or enable.
3. On the alarm detail page, select or clear **Alarm is Enabled**.

### Note

You can also disable and enable alarms when creating or editing an alarm.

### To move an alarm to a different compartment

Associated metrics remain in their current compartments. For more information, see **Moving Alarms to a Different Compartment** on page 2670.

### Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see **Details for Monitoring** on page 2320.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. In the **List Scope** section, select a compartment.
3. Click the alarm that you want to move.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To update an alarm
1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. Click the alarm that you want to update.
3. Go to Actions on the right, and then click Edit Alarm.
4. On the Edit Alarm page, under Define alarm, update alarm settings as needed:
   
   **Basic Mode (default)**
   
   By default, this page uses Basic Mode, which separates the metric from its dimensions and its trigger rule.
   
   - **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.
   
   **Rendering of the title by protocol**

<table>
<thead>
<tr>

</table>

   - **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
   - **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
   - **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
   - **Metric description**: The metric to evaluate for the alarm condition.
     
     - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
     
     - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
     
     - **Resource Group (optional)**: The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
     
     - **Metric Name**: The name of the metric. Only one metric can be specified. Example: CpuUtilization
     
     - **Interval**: The aggregation window, or the frequency at which data points are aggregated.

   **Interval values**

   **Note:**

   Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To

Oracle Cloud Infrastructure User Guide
determine valid alarm intervals for a given metric, check the relevant service's metric reference.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic:** The aggregation function.

  **Statistic values**
  - **COUNT** - The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.
  - **MEAN** - The value of Sum divided by Count during the specified time period.
  - **MIN** - The lowest value observed during the specified time period.
  - **P50** - The value of the 50th percentile.
  - **P90** - The value of the 90th percentile.
  - **P95** - The value of the 95th percentile.
  - **P99** - The value of the 99th percentile.
  - **P99.5** - The value of the 99.5th percentile.
  - **RATE** - The per-interval average rate of change.
  - **SUM** - All values added together.

- **Metric dimensions:** Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension Name:** A qualifier specified in the metric definition. For example, the dimension resourceId is specified in the metric definition for CpuUtilization.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.
- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.
  - **Operator**: The operator used in the condition threshold.
    - **Operator values**
      - greater than
      - greater than or equal to
      - equal to
      - less than
      - less than or equal to
      - between (inclusive of specified values)
      - outside (inclusive of specified values)
      - absent
    - **Value**: The value to use for the condition threshold.
    - **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference on page 2741.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>

<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.</td>
</tr>
</tbody>
</table>

Example alarm query:

```
CpuUtilization[1m]
{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
5. Under **Notifications**, update settings as needed:

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    
    Available options:
    
    - **Notifications Service**.
  
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  
  - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
  
  - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
    
    - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    
    - **Topic Description**: Description of the new topic.
    
    - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      
      - **Email subscription**
        
        Sends an email message when you publish a *message* to the subscription's parent *topic*.
        
        Message contents and appearance vary by message type. See [alarm messages](#), [event messages](#), and [service connector messages](#).
        
        Some message types allow **friendly formatting**.
        
        - **Subscription Protocol**: Select **Email**.
        
        - **Subscription Email**: Type an email address.
      
      - **HTTPS (Custom URL) subscription**
        
        Sends specified information when you publish a *message* to the subscription's parent *topic*.
        
        Endpoint format (URL using HTTPS protocol):
        
        ```
        https://<anyvalidURL>
        ```
        
        Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

### PagerDuty subscription

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the [PagerDuty documentation](https://www.pagerduty.com/docs).

- **Subscription Protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

### Slack subscription

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the [Slack documentation](https://api.slack.com/

- **Subscription Protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

### SMS subscription

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: [E.164 format](https://docs.oracle.com/en/middleware/oci-monitoring/monitoring-docs/monitoring-product-docs/).

**Note:**

SMS subscriptions are enabled only for messages sent by the following Oracle Cloud Infrastructure services: Monitoring, Service...
Connector Hub. SMS messages sent by unsupported services are dropped. **Troubleshoot dropped messages.**

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

**Available Countries and Regions**

You can use Notifications to send SMS messages to the following countries and regions:

<table>
<thead>
<tr>
<th>Country or region</th>
<th>ISO code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>AU</td>
</tr>
<tr>

<tr>
<td>United States</td>
<td>US</td>
</tr>
</tbody>
</table>

- **Additional destination service**: Adds another destination service and topic to use for notifications.

**Note:**

Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression Description**
  - **Start Time**
  - **End Time**

6. Select or clear **Enable this alarm?**.
7. Click **Save alarm**.
   
The updated alarm settings are listed on the **Alarm Definitions** page.

### To update an alarm after moving a resource

This section shows how to update the metric compartment of an alarm after you move a resource that is emitting metrics monitored by the alarm. For example, if you move a block volume to another compartment, then the alarm must be updated if you want to continue monitoring metrics from the moved block volume.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click the alarm that you want to update.
3. Go to **Actions** on the right, and then click **Edit Alarm**.
4. Update the metric compartment: On the **Edit Alarm** page, under **Metric description** (or **Metric description, dimensions, and trigger rule** for Advanced mode), change the **Compartent** to the compartment where the resource has been moved.

   The chart below the **Define alarm** section dynamically updates according to the selected compartment, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

   If the chart is not showing the expected data, then the old compartment might be specified in the query (MQL), as in the following example:

   ```
   IopsRead[1m]
   {compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID"}.grouping()
   ```
5. If the old compartment is specified in the query, then update the query to reference the new compartment:
   a. Click Advanced Mode or Switch to Advanced Mode to view the alarm query as a Monitoring Query Language (MQL) expression.
   b. In Query Code Editor, update the query to reference the new compartment.

   View example
   Original query:
   ```
   IopsRead[1m]
   {compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID"}.grouping().max()
   ```
   Updated query:
   ```
   Read[1m]
   {compartmentId="ocid1.compartment.oc1.phx..newcompartmentexampleuniqueID"}.grouping()
   ```

   For more information about query syntax and more examples, see Working with Metric Queries on page 2700.

   The chart below the Define alarm section dynamically updates according to the updated query, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

   If the chart is not showing the expected data, then confirm that every compartment reference (Compartment, Query Code Editor) points to the new compartment.

6. Click Save alarm.

   The alarm now monitors metrics from the new compartment.

### To suppress alarms

**Important:**

Only one suppression can be configured per alarm. Any existing suppression for the alarm is overwritten when you apply a new suppression.

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. On the Alarm Definitions page, select the check boxes for the alarms you want to suppress.

   **Note:**
   
   You can also suppress alarms from the Alarm Status page or when creating or editing an alarm.

3. Go to Actions and select AddSuppressions.
4. In the Suppress alarms dialog box, select a Start Time and End Time and then optionally fill in a Suppression Description.
5. Click Apply suppressions.

   A suppression is created for each selected alarm. The updated alarm settings are listed on the Alarm Definitions page.

### To delete alarms

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Alarm Definitions.
2. On the **Alarm Definitions** page, select the check boxes for the alarms you want to delete.

   **Note:**
   
   You can also delete an alarm from its detail page.

3. Go to **Actions** and select **Delete Alarms**.

   The deleted alarms are removed from the compartment and are no longer displayed on the **Alarm definitions** page.

**To view alarm history**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.

2. On the **Alarm Definitions** page, click the alarm that you want to view history for.

   The alarm detail page displays a chart showing data for the indicated time range and a list of timestamped transitions, such as Firing to OK.

   Alarm history is retained for 90 days.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage alarms:

- ListAlarms
- GetAlarm
- CreateAlarm
- ChangeAlarmCompartment
- UpdateAlarm
- DeleteAlarm
- ListAlarmsStatus
- RemoveAlarmSuppression
- GetAlarmHistory

**Best Practices for Your Alarms**

This topic describes best practices for working with your **alarms**.

### Create a Set of Alarms for Each Metric

For each metric emitted by your resources, **create alarms** that define the following resource behaviors:

- At risk. The resource is at risk of becoming inoperable, as indicated by metric values.
- Non-optimal. The resource is performing at non-optimal levels, as indicated by metric values.
- Resource is up or down. The resource is either not reachable or not operating.

The following examples use the CpuUtilization metric emitted by the **oci_computeagent metric namespace**. This metric monitors the utilization of the Compute instance and the activity level of any services and applications running on the instance. CpuUtilization is a key performance metric for a cloud service because it indicates CPU usage for the Compute instance and it can be used to investigate performance issues. To learn more about CPU usage, see the following URL: [https://en.wikipedia.org/wiki/CPU_time](https://en.wikipedia.org/wiki/CPU_time).

### At-Risk Example

A typical at-risk threshold for the CpuUtilization metric is any value greater than 80 percent. A Compute instance breaching this threshold is at risk of becoming inoperable. Often the cause of this behavior is one or more applications consuming a high percentage of the CPU.
In this example, you decide to notify the operations team immediately, setting the severity of the alarm as “Critical” because repair is required to bring the instances back to optimal operational levels. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and appropriate fixes before the instances go into an inoperable state. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of suppressing the alarm. Once metrics return to optimal values, you remove the suppression.

Non-Optimal Example
A typical non-optimal threshold for the CpuUtilization metric is from 60 to 80 percent. When the metric values for a Compute instance are within this range, the instance is above the optimal operational range.

In this example, you decide to notify the appropriate individual or team that an application or process is consuming more CPU than usual. You configure a threshold alarm to notify the appropriate contacts, setting the severity of the alarm as “Warning,” as no immediate actions are required to investigate and reduce the CPU. You set notification to email only, directed to the appropriate developer or team, with repeat notifications every 24 hours to reduce email notification noise.

Resource is Up or Down Example
A typical indicator of resource availability is a five-minute absence of the CpuUtilization metric. A Compute instance breaching this threshold is either not reachable or not operating. The resource may have stopped responding, or it might have become unavailable because of connectivity issues.

In this example, you decide to notify the operations team immediately, setting the severity of your absence alarm as “Critical” because repair is required to bring the instances online. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and a move of the workloads to another available resource. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of suppressing the alarm. When the CpuUtilization metric is once again detected from the resource, you remove the suppression.

Select the Correct Alarm Interval for your Metric
Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

Suppress Alarms During Investigations
Once a team member responds to an alarm, suppress notifications during the effort to investigate or mitigate the issue. Temporarily stopping notifications helps to avoid distractions during the investigation and mitigation. Remove the suppression when the issue has been resolved. For instructions, see To suppress alarms on page 2738.

Routinely Tune Your Alarms
On a regular basis, such as weekly, review your alarms to ensure optimal configuration. Calibrate each alarm's threshold, severity, and notification details, including method, frequency, and targeted audience.
Optimal alarm configuration addresses the following factors:

- Criticality of the resource.
- Appropriate resource behavior. Assess behavior singly and within the context of the service ecosystem. Review metric value fluctuations for a given period of time and then adjust thresholds as needed.
- Acceptable notification noise. Assess the notification method (for example, email or PagerDuty), the appropriate recipients, and the frequency of repeated notifications.

For instructions, see To update an alarm on page 2730.

**Monitoring Query Language (MQL) Reference**

This topic describes the components that appear in *Monitoring Query Language* (MQL) expressions, the order that they appear in, and valid values.

*MQL* syntax governs expressions for querying metrics that are published to the Monitoring service. In the Console, MQL expressions appear in **Advanced Mode**. If you don't need to aggregate results by group or to use other advanced query functionality, then you can create simpler versions of metric queries using **Basic Mode** in the Console.

**Components in an MQL Expression**

An MQL expression includes the following components:

- *metric*
- *interval*
- *dimensions*, as one or more name-value pairs (optional)
- grouping function (optional)
- *statistic*
- comparison operation (optional). Useful for defining alarms.

The query components appear in the following order (boldface components are required):

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Comparison operation queries used for *alarms* can take the following formats (boldface components are required):

- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic (where the statistic is absent())`
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator value`
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator (value1, value2)`

You can nest alarm queries and metric queries.

**Note:**

Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.
In a nested query, the alarm portion appears at the beginning (surrounded with parentheses), followed by the grouping function (optional) and the statistic. The following syntax indicates required components using boldface type.

\[(\text{metric}[\text{interval}])\{\text{dimensionname}="\text{dimensionvalue}"\}.\text{groupingfunction}.\text{statistic}\].\text{groupingfunction}.\text{statistic}

Example 1: The number of hosts with CPU utilization greater than 80 percent:

\[(\text{CpuUtilization}[1m].\text{max()} > 80).\text{grouping()}.\text{sum()}\]

Example 2: The number of availability domains with a success rate lower than 0.99:

\[(\text{SuccessRate}[1m].\text{groupBy(availabilityDomain)}.\text{mean()} < 0.99).\text{grouping()}.\text{sum()}\]

### Metric Query Component

The *metric* component of the query appears before the interval.

\[\text{metric}[\text{interval}]{\text{dimensionname}="\text{dimensionvalue}"}.\text{groupingfunction}.\text{statistic}\]

Valid values for *metric* depend on the *resource*. An example of a metric is CpuUtilization, sent by Compute instances. For a list of supported resources with links to their metric references, see [Supported Services](#) on page 2669. You can also use the [ListMetrics](#) operation to find metrics sent by a particular service, such as the Compute service. This operation returns *metric definitions*.

### Interval Query Component

The *interval* component of the query appears between the metric and statistic (before the optional dimension name-value pair and grouping function).

\[\text{metric}[\text{interval}]{\text{dimensionname}="\text{dimensionvalue}"}.\text{groupingfunction}.\text{statistic}\]

Supported values for *interval* depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the *1h* or *1d* interval values are supported.

The Monitoring Query Language (MQL) syntax (**Advanced Mode** in the Console) supports the following range of values for *interval*:

1m-60m, 1h-24h, 1d

The **Interval** option in the Console (**Basic Mode**) supports the following range of values:

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

### Note:

Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service’s metric reference.

For metric queries, the *interval* you select drives the default *resolution* of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see [SummarizeMetricsData](#).

---

**Oracle Cloud Infrastructure User Guide** 2742
Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.

The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the SummarizeMetricsData operation.

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z). Therefore, only 5 days of metric data points can be returned in this example.

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

Dimension Query Component

The dimensionname="dimensionvalue" component of the query appears between the interval and statistic (before the optional grouping function).

metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic

Surround the dimension value with double quotes. Example dimension name-value pair for filtering by availability domain: availabilityDomain = "VeBZ:PHX-AD-1"

You can specify multiple dimension name-value pairs. Place each pair within the brackets and separate the pairs with commas.
Valid values for `dimensionname` depend on the `metric`. An example of a dimension name is `resourceDisplayName`, included with the `CpuUtilization` metric sent by Compute instances. For a list of supported resources with links to their metric references, including dimensions, see Supported Services on page 2669. You can also use the ListMetrics operation to find metrics (and their dimensions) sent by a particular application or service, such as the Compute service.

### Grouping Function Query Component

The `groupingfunction` component of the query appears between the interval and statistic (after the optional dimension name-value pair).

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Valid grouping functions are as follows.

<table>
<thead>
<tr>
<th>Grouping function (MQL expression; Advanced Mode in the Console)</th>
<th>Grouping function option (Basic Mode in the Console)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>groupBy()</code></td>
<td>(not available)</td>
<td>Aggregates query results by group (dimension or resource group). For example, <code>groupBy(availabilityDomain)</code> groups results by availability domain so that results from each availability domain are together.</td>
</tr>
<tr>
<td><code>grouping()</code></td>
<td>Aggregate Metric Streams</td>
<td>Aggregates all query results.</td>
</tr>
</tbody>
</table>

### Statistic Query Component

The `statistic` component of the query appears after the interval and optional dimension name-value pair and grouping function.

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Valid statistics are as follows.

<table>
<thead>
<tr>
<th>Statistic (MQL expression; Advanced Mode in the Console)</th>
<th>Statistic option (Basic Mode in the Console)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>absent()</code></td>
<td>(see absent)</td>
<td>Returns 1 if the metric is not present in the whole interval. Otherwise, returns 0. Useful for defining alarms.</td>
</tr>
<tr>
<td><code>avg()</code></td>
<td>(not available)</td>
<td>Returns the value of Sum divided by Count during the specified time period. Identical to <code>mean()</code>.</td>
</tr>
<tr>
<td><code>count()</code></td>
<td>COUNT</td>
<td>Returns the number of observations received in the specified time period.</td>
</tr>
<tr>
<td><code>increment()</code></td>
<td>(not available)</td>
<td>Returns the per-interval change.</td>
</tr>
<tr>
<td><code>max()</code></td>
<td>MAX</td>
<td>Returns the highest value observed during the specified time period.</td>
</tr>
<tr>
<td><code>mean()</code></td>
<td>MEAN</td>
<td>Returns the value of Sum divided by Count during the specified time period.</td>
</tr>
<tr>
<td>Statistic (MQL expression; Advanced Mode in the Console)</td>
<td>Statistic option (Basic Mode in the Console)</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>---------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>min()</td>
<td>MIN</td>
<td>Returns the lowest value observed during the specified time period.</td>
</tr>
<tr>
<td>percentile()</td>
<td>P50 P90 P95 P99 P99.9</td>
<td>Returns the estimated value of the specified percentile. Valid values are greater than 0.0 and less than 1.0. For example, percentile(0.8) returns the value of the 80th percentile.</td>
</tr>
<tr>
<td>rate()</td>
<td>RATE</td>
<td>Returns the per-interval average rate of change. The unit is per-second.</td>
</tr>
<tr>
<td>sum()</td>
<td>SUM</td>
<td>Returns all values added together.</td>
</tr>
</tbody>
</table>

### Operator and Value Query Component

The *operator value* component of the query appears after the statistic in threshold alarm queries. Either one or two values are needed, depending on the operator:

- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator value`  
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic operator (value1, value2)`

Valid operators are as follows.

<table>
<thead>
<tr>
<th>Operator (MQL expression; Advanced Mode in the Console)</th>
<th>Operator option (Basic Mode in the Console)</th>
<th>Number of values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>1</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>1</td>
</tr>
<tr>
<td>==</td>
<td>equal to</td>
<td>1</td>
</tr>
<tr>
<td>!= (not equal to)</td>
<td>(not available)</td>
<td>1</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>1</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>1</td>
</tr>
<tr>
<td>in (inclusive of specified values)</td>
<td>between (inclusive of specified values)</td>
<td>2</td>
</tr>
<tr>
<td>not in (inclusive of specified values)</td>
<td>outside (inclusive of specified values)</td>
<td>2</td>
</tr>
<tr>
<td>Not applicable. See absent().</td>
<td>absent</td>
<td>0</td>
</tr>
</tbody>
</table>
Chapter 26

Networking

This chapter explains how to set up cloud networks.

Networking Components

Get a high-level overview of the Networking service.

Manage VNICS

Manage Virtual Network Interface Cards (VNICS) in a virtual cloud network.

Set up VPN Connect

Set up a site-to-site virtual private network (VPN).

Troubleshoot Networking

Troubleshoot common issues and error messages.

Features

Virtual Cloud Network (VCN)

A virtual, private network that you set up in Oracle data centers. It closely resembles a traditional network, with firewall rules and specific types of communication gateways that you can choose to use. A VCN resides in a single Oracle Cloud Infrastructure region and covers one or more CIDR blocks of your choice.

See Virtual Cloud Networks for more information.
FastConnect
Oracle Cloud Infrastructure FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

See FastConnect for more information.

VPN Connect
The VPN connection uses industry-standard IPSec protocols. The Oracle service that provides site-to-site connectivity is named VPN Connect (also referred to as an IPSec VPN).

Other secure VPN solutions include OpenVPN, a Client VPN solution that can be accessed in the Oracle Marketplace. OpenVPN connects individual devices to your VCN, but not whole sites or networks.

See VPN Connect for more information.

DNS
The Domain Name System (DNS) lets computers use hostnames instead of IP addresses to communicate with each other. See DNS in VCNs for more information.

The Oracle Cloud Infrastructure Domain Name System (DNS) service lets you create and manage your DNS zones. You can create zones, add records to zones, and allow Oracle Cloud Infrastructure’s edge network to handle your domain's DNS queries. Also see DNS Service for more information about the DNS service.

Load Balancing
The Oracle Cloud Infrastructure Load Balancing service provides automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). The service offers a load balancer with your choice of a public or private IP address, and provisioned bandwidth.

A load balancer improves resource utilization, facilitates scaling, and helps ensure high availability. You can configure multiple load balancing policies and application-specific health checks to ensure that the load balancer directs traffic only to healthy instances. The load balancer can reduce your maintenance window by draining traffic from an unhealthy application server before you remove it from service for maintenance.

See Load Balancing for more information.

Traffic Management
The Oracle Cloud Infrastructure Traffic Management Steering Policies service is a critical component of DNS. Traffic Management Steering Policies enable you to configure policies to serve intelligent responses to DNS queries, meaning different answers (endpoints) may be served for the query depending on the logic the customer defines in the policy.

See Traffic Management for more information.

Health Checks
The Oracle Cloud Infrastructure Health Checks service provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. By using Health Checks, users can ensure that they are immediately aware of any availability issue affecting their customers.

See Health Checks for more information.

Service Gateway
Another optional virtual router that you can add to your VCN. It provides a path for private network traffic between your VCN and supported services in the Oracle Services Network (examples: Oracle Cloud Infrastructure Object Storage and Autonomous Database). For example, DB Systems in a private subnet in your VCN can back up data.
Networking Overview

When you work with Oracle Cloud Infrastructure, one of the first steps is to set up a virtual cloud network (VCN) for your cloud resources. This topic gives you an overview of Oracle Cloud Infrastructure Networking components and typical scenarios for using a VCN.

Networking Components

The Networking service uses virtual versions of traditional network components you might already be familiar with:

**VIRTUAL CLOUD NETWORK (VCN)**

A virtual, private network that you set up in Oracle data centers. It closely resembles a traditional network, with firewall rules and specific types of communication gateways that you can choose to use. A VCN resides in a single Oracle Cloud Infrastructure region and covers one or more CIDR blocks of your choice. See Allowed VCN Size and Address Ranges on page 2750. The terms *virtual cloud network, VCN,* and *cloud network* are used interchangeably in this documentation. For more information, see VCNs and Subnets on page 2821.

**SUBNETS**

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual network interface cards (VNICs), which attach to instances. Each subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. You can designate a subnet to exist either in a single availability domain or across an entire region (regional subnets are recommended). Subnets act as a unit of configuration within the VCN: All VNICs in a given subnet use the same route table, security lists, and DHCP options (see the definitions that follow). You can designate a subnet as either public or private when you create it. Private means VNICs in the subnet can't have public IP addresses. Public means VNICs in the subnet can have public IP addresses at your discretion. See Access to the Internet on page 2752.

**VNIC**

A virtual network interface card (VNIC), which attaches to an instance and resides in a subnet to enable a connection to the subnet's VCN. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC), and remove them as you like. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance. For more information, see Virtual Network Interface Cards (VNICs) on page 2855.

**PRIVATE IP**

A private IPv4 address and related information for addressing an instance (for example, a hostname for DNS). Each VNIC has a primary private IP, and you can add and remove secondary private IPs. The primary private IP address on an instance doesn't change during the instance's lifetime and cannot be removed from the instance. For more information, see Private IP Addresses on page 2864.

**PUBLIC IP**

A public IPv4 address and related information. You can optionally assign a public IP to your instances or other resources that have a private IP. Public IPs can be either *ephemeral* or *reserved.* For more information, see Public IP Addresses on page 2875.

**IPV6**

An IPv6 address and related information. IPv6 is currently supported only in the Government Cloud. For more information, see IPv6 Addresses on page 2889.
DYNAMIC ROUTING GATEWAY (DRG)

An optional virtual router that you can add to your VCN. It provides a path for private network traffic between your VCN and on-premises network. You can use it with other Networking components and a router in your on-premises network to establish a connection by way of IPSec VPN or Oracle Cloud Infrastructure FastConnect. It can also provide a path for private network traffic between your VCN and another VCN in a different region. For more information, see Access to Your On-Premises Network on page 2753, Dynamic Routing Gateways (DRGs) on page 2927, and Remote VCN Peering (Across Regions) on page 3280.

INTERNET GATEWAY

Another optional virtual router that you can add to your VCN for direct internet access. For more information, see Access to the Internet on page 2752 and also Scenario A: Public Subnet on page 2756.

NETWORK ADDRESS TRANSLATION (NAT) GATEWAY

Another optional virtual router that you can add to your VCN. It gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections. For more information, see Public vs. Private Subnets on page 2752 and also NAT Gateway on page 3247.

SERVICE GATEWAY

Another optional virtual router that you can add to your VCN. It provides a path for private network traffic between your VCN and supported services in the Oracle Services Network (examples: Oracle Cloud Infrastructure Object Storage and Autonomous Database). For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. For more information, see Access to Oracle Services: Service Gateway on page 3256.

LOCAL PEERING GATEWAY (LPG)

Another optional virtual router that you can add to your VCN. It lets you peer one VCN with another VCN in the same region. Peering means the VCNs communicate using private IP addresses, without the traffic traversing the internet or routing through your on-premises network. A given VCN must have a separate LPG for each peering it establishes. For more information, see Local VCN Peering (Within Region) on page 3267.

REMOTE PEERING CONNECTION (RPC)

A component that you can add to a DRG. It lets you peer one VCN with another VCN in a different region. For more information, see Remote VCN Peering (Across Regions) on page 3280.

ROUTE TABLES

Virtual route tables for your VCN. They have rules to route traffic from subnets to destinations outside the VCN by way of gateways or specially configured instances. Your VCN comes with an empty default route table, and you can add custom route tables of your own. For more information, see Route Tables on page 2921.

SECURITY RULES

Virtual firewall rules for your VCN. They are ingress and egress rules that specify the types of traffic (protocol and port) allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. For example, you can allow incoming SSH traffic from anywhere to a set of instances by setting up a stateful ingress rule with source CIDR 0.0.0.0/0, and destination TCP port 22. To implement security rules, you can use network security groups or security lists. A network security group consists of a set of security rules that apply only to the resources in that group. Contrast this with a security list, where the rules apply to all the resources in any subnet that uses the list. Your VCN comes with a default security list with default security rules. For more information, see Security Rules on page 2833.

DHCP OPTIONS

Configuration information that is automatically provided to the instances when they boot up. For more information, see DHCP Options on page 2917.
Allowed VCN Size and Address Ranges

A VCN covers one or more IPv4 CIDR blocks of your choice. The allowable VCN size range is /16 to /30. Example: 10.0.0.0/16. The Networking service reserves the first two IP addresses and the last one in each subnet's CIDR.

For your VCN, Oracle recommends using the private IP address ranges specified in RFC 1918 (10.0.0.0/16, 172.16/16, and 192.168/16). However, you can use a publicly routable range. Regardless, this documentation uses the term private IP address when referring to IP addresses in your VCN's CIDR. Address ranges that are disallowed are described in IP Addresses Reserved for Use by Oracle on page 2754.

The VCN's CIDR blocks must not overlap with each other, with CIDRs in your on-premises network, or with the CIDRs of another VCN you peer with. The subnets in a given VCN must not overlap with each other. For reference, here's a CIDR calculator.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

Availability Domains and Your VCN

Your VCN resides in a single Oracle Cloud Infrastructure region. A region can have multiple availability domains to provide isolation and redundancy. For more information, see Regions and Availability Domains.

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all AD-specific, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or regional. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.
Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. Oracle recommends using regional subnets because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

**Default Components that Come With Your VCN**

Your VCN automatically comes with these default components:

- Default route table, with no route rules
- Default security list, with default security rules
- Default set of DHCP options, with default values
You can't delete these default components. However, you can change their contents (for example, the rules in the default security list). And you can create your own custom versions of each kind of component in your VCN. There are limits to how many you can create and the maximum number of rules. For more information, see Service Limits on page 215.

Each subnet always has these components associated with it:

- One route table
- One or more security lists (for the maximum number, see Service Limits on page 215)
- One set of DHCP options

During subnet creation, you can choose which route table, security list, and set of DHCP options the subnet uses. If you don't specify a particular component, the subnet automatically uses the VCN's default component. You can change which components the subnet uses at any time.

**Tip:**

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

**Connectivity Choices**

You can control whether subnets are public or private, and whether instances get public IP addresses. You can set up your VCN to have access to the internet if you like. You can also privately connect your VCN to public Oracle Cloud Infrastructure services such as Object Storage, to your on-premises network, or to another VCN.

**Public vs. Private Subnets**

When you create a subnet, by default it's considered public, which means instances in that subnet are allowed to have public IP addresses. Whoever launches the instance chooses whether it has a public IP address. You can override that behavior when creating the subnet and request that it be private, which means instances launched in the subnet are prohibited from having public IP addresses. Network administrators can therefore ensure that instances in the subnet have no internet access, even if the VCN has a working internet gateway, and security rules and firewall rules allow the traffic.

**How IP Addresses Are Assigned**

Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC) and remove them as you like.

Every VNIC has a private IP address from the associated subnet's CIDR. You can choose the particular IP address (during instance launch or secondary VNIC creation), or Oracle can choose it for you. The private IP address does not change during the lifetime of the instance and cannot be removed. You can also add secondary private IPs to a VNIC.

If the VNIC is in a public subnet, then each private IP on that VNIC can have a public IP assigned to it at your discretion. Oracle chooses the particular IP address. There are two types of public IPs: ephemeral and reserved. An ephemeral public IP exists only for the lifetime of the private IP it's assigned to. In contrast, a reserved public IP exists as long as you want it to. You maintain a pool of reserved public IPs and allocate them to your instances at your discretion. You can move them from resource to resource in a region as you need to.

**Access to the Internet**

There are two optional gateways (virtual routers) that you can add to your VCN depending on the type of internet access you need:

- **Internet gateway:** For resources with public IP addresses that need to be reached from the internet (example: a web server) or need to initiate connections to the internet.
- **NAT gateway:** For resources without public IP addresses that need to initiate connections to the internet (example: for software updates) but need to be protected from inbound connections from the internet.
Networking

Just having an internet gateway alone does not expose the instances in the VCN's subnets directly to the internet. The following requirements must also be met:

- The **internet gateway** must be enabled (by default, the internet gateway is enabled upon creation).
- The subnet must be **public**.
- The subnet must have a **route rule** that directs traffic to the internet gateway.
- The subnet must have **security list rules** that allow the traffic (and each instance's firewall must allow the traffic).
- The instance must have a **public IP address**.

**Tip:**

To access public services such as Object Storage from your VCN without the traffic going over the internet, use a **service gateway**.

Also, notice that traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure (such as Object Storage) is routed without being sent over the internet.

You can also give a subnet **indirect** access to the internet by setting up an internet proxy in your on-premises network and then connecting that network to your VCN by way of a DRG. For more information, see **Access to Your On-Premises Network** on page 2753.

**Access to Public Oracle Cloud Infrastructure Services**

You can use a service gateway with your VCN to enable private access to public Oracle Cloud Infrastructure services such as Object Storage. For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. No internet gateway or NAT is required. For more information, see **Access to Oracle Services: Service Gateway** on page 3256.

**Access to Your On-Premises Network**

There are two ways to connect your on-premises network to Oracle Cloud Infrastructure:

- **VPN Connect**: Offers multiple IPSec tunnels between your existing network's edge and your VCN, by way of a DRG that you create and attach to your VCN.
- **Oracle Cloud Infrastructure FastConnect**: Offers a private connection between your existing network's edge and Oracle Cloud Infrastructure. Traffic does not traverse the internet. Both private peering and public peering are supported. That means your on-premises hosts can access private IPv4 addresses in your VCN as well as regional public IPv4 addresses in Oracle Cloud Infrastructure (for example, Object Storage or public load balancers in your VCN).

You can use one or both types of the preceding connections. If you use both, you can use them simultaneously, or in a redundant configuration. These connections come to your VCN by way of a single DRG that you create and attach to your VCN. Without that DRG attachment and a route rule for the DRG, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining components that form the rest of the connection. You could then reattach the DRG again, or attach it to another VCN.

**Access to Another VCN**

You can connect your VCN to another VCN over a private connection that doesn't require the traffic to traverse the internet. In general, this type of connection is referred to as **VCN peering**. Each VCN must have specific components to enable peering. The VCNs must also have specific IAM policies, route rules, and security rules that permit the connection to be made and the wanted network traffic to flow over the connection. For more information, see **Access to Other VCNs: Peering** on page 3265.

**Connection to Oracle Cloud Infrastructure Classic**

You can set up a connection between your Oracle Cloud Infrastructure environment and Oracle Cloud Infrastructure Classic environment. This connection can facilitate hybrid deployments between the two environments, or migration from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. For more information, see **Access to Oracle Cloud Infrastructure Classic** on page 3289.
Connection to Microsoft Azure

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. For more information, see Access to Microsoft Azure on page 3299.

Connection to Other Clouds with Libreswan

You can connect your VCN to another cloud provider by using an IPSec VPN with a Libreswan VM as the customer-premises equipment (CPE). For more information, see Access to Other Clouds with Libreswan on page 3310.

Networking Scenarios

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See these topics:

- Scenario A: Public Subnet on page 2756
- Scenario B: Private Subnet with a VPN on page 2761
- Scenario C: Public and Private Subnets with a VPN on page 2769

Transit Routing

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then transits through the VCN to its destination. See these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region on page 2780: Your on-premises network has access to multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke topology, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- Transit Routing: Private Access to Oracle Services on page 2803: Your on-premises network has private access to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's service gateway. The traffic does not go over the internet.

Regions and Availability Domains

Your VCN resides in a single Oracle Cloud Infrastructure region. Each subnet resides in a single availability domain (AD). Availability domains are designed to provide isolation and redundancy in your VCN, as illustrated in Scenario B and C earlier. For example, you could set up your primary set of subnets in a single AD, and then set up a duplicate set of subnets in a secondary AD. The two ADs are isolated from each other in the Oracle data centers, so if one fails, you can easily switch over to the other AD. For more information, see Regions and Availability Domains.

Public IP Address Ranges

For a list of Oracle Cloud Infrastructure public IP ranges, see IP Address Ranges on page 193.

IP Addresses Reserved for Use by Oracle

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

169.254.0.0/16

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.
**Class D and Class E**

All addresses from 224.0.0.0 to 239.255.255.255 (Class D) are prohibited for use in a VCN, they are reserved for multicast address assignments in the IP standards. See RFC 3171 for details.

All addresses from 240.0.0.0 to 255.255.255.255 (Class E) are prohibited for use in a VCN, they are reserved for future use in the IP standards. See RFC 1112, Section 4 for details.

**Three IP Addresses in Each Subnet**

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.

**Creating Automation with Events**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.
If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Limits on Your Networking Components**

See [Service Limits](#) on page 215 for a list of applicable limits and instructions for requesting a limit increase.

**Networking Scenarios**

Here are a few basic networking scenarios to help you understand the Networking service and generally how the components work together.

- [Scenario A: Public Subnet](#) on page 2756
- [Scenario B: Private Subnet with a VPN](#) on page 2761
- [Scenario C: Public and Private Subnets with a VPN](#) on page 2769

**Advanced Scenarios with Transit Routing Through a Single VCN**

Scenarios A–C show your on-premises network connected to a VCN by way of [FastConnect](#) or [VPN Connect](#), and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then *transits through* the VCN to its destination. See these topics:

- [Transit Routing: Access to Multiple VCNs in the Same Region](#) on page 2780: Your on-premises network has access to *multiple* VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke topology, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- [Transit Routing: Private Access to Oracle Services](#) on page 2803: Your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's *service gateway*. The traffic does not go over the internet.

**Advanced Scenario with Multiple DRGs and Multiple VCNs**

There's an extra advanced scenario that illustrates the use of multiple VCNs. In this case, each VCN has its own *dynamic routing gateway (DRG)* and its own FastConnect *private virtual circuit*. Contrast this with [Transit Routing: Access to Multiple VCNs in the Same Region](#) on page 2780, in which there's a single DRG with either VPN Connect or a single FastConnect private virtual circuit.

Here are some restrictions for using the scenario that has multiple DRGs:

- The scenario works only with FastConnect through a *third-party provider* or through colocation with Oracle. It is not supported for FastConnect through an Oracle partner.
- The scenario is supported only for VCNs in the same region and same tenancy.

See [FastConnect with Multiple DRGs and VCNs](#) on page 2816.

**Scenario A: Public Subnet**

This topic explains how to set up Scenario A, which consists of a virtual cloud network (VCN) and a regional *public subnet*. There are public servers in separate *availability domains* for redundancy. The VCN is directly connected to the internet by way of an *internet gateway*. The gateway is also used for connectivity to your on-premises network. Any resource in the on-premises network that needs to communicate with resources in the VCN must have a public IP address and access to the internet.

The subnet uses the *default security list*, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only *allow* traffic. Any traffic not explicitly covered by a security list rule is implicitly denied.
In this scenario, you add additional rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.

**Tip:**

Security lists are one way to control traffic in and out of the VCN’s resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the internet gateway.

See the following figure.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re a member of the Administrators group, you already have the required access to execute Scenario A. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 2832.

**Setting Up Scenario A in the Console**

Setup is easy in the Console.

**Task 1: Create the VCN**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.

3. Click Create Virtual Cloud Network.

4. Enter the following:
   - **Name**: A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **CIDR Blocks**: One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the Government Cloud. For more information, see IPv6 Addresses on page 2889.
   - **Use DNS Hostnames in this VCN**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

Task 2: Create the regional public subnet

1. While still viewing the VCN, click Create Subnet.

2. Enter the following:
   - **Name**: A friendly name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Regional or Availability Domain-Specific**: Select Regional (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it in any availability domain in the region. For more information, see Overview of VCNs and Subnets on page 2822.
   - **CIDR Block**: A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You cannot change this value later. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
   - **Route Table**: Select the default route table.
   - **Private or public subnet**: Select Public Subnet, which means instances in the subnet can optionally have public IP addresses. For more information, see Access to the Internet on page 2752.
   - **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - **DHCP Options**: Select the default set of DHCP options.
   - **Security Lists**: Make sure the default security list is selected (the default).
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
3. Click Create Subnet.
   The subnet is then created and displayed on the Subnets page.

**Task 3: Create the internet gateway**

1. Under Resources, click Internet Gateways.
2. Click Create Internet Gateway.
3. Enter the following:
   - **Name:** A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
4. Click Create Internet Gateway.

Your internet gateway is created and displayed on the Internet Gateways page. It's already enabled, but you must add a route rule that allows traffic to flow to the gateway.

**Task 4: Update the default route table to use the internet gateway**

The default route table starts out with no rules. Here you add a rule that routes all traffic destined for addresses outside the VCN to the internet gateway. The existence of this rule also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security list rules to control the types of traffic that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required in order to route traffic within the VCN itself.

1. Under Resources, click Route Tables.
2. Click the default route table to view its details.
3. Click Add Route Rule.
4. Enter the following:
   - **Target Type:** Internet Gateway
   - **Destination CIDR block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule)
   - **Compartment:** The compartment where the internet gateway is located.
   - **Target:** The internet gateway you created.
   - **Description:** An optional description of the rule.
5. Click Add Route Rule.

The default route table now has a rule for the internet gateway. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.

**Task 5: Update the default security list**

Earlier you set up the subnet to use the VCN's default security list. Now you add security list rules that allow the types of connections that the instances in the VCN will need.

For example: This is a public subnet with an internet gateway, so the instances your launch might need to receive inbound HTTPS connections from the internet (if they're web servers). Here's how to add another rule to the default security list to enable that traffic:

2. Click the default security list to view its details. By default, you land on the Ingress Rules page.
3. Click Add Ingress Rule.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - Stateless: Unselected (this is a stateful rule)
   - Source Type: CIDR
   - Source CIDR: 0.0.0.0/0
   - IP Protocol: TCP
   - Source Port Range: All
   - Destination Port Range: 443
   - Description: An optional description of the rule.

5. Click Add Ingress Rule.

**Important:**

Security List Rule for Windows Instances

If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Lists on page 2850.

For a production VCN, you typically set up one or more custom security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

**Task 6: Create instances in separate availability domains**

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a public subnet, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you must give each instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

**Setting Up Scenario A with the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:

1. CreateVcn: Make sure to include a DNS label for the VCN if you want the instances to have hostnames (see DNS in Your Virtual Cloud Network on page 2910).
2. CreateSubnet: Create one regional public subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.
3. CreateInternetGateway
4. UpdateRouteTable: To enable communication with the internet gateway, update the default route table to include a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway. This rule routes all traffic destined for addresses outside the VCN to the internet gateway. No route rule is required in order to route traffic within the VCN itself.
5. UpdateSecurityList: To allow specific types of connections to and from the instances in the subnet.

**Important:**

Security List Rule for Windows Instances
If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Lists on page 2850.

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a public subnet, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you must give each instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

Scenario B: Private Subnet with a VPN

This topic explains how to set up Scenario B, which consists of a virtual cloud network (VCN) with a regional private subnet. There are servers in separate availability domains for redundancy. The VCN has a dynamic routing gateway (DRG) and IPSec VPN for connectivity to your on-premises network. The VCN has no direct connection to the internet. Any connection to the internet would need to come indirectly by way of the on-premises network.

The subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only allow traffic. Any traffic not explicitly covered by a security list rule is denied.

In this scenario, you add additional rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.

Tip:

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the DRG. No route rule is required in order to route traffic within the VCN itself.

See the following figure.
Tip:
The scenario uses an IPSec VPN for connectivity. However, you could instead use Oracle Cloud Infrastructure FastConnect.

Prerequisites
To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the customer-premises equipment (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You will provide Oracle this information and in return receive the information your network administrator must have to configure the CPE at your end of the VPN.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re a member of the Administrators group, you already have the required access to execute Scenario B. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 2832.
Setting Up Scenario B

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you execute the individual operations yourself.

**Important:**

Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the desired Networking components. But there's also a critical step that requires a network administrator in your organization to take information you receive from setting up the components and use it to configure the CPE at your end of the VPN. Therefore you can't complete this process in one short session. You'll need to break for an unknown period of time while the network administrator completes the configuration and then return afterward to confirm communication with your instances over the VPN.

Using the Console

**Task 1: Set up the VCN and subnet**

1. Create the VCN:
   
a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   
b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.
   
c. Click Create Virtual Cloud Network.
   
d. Enter the following:

   - **Name:** A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **CIDR Block:** One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
   - **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   
e. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.
2. Create the regional private subnet:
   a. While still viewing the VCN, click **Create Subnet**.
   b. Enter the following:
      - **Name**: A friendly name for the subnet (for example, *Regional Private Subnet*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Regional or Availability Domain-Specific**: Select **Regional** (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any availability domain in the region. For more information, see *Overview of VCNs and Subnets* on page 2822.
      - **CIDR Block**: A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You cannot change this value later. For reference, here's a [CIDR calculator](#).
      - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see *IPv6 Addresses* on page 2889.
      - **Route Table**: Select the default route table.
      - **Private or public subnet**: Select **Private Subnet**, which means instances in the subnet cannot have public IP addresses. For more information, see *Access to the Internet* on page 2752.
      - **Use DNS Hostnames in this Subnet**: This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see *DNS in Your Virtual Cloud Network* on page 2910.
      - **DHCP Options**: Select the default set of DHCP options.
      - **Security Lists**: Select the default security list.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see *Resource Tags* on page 211.
   c. Click **Create Subnet**.

   The subnet is then created and displayed on the **Subnets** page.
3. Update the default security list to include rules to allow the types of connections that your instances in the VCN will need:

a. While still on the page displaying your VCN’s subnets, click Security Lists, and then click the default security list.

b. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with. You can add one rule at a time by clicking either Add Ingress Rule or Add Egress Rule.

c. Add your desired rules. Here are suggested ones to add to the default ones already in the default security list:

Example: Ingress HTTP access

- **Type:** Ingress
- **Stateless:** Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 80
- **Description:** An optional description of the rule.

Example: Ingress HTTPS access

- **Type:** Ingress
- **Stateless:** Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 443
- **Description:** An optional description of the rule.

Example: Ingress SQL*Net access for Oracle databases

- **Type:** Ingress
- **Stateless:** Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 1521
- **Description:** An optional description of the rule.

Example: Ingress RDP access required for Windows instances

- **Type:** Ingress
- **Stateless:** Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 3389
- **Description:** An optional description of the rule.

**Tip:**

For additional security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. You
Networking

Networking would need to create separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.

For a production VCN, you typically set up one or more custom security lists for each subnet. You can edit the subnet to use different security lists if you like. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

**Task 2: Create instances in separate availability domains**

You can now create one or more instances in the subnet (see Launching an Instance). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

However, you can't yet communicate with the instances because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through creating an IPSec VPN connection to enable that communication.

**Task 3: Add an IPSec VPN to your VCN**

1. Create a customer-premises equipment (CPE) object:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Customer-Premsises Equipment.
   b. Click Create Customer-Premsises Equipment.
   c. Enter the following:
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - **Name**: A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **IP Address**: The public IP address of the CPE at your end of the VPN (see Prerequisites on page 2762).
   d. Click Create.

   The CPE object will be in the "Provisioning" state for a short period.

2. Create a dynamic routing gateway (DRG):
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.
   b. Click Create Dynamic Routing Gateway.
   c. For Create in Compartment: Leave the default value (the compartment you're currently working in).
   d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   e. Click Create.

   The DRG will be in the "Provisioning" state for a short period. Make sure it is done being provisioned before continuing.

3. Attach the DRG to your VCN:
   a. Click the DRG that you just created.
   b. Under Resources, click Virtual Cloud Networks.
   c. Click Attach to Virtual Cloud Network.
   d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called transit routing, which is not relevant here.
   e. Click Attach.

   The attachment will be in the "Attaching" state for a short period before it's ready.
4. Update the default route table (which has no rules yet):
   
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Click your VCN.
   c. Under **Resources**, click **Route Tables**, and then click the default route table.
   d. Click **Add Route Rule**.
   e. Enter the following:
      
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
      - **Description**: An optional description of the rule.
   
   f. Click **Add Route Rule**.
      
      The VCN's default route table now directs outbound traffic to the DRG and ultimately to your on-premises network.

5. Create an IPSec Connection:
   
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.
   b. Click **Create IPSec Connection**.
   c. Enter the following:
      
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - **Name**: Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
      - **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
      - **Customer-Premises Equipment**: Select the CPE object you created earlier.
      - **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
      - **Dynamic Routing Gateway**: Select the DRG that you created earlier.
      - **Static Route CIDR**: Enter at least one static route CIDR (see Prerequisites on page 2762). If you need to add another, click **Add Static Route**. You can enter up to 10 static routes, and you can change the static routes later if you like.
   
   d. Click **Show Advanced Options** and optionally provide the following items:
      
      - **CPE IKE Identifier**: Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
      - **Tunnel 1** and **Tunnel 2**: Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing on page 3160.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   
   e. Click **Create IPSec Connection**.
      
      The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
      
      The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click **View Shared Secret**.
   
   f. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the on-premises router.
      
      For more information, see CPE Configuration on page 2967. You can view this tunnel information here in the Console at any time.
You have now created all the components required for the IPSec VPN. But your network administrator must configure the CPE before network traffic can flow between your on-premises network and VCN.

**Task 4: Configure your CPE**

These instructions are for the network administrator.

1. Make sure you have the tunnel configuration information that Oracle provided during IPSec VPN setup. See **Task 3: Add an IPSec VPN to your VCN** on page 2766.
2. Configure your CPE according to the information in **CPE Configuration** on page 2967.

If there are already instances in the subnet, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the following operations:

1. **CreateVcn**: Make sure to include a DNS label for the VCN if you want the instances to have hostnames (see **DNS in Your Virtual Cloud Network** on page 2910).
2. **CreateSubnet**: Create one regional private subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.
3. **CreateDrg**: This creates a new dynamic routing gateway (DRG)
4. **CreateDrgAttachment**: This attaches the DRG to the VCN.
5. **CreateCpe**: Here you'll provide the public IP address of the CPE at your end of the VPN (see **Prerequisites** on page 2762).
6. **CreateIPSecConnection**: Here you'll provide the static routes for your on-premises network (see **Prerequisites** on page 2762). In return, you'll receive the configuration information that your network administrator needs in order to configure your CPE. If you need that information later, you can get it with **GetIPSecConnectionDeviceConfig**. For more information about the configuration, see **CPE Configuration** on page 2967.
7. **UpdateRouteTable**: To enable communication via the VPN, update the default route table to include this route: a route rule with destination = 0.0.0.0/0, and destination target = the DRG you created earlier.
8. First call **GetSecurityList** to get the default security list, and then call **UpdateSecurityList** to add rules for the types of connections that your instances in the VCN will need. Be aware that **UpdateSecurityList** overwrites the entire set of rules. Here are some suggested rules to add:

   - **Stateful ingress**: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=80 (for HTTP).
   - **Stateful ingress**: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=443 (for HTTPS).
   - **Stateful ingress**: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=1521 (for SQL*Net access to Oracle databases).
   - **Stateful ingress**: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port=all, destination port=3389 (for RDP; required only if using Windows instances).
9. **LaunchInstance**: Create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics. For more information, see **Creating an Instance** on page 695.

**Tip:**

For additional security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. You would need to create separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.
Important:

Although you can create instances in the subnet, you won't be able to communicate with them from your on-premises network until your network administrator configures your CPE (see CPE Configuration on page 2967). After that, your IPSec connection should be up and running. You can confirm its status by using GetIPSecConnectionDeviceStatus. You can also confirm the IPSec connection is up by connecting to the instances from your on-premises network.

Scenario C: Public and Private Subnets with a VPN

This topic explains how to set up Scenario C, which is a simple example of a multi-tier setup. It consists of a virtual cloud network (VCN) with a regional public subnet to hold public servers (such as web servers), and a regional private subnet to hold private servers (such as database servers). There are servers in separate availability domains for redundancy.

The VCN has a dynamic routing gateway (DRG) and IPSec VPN for connectivity to your on-premises network. Instances in the public subnet have direct access to the internet by way of an internet gateway. Instances in the private subnet can initiate connections to the internet by way of a NAT gateway (for example, to get software updates), but cannot receive inbound connections from the internet through that gateway.

Each subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only allow traffic. Any traffic not explicitly covered by a security list rule is denied.

Tip:

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

Each subnet also has its own custom security list and custom route table with rules specific to the needs of the subnet's instances. In this scenario, the VCN's default route table (which is always empty to start with) is not used.

See the following figure.
Networking

Tip:
The scenario uses an IPSec VPN for connectivity. However, you could instead use Oracle Cloud Infrastructure FastConnect.

Prerequisites
To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the customer-premises equipment (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You will provide Oracle this information and in return receive the information your network administrator needs in order to configure the on-premises router at your end of the VPN.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute Scenario C. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking on page 2832.

Setting Up Scenario C
Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you execute the individual operations yourself.

Important:
Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the desired Networking components. But there's also a critical step that requires a network administrator in your organization to take information you receive from setting up the components and use it to configure the on-premises router at your end of the VPN. Therefore you can't complete this process in one short session. You'll need to break for an unknown period of time while the network administrator completes the configuration and then return afterward to confirm communication with your instances over the VPN.

Using the Console
Task 1: Set up the VCN and subnets

1. Create the VCN:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.
   c. Click **Create Virtual Cloud Network**.
   d. Enter the following:
      - **Name**: A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave as is.
      - **CIDR Block**: One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a [CIDR calculator](#).
      - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
      - **Use DNS Hostnames in this VCN**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   e. Click **Create Virtual Cloud Network**.

   The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

2. Create an internet gateway for your VCN:
   a. Under **Resources**, click **Internet Gateways**.
   b. Click **Create Internet Gateway**.
   c. Enter the following:
      - **Name**: A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave as is.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   d. Click **Create Internet Gateway**.

   The internet gateway is then created and listed on the page.
3. Create a NAT gateway for your VCN:
   a. Under Resources, click NAT Gateways.
   b. Click Create NAT Gateway.
   c. Enter the following:
      • Name: A friendly name for the NAT gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • Create in Compartment: Leave as is.
      • Tags: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   d. Click Create NAT Gateway.

   The NAT gateway is then created and listed on the page.

4. Create the custom route table for the public subnet (which you will create later):
   a. Under Resources, click Route Tables.
   b. Click Create Route Table.
   c. Enter the following:
      • Name: A friendly name for the route table (for example, Public Subnet Route Table). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • Create in Compartment: Leave the default value (the compartment you're currently working in).
      • Click + Additional Route Rule and enter the following:
         • Target Type: Internet Gateway.
         • Destination CIDR Block: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
         • Compartment: Leave as is.
         • Target: The internet gateway you just created.
         • Description: An optional description of the rule.
   d. Tags: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   e. Click Create Route Table.

   The route table is then created and listed on the page.
5. Create the custom route table for the private subnet (which you will create later):
   a. Click Create Route Table.
   b. Enter the following:
      - **Name**: A friendly name for the route table (for example, *Private Subnet Route Table*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - **Click + Additional Route Rule** and enter the following:
        - **Target Type**: NAT Gateway.
        - **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
        - **Compartment**: Leave as is.
        - **Target**: The NAT gateway you just created.
        - **Description**: An optional description of the rule.
      c. **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
      d. Click Create Route Table.

   The route table is then created and listed on the page. Later on after you've set up the IPSec VPN, you will update the Private Subnet Route Table so it routes traffic from the private subnet to the on-premises network by way of the DRG.

6. Update the **default security list** to include rules to allow the types of connections that your instances in the VCN will need:
   b. Click the default security list to view its details. By default, you land on the Ingress Rules page.
   c. Edit each of the existing stateful ingress rules so that the **Source CIDR** is the CIDR for your on-premises network (10.0.0.0/16 in this example) and not 0.0.0.0/0. To edit an existing rule, click the Actions icon (three dots) for the rule, and then click **Edit**.
   d. If you plan to launch Windows instances, add a rule to enable RDP access:
7. Create a custom security list for the public subnet:

   a. Return to the Security Lists page for the VCN.
   b. Click Create Security List.
   c. Enter the following:
      
      • **Name:** Enter a friendly name for the list (for example, *Public Subnet Security List*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      
      • **Create in Compartment:** Leave the default value (the compartment you're currently working in).

d. Add the following ingress rules:

   Example: Ingress HTTP access

   • **Type:** Ingress
   • **Stateless:** Unselected (this is a *stateful rule*)
   • **Source Type:** CIDR
   • **Source CIDR:** 0.0.0.0/0
   • **IP Protocol:** TCP
   • **Source Port Range:** All
   • **Destination Port Range:** 80
   • **Description:** An optional description of the rule.

   Example: Ingress HTTPS access

   • **Type:** Ingress
   • **Stateless:** Unselected (this is a *stateful rule*)
   • **Source Type:** CIDR
   • **Source CIDR:** 0.0.0.0/0
   • **IP Protocol:** TCP
   • **Source Port Range:** All
   • **Destination Port Range:** 443
   • **Description:** An optional description of the rule.

e. Add the following egress rule:

   f. Click Create Security List.

   The custom security list for the public subnet is then created and listed on the page.
8. Create a custom security list for the *private* subnet:
   a. Click **Create Security List**.
   b. Enter the following:
      - **Name**: Enter a friendly name for the list (for example, *Private Subnet Security List*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
   c. Add the following ingress rules:
      - Example: Ingress SQL*Net access from clients in the public subnet
         - **Type**: Ingress
         - **Stateless**: Unselected (this is a *stateful rule*)
         - **Source Type**: CIDR
         - **Source CIDR**: CIDR for the public subnet (172.16.2.0/24 in this example)
         - **IP Protocol**: TCP
         - **Source Port Range**: All
         - **Destination Port Range**: 1521
         - **Description**: An optional description of the rule.
      - Example: Ingress SQL*Net access from clients in the private subnet
         - **Type**: Ingress
         - **Stateless**: Unselected (this is a *stateful rule*)
         - **Source Type**: CIDR
         - **Source CIDR**: CIDR for the private subnet (172.16.2.1/24 in this example)
         - **IP Protocol**: TCP
         - **Source Port Range**: All
         - **Destination Port Range**: 1521
         - **Description**: An optional description of the rule.
   d. Add the following egress rules:
   e. Click **Create Security List**.
      - The custom security list for the private subnet is then created and listed on the page.

9. Create the subnets in the VCN:
   a. Under **Resources**, click **Subnets**.
   b. Click **Create Subnet**.
   c. Enter the following:
      - **Name**: A friendly name for the regional public subnet (for example, *Regional Private Subnet*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Regional or Availability Domain-Specific**: Select **Regional** (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any
Networking

availability domain in the region. For more information, see Overview of VCNs and Subnets on page 2822.

- **CIDR Block:** A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.1.0/24. You cannot change this value later. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see **IPv6 Addresses** on page 2889.
- **Route Table:** Select the Private Subnet Route Table you created earlier.
- **Private or public subnet:** Select **Private Subnet**, which means VNICs in the subnet are not allowed to have public IP addresses. For more information, see Access to the Internet on page 2752.
- **Use DNS Hostnames in this Subnet:** This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the **Internet and VCN Resolver**). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
- **DHCP Options:** Select the default set of DHCP options.
- **Security Lists:** Select two security lists: Both the default security list and the Private Subnet Security List you created earlier.

d. Click **Create Subnet**.

The private subnet is then created and displayed on the **Subnets** page.

e. Repeat the preceding steps a-d to create the **regional public subnet**. Instead use a name such as **Regional Public Subnet**, select **Public Subnet** instead of **Private Subnet**, use the Public Subnet Route Table, and use both the default security list and Public Subnet Security List you created earlier.

Example: Ingress RDP access required for Windows instances

- **Type:** Ingress
- **Stateless:** Unselected (this is a **stateful rule**)
- **Source Type:** CIDR
- **Source CIDR:** Your on-premises network (10.0.0.0/16 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 3389
- **Description:** An optional description of the rule.

Example: Egress SQL*Net access to Oracle databases

- **Type:** Egress
- **Stateless:** Unselected (this is a **stateful rule**)
- **Destination Type:** CIDR
- **Destination CIDR:** CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 1521
- **Description:** An optional description of the rule.

Example: Egress SQL*Net access to instances in the private subnet

- **Type:** Egress
- **Stateless:** Unselected (this is a **stateful rule**)
- **Destination Type:** CIDR
- **Destination CIDR:** CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
• **Destination Port Range:** 1521
• **Description:** An optional description of the rule.

**Task 2: Create instances in separate availability domains**

You can now create one or more instances in the subnet (see Launching an Instance). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

For each instance in the public subnet, make sure to assign the instance a public IP address. Otherwise, you won't be able to reach the instance from your on-premises network.

You can't yet reach the instances in the private subnet because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through creating an IPSec VPN connection to enable that communication.

**Task 3: Add an IPSec VPN to your VCN**

1. Create a customer-premises equipment object:
   
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
   
   b. Click **Create Customer-Premises Equipment**.
   
   c. Enter the following:
      
      - **Create in Compartment:** Leave the default value (the compartment you're currently working in).
      
      - **Name:** A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      
      - **IP Address:** The IP address of the on-premises router at your end of the VPN (see Prerequisites on page 2770).
   
   d. Click **Create**.

   The CPE object is in the "Provisioning" state for a short period.

2. Create a dynamic routing gateway (DRG):

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.

   b. Click **Create Dynamic Routing Gateway**.

   c. For **Create in Compartment:** Leave the default value (the compartment you're currently working in).

   d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

   e. Click **Create**.

   The DRG will be in the "Provisioning" state for a short period. Make sure it is done being provisioned before continuing.

3. Attach the DRG to your VCN:

   a. Click the DRG that you just created.

   b. Under **Resources**, click **Virtual Cloud Networks**.

   c. Click **Attach to Virtual Cloud Network**.

   d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called *transit routing*, which is not relevant here.

   e. Click **Attach**.

   The attachment will be in the "Attaching" state for a short period before it's ready.
4. Update the private subnet's route table (which already has one rule for the NAT gateway):
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   b. Click your VCN.
   c. Click Route Tables, and then click the Private Subnet Route Table you created earlier.
   d. Click Add Route Rule.
   e. Enter the following:
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
      - **Description**: An optional description of the rule.
   f. Click Add Route Rule.
      The table is updated to route any traffic destined for your on-premises network to the DRG. The original rule for 0.0.0.0/0 routes any remaining traffic leaving the subnet to the NAT gateway.

5. Create an IPSec Connection:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
   b. Click Create IPSec Connection.
   c. Enter the following:
      - **Create in Compartment**: Leave the default value (the compartment you're currently working in).
      - **Name**: Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
      - **Customer-Premises Equipment Compartment**: Leave as is (the VCN's compartment).
      - **Customer-Premises Equipment**: Select the CPE object you created earlier.
      - **Dynamic Routing Gateway Compartment**: Leave as is (the VCN's compartment).
      - **Dynamic Routing Gateway**: Select the DRG that you created earlier.
      - **Static Route CIDR**: Enter at least one static route CIDR (see Prerequisites on page 2770). If you need to add another, click Add Static Route. You can enter up to 10 static routes, and you can change the static routes later if you like.
   d. Click Show Advanced Options and optionally provide the following items:
      - **CPE IKE Identifier**: Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
      - **Tunnel 1** and **Tunnel 2**: Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing on page 3160.
      - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
   e. Click Create IPSec Connection.
      The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
      The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click View Shared Secret.
   f. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the on-premises router.
      For more information, see CPE Configuration on page 2967. You can view this tunnel information here in the Console at any time.
You have now created all the components required for the IPSec VPN. But your network administrator must configure the on-premises router before network traffic can flow between your on-premises network and VCN.

**Task 4: Configure your on-premises router (CPE)**

These instructions are for the network administrator.

1. Make sure you have the tunnel configuration information that Oracle provided during VPN setup. See Task 3: Add an IPSec VPN to your VCN on page 2777.
2. Configure your on-premises router according to the information in CPE Configuration on page 2967.

If there are already instances in one of the subnets, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network. To connect to instances in the public subnet, you must connect to the instance’s public IP address.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations:

1. **CreateVcn**: Make sure to include a DNS label if you want the VCN to use the VCN Resolver (see DNS in Your Virtual Cloud Network on page 2910).
2. **CreateInternetGateway**
3. **CreateNatGateway**
4. **CreateRouteTable**: Call it to create the Public Subnet Route Table. To enable communication by way of the internet gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway you created earlier.
5. **CreateRouteTable**: Call it again to create the Private Subnet Route Table. To enable communication by way of the NAT gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the NAT gateway you created earlier.
6. First call **GetSecurityList** to get the default security list, and then call **UpdateSecurityList**:
   - Change the existing stateful ingress rules to use your on-premises network’s CIDR as the source CIDR, instead of 0.0.0.0/0.
   - If you plan to launch Windows instances, add this stateful ingress rule: Source type = CIDR, source CIDR = your on-premises network on TCP, source port = all, destination port = 3389 (for RDP).
7. **CreateSecurityList**: Call it to create the Public Subnet Security List with these rules:
   - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 80 (HTTP)
   - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 443 (HTTPS)
   - Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
8. **CreateSecurityList**: Call it again to create the Private Subnet Security List with these rules:
   - Stateful ingress: Source type = CIDR, source CIDR blocks of public subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
   - Stateful ingress: Source type = CIDR, source CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
   - Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
9. **CreateSubnet**: Call it to create regional public subnet. Include a DNS label for the subnet if you want the VCN Resolver to resolve hostnames for VNICs in the subnet. Use the Public Subnet Route Table you created earlier. Use both the default security list and the Public Subnet Security List that you created earlier. Use the default set of DHCP options.
10. **CreateSubnet**: Call it again to create regional private subnet. Include a DNS label for the subnet if you want the VCN Resolver to resolve hostnames for VNICs in the subnet. Use the Private Subnet Route Table you created
11. **CreateDrg**: This creates a new dynamic routing gateway (DRG).

12. **CreateDrgAttachment**: This attaches the DRG to the VCN.

13. **CreateCpe**: Here you provide the IP address of the router at your end of the VPN (see Prerequisites on page 2770).

14. **CreateIPSecConnection**: Here you provide the static routes for your on-premises network (see Prerequisites on page 2770). In return, you receive the configuration information your network administrator needs in order to configure your router. If you need that information later, you can get it with `GetIPSecConnectionDeviceConfig`. For more information about the configuration, see CPE Configuration on page 2967.

15. First call `GetRouteTable` to get the Private Subnet Route Table. Then call `UpdateRouteTable` to add a route rule with destination = the on-premises network CIDR (10.0.0.0/16 in this example), and destination target = the DRG you created earlier.

16. **LaunchInstance**: Launch at least one instance in each subnet. By default, the instances in the public subnets are assigned public IP addresses. For more information, see Creating an Instance on page 695.

You can now communicate from your on-premises network with the instances in the public subnet over the internet gateway.

---

**Important:**

Although you can launch instances into the private subnets, you can't communicate with them from your on-premises network until your network administrator configures your on-premises router (see CPE Configuration on page 2967). After that, your IPSec connection should be up and running. You can confirm its status by using `GetIPSecConnectionDeviceStatus`. You can also confirm the IPSec connection is up by connecting to the instances from your on-premises network.

---

**Transit Routing: Access to Multiple VCNs in the Same Region**

Transit routing refers to a network topology in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with FastConnect or VPN Connect, and then configure the VCN routing so that traffic transits through the VCN to its destination beyond the VCN.

There are two primary transit routing scenarios:

- **Access to multiple VCNs in the same region**: The scenario covered in this topic. This scenario enables communication between your on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect.
- **Private access to Oracle services**: This scenario gives your on-premises network private access to Oracle services, so that your on-premises hosts can use their private IP addresses and the traffic does not go over the internet. See Transit Routing: Private Access to Oracle Services on page 2803.

**Highlights**

- You can use a single FastConnect or IPSec VPN to connect your on-premises network with multiple VCNs in the same region, in a hub-and-spoke topology.
- The VCNs must be in the same region but can be in different tenancies. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.
- The VCN that acts as the hub uses a dynamic routing gateway (DRG) to communicate with the on-premises network. This hub VCN peers with each VCN that is acting as a spoke (referred to as spoke VCNs in this topic). The hub and spoke VCNs use local peering gateways (LPGs) to communicate.
- To enable the desired traffic from the on-premises network through the hub VCN to a peered spoke VCN, you implement route rules for the hub VCN’s DRG attachment and LPG, and for the spoke VCN’s subnets.
- If you like, you can set up transit routing through a private IP in the hub VCN. For example, you might want to filter or inspect the traffic between the on-premises network and a spoke VCN. In that case, you route the traffic...
Networking

to a private IP on an instance in the hub VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the hub VCN, and transit routing through a private IP.

- By configuring route tables that reside in the hub VCN, you can control whether a particular subnet in a peered spoke VCN is advertised to the on-premises network, and whether a particular subnet in the on-premises network is advertised to a peered spoke VCN.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tip: There's another scenario that lets you connect your on-premises network to multiple VCNs. Instead of using a single DRG and hub-and-spoke topology, you set up a separate DRG for each VCN and a separate private virtual circuit over a single FastConnect. However, the scenario can be used only with FastConnect through a third-party provider or through colocated with Oracle. The VCNs must be in the same region and same tenancy. For more information, see FastConnect with Multiple DRGs and VCNs on page 2816.</td>
</tr>
</tbody>
</table>

Overview of Transit Routing

A basic networking scenario involves connecting your on-premises network to a VCN with either Oracle Cloud Infrastructure FastConnect or an IPSec VPN. These two basic scenarios illustrate that topology: Scenario B: Private Subnet with a VPN on page 2761 and Scenario C: Public and Private Subnets with a VPN on page 2769.

There's an advanced networking scenario that lets you use your single FastConnect or IPSec VPN to communicate with multiple VCNs from your on-premises network. The VCNs must be in the same region but can be in different tenancies.

Here's a basic example of why you might use transit routing: you have a large organization with different departments, each with their own VCN. Your on-premises network needs access to the different VCNs, but you don't want the administration overhead of maintaining a secure connection from each VCN to the on-premises network. Instead you want to use a single FastConnect or IPSec VPN.

The scenario uses a hub-and-spoke topology, as illustrated in the following diagram. The term hub VCN here means only that a VCN is acting as the hub in this hub-and-spoke design.
One of the VCNs acts as the hub (VCN-H) and connects to your on-premises network by way of FastConnect or an IPSec VPN. The other VCNs are locally peered with the hub VCN. The traffic between the on-premises network and the peered VCNs transits through the hub VCN. The VCNs must be in the same region but can be in different tenancies.

**Gateways Involved in Transit Routing**

The next diagram shows the gateways on the VCNs. The hub VCN has a dynamic routing gateway (DRG), which is the communication path with the on-premises network. For each locally peered spoke VCN, there’s a pair of local peering gateways (LPGs) that anchor the peering connection. One LPG is on the hub VCN, and the other is on the spoke VCN.
Networking

Transit Routing Through a Private IP in the Hub VCN

If you want, you can route all the traffic through a private IP on an instance in the hub VCN. For example, you could set up a firewall or intrusion detection system on the instance in the hub VCN to filter or inspect the traffic between the on-premises network and spoke VCNs. Then you would configure the hub VCN’s routing so that the transit traffic is routed to a private IP on that instance. You must disable the source/destination check for the private IP’s VNIC. The resulting traffic would then travel on to its destination in either the spoke VCN or on-premises network. The following diagram illustrates the idea. Regardless of whether you choose to route through a private IP or not, the same gateways are required. However, you configure the hub VCN’s routing a little differently.
If you're already familiar with the Networking service and local VCN peering, these are the most important new concepts to understand:

- For each spoke VCN subnet that needs to communicate with the on-premises network, you must update the subnet's route table with a rule that sets the target (the next hop) as the spoke VCN's LPG for all traffic destined for the on-premises network.

- You must add a route table to the hub VCN, associate it with the DRG attachment, and add a route rule with a target that depends on your situation:
  - **Transit routing directly through gateways:** Set the target (the next hop) to the hub VCN's LPG (for that spoke) for all traffic destined for that spoke VCN (or a specific subnet in that VCN).
  - **Transit routing through a private IP:** Set the target (the next hop) to a private IP on the instance, for all traffic destined for that spoke VCN (or a specific subnet in that VCN). Make sure to disable the source/destination check for the private IP's VNIC.

---

**Legend:**
- **dynamic routing gateway (DRG)**
- **local peering gateway (LPG)**
- **instance with private IPs**

**Summary of New Concepts for Experienced Networking Service Users**

If you're already familiar with the Networking service and local VCN peering, these are the most important new concepts to understand:

- For each spoke VCN subnet that needs to communicate with the on-premises network, you must update the subnet's route table with a rule that sets the target (the next hop) as the spoke VCN's LPG for all traffic destined for the on-premises network.

- You must add a route table to the hub VCN, associate it with the DRG attachment, and add a route rule with a target that depends on your situation:
  - **Transit routing directly through gateways:** Set the target (the next hop) to the hub VCN's LPG (for that spoke) for all traffic destined for that spoke VCN (or a specific subnet in that VCN).
  - **Transit routing through a private IP:** Set the target (the next hop) to a private IP on the instance, for all traffic destined for that spoke VCN (or a specific subnet in that VCN). Make sure to disable the source/destination check for the private IP's VNIC.
• You must add another route table to the hub VCN, associate it with the hub VCN's LPG (for that spoke), and add a route rule with a target that depends on your situation:

  • **Transit routing directly through gateways:** Set the target (the next hop) as the DRG for all traffic destined for the on-premises network (or a specific subnet in that network).

  • **Transit routing through a private IP:** Set the target (the next hop) to another private IP on that instance, for all traffic destined for the on-premises network (or a specific subnet in that network). Again, make sure to disable the source/destination check for the private IP's VNIC. In the example presented here, the private IP is on a secondary VNIC on the instance, in a different subnet. In the subsequent diagrams, the subnets are referred to as the frontend subnet and backend subnet.

For transit routing directly through gateways, see these specific tasks for more information:

• For routing directly between gateways on page 2791

• Task 6: Set up ingress routing for the DRG and LPG on the hub VCN on page 2794

For transit routing through a private IP: see these specific tasks for more information:

• Task 5: Add a route rule to the spoke VCN's subnet on page 2793

• Task 6: Set up the private IPs on an instance in the hub VCN on page 2799

• Task 7: Set up ingress routing for the DRG and LPG on the hub VCN on page 2800

**Example: Components and Routing for a Hub and Single Spoke**

The examples in this section show a VCN acting as a hub and only a single spoke VCN for simplicity.

---

**Note:**

In a hub-and-spoke model, the hub VCN can have multiple spokes and therefore multiple LPGs (one per spoke). This topic uses the phrase the hub VCN's LPG, which could therefore be ambiguous. When the phrase is used here, it means the hub LPG for the particular spoke of interest. In the following diagrams, it's LPG-H-1. Additional spokes would involve creation of an LPG-H-2, LPG-H-3, and so on.

---

**For transit routing directly through gateways**

The following diagram shows the required Networking service route tables and route rules for transit routing directly through gateways. Although the hub VCN does not require a subnet to make transit routing work, the example presented here includes a subnet called Subnet-H.
The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send that traffic to LPG-H-1.

- **LPG-H-1:**
  - This route table belongs to the hub VCN and is associated with LPG-H-1.
  - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the DRG.

- **Subnet-H:**
  - This route table belongs to the hub VCN and is associated with Subnet-H.
  - This route table has a rule to route traffic that is destined for the on-premises network to the DRG. It has another rule to route traffic that is destined for the spoke VCN to LPG-H-1.

- **Subnet-1:**
  - This route table belongs to the spoke VCN and is associated with Subnet-1.
  - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

**For transit routing through a private IP**

The following diagram shows the required Networking service route tables and route rules for transit routing through a private IP on an instance in the hub VCN. You can choose to implement this scenario with either a single VNIC or multiple VNICs. The diagram and example here shows two VNICs: one in a subnet called Subnet-H-Frontend, and another in a subnet called Subnet-H-Backend. The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.
The diagram shows five route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send the traffic to the private IP in the frontend subnet.

- **LPG-H-1:**
  - This route table belongs to the hub VCN and is associated with LPG-H-1.
  - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.

- **Subnet-H-Frontend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Frontend.
  - This route table has a rule to route traffic that is destined for the on-premises network to the DRG.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. The second rule is shown here to give a more complete picture of routing for this example.

- **Subnet-H-Backend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Backend.
  - This route table has a rule to route traffic that is destined for the spoke VCN (VCN-1) to LPG-H-1.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic that is destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The second rule is shown here to give a more complete picture of routing for this example.

- **Subnet-1:**
  - This route table belongs to the spoke VCN and is associated with Subnet-1.
  - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

**Important Transit Routing Restrictions to Understand**

This section includes some additional important details about routing:
- **Route table for the DRG attachment:**
  - A route table that is associated with a DRG attachment can have only rules that target an LPG or a private IP.
  - A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

- **Route table for an LPG:**
  - A route table that is associated with an LPG can have only rules that target a DRG or a private IP.
  - An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

- **Traffic through the hub VCN:** The route tables discussed here are intended only for moving traffic through the hub VCN between locations in the on-premises network and locations in the spoke VCN. If you're using a private IP in the hub, you configure those route tables so that the private IP is placed in that traffic path going through the hub.

- **Inbound traffic to the hub VCN:** Even though the preceding statement is true (about traffic through the hub), inbound traffic to subnets within the hub VCN is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or hub LPG's route table. When this kind of inbound traffic reaches the DRG or the hub LPG, the traffic is automatically routed to its destination in the hub VCN by the VCN local routing. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a sub-section) as the rule's destination.

- **Hub VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you should use the hub VCN only for transit between the on-premises network and spoke VCNs. Do not set up workloads in the hub VCN itself. More explicitly, if you set up transit routing through a private IP in the hub VCN, you can't also route the hub VCN's traffic through that private IP. For example, in the preceding diagram, if you were to change the route rule in the LPG-H-1 route table so that the destination CIDR is 0.0.0.0/0 instead of 172.16.0.0/12, only traffic coming from VCN-1 and destined for addresses outside the hub VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the LPG-H-1 route table (in general, over any of the VCN's route tables).

**About CIDR Overlap**

In this example, the various networks do not have overlapping CIDR blocks (172.16.0.0/12 versus 10.0.0.0/16 versus 192.168.0.0/16). The Networking service does not allow local VCN peering between two VCNs with overlapping CIDRs. That means each spoke must not overlap with the hub.

However, the Networking service does not validate whether the spoke VCNs themselves overlap with each other, or if any of the VCNs overlap with the on-premises network. You must ensure that CIDRs for all the subnets that need to communicate with each other don't overlap. Otherwise, traffic may be dropped.

A Networking service route table cannot contain two rules with the exact same destination CIDR. However, if two rules in the same route table have overlapping destination CIDRs, the most specific rule in the table is used to route the traffic (that is, the rule with the longest prefix match).

**Route Advertisement to the On-Premises Network and Spoke VCNs**

From a security standpoint, you can control route advertisement so that only specific subnets in the on-premises network are advertised to the spoke VCNs. Similarly, you can control which subnets in the spoke VCNs are advertised to the on-premises network.

The routes advertised to the on-premises network consist of:
- The rules listed in the route table associated with the DRG attachment (192.168.0.0/16 in the preceding diagram)
- The individual subnets in the hub VCN

The routes advertised to the spoke VCN consist of:
- The individual subnets in the hub VCN
Networking

- The rules listed in the route table associated with the hub VCN’s LPG for the spoke (172.16.0.0/12 in the preceding diagram)

Therefore, the administrator of the hub VCN alone can control which routes are advertised to the on-premises network and spoke VCNs.

In the preceding example, the relevant routes use the full CIDR block of the on-premises network and spoke VCN as the destination (172.16.0.0/12 and 192.168.0.0/16, respectively), but they could instead use a subnet of those networks to restrict routing to specific subnets.

*Details About Routing for Different Traffic Paths*

To further illustrate how routing takes place in the preceding example, let’s look more closely at different paths of traffic. Here are the same diagrams again.

First, if you are transit routing directly through gateways on the hub VCN:

Second, if you are transit routing through a private IP in the hub VCN:
Traffic from the on-premises network to the spoke VCN

1. Traffic leaves the on-premises network and reaches the DRG. The traffic's destination is in Subnet-1 (for example, 192.168.0.5).

2. The DRG attachment's associated route table has a rule for 192.168.0.0/16. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways**: The rule's target is LPG-H-1.
   - **Transit routing through a private IP**: The rule's target is the private IP 10.0.4.3. The instance receives and processes the traffic and sends any resulting traffic out of the backend subnet's VNIC. The backend subnet's route table sends that traffic to LPG-H-1.

Remember that you can use the rules in the DRG attachment's route table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a subnet of the spoke VCN.

3. LPG-H-1 receives the traffic.

4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.

5. LPG-1 receives the traffic.

6. Traffic coming in to a VCN through the LPG is automatically routed to the destination within the VCN because of VCN local routing. No explicit route rules are required.

Traffic from the spoke VCN to the on-premises network

1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in the on-premises network (for example, 172.16.0.3).

2. Subnet-1's associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target, LPG-1.

3. LPG-1 receives the traffic.

4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.

5. LPG-H-1 receives the traffic.

6. LPG-H-1's associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways**: The rule's target is the DRG.
   - **Transit routing through a private IP**: The rule's target is the private IP 10.0.8.3. The instance receives and processes the traffic and sends any resulting traffic out of the frontend subnet's VNIC. The frontend subnet's route table sends that to the DRG.

Remember that you can use the rules in the LPG's route table to control which subnets in the on-premises network are advertised to the spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network.

7. The DRG receives the traffic.

8. Egress traffic leaving the VCN through the DRG is routed based on the IPSec VPN and FastConnect configuration. No explicit rules in the DRG attachment's route table are required.

Notice that Subnet-1 in the spoke VCN and LPG-H-1 both have route rules with 172.16.0.0/12 as the destination CIDR. Those rules don't have to use the exact same CIDR block. However, make sure both rules cover the traffic you want to route from the spoke to the on-premises network. The rule in Subnet-1's route table controls which traffic is routed from Subnet-1 to LPG-H-1. The rule in LPG-H-1's route table controls which traffic is routed from the spoke VCN to the on-premises network. If LPG-H-1's route rule is more restrictive than Subnet-1's route rule, some traffic leaving the subnet could ultimately be dropped and not reach the DRG.

Traffic from the spoke VCN to a subnet in the hub VCN (routing directly between gateways only)

Depending on your situation, you might want to enable traffic between instances in the hub VCN and a spoke VCN, and not just traffic between the on-premises network and a spoke VCN. You can do this if you're routing...
directly between gateways. **You can't route the traffic from a spoke VCN through the private IP and on to other instances in the hub VCN.** The note at the end of this section explains why.

Here's how traffic would flow from the spoke VCN to a destination with an address in the hub VCN:

1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in a subnet in the hub VCN (for example, 10.0.0.3).
2. Subnet-1's associated route table has a rule for 10.0.0.0/16. It matches the destination and sends the traffic to the route target, LPG-1.
3. LPG-1 receives the traffic.
4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.
5. LPG-H-1 receives the traffic.
6. Traffic coming in to a VCN through an LPG and destined for an address in the VCN is automatically routed to the destination by VCN local routing. No explicit route rules are required.

A similar series of routing steps occurs for traffic going from Subnet-H to Subnet-1, but in the reverse direction. Subnet-H's route table has a rule that matches the spoke VCN's CIDR (192.168.0.0/16) and sends the traffic to LPG-H-1, which forwards it on to LPG-1.

**Note:**

If you set up transit routing through a private IP in the hub VCN, remember that the LPG-H-1 route table only controls routing of traffic that is destined for addresses *outside the hub VCN*. Traffic destined for addresses within the VCN is instead handled by the hub VCN local routing, which takes precedence and always routes the traffic directly to the packet's destination address. This means that you cannot route traffic that is destined for addresses inside the hub VCN *through the private IP* that is being used for the transit traffic through the hub. Even if the LPG-H-1 route rule uses a destination = 0.0.0.0/0 and target = 10.0.8.3, the hub VCN local routing takes precedence and routes the traffic directly to the destination in the hub VCN instead of the private IP.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

If you’re a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See *IAM Policies for Networking* on page 2832.

**Setting Up VCN Transit Routing in the Console**

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network access to multiple VCNs in the same region.

*For routing directly between gateways*

**Tip:**

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network topology with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Task 5 and Task 6 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.
Networking

Task 1: Set up the hub VCN

In this task, you set up the hub VCN. A subnet in the hub VCN is optional. However, this example includes one. The subnet can contain cloud resources that your on-premises network or the spoke VCN need to use.

For more information and instructions:
- VCNs and Subnets on page 2821

Task 2: Connect the hub VCN with your on-premises network

In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step. For more information and instructions:
- FastConnect on page 3173
- VPN Connect on page 2932
- Dynamic Routing Gateways (DRGs) on page 2927

Task 3: Set up a spoke VCN with at least one subnet
In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- [VCNs and Subnets](#) on page 2821

Task 4: Set up a local peering between the hub VCN and the spoke VCN

In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.

**Important:**

When setting up local peering between two VCNs, make sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not yet create the route table that will be associated with the LPG on the hub VCN (LPG-H-1). That comes in a later step. For more information and instructions:

- [Setting Up a Local Peering](#) on page 3271

Task 5: Add a route rule to the spoke VCN's subnet
Networking

In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram). Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      • **Target Type**: Local Peering Gateway.
      • **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • **Compartment**: The compartment where the spoke VCN's LPG is located.
      • **Target Local Peering Gateway**: The spoke VCN's LPG.
      • **Description**: An optional description of the rule.
   c. Click Add Route Rules.

Task 6: Set up ingress routing for the DRG and LPG on the hub VCN
In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

Prerequisites:

• You already have a DRG attached to the hub VCN.
• You already have a hub VCN LPG for the spoke of interest.

1. Create a route table for the DRG attachment:
   a. In the Console, view the hub VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      • Name: A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
      • Create in Compartment: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Local Peering Gateway.
      • Destination CIDR Block: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that the on-premises network.
      • Compartment: The compartment where the hub VCN's LPG is located.
      • Target: The hub VCN's LPG.
      • Description: An optional description of the rule.
   f. Click Create Route Table.

   The route table is created and displayed in the list.
2. Associate the route table (called DRG Route Table in this example) with the hub VCN's DRG attachment:
   a. While still viewing the hub VCN's details, click Dynamic Routing Gateways to view the attached DRG.
   b. Click the Actions icon (three dots), and then click Associate Route Table.
   c. Select the route table.
   d. Click Associate Route Table.
      The route table is associated with the DRG attachment.
3. Create a route table for the hub VCN's LPG for this spoke:
   a. While still viewing the hub VCN's details, click Route Tables.
   b. Click Create Route Table.
   c. Enter the following:
      • Create in Compartment: Leave as is.
      • Name: A descriptive name for the route table. Example: Hub LPG-# Route Table (where # indicates which spoke). Avoid entering confidential information.
   d. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example). Remember that you can use the routes in this table to control which subnets in the on-premises network are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network that needs to communicate with this spoke.
      • Description: An optional description of the rule.
   e. Click Create Route Table.
      The route table is created and displayed in the list.
4. Associate the route table (called Hub LPG-# Route Table in this example) with the hub VCN's LPG for the spoke of interest:
   a. While still viewing the hub VCN's details, click Local Peering Gateways to view the hub VCN's LPG for this spoke.
   b. For the LPG you're interested in, click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the LPG.
      • Route Table: Select the route table for the LPG.
   d. Click Associate.
      The route table is associated with the LPG.

Later if you need more spoke VCNs

1. Repeat Tasks 3-5 for the new spoke VCN.
2. Repeat Task 6 with these changes:
   • For Step 1: Instead of creating a new route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the hub VCN's LPG for the new spoke.
   • For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
   • For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, Hub LPG-2 Route Table for the second spoke).
   • For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.
For routing through a private IP

Tip:
You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network topology with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Tasks 5 through 7 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the hub VCN

In this task, you set up the hub VCN. The hub VCN must have two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional *private* subnets, unless there will be resources in the frontend subnet that need internet access.

For more information and instructions:
- VCNs and Subnets on page 2821

Task 2: Connect the hub VCN with your on-premises network

In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step. For more information and instructions:
- FastConnect on page 3173
- VPN Connect on page 2932
- Dynamic Routing Gateways (DRGs) on page 2927

Task 3: Set up a spoke VCN with at least one subnet
In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- **VCNs and Subnets** on page 2821

Task 4: Set up a local peering between the hub VCN and the spoke VCN

In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.

**Important:**

When setting up local peering between two VCNs, make sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not yet create the route table that will be associated with the LPG on the hub VCN (LPG-H-1). That comes in a later step. For more information and instructions:

- **Setting Up a Local Peering** on page 3271

Task 5: Add a route rule to the spoke VCN's subnet
In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram). Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      - **Target Type**: Local Peering Gateway.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      - **Compartment**: The compartment where the spoke VCN's LPG is located.
      - **Target Local Peering Gateway**: The spoke VCN's LPG.
      - **Description**: An optional description of the rule.
   c. Click Add Route Rules.

Task 6: Set up the private IPs on an instance in the hub VCN

In this task, you set up the instance to have 2 private IPs.

Prerequisites:
- You already have a hub VCN with a subnet.
- Review this information: Using a Private IP as a Route Target on page 2924.

1. If you haven't already, create the instance in the hub VCN. See Creating an Instance on page 695. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See Using the Console on page 2858.
3. Disable the source/destination check on each of the VNICs. See Overview of VNICs and Physical NICs on page 2856.

4. For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC's primary private IP, assign that secondary private IP and configure the OS to use it. See Using the Console on page 2866.

5. For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).

6. Configure the instance as necessary for the job it will perform (for example, configure the firewall or intrusion detection system on the instance).

**Task 7: Set up ingress routing for the DRG and LPG on the hub VCN**

In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

**Prerequisites:**
- You already have a DRG attached to the hub VCN.
- You already have a hub VCN LPG for the spoke of interest.
- You already have the two private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
   a. In the Console, view the hub VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      - **Name:** A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
      - **Create in Compartment:** Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      - **Target Type:** Private IP.
      - **Destination CIDR Block:** This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-
Networking

premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that the on-premises network.

- **Compartment**: The compartment where the frontend subnet's private IP is located.
- **Target**: The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
- **Description**: An optional description of the rule.

f. Click **Create Route Table**.

The route table is created and displayed in the list.

2. Associate the route table (called **DRG Route Table** in this example) with the hub VCN's DRG attachment:

a. While still viewing the hub VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.

b. Click the Actions icon (three dots), and then click **Associate With Route Table**.

c. Enter the following:

- **Route Table Compartment**: Select the compartment of the route table for the DRG attachment.
- **Route Table**: Select the route table for the DRG attachment.

d. Click **Associate**.

The route table is associated with the DRG attachment.

3. Create a route table for the hub VCN's LPG for this spoke:

a. While still viewing the hub VCN's details, click **Route Tables**.

b. Click **Create Route Table**.

c. Enter the following:

- **Create in Compartment**: Leave as is.
- **Name**: A descriptive name for the route table. Example: Hub LPG-# Route Table (where # indicates which spoke). Avoid entering confidential information.

d. Click **+ Additional Route Rule**, and enter this information for the route rule:

- **Target Type**: Private IP.
- **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example). Remember that you can use the routes in this table to control which subnets in the on-premises network are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network that needs to communicate with this spoke.
- **Compartment**: The compartment where the private IP is located.
- **Target**: The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
- **Description**: An optional description of the rule.

e. Click **Create Route Table**.

The route table is created and displayed in the list.

4. Associate the route table (called **Hub LPG-# Route Table** in this example) with the hub VCN's LPG for the spoke of interest:

a. While still viewing the hub VCN's details, click **Local Peering Gateways** to view the hub VCN's LPG for this spoke.

b. For the LPG you're interested in, click the Actions icon (three dots), and then click **Associate With Route Table**.

c. Enter the following:

- **Route Table Compartment**: Select the compartment of the route table for the LPG.
- **Route Table**: Select the route table for the LPG.

d. Click **Associate**.

The route table is associated with the LPG.
Although Oracle does not recommend putting workloads in the hub VCN's subnets, to give you a more complete picture of routing in the example, the diagram shows two additional route rules in the hub VCN's subnet route tables. For the frontend subnet, there's a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. For the backend subnet, there's a route rule to route traffic that is destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The following procedure adds those two route rules.

1. For the spoke VCN, view the list of subnets.
2. For the frontend subnet, look at its details and click the link for its associated route table.
3. Edit the frontend subnet's route table to include a rule that sends traffic destined for the spoke VCN to the private IP in the frontend subnet:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      - **Target Type**: Private IP.
      - **Destination CIDR Block**: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example).
      - **Compartment**: The compartment where the frontend subnet's private IP is located.
      - **Target**: The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
      - **Description**: An optional description of the rule.
   c. Click Add Route Rules.
4. For the backend subnet, look at its details and click the link for its associated route table.
5. Edit the backend subnet's route table to include a rule that sends traffic destined for the on-premises network to the private IP in the backend subnet:
   a. Click Add Route Rules.
   b. Enter this information for the route rule:
      - **Target Type**: Private IP.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      - **Compartment**: The compartment where the backend subnet's private IP is located.
      - **Target**: The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
      - **Description**: An optional description of the rule.
   c. Click Add Route Rules.

Later if you need more spoke VCNs

1. Repeat Tasks 3-5 for the new spoke VCN.
2. Repeat task 7 with these changes:
   - For Step 1: Instead of creating a new route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the frontend subnet private IP 10.0.4.3.
   - For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
   - For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, Hub LPG-2 Route Table for the second spoke).
   - For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.

**Turning Off Transit Routing**

To turn off transit routing, remove the rules from:

- The route table associated with the DRG attachment.
- The route table associated with each LPG on the hub VCN.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.
A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table’s rules, or delete some or all of the rules.

Changes to the API

For information about changes to the Networking service API to support transit routing, see the transit routing release notes.

Transit Routing: Private Access to Oracle Services

*Transit routing* refers to a network topology in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with FastConnect or VPN Connect, and then configure the VCN routing so that traffic *transits through the VCN* to its destination beyond the VCN.

There are two primary transit routing scenarios:

- **Private access to Oracle services:** The scenario covered in this topic. This scenario gives your on-premises network private access to Oracle services, so that your on-premises hosts can use their private IP addresses and the traffic does not go over the public internet. Instead, the traffic travels over a FastConnect private virtual circuit or VPN Connect, transits through a virtual cloud network (VCN), and then through a *service gateway* to the Oracle service of interest.

- **Access to multiple VCNs in the same region:** This scenario enables communication between an on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. See Transit Routing: Access to Multiple VCNs in the Same Region on page 2780.

Highlights

- You can set up a VCN so that your on-premises network has private access to Oracle services in the Oracle Services Network by way of the VCN. The hosts in your on-premises network communicate with their private IP addresses.

- The VCN uses a *dynamic routing gateway* (DRG) to communicate with the on-premises network. Access to Oracle services is through a *service gateway* on the VCN. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the public internet.

- The service gateway is regional and enables access only to supported Oracle services *in the same region* as the VCN.

- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.

- The service gateway uses the concept of a *service CIDR label*, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, *OCI PHX Object Storage* is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service’s public IP addresses change in the future, you don’t have to adjust those rules.

- To enable the desired traffic from the on-premises network through the VCN to Oracle services, you implement route rules for the VCN’s DRG attachment and service gateway.

- If you want, you can set up transit routing through a private IP in the VCN. For example, you might want to filter or inspect the traffic between the on-premises network and the Oracle service. In that case, you route the traffic to a private IP on an instance in the VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the VCN, and transit routing through a private IP.

Overview of the Oracle Services Network

The Oracle Services Network is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the public internet. However, you can access the Oracle Services Network *without the traffic going over the public internet*. There are different ways, depending on which of your hosts need the access:
• **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or VPN Connect: This is the scenario covered in this topic. The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the VCN’s service gateway.
  - **Public access with FastConnect public peering:** The on-premises hosts use public IP addresses.

• **Hosts in your VCN:**
  - Private access through a service gateway: The VCN’s hosts use private IP addresses.

**Overview of On-Premises Network Private Access to Oracle Services**

The following diagram illustrates the basic layout for giving your on-premises network private access to Oracle services.

![Diagram](image_url)

**Legend:**
- □ dynamic routing gateway (DRG)
- ◊ service gateway

Your on-premises network connects to the VCN by way of a FastConnect private virtual circuit or VPN Connect on page 2932. Each of these types of connections terminates on a dynamic routing gateway (DRG) that is attached to the VCN. The VCN also has a service gateway, which gives the VCN access to the Oracle Services Network. The traffic from your on-premises network transits through the VCN, through the service gateway, and to the Oracle service of interest. The responses return through the service gateway and VCN to your on-premises network.

When you set up a service gateway, you enable a *service CIDR label*, which is a string that represents all the regional public IP address ranges for the service or group of services that you want to access through the service gateway. For example, *All PHX Services in Oracle Services Network* is the service CIDR label for the Oracle services available in US West (Phoenix) through a service gateway. Oracle uses Border Gateway Protocol (BGP) on the DRG to advertise those regional public IP address ranges to the edge device (also called the customer-premises equipment or CPE) in your on-premises network. For a list of those ranges available through the service gateway, see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

**Multiple Connection Paths to Oracle Services**

You can configure your on-premises network with multiple connection paths to Oracle Cloud Infrastructure and Oracle services for redundancy or other reasons. For example, you could use both FastConnect public peering and FastConnect private peering. If you have multiple paths, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network on page 2942.

**Multiple VCNs with Private Access to Oracle Services**

Your organization might choose to use multiple VCNs, each with a service gateway to give the VCN's resources access to Oracle services. For example, you might have a different VCN for each department in your organization.

If you *also* want to set up your on-premises network with private access to Oracle services through a VCN with a service gateway, this section describes two different network layouts you could use.
In the first layout, you set up a single DRG, with the VCNs in a hub-and-spoke layout as shown in the next diagram. The VCN that acts as the hub is dedicated to providing the on-premises network with private access to Oracle services. The other VCNs are locally peered with the hub VCN. You configure only the hub VCN according to instructions in Setting Up Private Access to Oracle Services on page 2809. This hub-and-spoke layout is recommended and described further in Transit Routing: Access to Multiple VCNs in the Same Region on page 2780.

In the second layout, there’s a separate DRG for each VCN, with a separate FastConnect private virtual circuit or VPN Connect from your on-premises network to each DRG. You dedicate one DRG and VCN to providing your on-premises network with private access to Oracle services. In the next diagram, it’s the VCN in the center. To configure that VCN, follow the instructions in Setting Up Private Access to Oracle Services on page 2809.

Notice that in both of these layouts, the on-premises network can reach the Oracle services only through a single VCN’s service gateway (the one dedicated for this purpose) and not through the service gateways of the other VCNs. For those other VCNs, only the resources inside those VCNs can reach Oracle services through their VCN’s service gateway.

Regardless of which layout you choose, you can write an IAM policy to restrict access to an Object Storage bucket so that only requests that come through a specific VCN’s service gateway are allowed for that bucket. With either of these layouts, you might want to write the policy to allow requests from multiple VCNs. To restrict access to specific
Networking

VCNs, create a network source to specify the allowed VCN, and then write the policy restricting access to only the network source. One network source can specify multiple VCNs or you can create one network source for each VCN. For information on creating networks sources, see Managing Network Sources on page 2427.

The following example policy assumes you set up one network source for each of your VCNs. The policy lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a compartment called ABC. When writing a policy like this one, you can specify one or more network sources. This example shows three.

Allow group ObjectBackup to read buckets in compartment ABC
Allow group ObjectBackup to manage objects in compartment ABC where
   all {target.bucket.name='db-backup',
       any {request.networkSource.name='<hub_VCN_network_source>',
            request.networkSource.name='<spoke_1_VCN_network_source>',
            request.networkSource.name='<spoke_2_VCN_network_source>'},
       any {request.permission='OBJECT_CREATE',
            request.permission='OBJECT_INSPECT'}

For more information, see Setting Up a Service Gateway in the Console on page 3260 in the procedure for setting up a service gateway.

Requests from Oracle Services to Your Clients

The service gateway does not allow incoming connection requests to the VCN or your on-premises network. Any connection requests coming from an Oracle service to your on-premises network must come over a public path such as the internet or FastConnect public peering.

If you use Oracle Analytics Cloud so that it initiates connection requests to clients, and you also want to set up private access to Oracle services for your on-premises network, see this known issue.

Transit Routing Options for Private Access to Oracle Services

There are two options for routing through the VCN for private access to Oracle services:

- **Transit routing directly through gateways:** You route the traffic directly through the VCN, from one gateway to the other.
- **Transit routing through a private IP:** You set up an instance in the VCN to filter or inspect the traffic between the on-premises network and Oracle Services Network, and route traffic through a private IP on the instance.

The examples shown in the following sections assume that the VCN contains no workloads that need to access the on-premises network or Oracle Services Network. The VCN is being used only for transit routing of traffic through the VCN.

**Transit routing directly through gateways**

In this example, you route directly through the two gateways on the VCN: the dynamic routing gateway (DRG) and the service gateway. See the following diagram.
Networking

The diagram shows two route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the VCN and is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send that traffic to the service gateway.

- **Service gateway:**
  - This route table belongs to the VCN and is associated with the service gateway.
  - The route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the DRG.

**Transit routing through a private IP in the VCN**

In this example, you set up an instance in the VCN to act as a firewall or intrusion detection system to filter or inspect the traffic between the on-premises network and Oracle Services Network. See the following diagram.
The instance has two VNICs, each with a private IP. One of the VNICs is in a subnet that faces the on-premises network (referred to here as the *frontend subnet*). The other VNIC is in a subnet that faces the Oracle Services Network (referred to here as the *backend subnet*). The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.

The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the VCN and is associated with the DRG attachment. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send the traffic to the private IP in the frontend subnet.

- **Service gateway:**
  - This route table belongs to the VCN and is associated with the service gateway.
  - The route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.

- **Subnet/frontend:**
  - This route table belongs to the VCN and is associated with Subnet/frontend.
  - It includes a rule to enable traffic with the on-premises network.

- **Subnet-backend:**
  - This route table belongs to the VCN and is associated with Subnet-backend.
  - It includes a rule to enable traffic with the regional Oracle Services Network.

**Important Transit Routing Restrictions to Understand**

This section includes some additional important details about routing:

- **Route table for the DRG attachment:**
  - A route table that is associated with a DRG attachment can only have rules that target a service gateway, a private IP, or a local peering gateway.
  - A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

- **Route table for a service gateway:**
  - A route table that is associated with a service gateway can only have rules that target a DRG or a private IP.
  - A service gateway can exist without a route table associated with it. However, after you associate a route table with a service gateway, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

- **Traffic transiting through the VCN:** The route tables discussed here are intended only for moving traffic through the VCN between locations in the on-premises network and the Oracle Services Network. If you're using a private IP in the VCN, you configure the route tables so that the private IP is placed in that traffic path going through the VCN.

- **Inbound traffic to the VCN:** Even though the preceding statement is true (about traffic through the VCN), inbound traffic to subnets within the VCN is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or service gateway's route table. When this kind of inbound traffic reaches the DRG or the service gateway, the traffic is automatically routed to its destination in the VCN by the VCN local routing. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a subsection) as the rule's destination.

- **VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you should use the VCN only for transit between the on-premises network and spoke VCNs. You should not set up workloads in the VCN itself. More explicitly, if you set up transit routing through a private IP in the VCN, you can't also route the VCN's traffic through that private IP. For example, in the preceding diagram, if you were to change the route rule in the service gateway's route table so that the destination CIDR...
is 0.0.0.0/0 instead of 172.16.0.0/12, only traffic coming from the Oracle Services Network and destined for addresses outside the VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the service gateway’s route table (in general, over any of the VCN’s route tables).

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

If you're a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See [IAM Policies for Networking](#) on page 2832.

**Setting Up Private Access to Oracle Services**

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network private access to Oracle services.

*For routing directly between gateways*

**Tip:**

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. *If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Task 4 is the most important.* It enables traffic to be routed between your on-premises network and the Oracle Services Network.

**Task 1: Set up the VCN**

In this task, you set up the VCN. For this example, no subnet is required.

For more information and instructions:

- [VCNs and Subnets](#) on page 2821

**Task 2: Add a service gateway to the VCN**
Networking

In this task, you add a service gateway to the VCN and enable the gateway for the regional Oracle Services Network. Notice that you do not yet create the route table that will be associated with the service gateway. That comes in a later task.

1. In the Console, view the VCN's details.
2. Under Resources, click Service Gateways.
3. Click Create Service Gateway.
4. Enter the following values:
   - **Name**: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - **Services**: All <region> Services in Oracle Services Network.
5. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network

In this task, you set up either FastConnect or VPN Connect between your VCN and your on-premises network. As part of this process, you attach a DRG to the VCN and set up routing between the VCN and your on-premises network. Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later task. For more information and instructions:

- FastConnect on page 3173
- VPN Connect on page 2932
- Dynamic Routing Gateways (DRGs) on page 2927
Important:

If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

Task 4: Set up ingress routing for the DRG and service gateway

In this task, you set up the route tables for the DRG attachment and the service gateway.

Prerequisites:

- You already have a DRG attached to the VCN.
- You already have a service gateway.

1. Create a route table for the DRG attachment:
   
   a. In the Console, view the VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      
     - **Name**: A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
     - **Create in Compartment**: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      
     - **Target Type**: Service gateway.
     - **Destination Service**: All `<region>` Services in Oracle Services Network.
     - **Compartment**: The compartment where the service gateway is located.
     - **Target**: The service gateway.
     - **Description**: An optional description of the rule.
   f. Click Create Route Table.

   The route table is created and displayed in the list.
2. Associate the route table (called DRG Route Table in this example) with the VCN's DRG attachment:
   a. While still viewing the VCN's details, click Dynamic Routing Gateways to view the attached DRG.
   b. Click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the DRG attachment.
      • Route Table: Select the route table for the DRG attachment.
   d. Click Associate.
      The route table is associated with the DRG attachment.

3. Create a route table for the service gateway:
   a. While still viewing the VCN's details, click Route Tables.
   b. Click Create Route Table.
   c. Enter the following:
      • Create in Compartment: Leave as is.
      • Name: A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.
   d. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • Description: An optional description of the rule.
   e. Click Create Route Table.
      The route table is created and displayed in the list.

4. Associate the route table (called Service Gateway Route Table in this example) with the service gateway:
   a. While still viewing the VCN's details, click Service Gateways.
   b. For the service gateway, click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the service gateway.
      • Route Table: Select the route table for the service gateway.
   d. Click Associate.
      The route table is associated with the service gateway.

For routing through a private IP

Tip:
You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Tasks 4 and 5 are the most important. They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the VCN
Networking

In this task, you set up the VCN. This example also has two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional private subnets.

For more information and instructions:
- VCNs and Subnets on page 2821

Task 2: Add a service gateway to the VCN

1. In the Console, view the VCN's details.
2. Under Resources, click Service Gateways.
3. Click Create Service Gateway.
4. Enter the following values:
   - Name: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - Create in compartment: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - Services: All <region> Services in Oracle Services Network.
5. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network
Networking

In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network. Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step. For more information and instructions:

- FastConnect on page 3173
- VPN Connect on page 2932
- Dynamic Routing Gateways (DRGs) on page 2927

**Important:**

If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

Task 4: Set up the private IPs on an instance in the VCN

In this task, you set up the instance to have 2 private IPs. Prerequisites:

- You already have a VCN with two subnets.
- Review this information: Using a Private IP as a Route Target on page 2924.

1. If you haven't already, create the instance in the VCN. See Creating an Instance on page 695. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See Using the Console on page 2858.
3. Disable the source/destination check on each of the VNICs. See Overview of VNICs and Physical NICs on page 2856.
4. For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC's primary private IP, assign that secondary private IP and configure the OS to use it. See Using the Console on page 2866.

5. For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).

6. Configure the instance as necessary for the job it will perform (for example, configure the firewall or intrusion detection system on the instance).

Task 5: Set up ingress routing for the DRG and service gateway

In this task, you set up the route tables for the DRG attachment and service gateway.

Prerequisites:
- You already have a DRG attached to the VCN.
- You already have a service gateway.
- You already have the 2 private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
   a. In the Console, view the VCN's details.
   b. Under Resources, click Route Tables to view the VCN's route tables.
   c. Click Create Route Table.
   d. Enter the following:
      - Name: A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
      - Create in Compartment: Leave as is.
   e. Click + Additional Route Rule, and enter this information for the route rule:
      - Target Type: Private IP.
      - Destination: Service.
      - Destination Service: All <region> Services in Oracle Services Network
      - Compartment: The compartment where the frontend subnet's private IP is located.
      - Target: The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
      - Description: An optional description of the rule.
   f. Click Create Route Table.

The route table is created and displayed in the list.
2. Associate the route table (called DRG Route Table in this example) with the VCN's DRG attachment:
   a. While still viewing the VCN's details, click Dynamic Routing Gateways to view the attached DRG.
   b. Click the Actions icon (three dots), and then click Associate Route Table.
   c. Select the route table.
   d. Click Associate Route Table.

   The route table is associated with the DRG attachment.

3. Create a route table for the service gateway:
   a. While still viewing the VCN's details, click Route Tables.
   b. Click Create Route Table.
   c. Enter the following:
      • Create in Compartment: Leave as is.
      • Name: A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.
   d. Click + Additional Route Rule, and enter this information for the route rule:
      • Target Type: Private IP.
      • Destination: CIDR Block.
      • Destination CIDR Block: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      • Compartment: The compartment where the private IP is located.
      • Target: The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
      • Description: An optional description of the rule.
   e. Click Create Route Table.

   The route table is created and displayed in the list.

4. Associate the route table (called Service Gateway Route Table in this example) with the service gateway:
   a. While still viewing the VCN's details, click Service Gateways.
   b. For the service gateway, click the Actions icon (three dots), and then click Associate With Route Table.
   c. Enter the following:
      • Route Table Compartment: Select the compartment of the route table for the service gateway.
      • Route Table: Select the route table for the service gateway.
   d. Click Associate.

   The route table is associated with the service gateway.

Turning Off Transit Routing

To turn off transit routing, remove the rules from:

• The route table associated with the DRG attachment.
• The route table associated with service gateway.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.

A DRG attachment or service gateway can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or service gateway, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

FastConnect with Multiple DRGs and VCNs

This topic summarizes an advanced networking scenario that enables communication between an on-premises network and multiple virtual cloud networks (VCNs) over a single Oracle Cloud Infrastructure FastConnect. Each VCN has its own dynamic routing gateway (DRG), and you set up a separate FastConnect private virtual circuit to each DRG.
This scenario is supported for only certain FastConnect setups:

- Using a third-party provider or a Colocation with Oracle in a FastConnect location is fully supported.
- Using multiple DRGs and VCNs with an Oracle partner depends on your partner's support of this feature. Some partners also provide alternative solutions to achieve the same goal, so check with your chosen Oracle partner for details.

There's a scenario called transit routing that also involves using multiple VCNs, but only a single DRG. It can be used with VPN Connect or FastConnect. It involves setting up the VCNs in a hub-and-spoke layout and using the hub VCN for transit routing of traffic to the other VCNs. You might use this scenario if you need multiple VCNs for different parts of your organization, but you want to use one VCN for centralized services that all parts of the organization need. For more information, see Transit Routing: Access to Multiple VCNs in the Same Region on page 2780.

Highlights

- You can use a single FastConnect to connect your on-premises network with multiple VCNs in the same region. The scenario is supported only for FastConnect through a third-party provider or through colocation with Oracle. You need at least one physical connection (cross-connect) in your connection.
- The VCNs must be in the same region and same tenancy. The VCNs can be in the same compartment or different ones in the tenancy. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.
- Each VCN has its own dynamic routing gateway (DRG) and private virtual circuit. You must use a different VLAN and different set of BGP IP addresses for each private virtual circuit.
- You can also use FastConnect public peering to give your on-premises network access to public endpoints of Oracle services. In this case, you set up a single public virtual circuit, which covers all the VCNs. With public peering, configure your edge device (also known as your customer-premises equipment or CPE) to prefer FastConnect over your ISP for the Oracle Cloud Infrastructure public IP prefixes. Or, if you plan to also set up private access to Oracle services through one of the VCNs, see the important routing details in Routing Details for Connections to Your On-Premises Network on page 2942.

Overview of the Scenario

In this scenario, you have a single FastConnect that connects your existing on-premises network to Oracle Cloud Infrastructure. That FastConnect has at least one physical connection, or cross-connect.

In Oracle Cloud Infrastructure, you have multiple VCNs, all in the same region. Each VCN has its own DRG. For each VCN, there's a private virtual circuit that runs on the FastConnect and terminates at your CPE on one end, and on the VCN's DRG on the other end. The private virtual circuit enables communication that uses private IP addresses between the VCN and the on-premises network. See the following diagram.
For example, imagine that each department in your organization has its own subnet in your on-premises network and a corresponding departmental VCN in Oracle Cloud Infrastructure. You want to enable private communication between each department's subnet and VCN over the FastConnect.

Or, perhaps all the departments need to communicate with all the VCNs. For example, instead perhaps the VCNs are for separate development, test, and production environments, and each department needs access to all three VCNs.

The FastConnect and virtual circuits give you the general private connection where none of the traffic traverses the internet. You can separately control which on-premises subnets and VCNs can communicate by configuring route rules in your on-premises network and VCN route tables. You can optionally configure VCN security rules and other firewalls that you maintain to allow only certain types of traffic (such as SSH) between your on-premises network and VCN.

Public Peering

You can also set up public peering on that same FastConnect by creating a public virtual circuit. In the following diagram, the public virtual circuit is shown separate from the private virtual circuits. It terminates at Oracle's edge. The public virtual circuit enables communication that uses public IP addresses but does not traverse the internet. If a given VCN happens to also have an internet gateway, Oracle's edge prefers the FastConnect route over the VCN's internet gateway. For other important details about how you can control route preferences when you have multiple connections between your on-premises network and Oracle, see Routing Details for Connections to Your On-Premises Network on page 2942.
When you set up public peering for your FastConnect, the public IP prefixes that you designate for the public virtual circuit are advertised to all the VCNs in your tenancy. The routes advertised to your on-premises network are all the Oracle Cloud Infrastructure public IP addresses (including the CIDRs for each of the VCNs in the tenancy).

**Important:**

Your network receives Oracle's public IP addresses through both FastConnect and your Internet Service Provider (ISP). When configuring your edge, give higher preference to FastConnect over your ISP, or you will not receive the benefits of FastConnect. If you plan to also set up private access to Oracle services through one of the VCNs, see the important routing details in Routing Details for Connections to Your On-Premises Network on page 2942.

For more information, see Basic Network Diagrams on page 3176.

**General Setup Process**

The setup process and instructions are in these topics, based on your particular FastConnect setup:

- FastConnect: With a Third-Party Provider on page 3200
- FastConnect: Colocation with Oracle on page 3210

However, remember that:
• You set up a separate DRG for each VCN. A DRG can be attached to only a single VCN, and each VCN can be attached to only a single DRG.
• You set up a separate private virtual circuit for each DRG.
• For each private virtual circuit, you must specify a different VLAN and a different set of BGP IP addresses.
• When you configure your CPE, you can advertise the same on-premises routes to each VCN, or different ones, based on your own requirements.

Virtual Networking Quickstart

To make it easier to set up a virtual cloud network (VCN) and connect to it, the Console has the following wizards that walk you through network setup.

VCN with Internet Connectivity

What this wizard does:

• Creates a VCN.
• Creates an internet gateway, NAT gateway, and service gateway for the VCN.
• Creates a regional public subnet with routing to the internet gateway. Instances in a public subnet may optionally have public IP addresses.
• Creates a regional private subnet with routing to the NAT gateway and service gateway (and therefore the Oracle Services Network). Instances in a private subnet cannot have public IP addresses.
• Sets up basic security list rules for the two subnets, including SSH access.

Notice that this wizard does not support the creation of a VCN with IPv6 addresses. Also be aware that IPv6 addressing is currently supported only in the US Government Cloud. See For All US Government Cloud Customers on page 148.

Where to access this wizard:

Option 1:
1. In the Console, click the Oracle Cloud icon at the top of the page to go to the Console home page. The page has a Quick Actions section to take you directly to common tasks.
2. Click the quick action for Networking: Set up a network with a wizard.
3. Select VCN with Internet Connectivity, and then click Start Workflow.

Option 2:
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click Networking Quickstart.
3. Select VCN with Internet Connectivity, and then click Start Workflow.

VCN with VPN Connect and Internet Connectivity

What this wizard does:

• Creates a VCN.
• Creates an internet gateway for the VCN.
• Creates a regional public subnet with access to the internet gateway. Instances in a public subnet may optionally have public IP addresses.
• Sets up basic security list rules for the subnet, including SSH access.
• Sets up all the Networking service resources required for a VPN Connect between the VCN and your on-premises network.

Notice that this wizard does not support the creation of a VCN with IPv6 addresses. Also be aware that IPv6 addressing is currently supported only in the Government Cloud. See For All US Government Cloud Customers on page 148.
Networking

**Note:**

For the IPSec connection to work, your network engineer must also configure the customer-premises equipment (CPE) in your edge network.

More information about this wizard: VPN Connect Quickstart on page 2939

Where to access this wizard:

Option 1:

1. In the Console, click the **Oracle Cloud** icon at the top of the page to go to the Console home page.
   
   The page has a **Quick Actions** section to take you directly to common tasks.
2. Click the quick action for **Networking: Set up a network with a wizard**.
3. Select **VCN with VPN Connect and Internet Connectivity**, and then click **Start Workflow**.

Option 2:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click **Networking Quickstart**.
3. Select **VCN with VPN Connect and Internet Connectivity**, and then click **Start Workflow**.

**VCNs and Subnets**

A virtual cloud network (VCN) is a customizable and private network set up in Oracle Cloud Infrastructure.

Create a service request Ask the community

VCN and Subnet Overview

- Get a high-level overview of VCNs and subnets.

Create a peering connection

- Connect multiple VCNs to each other.

Enable transit routing

- Connect your on-premises network to Oracle resources.

Troubleshoot VCN issues

- Troubleshoot common issues and error messages.
Networking

Features

Customizable Virtual Cloud Networks
Fully configurable IP addresses, subnets, routing, and firewalls support new or existing private networks.

End-to-End Security
Multiple security layers, encryption, and private connectivity to other networks and critical Oracle services.

Highest Performance
High bandwidth, microsecond latency network enables high performance and big data applications with networked storage.

Highest Availability
Active and passive logical and physical network redundancy, including default redundant IPSec VPN connectivity.

Overview of VCNs and Subnets

This topic describes how to manage virtual cloud networks (VCNs) and the subnets in them. This topic uses the terms virtual cloud network, VCN, and cloud network interchangeably. The Console uses the term Virtual Cloud Network, whereas for brevity the API uses VCN.

A VCN is a software-defined network that you set up in the Oracle Cloud Infrastructure data centers in a particular region. A subnet is a subdivision of a VCN. For an overview of VCNs, allowed size, default VCN components, and scenarios for using a VCN, see Networking Overview on page 2748.

A VCN can have multiple non-overlapping CIDR blocks that you can change after you create the VCN. Regardless of the number of CIDR blocks, the max number of private IPs you can create within the VCN is 64,000.

You can privately connect a VCN to another VCN so that the traffic does not traverse the internet. The CIDRs for the two VCNs must not overlap. For more information, see Access to Other VCNs: Peering on page 3265. For an example of an advanced routing scenario that involves the peering of multiple VCNs, see Transit Routing: Access to Multiple VCNs in the Same Region on page 2780.

Each subnet in a VCN consists of a contiguous range of IPv4 addresses that do not overlap with other subnets in the VCN. Example: 172.16.1.0/24. The first two IPv4 addresses and the last in the subnet's CIDR are reserved by the Networking service. You can change the size of the subnet after creation.

Subnets act as a unit of configuration: all instances in a given subnet use the same route table, security lists, and DHCP options. For more information, see Default Components that Come With Your VCN on page 2751.

Subnets can be either public or private (see Public vs. Private Subnets on page 2752). The choice of public or private happens during subnet creation, and you can't change it later.

You can think of each Compute instance as residing in a subnet. But to be precise, each instance is attached to a virtual network interface card (VNIC), which in turn resides in the subnet and enables a network connection for that instance.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

About Regional Subnets

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all AD-specific, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or regional. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.
Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. **Oracle recommends using regional subnets** because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

**Caution:**

If anyone in your organization implements a regional subnet, be aware that you **may need to update any client code that works with Networking service subnets and private IPs**. There are possible breaking API changes. For more information, see the [regional subnet release note](#).
Working with VCNs and Subnets

One of the first things you do when working with Oracle Cloud Infrastructure resources is create a VCN with one or more subnets. You can easily get started in the Console with a simple VCN and some related resources that enable you to launch and connect to an instance. See Tutorial - Launching Your First Linux Instance on page 61 or Tutorial - Launching Your First Windows Instance on page 73.

For the purposes of access control, when you create a VCN or subnet, you must specify the compartment where you want the resource to reside. Consult an administrator in your organization if you're not sure which compartment to use.

You may optionally assign descriptive names to the VCN and its subnets. The names don't have to be unique, and you can change them later. Oracle automatically assigns each resource a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can also add a DNS label for the VCN and each subnet, which are required if you want the instances to use the Internet and VCN Resolver feature for DNS in the VCN. For more information, see DNS in Your Virtual Cloud Network on page 2910.

When you create a subnet, you may optionally specify a route table for the subnet to use. If you don't, the subnet uses the cloud network's default route table. You can change which route table the subnet uses at any time.

Also, you may optionally specify one or more security lists for the subnet to use (up to five). If you don't specify any, the subnet uses the cloud network's default security list. You can change which security list the subnet uses at any time. Remember that the security rules are enforced at the instance level, even though the list is associated at the subnet level. Network security groups are an alternative to security lists and let you apply a set of security rules to a set of resources that all have the same security posture, instead of all the resources in a particular subnet.

You may optionally specify a set of DHCP options for the subnet to use. All instances in the subnet receive the configuration specified in that set of DHCP options. If you don't specify a set, the subnet uses the cloud network's default set of DHCP options. You can change which set of DHCP options the subnet uses at any time.

To delete a subnet, it must contain no resources (no instances, load balancers, DB systems, and orphaned mount targets). For more details, see Subnet or VCN Deletion on page 3334.

To delete a VCN, its subnets must contain no resources. Also, the VCN must have no attached gateways. If you're using the Console, there's a “Delete All” process you can use after first ensuring the subnets are empty. See To delete a VCN on page 2828.

For information about the number of VCNs and subnets you can have, see Service Limits on page 215.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to manage VCNs and subnets:

- Subnets in a security zone can’t be public. All subnets must be private.
- You can’t move a subnet from a security zone to a standard compartment.

Using the Console
To create a VCN

**Note:**
The following procedure creates a VCN without any subnets or gateways for access. You must manually create the subnets and other resources before you can use the VCN. For a quick procedure that creates a VCN that you can try out immediately (that is, with subnets and an internet gateway), see the information about the "VCN with Internet Connectivity" wizard in Virtual Networking Quickstart on page 2820. Or see Scenario A: Public Subnet on page 2756.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.
3. Click Create Virtual Cloud Network.
4. Enter the following:
   - **Name:** A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **CIDR Blocks:** One or more non-overlapping CIDR blocks for the VCN. For example: 172.16.0.0/16. You can add or remove CIDR blocks later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a [CIDR calculator](#).
   - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the Government Cloud. For more information, see IPv6 Addresses on page 2889.
   - **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click Create Virtual Cloud Network.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

Next you'll typically want to create one or more subnets in the cloud network.

To create a subnet

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Create Subnet.
4. In the Create Subnet dialog box, you specify the resources to associate with the subnet (for example, a route table). By default, the subnet is created in the current compartment, and you choose the resources from the same
Networking

compartment. Click the click here link in the dialog box if you want to enable compartment selection for the subnet and each of those resources.

Enter the following:

- **Create in Compartment:** If you've enabled compartment selection, specify the compartment where you want to put the subnet.
- **Name:** A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Regional or AD-specific subnet:** Oracle recommends creating only regional subnets, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose Availability Domain-Specific (the only type of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.
- **CIDR Block:** A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Ensure that it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You can change the size of this CIDR block later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
- **Route Table:** The route table to associate with the subnet. If you've enabled compartment selection, under Route Table Compartment, you must specify the compartment that contains the route table.
- **Private or public subnet:** This controls whether VNICs in the subnet can have public IP addresses. For more information, see Access to the Internet on page 2752.
- **Use DNS Hostnames in this Subnet:** This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.
- **DHCP Options:** The set of DHCP options to associate with the subnet. If you've enabled compartment selection, under DHCP Options Compartment, you must specify the compartment that contains the set of DHCP options.
- **Security Lists:** One or more security lists to associate with the subnet. If you've enabled compartment selection, you must specify the compartment that contains the security list.
- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create. The subnet is then created and displayed on the Subnets page in the compartment you chose.

*To edit a subnet*

You can change these characteristics of a subnet:

- **Name**
- **Size of the CIDR block**

**Note:**

- The CIDR block IP range you specify must be completely within one of the VCN's CIDR block ranges.
- The new range must use the same network address as the previous range. For example, the previous and new ranges could be 10.0.0.0/25 and 10.0.0.0/24.
• If you are reducing the CIDR range, ensure that no IP addresses outside of the reduced range are in use.
• The new CIDR range's broadcast address (last IP address of CIDR range) must not be an IP address in use in the previous CIDR range.
• You cannot create VNICs or private IPs for this subnet while a CIDR block update is in progress.
• After the CIDR block update is complete, the DHCP lease for each host within the subnet must be renewed. Renewal happens automatically within 24 hours. To renew the lease immediately, refer to the applicable operating system documentation for guidance on how to renew the lease manually.
• Ensure that you adjust your secondary VNICs and secondary IPs as applicable to match your updated VCN configuration.

- Which set of DHCP options the subnet uses
- Which route table the subnet uses
- Which security lists the subnet uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Click **Edit**.
7. Click **Save Changes**.

   The changes take effect within a few seconds.

To delete a subnet

Prerequisite: The subnet must have no instances, load balancers, DB systems, and orphaned mount targets in it. For more information, see **Subnet or VCN Deletion** on page 3334.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Click **Terminate**.
6. Confirm when prompted.

If the subnet is empty, its state changes to TERMINATING briefly and then TERMINATED. If the subnet is not empty, you get an error indicating that there are still instances or other resources in it that you must delete first.

To add a CIDR block to a VCN

- The CIDR block you add must not overlap with any other CIDR block in the VCN or in a peered VCN.
- The new CIDR block must not include an IP address used in an existing route rule.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **CIDR Blocks**.
4. Click **Add CIDR Block**.
5. Enter the value of the CIDR block you want to add to the VCN.
6. Click **Add CIDR Block**.

   The VCN's state changes to UPDATING. The time to completion can take a few minutes. You can view work requests to monitor the status of the update.
To change a VCN CIDR block

- The CIDR block range you specify must not overlap with any other CIDR block in this VCN or in a peered VCN.
- You cannot change the CIDR block to a range that excludes an IP address in use in the current CIDR block range.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click CIDR Blocks.
4. Find the CIDR block in the list, click the Actions icon (three dots), and then click Edit CIDR Block.
5. Make the applicable change.
6. Click Save Changes.

The VCN’s state changes to UPDATING. The time to completion can vary depending on the size of your network. Updating a small network could take about a minute, and updating a large network could take up to an hour. You can view work requests to monitor the status of the update.

To remove a CIDR block from a VCN

- You cannot remove a CIDR block if an IP address in that range is in use.
- You cannot create or update the VCN's subnets, VLANs, LPGs, or route tables while this VCN update is in progress.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click CIDR Blocks.
4. Find the CIDR block in the list, click the Actions icon (three dots), and then click Remove CIDR Block.
5. Click Remove CIDR Block.

The VCN’s state changes to UPDATING. The time to completion can vary depending on the size of your network. Updating a small network could take about a minute, and updating a large network could take up to an hour. You can view work requests to monitor the status of the update.

To delete a VCN

Important:

The Console has an easy "Delete all" process that deletes a VCN and its related Networking resources (subnets, route tables, security lists, sets of DHCP options, internet gateway, and so on). If the VCN is attached to a dynamic routing gateway (DRG), the attachment is deleted, but the DRG remains.

The "Delete All" process deletes one resource at a time and takes a minute or two. A progress report is displayed to show you what's been deleted so far.

Before using the "Delete All" process, verify there are no instances, load balancers, DB systems, or orphaned mount targets in any of the subnets. For more information, see Subnet or VCN Deletion on page 3334.

If there are still resources in any subnet, or if you don't have permission to delete a particular Networking resource, the "Delete All" process stops and an error message is displayed. Any resources deleted up to that point cannot be restored. You might need to contact your tenancy administrator to help you delete any remaining resources.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click **Terminate**.
   The resulting dialog box displays a list of the resources to be deleted. The list doesn't include the default components that come with the VCN, but they are deleted along with the VCN.

4. Click **Delete All**.
   The process begins. The progress is displayed as each resource is deleted.

5. When the process is complete, click **Close**.

---

### To manage tags for a VCN

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see **Resource Tags** on page 211.

### To manage tags for a subnet

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the subnet you're interested in.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see **Resource Tags** on page 211.

### To move a VCN to a different compartment

You can move a VCN from one compartment to another. When you move a VCN, its associated VNICs, private IPs, and ephemeral IPs move with it to the new compartment. For more information, see **To move a resource to a different compartment** on page 2444.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Find the VCN in the list, click the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the VCN, update the alarms to reference the new compartment. See **To update an alarm after moving a resource** on page 2737 for more information.

### To move a subnet to a different compartment

You can move a subnet from one compartment to another. For more information, see **Working with Compartments** on page 2432.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Find the subnet in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

To manage your VCNs, use these operations:

- `ListVcns`
- `CreateVcn`
- `GetVcn`
- `UpdateVcn`
- `AddVcnCidr`
- `ModifyVcnCidr`
Networking

- **RemoveVcnCidr**
- **DeleteVcn**: Deletes only the VCN and not its related resources. For more information, see Subnet or VCN Deletion on page 3334. Note that the Console offers a “Delete All” process that makes it easy to delete the VCN and its related resources. See To delete a VCN on page 2828.
- **ChangeVcnCompartment**

To manage a VCN's subnets, use these operations:

- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

Access and Security

See these topics for more information about access and security in your cloud network:

- **Ways to Secure Your Network** on page 2830
- **Access Control** on page 2831
- **Virtual firewall for your VCN**:
  - **Security Rules** on page 2833
  - **Network Security Groups** on page 2841
  - **Security Lists** on page 2850

**Ways to Secure Your Network**

There are several ways you can control security for your cloud network and compute instances:

- **Public versus private subnets**: You can designate a subnet to be private, which means instances in the subnet cannot have public IP addresses. For more information, see Public vs. Private Subnets on page 2752.
- **Security rules**: To control packet-level traffic in and out of an instance. You configure security rules in the Oracle Cloud Infrastructure API or Console. To implement security rules, you can use network security groups or security lists. For more information, see Security Rules on page 2833.
- **Firewall rules**: To control packet-level traffic in/out of an instance. You configure firewall rules directly on the instance itself. Notice that Oracle Cloud Infrastructure images that run Oracle Linux automatically include default rules that allow ingress on TCP port 22 for SSH traffic. Also, the Windows images include default rules that allow ingress on TCP port 3389 for Remote Desktop access. For more information, see Oracle-Provided Images on page 629.

**Important:**

Firewall rules and security rules both operate at the instance level. However, you configure security lists at the subnet level, which means all resources in a given subnet have the same set of security list rules. Also, the security rules in a network security group apply only to the resources in the group. When troubleshooting access to an instance, ensure that all the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, or Oracle Linux 7, you need to use `firewalld` to interact with the `iptables` rules.
Networking rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

- **Gateways and route tables**: To control general traffic flow from your cloud network to outside destinations (the internet, your on-premises network, or another VCN). You configure your cloud network's gateways and route tables in the Oracle Cloud Infrastructure API or Console. For more information about the gateways, see Networking Components on page 2748. For more information about route tables, see Route Tables on page 2921.

- **IAM policies**: To control who has access to the Oracle Cloud Infrastructure API or Console itself. You can control the type of access, and which cloud resources can be accessed. For example, you can control who can set up your network and subnets, or who can update route tables, network security groups, or security lists. You configure policies in the Oracle Cloud Infrastructure API or Console. For more information, see Access Control on page 2831.

- **Security zones**: To ensure that your network and other cloud resources comply with Oracle security principles and best practices, you can create them in a security zone. A security zone is associated with a compartment and checks all network management operations against security zone policies. For example, a security zone does not permit the use of public IP addresses and can contain only private subnets. For more information, see Security Zones.

## Access Control

This topic gives basic information about using **compartments** and IAM **policies** to control access to your cloud network.

### Compartments and Your Cloud Network

Anytime you create a cloud resource such as a virtual cloud network (VCN) or compute instance, you must specify which IAM **compartment** you want the resource in. A compartment is a collection of related resources that can only be accessed by certain groups that have been given permission by an administrator in your organization. The administrator creates compartments and corresponding IAM policies to control which users in your organization access which compartments. Ultimately, the goal is to ensure that each person can only access the resources they need.

If your company is starting to try out Oracle Cloud Infrastructure, only a few people need to create and manage the VCN and its components, launch instances into the VCN, and attach block storage volumes to those instances. Those few people need access to **all** these resources, so all those resources could be in the same compartment.

In an enterprise production environment with a VCN, your company can use multiple compartments to more easily control access to certain types of resources. For example, your administrator could create Compartment_A for your VCN and other networking components. The administrator could then create Compartment_B for all the compute instances and block storage volumes that the HR organization uses, and Compartment_C for all the instances and block storage volumes that the Marketing organization uses. The administrator would then create IAM policies that give users only the level of access they need in each compartment. For example, the HR instance administrator is not entitled to modify the existing cloud network. So they would have full permissions for Compartment_B, but limited access to Compartment_A (just what's required to launch instances into the network). If they tried to modify other resources in Compartment_A, the request would be denied.

Network resources such as VCNs, subnets, route tables, security lists, service gateways, NAT gateways, VPNs, and FastConnect connections can be moved from one compartment to another. When you move a resource to a new compartment, inherent policies apply immediately.
For more information about compartments and how to control access to your cloud resources, see "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide and Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2124.

IAM Policies for Networking

The simplest approach to granting access to Networking is the policy listed in Let network admins manage a cloud network on page 2143. It covers the cloud network and all the other Networking components (subnets, security lists, route tables, gateways, and so on). To also give network admins the ability to launch instances (to test network connectivity), see Let users launch compute instances on page 2143.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

For reference material for writing more detailed policies for Networking, see Details for the Core Services on page 2181.

Individual Resource-Types

If you'd like, you can write policies that focus on individual resource-types (for example, security lists only) instead of the broader virtual-network-family. The instance-family resource-type also includes several permissions for VNICS, which reside in a subnet but attach to an instance. For more information, see Details for Verb + Resource-Type Combinations on page 2183 and Virtual Network Interface Cards (VNICS) on page 2855.

There's a resource-type called local-peering-gateways that is included within virtual-network-family and includes two other resource-types related to local VCN peering (within region):

- local-peering-from
- local-peering-to

The local-peering-gateways resource-type covers all permissions related to local peering gateways (LPGs). The local-peering-from and local-peering-to resource-types are for granting permission to connect two LPGs and define a peering relationship within a single region. For more information, see Local VCN Peering (Within Region) on page 3267.

Similarly, there's a resource-type called remote-peering-connections that is included within virtual-network-family and includes two other resource-types related to remote VCN peering (across regions):

- remote-peering-from
- remote-peering-to

The remote-peering-connections resource-type covers all permissions related to remote peering connections (RPCs). The remote-peering-from and remote-peering-to resource-types are for granting permission to connect two RPCs and define a peering relationship across regions. For more information, see Remote VCN Peering (Across Regions) on page 3280.

Nuances of Different Verbs

If you'd like, you can write policies that limit the level of access by using a different policy verb (manage versus use, and so on). If you do, there are some nuances to understand about the policy verbs for Networking.

Be aware that the inspect verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).

Also, the following types of abilities are available only with the manage verb, not the use verb:

- Update (enable/disable) internet-gateways
- Update security-lists
- Update route-tables
- Update dhcp-options
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
• Peer VCNs

**Important:**

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to update that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you're implicitly trusting them with controlling the network's behavior.

For more information about policy verbs, see [Policy Basics on page 2137](#).

**Security Rules**

The Networking service offers two virtual firewall features that both use *security rules* to control traffic at the packet level. The two features are:

- **Security lists**: The original virtual firewall feature from the Networking service.
- **Network security groups (NSGs)**: A subsequent feature designed for application components that have different security postures. NSGs are supported only for specific services.

These two features offer different ways to apply security rules to a set of *virtual network interface cards (VNICs)* in the virtual cloud network (VCN).

This topic summarizes basic differences between the two features. It also explains important security rule concepts that you need to understand. How you create, manage, and apply security rules varies between security lists and network security groups. For implementation details, see these related topics:

- [Security Lists on page 2850](#)
- [Network Security Groups on page 2841](#)

**Comparison of Security Lists and Network Security Groups**

*Security lists* let you define a set of security rules that applies to all the VNICs in an entire subnet. To use a given security list with a particular subnet, you *associate* the security list with the subnet either during subnet creation or later. A subnet can be associated with a maximum of five security lists. Any VNICs that are created in that subnet are subject to the security lists associated with the subnet.

*Network security groups* (NSGs) let you define a set of security rules that applies to a *group of VNICs of your choice* (or the VNICs' parent resources such as load balancers or DB systems). For example: the VNICs that belong to a set of Compute instances that all have the same security posture. To use a given NSG, you add the VNICs of interest to the group. Any VNICs added to that group are subject to that group's security rules. A VNIC can be added to a maximum of five NSGs.

The following diagram illustrates the concept.
Oracle recommends using NSGs instead of security lists because NSGs let you separate the VCN's subnet architecture from your application security requirements.

However, you can use both security lists and NSGs together if you want. For more information, see If You Use Both Security Lists and Network Security Groups on page 2837.

About VNICs and Parent Resources

A VNIC is a Networking service component that enables a networked resource such as a Compute instance to connect to a virtual cloud network (VCN). The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN.

When you create a Compute instance, a VNIC is automatically created for the instance in the instance's subnet. The instance is considered to be the parent resource for the VNIC. You can add more (secondary) VNICs to a Compute instance. For this reason, an instance's VNICs are displayed prominently as part of a Compute instance's related resources in the Console.

There are other types of parent resources that you can create that also result in a VNIC automatically being created. For example: when you create a load balancer, the Load Balancing service automatically creates VNICs for balancing traffic across the backend set. Also, when you create a DB system, the Database service automatically creates VNICs as DB system nodes. Those services create and manage those VNICs for you. For this reason, those VNICs are not readily apparent in the Console the same way VNICs are for Compute instances.

To use an NSG, you put VNICs of your choice into the group. However, you typically work with the parent resource when you add a VNIC to the group, not the VNIC itself. For example, when you create a Compute instance, you can optionally specify an NSG for the instance. Although you conceptually put the instance in the group, you're actually putting the instance's primary VNIC in the network security group. The group's security rules apply to that VNIC, not the instance. Also, if you add a secondary VNIC to the instance, you can optionally specify an NSG for that VNIC, and the rules apply to that VNIC, not the instance. Note that all the VNICs in a given NSG must be in the VCN that the NSG belongs to.

Likewise, when you put a load balancer in a network security group, you conceptually put the load balancer in the group. But you're actually putting VNICs managed by the Load Balancing service into the network security group.

You manage the VNIC membership of an NSG at the parent resource, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the parent resource (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For example, to add an existing Compute instance's VNIC to an NSG, you update that VNIC's properties and specify the NSG. For example, with the REST API, you call UpdateVnic. In the Console, you view the instance and then the VNIC of interest, and then edit the VNIC's properties there.

For a list of parent resources that support the use of NSGs, see Support for Network Security Groups on page 2842.
**Network Security Group as Source or Destination of a Rule**

There's an important difference in how you can write security rules for NSGs compared to security lists.

When writing rules for an NSG, you can specify an *NSG* as the source of traffic (for ingress rules) or the traffic's destination (for egress rules). Contrast this with security list rules, where you specify a *CIDR* as the source or destination.

The ability to specify an NSG means that you can easily write rules to control traffic between two different NSGs. The NSGs must be in the same VCN.

Also, if you want to control traffic between *VNICS in a specific NSG*, you can write rules that specify the *rule's own NSG* as the source (for ingress rules) or destination (for egress rules).

For more information, see [Overview of Network Security Groups](#) on page 2842.

**REST API Differences**

There are a few basic differences in the REST API model for NSGs compared to security lists. For more information, see [Using the API](#) on page 2849.

**Default Rules**

Your VCN automatically comes with a *default security list* that contains several default security rules to help you get started using the Networking service. When you create a subnet, the default security list is associated with the subnet unless you specify a custom security list that you've already created in the VCN. For comparison, the VCN does NOT have a default network security group.

**Limits**

The two features have different limits.

**Security List Limits**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Scope</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>

<td>120 (total ingress plus egress)</td>
</tr>
</tbody>
</table>

* Limit for this resource cannot be increased

**Best Practices for Security Rules**

**Use Network Security Groups**

Oracle recommends using NSGs for components that all have the same security posture. For example, in a multi-tier architecture, you would have a separate NSG for each tier. A given tier's VNICS would all belong to that tier's NSG. Within a given tier, you might have a particular subset of the tier's VNICS that have additional, special security requirements. Therefore you would create another NSG for those additional rules, and place that subset of VNICS into both the tier's NSG and the additional NSG.

Oracle also recommends using NSGs because Oracle will prioritize NSGs over security lists when implementing future enhancements.

**Get Familiar with the Default Security List Rules**

Your VCN automatically comes with a default security list that contains several default security rules to help you get started using the Networking service. Those rules exist because they enable basic connectivity. Even if you choose not to use security lists or the default security list, get familiar with the rules so you better understand the types of traffic that your networked cloud resources require. You might want to use those rules in your NSGs or any custom security lists that you set up.

The default security list does not include rules to enable ping. If you need to use ping, see Rules to Enable Ping on page 2841.

**Don't Delete Default Security Rules Indiscriminately**

Your VCN might have subnets that use the default security list by default. Do not delete any of the list's default security rules unless you've first confirmed that resources in your VCN do not require them. Otherwise, you might disrupt your VCN's connectivity.

**Confirm That Your OS Firewall Rules Align with Your Security Rules**

Your instances running Oracle-provided Linux images or Windows images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance's subnet
- The instance's OS firewall rules

For more information, see Oracle-Provided Images on page 629.
If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, or Oracle Linux 7, you need to use `firewalld` to interact with the `iptables` rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see [Instances experience system hang after running firewall-cmd --reload](#).

**Use VNIC Metrics to Troubleshoot Packets Dropped Because of Security Rules**

The Networking service offers metrics for VNICs, which show the levels of VNIC traffic (packets and bytes). Two of the metrics are for ingress and egress packets that violate security rules and are therefore dropped. You can use these metrics to help you troubleshoot issues related to security rules and whether your VNICs are receiving the desired traffic.

**If You Use Both Security Lists and Network Security Groups**

You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you have security rules that you want to enforce for all VNICs in a VCN: the easiest solution is to put the rules in one security list, and then associate that security list with all subnets in the VCN. This way you can ensure that the rules are applied, regardless of who in your organization creates a VNIC in the VCN. If you like, you can use the VCN's default security list, which automatically comes with the VCN and contains a set of essential rules by default.

If you choose to use both security lists and network security groups, the set of rules that applies to a given VNIC is the union of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

The following diagram is a simple illustration of the idea.

![Diagram](#)

A packet in question is allowed if *any rule in any of the relevant lists and groups* allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see [Stateful Versus Stateless Rules](#) on page 2839.

**Parts of a Security Rule**

A security rule allows a particular type of traffic in or out of a VNIC. For example, a commonly used security rule allows ingress TCP port 22 traffic for establishing SSH connections to the instance (more specifically to the instance's VNICs). Without security rules, no traffic is allowed in and out of VNICs in the VCN.

**Note:**

Security rules are not enforced for traffic involving the 169.254.0.0/16 CIDR block, which includes services such as iSCSI and instance metadata.
Each security rule specifies the following items:

- **Direction (ingress or egress):** Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC. The REST API model for security lists is different from network security groups. With security lists, there is an `IngressSecurityRule` object and a separate `EgressSecurityRule` object. With network security groups, there is only a `SecurityRule` object, and the object's `direction` attribute determines whether the rule is for ingress or egress traffic.

- **Stateful or stateless:** If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. See Stateful Versus Stateless Rules on page 2839.

- **Source type and source (ingress rules only):** The source you provide for an ingress rule depends on the source type you choose.

  **Allowed source types**

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
<tr>
<td></td>
<td>This source type is available only if the rule belongs to an NSG and not a security list.</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets coming from an Oracle service through a service gateway.</td>
</tr>
<tr>
<td></td>
<td>The source service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>

- **Destination type and destination (egress rules only):** The destination you provide for an egress rule depends on the destination type you choose.

  **Allowed destination types**

<table>
<thead>
<tr>
<th>Destination Type</th>
<th>Allowed Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
<tr>
<td></td>
<td>This destination type is available only if the rule belongs to an NSG and not a security list.</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets going to an Oracle service through a service gateway.</td>
</tr>
<tr>
<td></td>
<td>The destination service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>

- **IP Protocol:** Either a single IPv4 protocol or "all" to cover all protocols.

- **Source port:** The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source port number, or a range.

- **Destination port:** The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination port number, or a range.

- **ICMP type and code:** For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.

- **Description** (NSG rules only): NSG security rules include an optional attribute where you can provide a friendly description of the rule. This is currently not supported for security list rules.

For examples of security rules, see Networking Scenarios on page 2756.

For the limit on the number of rules you can have, see Comparison of Security Lists and Network Security Groups on page 2833.
Note:

If you're using NSGs, and two VNICs that are in the same VCN need to communicate using their public IP addresses, you must use the VNIC's public IP address and not the VNIC's NSG as the source (for ingress) or destination (for egress) in the relevant security rules. The packet is routed to the VCN's internet gateway, and at that point, the VNIC's NSG information is not available. Therefore a security rule that specifies the NSG as the source or destination will be ineffective in allowing that specific type of traffic.

Stateful Versus Stateless Rules

When you create a security rule, you choose whether it's stateful or stateless. The difference is described in the next sections. The default is stateful. Stateless rules are recommended if you have a high-volume internet-facing website (for the HTTP/HTTPS traffic).

This section refers specifically to Compute instances and their traffic. However, the discussion is applicable to all types of resources with VNICs. See Comparison of Security Lists and Network Security Groups on page 2833.

Stateful Rules

Marking a security rule as stateful indicates that you want to use connection tracking for any traffic that matches that rule. This means that when an instance receives traffic matching the stateful ingress rule, the response is tracked and automatically allowed back to the originating host, regardless of any egress rules applicable to the instance. And when an instance sends traffic that matches a stateful egress rule, the incoming response is automatically allowed, regardless of any ingress rules. For more details, see Stateful Versus Stateless Rules on page 2839.

The figure below illustrates a stateful ingress rule for an instance that needs to receive and respond to HTTP traffic. Instance A and Host B are communicating (Host B could be any host, whether an instance or not). The stateful ingress rule allows traffic from any source IP address (0.0.0.0/0) to destination port 80 only (TCP protocol). No egress rule is required to allow the response traffic.

Stateful Security Rule: Receive HTTP Traffic

![Diagram showing stateful ingress rule](attachment://diagram.stateful_ingress.png)

Stateless Rules

Marking a security rule as stateless indicates that you do NOT want to use connection tracking for any traffic that matches that rule. This means that response traffic is not automatically allowed. To allow the response traffic for a stateless ingress rule, you must create a corresponding stateless egress rule.

![Diagram showing stateless rule](attachment://diagram.stateless.png)
The next figure shows Instance A and Host B as before, but now with stateless security rules. As with the stateful rule in the preceding section, the stateless ingress rule allows traffic from all IP addresses and any ports, on destination port 80 only (using the TCP protocol). To allow the response traffic, there needs to be a corresponding stateless egress rule that allows traffic to any destination IP address (0.0.0.0/0) and any ports, from source port 80 only (using the TCP protocol).

**Stateless Security Rule: Receive HTTP Traffic**

![Diagram showing stateless security rules for receiving HTTP traffic]

If Instance A needs instead to *initiate* HTTP traffic and get the response, then a different set of stateless rules are required. As the next figure shows, the egress rule would have source port = all and destination port = 80 (HTTP). The ingress rule would then have source port 80 and destination port = all.

**Stateless Security Rule: Initiate HTTP Traffic**

![Diagram showing stateless security rules for initiating HTTP traffic]

If you were to use port binding on Instance A to specify exactly which port the HTTP traffic would come from, you could specify that as the source port in the egress rule and the destination port in the ingress rule.
Note:
If for some reason you use both stateful and stateless rules, and there's traffic that matches both a stateful and stateless rule in a particular direction (for example, ingress), the stateless rule takes precedence and the connection is not tracked. You would need a corresponding rule in the other direction (for example, egress, either stateless or stateful) for the response traffic to be allowed.

Connection Tracking Details for Stateful Rules
Oracle uses connection tracking to allow responses for traffic that matches stateful rules (see Stateful Versus Stateless Rules on page 2839). Each instance has a maximum number of concurrent connections that can be tracked, based on the instance's shape.

To determine response traffic for TCP, UDP, and ICMP, Oracle performs connection tracking on these items for the packet:
- Protocol
- Source and destination IP addresses
- Source and destination ports (for TCP and UDP only)

Note:
For other protocols, Oracle tracks only the protocol and IP addresses, and not the ports. This means that when an instance initiates traffic to another host and that traffic is allowed by egress security rules, any traffic that the instance receives later from that host for a period is considered response traffic and is allowed.

Enabling Path MTU Discovery Messages for Stateless Rules
If you decide to use stateless security rules to allow traffic to/from endpoints outside the VCN, it's important to add a security rule that allows ingress ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages. This rule is critical for establishing a connection to your instances. Without it, you can experience connectivity issues. For more information, see Hanging Connection on page 3327.

Rules to Enable Ping
The VCN's default security list contains several default rules, but not one to allow ping requests. If you want to ping an instance, ensure that the instance's applicable security lists or NSGs include an additional stateful ingress rule to specifically allow ICMP traffic type 8 from the source network you plan to ping from. To allow ping access from the internet, use 0.0.0.0/0 for the source. Note that this rule for pinging is separate from the default ICMP-related rules in the default security list. Do not remove those rules.

Rules to Handle Fragmented UDP Packets
Instances can send or receive UDP traffic. If a UDP packet is too large for the connection, it is fragmented. However, only the first fragment from the packet contains the protocol and port information. If the security rules that allow this ingress or egress traffic specify a particular port number (source or destination), the fragments after the first one are dropped. If you expect your instances to send or receive large UDP packets, set both the source and destination ports for the applicable security rules to ALL (instead of a particular port number).

Network Security Groups
The Networking service offers two virtual firewall features to control traffic at the packet level:
- **Network security groups**: Covered in this topic. Network security groups are supported only for specific services.
Networking

- **Security lists**: The original type of virtual firewall offered by the Networking service. See Security Lists on page 2850.

Both of these features use security rules. For important information about how security rules work, and a general comparison of security lists and network security groups, see Security Rules on page 2833.

**Highlights**

- Network security groups (NSGs) act as a virtual firewall for your Compute instances and other kinds of resources. An NSG consists of a set of ingress and egress security rules that apply only to a set of VNICs of your choice in a single VCN (for example: all the Compute instances that act as web servers in the web tier of a multi-tier application in your VCN).
- Compared to security lists, NSGs let you separate your VCN's subnet architecture from your application security requirements. See Comparison of Security Lists and Network Security Groups on page 2833.
- You can use NSGs with certain resource types. For more information, see Support for Network Security Groups on page 2842.
- NSG security rules function the same as security list rules. However, for an NSG security rule's source (for ingress rules) or destination (for egress rules), you can specify an NSG instead of a CIDR. This means you can easily write security rules to control traffic between two NSGs in the same VCN, or traffic within a single NSG. See Parts of a Security Rule on page 2837.
- Unlike with security lists, the VCN does not have a default NSG. Also, each NSG you create is initially empty. It has no default security rules.
- Network security groups have separate and different limits compared to security lists. See Security List Limits on page 2835.

**Support for Network Security Groups**

NSGs are available for you to create and use. However, they are not yet supported by all the relevant Oracle Cloud Infrastructure services.

Currently, the following types of parent resources support the use of NSGs:

- **Compute instances**: When you create an instance, you can specify one or more NSGs for the instance's primary VNIC. If you add a secondary VNIC to an instance, you can specify one or more NSGs for that VNIC. You can also update existing VNICs on an instance so that they are in one or more NSGs.
- **Load balancers**: When you create a load balancer, you can specify one or more NSGs for the load balancer (not the backend set). You can also update an existing load balancer to use one or more NSGs.
- **DB systems**: When you create a DB system, you can specify one or more NSGs. You can also update an existing DB system to use one or more NSGs.
- **Autonomous Databases**: When you create an Autonomous Database on dedicated Exadata infrastructure, you can specify one or more NSGs for the infrastructure resource. You can also update an existing dedicated Exadata infrastructure instance to use NSGs.
- **Mount targets**: When you create a mount target for a file system, you can specify one or more NSGs. You can also update an existing mount target to use one or more NSGs.
- **DNS resolver endpoint**: When you create an endpoint for a private DNS resolver, you can specify one or more NSGs. You can also update an existing endpoint to use one or more NSGs.

For resource types that do not yet support NSGs, continue to use security lists to control traffic in and out of those parent resources.

**Overview of Network Security Groups**

A network security group (NSG) provides a virtual firewall for a set of cloud resources that all have the same security posture. For example: a group of Compute instances that all perform the same tasks and thus all need to use the same set of ports.

An NSG consists of two types of items (as illustrated in the following diagram):

- **VNICs**: One or more VNICs (for example, the VNICs attached to the set of Compute instances that all have the same security posture). All the VNICs must be in the VCN that the NSG belongs to. Also see Comparison of Security Lists and Network Security Groups on page 2833.
**Security rules:** Security rules that define the types of traffic allowed in and out of the VNICs in the group. For example: ingress TCP port 22 SSH traffic from a particular source.

If you have resources with different security postures in the same VCN, you can write NSG security rules to control traffic between the resources with one posture versus another. For example, in the following diagram, NSG1 has VNICs running in one tier of a multi-tier architecture application. NSG2 has VNICs running in a second tier. Both NSGs must belong to the same VCN. The assumption is that both NSGs need to initiate connections to the other NSG.

For NSG1, you set up egress security rules that specify NSG2 as the destination, and ingress security rules that specify NSG2 as the source. Likewise for NSG2, you set up egress security rules that specify NSG1 as the destination, and ingress security rules that specify NSG1 as the source. The rules are assumed to be stateful in this example.

The preceding diagram assumes that each NSG needs to initiate connections to the other NSG.

The next diagram assumes that you instead want to only allow connections initiated from NSG1 to NSG2. To do that, remove the ingress rule from NSG1 and the egress rule from NSG2. The remaining rules do not allow connections initiated from NSG2 to NSG1.
Networking

The next diagram assumes that you want to control traffic between VNICs in the same NSG. To do that, set the rule's source (for ingress) or destination (for egress) as the rule's own NSG.

A VNIC can be in a maximum of five NSGs. A packet in question is allowed if any rule in any of the VNIC's NSGs allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless security rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules on page 2839.

Network security groups are regional entities. For limits related to network security groups, see Comparison of Security Lists and Network Security Groups on page 2833.

Security Rules

If you're not yet familiar with the basics of NSG security rules, see these sections in the security rules topic:

- Parts of a Security Rule on page 2837
Networking

- Stateful Versus Stateless Rules on page 2839

Working with Network Security Groups

General Process for Working with NSGs

1. Create an NSG.
2. Add security rules to the NSG.
3. Add parent resources (or more specifically, VNICs) to the NSG. You can do this when you create the parent resource, or you can update the parent resource and add it to one or more NSGs. When you create a Compute instance and add it to an NSG, the instance's primary VNIC is added to the NSG. Separately, you can create secondary VNICs and optionally add them to NSGs.

Before deleting an NSG, you must remove all VNICs from it.

See the next sections for more details.

Creating NSGs

Each VCN comes with a default security list that has default security rules in it to enable basic connectivity. However, there is no default NSG in the VCN.

When you create an NSG, it is initially empty, without any security rules or VNICs. If you're using the Console, you can add security rules to the NSG during creation.

You may optionally assign a friendly name to the NSG during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the NSG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers on page 197.

For the purposes of access control, you must specify the compartment where you want the NSG to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see Access Control on page 2831.

Updating Security Rules and Group Membership

After the NSG is created, you can add or remove security rules to allow the types of ingress and egress traffic that the VNICs in the group require.

If you're familiar with security lists and use the REST API, note that the model for updating existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call UpdateNetworkSecurityGroupSecurityRules, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call UpdateSecurityList, you must pass in the entire list of rules, including rules that are not being updated in the call.

When you manage an NSG's VNIC membership, you do it as part of working with the parent resource, not the NSG itself. For more information, see Comparison of Security Lists and Network Security Groups on page 2833.

Specifying an NSG in a Security Rule

As mentioned earlier in Overview of Network Security Groups on page 2842, you can specify an NSG as the source (for ingress rules) or destination (for egress rules) in a given NSG's security rule. The two NSGs must be in the same VCN. For example, if both NSG1 and NSG2 belong to the same VCN, you could add an ingress rule to NSG1 that lists NSG2 as the source. If someone deletes NSG2, the rule becomes invalid. The REST API uses an isValid Boolean in the SecurityRule object to convey that status.

Deleting NSGs

To delete an NSG, it must not contain any VNICs or parent resources. When a parent resource (or a Compute instance VNIC) is deleted, it is automatically removed from the NSGs it was in. You might not have permission to delete a particular parent resource. Contact your administrator to determine who owns a given resource.
The Console displays a list of parent resources that are in an NSG, with a link to each parent resource. If the parent resource is a Compute instance, the Console also displays the instance's VNIC or VNICs that are in the NSG.

To remove a parent resource from its NSGs without deleting the resource, first view the parent resource's details in the Console. There you can see a list of the NSGs that the resource belongs to. From there, you can click Edit and remove the resource from all NSGs. If you're instead working with a Compute instance, view the details of the specific VNIC that you want to remove from the NSGs.

If you're using the REST API: the `ListNetworkSecurityGroupVnics` lists the parent resources and VNICs in an NSG. Use the resource's Update operation to remove the resource from NSGs. For example, for a Compute instance, use the `UpdateVnic` operation. For a load balancer, use the `UpdateNetworkSecurityGroups` operation, and so on.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a `policy` by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which `compartment` you should work in.

For administrators: The policy in Let network admins manage a cloud network on page 2143 covers management of all Networking components, including NSGs.

If you have security admins who need to manage NSGs but not other components in the Networking service, you could write a more restrictive policy:

```plaintext
Allow group NSGAdmins to manage network-security-groups in tenancy
Allow group NSGAdmins to manage vcns in tenancy
  where ANY {request.operation = 'CreateNetworkSecurityGroup',
               request_operation = 'DeleteNetworkSecurityGroup'}
Allow group NSGAdmins to read vcns in tenancy
Allow group NSGAdmins to use VNICs in tenancy
```

The first statement lets the NSGAdmins group create and manage NSGs and their security rules.

The second statement is required because the creation or deletion of an NSG affects the VCN that the NSG is in. The statement restricts the VCN-related permissions to only those required to create or delete an NSG. The statement does not allow the NSGAdmins group to create or delete VCNs, or work with any resources in a VCN except NSGs.

The third statement is required for listing the VCNs, which is a prerequisite for creating or deleting an NSG in a VCN. For information about why both the second and third statements are required, see Conditions on page 2160.

The fourth statement is required if the NSGAdmins need to put VNICs into an NSG. Whoever creates the parent resource of the VNIC (for example, a Compute instance) must already have this level of permission to create the parent resource.

For more information about Networking service policies, see IAM Policies for Networking on page 2832.

**Using the Console**

*To view the security rules and resources in an NSG*

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in to view its details.

The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.
Networking

5. Under Resources, click VNICs to see the parent resources that belong to the NSG.

   If the parent resource is a Compute instance, the corresponding VNICs from that instance are also listed on the page.

   For other types of parent resources, the relevant service manages the VNICs on your behalf. Therefore only the parent resource (and not its corresponding VNICs) is listed on the page.

To create an NSG

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
5. Enter the following:

   a. Name: A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.

   b. Create in Compartment: The compartment where you want to create the network security group, if different from the compartment you're currently working in.

   c. Show Tagging Options: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. Click Next.

   If you want to create the NSG without any rules yet, click Create and you're done. Otherwise proceed to the next step.

7. For the first security rule, enter the following items (for examples of rules, see Networking Scenarios on page 2756):

   • Stateful or stateless: If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. By default, rules are stateful unless you specify otherwise. See Stateful Versus Stateless Rules on page 2839.

   • Direction (ingress or egress): Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC.

   • Source Type and Source (for ingress rules only):

     Allowed source types

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets coming from an Oracle service through a service gateway. The source service is the service CIDR label that you're interested in.</td>
</tr>
</tbody>
</table>
### Source Type

<table>
<thead>
<tr>
<th>Source Type</th>
<th>Allowed Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
</tbody>
</table>

**Destination Type** and **Destination** (for egress rules only):

Allowed destination types

<table>
<thead>
<tr>
<th>Destination Type</th>
<th>Allowed Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR</td>
<td>The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).</td>
</tr>
<tr>
<td>Service</td>
<td>Only for packets going to an Oracle service through a service gateway. The destination service is the service CIDR label that you're interested in.</td>
</tr>
<tr>
<td>Network Security Group</td>
<td>An NSG that is in the same VCN as this rule's NSG.</td>
</tr>
</tbody>
</table>

- **IP Protocol**: Either a single IPv4 protocol (for example, TCP or ICMP) or "all" to cover all protocols.
- **Source port range**: The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source port number, or a range.
- **Destination port range**: The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination port number, or a range.
- **ICMP type and code**: For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.

8. To add another security rule, click + Another Rule and enter the rule's information. Repeat for each rule you want to add.

9. When you're done, click Create.

The NSG is created and then displayed on the Network Security Group page in the compartment you chose. You can now specify this NSG when creating or managing instances or other types of parent resources.

When you view all the security rules in an NSG, you can filter the list by ingress or egress.

#### To add or remove a resource from an NSG

In general, you manage the resource membership of an NSG at the parent resource, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the parent resource (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For a list of the parent resources that support the use of NSG, see Support for Network Security Groups on page 2842.

Example: Compute instances

- **When creating an instance**: In the Configure networking section, select the check box for Use network security groups to control traffic, and then specify one or more NSGs. The instance's primary VNIC is added to the NSGs. See the procedure in Creating an Instance on page 695.

- **For an existing instance**: Adding an existing instance to an NSG means adding its primary VNIC to the NSG. You can also add a secondary VNIC to an NSG. See To add or remove a VNIC from a network security group on page 2859.

Example: Exadata DB systems

- **When creating an Exadata DB system**: In the Network Information section, you set up the client network and backup network. For each network, select the check box for Use network security groups to control traffic, and then specify one or more NSGs for the specific network. See To create an X7 or X8 Exadata DB system on page 1248. Also see Network Setup for Exadata Cloud Service Instances on page 1232.
For an existing Exadata DB system: An Exadata's details include a list of the NSGs that the client network belongs to (if any), and a list of the NSGs that the backup network belongs to (if any). Next to the relevant Network Security Groups, click Edit to change that list. See To edit the network security groups (NSGs) for your client or backup network on page 1261.

To delete an NSG

Prerequisite: To delete a security list, it must not be associated with a subnet. You can't delete the default security list in a VCN.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the security list you want to delete, click the Actions icon (three dots), and then click Terminate.
5. Confirm when prompted.

To manage security rules for an NSG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in to view its details.
5. The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.

To manage tags for an NSG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in.
5. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

For more information, see Resource Tags on page 211.

To move an NSG to a different compartment

You can move an NSG from one compartment to another. When you move an NSG to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the NSG you're interested in.
5. Click the the Actions icon (three dots) for the NSG, and then click Move Resource.
6. Choose the destination compartment from the list.
7. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage a VCN's network security groups, use these operations:

- ListNetworkSecurityGroups
- GetNetworkSecurityGroup
- UpdateNetworkSecurityGroup
- CreateNetworkSecurityGroup
- DeleteNetworkSecurityGroup
• ChangeNetworkSecurityGroupCompartment
• ListNetworkSecurityGroupVnics
• ListNetworkSecurityGroupSecurityRules
• AddNetworkSecurityGroupSecurityRules
• RemoveNetworkSecurityGroupSecurityRules
• UpdateNetworkSecurityGroupSecurityRules

There are some differences in the REST API model for NSGs compared to security lists:

• With security lists, there is an `IngressSecurityRule` object and a separate `EgressSecurityRule` object. With network security groups, there is only a `SecurityRule` object, and the object's `direction` attribute determines whether the rule is for ingress or egress traffic.

• With security lists, the rules are part of the `SecurityList` object, and you work with the rules by calling the security list operations (such as `UpdateSecurityList`). With NSGs, the rules are not part of the `NetworkSecurityGroup` object. Instead you use separate operations to work with the rules for a given NSG (example: `UpdateNetworkSecurityGroupSecurityRules`).

• The model for updating existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call `UpdateNetworkSecurityGroupSecurityRules`, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call `UpdateSecurityList`, you must pass in the `entire` list of rules, including rules that are not being updated in the call.

• There is a limit of 25 rules when calling the operations to add, remove, or update security rules.

**Security Lists**

The Networking service offers two virtual firewall features to control traffic at the packet level:

• **Security lists**: Covered in this topic. This is the original type of virtual firewall offered by the Networking service.

• **Network security groups**: Another type of virtual firewall that Oracle recommends over security lists. See Network Security Groups on page 2841.

Both of these features use security rules. For important information about how security rules work, and a general comparison of security lists and network security groups, see Security Rules on page 2833.

**Highlights**

• Security lists act as virtual firewalls for your Compute instances and other kinds of resources. A security list consists of a set of ingress and egress security rules that apply to all the VNICs in any subnet that the security list is associated with. This means that all the VNICs in a given subnet are subject to the same set of security lists. See Comparison of Security Lists and Network Security Groups on page 2833.

• Security list rules function the same as network security group rules. For a discussion of rule parameters, see Parts of a Security Rule on page 2837.

• Each VCN comes with a default security list that has several default rules for essential traffic. If you don’t specify a custom security list for a subnet, the default security list is automatically used with that subnet. You can add and remove rules from the default security list.

• Security lists have separate and different limits compared to network security groups. See Comparison of Security Lists and Network Security Groups on page 2833.

**Overview of Security Lists**

A security list acts as a virtual firewall for an instance, with ingress and egress rules that specify the types of traffic allowed in and out. Each security list is enforced at the VNIC level. However, you configure your security lists at the subnet level, which means that all VNICs in a given subnet are subject to the same set of security lists. The security lists apply to a given VNIC whether it’s communicating with another instance in the VCN or a host outside the VCN.

Each subnet can have multiple security lists associated with it, and each list can have multiple rules (for the maximum number, see Comparison of Security Lists and Network Security Groups on page 2833). A packet in question is allowed if any rule in any of the lists allows the traffic (or if the traffic is part of an existing connection being
Networking

There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules on page 2839.

Security lists are regional entities. For limits related to security lists, see Comparison of Security Lists and Network Security Groups on page 2833.

Security lists can control both IPv4 and IPv6 traffic. However, IPv6 addressing and related security list rules are currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

**Default Security List**

Unlike other security lists, the default security list comes with an initial set of stateful rules, which should in most cases be changed to only allow inbound traffic from authorized subnets relevant to the region that homes that VCN or subnet. A list of authorized subnet ranges relevant to each region can be found at https://docs.cloud.oracle.com/iaas/tools/public_ip_ranges.json.

- **Stateful ingress**: Allow TCP traffic on destination port 22 (SSH) from authorized source IP addresses and any source port. This rule makes it easy for you to create a new cloud network and public subnet, launch a Linux instance, and then immediately use SSH to connect to that instance without needing to write any security list rules yourself.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using Windows images, make sure to add a stateful ingress rule for TCP traffic on destination port 3389 from authorized source IP addresses and any source port. See To enable RDP access for more information.</td>
</tr>
</tbody>
</table>

- **Stateful ingress**: Allow ICMP traffic type 3 code 4 from authorized source IP addresses. This rule enables your instances to receive Path MTU Discovery fragmentation messages.

- **Stateful ingress**: Allow ICMP traffic type 3 (all codes) from your VCN's CIDR block. This rule makes it easy for your instances to receive connectivity error messages from other instances within the VCN.

- **Stateful egress**: Allow all traffic. This allows instances to initiate traffic of any kind to any destination. Notice that this means the instances with public IP addresses can talk to any internet IP address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Stateful Versus Stateless Rules on page 2839.

The default security list comes with no stateless rules. However, you can always add or remove rules from the default security list.

If your VCN is enabled for IPv6 addressing (which is currently supported in only the Government Cloud), the default security list contains some default rules for IPv6 traffic. For more information, see IPv6 Addresses on page 2889.

**Enabling Ping**

The default security list does not include a rule to allow ping requests. If you plan to ping an instance, see Rules to Handle Fragmented UDP Packets on page 2841.

**Security Rules**

If you're not yet familiar with the basics of security rules, see these sections in the security rules topic:

- Parts of a Security Rule on page 2837
- Stateful Versus Stateless Rules on page 2839

**Working with Security Lists**

**General Process for Working with Security Lists**

1. Create a security list.
2. Add security rules to the security list.
3. Associate the security list with one or more subnets.
4. Create resources in the subnet (for example, create Compute instances in the subnet). The security rules apply to all the VNICs in that subnet. See Comparison of Security Lists and Network Security Groups on page 2833.

**Additional Details**

When you create a subnet, you must associate at least one security list with it. It can be either the VCN's default security list or one or more other security lists that you've already created (for the maximum number, see Service Limits on page 215). You can change which security lists the subnet uses at any time.

You may optionally assign a friendly name to the security list during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the security list a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers on page 197.

For the purposes of access control, you must specify the compartment where you want the security list to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see Access Control on page 2831.

You can move security lists from one compartment to another. Moving a security list doesn’t affect its attachment to a subnet. When you move a security list to a new compartment, inherent policies apply immediately and affect access to the security list. For more information, see Managing Compartments on page 2431.

You can add and remove rules from the security list. A security list can have no rules. Notice that when you update a security list in the API, the new set of rules replaces the entire existing set of rules.

To delete a security list, it must not be associated with a subnet. You can't delete a VCN's default security list.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let network admins manage a cloud network on page 2143 covers management of all Networking components, including security lists.

If you have security admins who need to manage security lists but not other components in Networking, you could write a more restrictive policy:

```
Allow group SecListAdmins to manage security-lists in tenancy
Allow group SecListAdmins to manage vcns in tenancy
```

Both statements are needed because the creation of a security list affects the VCN the security list is in. The scope of the second statement also allows the SecListAdmins group to create VCNs. However, the group can't create subnets or manage any other components related to any of those VCNs (except for the security lists), because other permissions would be required for those resources. The group also can't delete any existing VCNs that already have subnets in them, because that action would require permissions related to subnets.

For more information, see IAM Policies for Networking on page 2832.

**Using the Console**

*To view a VCN's default security list*

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the default security list to view its details.

Under Resources, you can click Ingress Rules or Egress Rules to switch between the different types of rules.
**To update rules in an existing security list**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the security list you're interested in.
5. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
6. If you want to add a rule, click Add Ingress Rule (or Add Egress Rule). See details of adding a rule in To create a security list on page 2853.
7. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
8. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

---

**To create a security list**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click Create Security List.
5. Enter the following:
   a. **Name**: A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   b. **Create in Compartment**: The compartment where you want to create the security list, if different from the compartment you're currently working in.
6. Add either an ingress rule or egress rule (for examples of rules, see Networking Scenarios on page 2756):
   a. Click either Add Ingress Rule or Add Egress Rule.
   b. Choose whether it's a stateful or stateless rule (see Stateful Versus Stateless Rules on page 2839). By default, rules are stateful unless you specify otherwise.
   c. Enter either the source CIDR (for ingress) or destination CIDR (for egress). For example, use 0.0.0.0/0 to indicate all IP addresses. Other typical CIDRs you might specify in a rule are the CIDR block for your on-premises network, or for a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see Task 3: (Optional) Update security rules on page 3261.
   d. Select the IP protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).
   e. Enter further details depending on the protocol:
      - If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20–22).
      - If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.
   f. Enter an optional description of the rule to help manage your security list rules.
7. Repeat the preceding step for each rule you want to add to the list.
8. **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
9. When you're done, click Create Security List.

The security list is created and then displayed on the Security Lists page in the compartment you chose. You can now specify this security list when creating or updating a subnet.

When you view all the rules in a security list, notice that any stateless rules in the list are shown above any stateful rules. Stateless rules in the list take precedence over stateful rules. In other words: If there's traffic that matches
both a stateless rule and a stateful rule across all the security lists associated with the subnet, the stateless rule takes precedence and the connection is not tracked.

To change which security lists a subnet uses

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
6. If you want to add a security list, click Add Security List, and select the new security list you want the subnet to use.
7. If you want to remove a security list, click the Actions icon (three dots), and then click Remove. Remember that a subnet must always have at least one security list associated with it.

The changes take effect within a few seconds.

To move a security list to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Find the security list, click the the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To delete a security list

Prerequisite: To delete a security list, it must not be associated with a subnet. You can't delete the default security list in a VCN.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the security list you want to delete, click the Actions icon (three dots), and then click Terminate.
5. Confirm when prompted.

To manage tags for a security list

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. Click the security list you're interested in.
5. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage a VCN's security lists, use these operations:

- ListSecurityLists
- GetSecurityList
- UpdateSecurityList
- CreateSecurityList
- DeleteSecurityList
- ChangeSecurityListCompartment
**VCN Flow Logs**

This topic describes the contents of VCN flow logs and how to set up flow logs for resources in your VCN.

**Highlights**

- VCN flow logs shows details about traffic that passes through your VCN.
- VCN flow logs help you audit traffic and troubleshoot your security lists.
- Flow logs are enabled and managed using the Logging service. For more information, see Overview of the Logging Service.
- Flow logs can be generated from VNICS, PEs, and RCEs. For PEs and RCEs, they appear as from the VNIC associated with the PE/RCE.

**Overview of Flow Logs**

Each instance in a VCN has one or more Virtual Network Interface Cards (VNICS) on page 2855. The Networking service uses Security Lists on page 2850 to determine what traffic is allowed through a given VNIC. The VNIC is subject to all rules in all security lists associated with the VNIC's subnet.

To help you troubleshoot your security lists or audit the traffic in and out of your VNICS, you can set up VCN flow logs. Flow logs record details about traffic that has been accepted or rejected based on the security list rules.

**How Flow Logs Are Enabled and Delivered**

Flow logs are enabled and managed using the Logging service. You can enable flow logs for a given subnet, which means traffic is logged for all the existing and future VNICS in that subnet. Each flow log record contains information about traffic for a single VNIC. Here are the general steps for setting up flow logs:

1. **Enable flow logs for the subnet**: VCN flow logs are enabled for a subnet using the Logging service.
2. **View the subnet’s flow logs**: Assuming there is traffic for the given subnet, it can take up to 10 minutes for the first flow logs to be delivered. Then you receive batches of flow logs every minute.

After flow logs are enabled for a subnet, a batch of flow logs for each VNIC is collected in one-minute capture windows. It takes under eight minutes to process a batch, after which the flow logs are available for viewing.

**Flow Log Contents**

Each flow log record reflects logged traffic in one direction of a connection between two endpoints. For example, for a single TCP connection, you may have two records in the capture window: one for ingress traffic, and the other for egress traffic.

For more information about flow log contents, examples, and limitations and other considerations, see Details for VCN Flow Logs on page 2612.

**Setting Up Flow Logs for a Subnet**

See Enabling Logging for a Resource on page 2591 for instructions on setting up logging.

**Managing Flow Logs**

Flow log management tasks such as disabling logs, deleting logs, and editing logs are performed using the Logging service. For more information on log management, see Managing Logs and Log Groups on page 2577.

**Use VCN Flow Logs to Audit Traffic and Troubleshoot Security Lists**

To list details about traffic that passes to and from destinations in your VCN, enable flow logs for a given subnet. After you have them enabled, flow logs record traffic for all existing and future VNICS attached to compute instances in that subnet.

Flow logs are enabled and managed using the Logging service. For more information, see Overview of the Logging Service.

**Virtual Network Interface Cards (VNICS)**

This topic describes how to manage the virtual network interface cards (VNICS) in a virtual cloud network (VCN).
Overview of VNICs and Physical NICs

The servers in Oracle Cloud Infrastructure data centers have physical network interface cards (NICs). When you launch an instance on one of these servers, the instance communicates using Networking service virtual NICs (VNICs) associated with the physical NICs. The next sections talk about VNICs and NICs, and how they're related.

About VNICs

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN and includes these items:

- One primary private IPv4 address from the subnet the VNIC is in, chosen by either you or Oracle.
- Up to 31 optional secondary private IPv4 addresses from the same subnet the VNIC is in, chosen by either you or Oracle.
- An optional public IPv4 address for each private IP, chosen by Oracle but assigned by you at your discretion.
- An optional hostname for DNS for each private IP address (see DNS in Your Virtual Cloud Network on page 2910).
- A MAC address.
- A VLAN tag assigned by Oracle and available when attachment of the VNIC to the instance is complete (relevant only for bare metal instances).
- A flag to enable or disable the source/destination check on the VNIC’s network traffic (see Overview of VNICs and Physical NICs on page 2856).
- Optional membership in one or more network security groups (NSGs) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
- Up to 32 optional IPv6 addresses. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

Each VNIC also has a friendly name you can assign, and an Oracle-assigned OCID (see Resource Identifiers).

Each instance has a primary VNIC that is automatically created and attached during launch. That VNIC resides in the subnet you specify during launch. The primary VNIC cannot be removed from the instance.

How VNICs and Physical NICs Are Related

This section is relevant to bare metal instances.

The OS on a bare metal instance recognizes two physical network devices and configures them as two physical NICs, 0 and 1. Whether they're both active depends on the underlying hardware. You can determine which NICs are active for a shape by reviewing the network bandwidth specifications for bare metal shapes. If the network bandwidth is listed as "2 x <bandwidth> Gbps," it means that both NIC 0 and NIC 1 are active, and each physical NIC has the indicated amount of bandwidth. If the network bandwidth is listed as "1 x <bandwidth> Gbps," it means that only NIC 0 is active. On current generation Standard and DenseIO shapes, typically both NIC 0 and NIC 1 are active.

NIC 0 is automatically configured with the primary VNIC's IP configuration (the IP addresses, DNS hostname, and so on).

If you add a secondary VNIC to an instance, you must specify which physical NIC the secondary VNIC should use. You must also configure the OS so that the physical NIC has the secondary VNIC's IP configuration. For Linux instances, see Linux: Configuring the OS for Secondary VNICs on page 2861. For Windows instances, see Windows: Configuring the OS for Secondary VNICs on page 2862.

About Secondary VNICs

You can add secondary VNICs to an instance after it's launched. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance.
Here are some reasons why you might use secondary VNICs:

- **Use your own hypervisor on a bare metal instance:** The virtual machines on the bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For more information, see *Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC*.

- **Connect an instance to subnets in multiple VCNs:** For example, you might set up your own firewall to protect traffic between VCNs, so the instance needs to connect to subnets in different VCNs.

Here are more details about secondary VNICs:

- They're supported for these types of instances:
  - **Linux:** Both VM and bare metal instances. Also see *Linux: Configuring the OS for Secondary VNICs* on page 2861.
  - **Windows:** Both VM and bare metal instances (except for instances that use previous generation Standard1 and StandardB1 shapes). For bare metal instances, secondary VNICs are supported only on the second physical NIC. Remember that the first physical NIC is NIC 0, and the second is NIC 1. Also see *Windows: Configuring the OS for Secondary VNICs* on page 2862.

- There's a limit to how many VNICs can be attached to an instance, and it varies by shape. For those limits, see *Compute Shapes* on page 655.

- They can be added only after the instance is launched.

- They must always be attached to an instance and cannot be moved. The process of creating a secondary VNIC automatically attaches it to the instance. The process of detaching a secondary VNIC automatically deletes it.

- They are automatically detached and deleted when you terminate the instance.

- They are automatically detached and deleted when you terminate the instance.

- There's a limit to how many VNICs can be attached to an instance, and it varies by shape. For those limits, see *Compute Shapes* on page 655.

- They can be added only after the instance is launched.

- They must always be attached to an instance and cannot be moved. The process of creating a secondary VNIC automatically attaches it to the instance. The process of detaching a secondary VNIC automatically deletes it.

- They are automatically detached and deleted when you terminate the instance.

- The instance's bandwidth is fixed regardless of the number of VNICs attached. You can't specify a bandwidth limit for a particular VNIC on an instance.

- Attaching multiple VNICs from the same subnet CIDR block to an instance can introduce asymmetric routing, especially on instances using a variant of Linux. If you need this type of configuration, Oracle recommends assigning multiple private IP addresses to one VNIC, or using policy-based routing as shown in the script later in this topic.

### Source/Destination Check

By default, every VNIC performs the source/destination check on its network traffic. The VNIC looks at the source and destination listed in the header of each network packet. If the VNIC is not the source or destination, then the packet is dropped.

If the VNIC needs to forward traffic (for example, if it needs to perform Network Address Translation (NAT)), you must disable the source/destination check on the VNIC. For instructions, see *To update an existing VNIC* on page 2859. For information about the general scenario, see *Using a Private IP as a Route Target* on page 2924.

### VNIC Information in the Instance Metadata

The instance metadata service (IMDS) includes information about the VNICs at these URLs:

- IMDS version 2:

  ```
  ```

- Legacy IMDS version 1:

  ```
  ```

Here's an example response that shows the VNICs that are attached to an instance:

```json
[
  {
    "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
    "privateIp" : "10.0.3.6",
    "vlanTag" : 11,
```
Networking

```
{"macAddr" : "00:00:00:00:00:01",
"virtualRouterIp" : "10.0.3.1",
"subnetCidrBlock" : "10.0.3.0/24",
"nicIndex" : 0 },
{
"vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
"privateIp" : "10.0.4.3",
"vlanTag" : 12,
"macAddr" : "00:00:00:00:00:02",
"virtualRouterIp" : "10.0.4.1",
"subnetCidrBlock" : "10.0.4.0/24",
"nicIndex" : 0
}
```

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

VNICs reside in a subnet but attach to an instance. The VNIC’s *attachment to the instance* is a separate object from the VNIC or the instance itself. Be aware that the VNIC and subnet always exist together in the same compartment, but the VNIC’s *attachment to the instance* always exists in the instance's compartment. This distinction isn't important if you have a simple access control scenario where all the cloud resources are in the same compartment (for example, for a proof-of-concept). When you move to a production implementation, you might decide to have network administrators manage the network, and other personnel administer instances. That means you might put instances in a different compartment than the subnet.

For administrators: see [IAM Policies for Networking](#) on page 2832.

**Monitoring VNICs**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see [Monitoring Overview](#) on page 2660 and [Notifications Overview](#) on page 3350.

For information about monitoring the traffic coming in and out of VNICs, see [VNIC Metrics](#) on page 3321.

**Using the Console**

**To view an instance's VNICs**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Instances*.
3. Click the instance to view its details.
4. Under *Resources*, click *Attached VNICs*.

   The primary VNIC and any secondary VNICs attached to the instance are displayed. If the instance has two active physical NICs, the VNICs are grouped by NIC 0 and NIC 1.

**To create and attach a secondary VNIC**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Instances*.
3. Click the instance to view its details.
4. Under *Resources*, click *Attached VNICs*.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click *Create VNIC*.  

Oracle Cloud Infrastructure User Guide 2858
6. In the **Create VNIC** dialog box, you specify which VCN and subnet to put the VNIC in. By default, the VNIC will be created in the current compartment. You can choose a VCN and subnet from the same compartment or a different compartment.

Enter the following:

- **Name**: A friendly name for the secondary VNIC. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Virtual cloud network**: The VCN that contains the subnet of interest.
- **Network**: Select **Normal Setup: Subnet**.
- **Subnet**: The subnet of interest. The secondary VNIC must be in the same availability domain as the instance's primary VNIC, so the subnet list includes any regional subnets or AD-specific subnets in the primary VNIC's availability domain.
- **Physical NIC**: Only relevant if this is a bare metal instance with two active physical NICs. Select which one you want the secondary VNIC to use. When you later view the instance's details and the list of VNICs attached to the instance, they'll be grouped by NIC 0 and NIC 1.
- **Use network security groups to control traffic**: Select this check box to add the secondary VNIC to at least one network security group (NSG) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
- **Skip source/destination check**: By default, this check box is NOT selected, which means the VNIC performs the source/destination check. Only select this check box if you want the VNIC to be able to forward traffic. See **Overview of VNICs and Physical NICs** on page 2856.
- **Private IP Address**: Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
- **Assign a public IPv4 address**: Whether to assign a public IP address to the VNIC's primary private IP. Available only if the subnet is public. Choose this option to specify an existing reserved public IP address by name, or to create a new reserved IP address by assigning a name and selecting a source IP pool for the address. If you don't select an IP pool you've created, the default Oracle IP pool is used.
- **Hostname**: Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see **DNS in Your Virtual Cloud Network** on page 2910.
- **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

7. Click **Submit**. The secondary VNIC is created and then displayed on the **Attached VNICs** page for the instance. It can take several seconds before the secondary VNIC appears on the page.

8. Configure the OS to use the VNIC. See **Linux: Configuring the OS for Secondary VNICs** on page 2861 or **Windows: Configuring the OS for Secondary VNICs** on page 2862.

### To update an existing VNIC

You can update the VNIC's friendly name or hostname, or whether the VNIC performs the source/destination check.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to edit, click the Actions icon (three dots), and then click **Edit VNIC**.
6. Make your changes. Avoid entering confidential information. Then, click **Save Changes**.

### To add or remove a VNIC from a network security group

You can change which network security groups (NSGs) a VNIC belongs to, or remove a VNIC from all NSGs.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you’re interested in.
   Each VNIC's details page includes a list of the NSGs that the VNIC belongs to (if any).
6. Next to **Network Security Groups**, click **Edit**.
7. Make your changes and click **Save Changes**.

### To delete a secondary VNIC

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the VNIC has a private IP that is the target of a route rule, deleting the VNIC causes the route rule to blackhole and traffic will be dropped.</td>
</tr>
</tbody>
</table>

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to delete, click the Actions icon (three dots), and then click **Delete VNIC**.
6. Confirm when prompted.

It takes typically a few seconds before the VNIC is deleted.

If the secondary VNIC is on a Linux instance: If you then run the provided script in [Linux: Configuring the OS for Secondary VNICs](page 2861), it removes the secondary VNIC from the OS configuration.

### To manage tags for a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see [Resource Tags](page 211).

### Using the API

For information about using the API and signing requests, see [REST APIs](page 4368) and [Security Credentials](page 179). For information about SDKs, see [Software Development Kits and Command Line Interface](page 4225).

To manage VNICs on an instance, use these operations:

- **ListVnicAttachments**: Use this to list the VNICs attached to an instance.
- **GetVnicAttachment**: Use this to get the VNIC’s VLAN tag and other properties.
- **GetVnic**: Use this to get the VNIC’s private IP address, MAC address, optional public IP address, optional DNS hostname, and other properties.
- **AttachVnic**
- **DetachVnic**
- **UpdateVnic**
Linux: Configuring the OS for Secondary VNICs

This section gives details about OS configuration that is required for secondary VNICs on instances that run a variant of Linux.

At the end of the section is a script that you can use to configure secondary VNICs on either VM instances or bare metal instances.

Linux VM Instances

When you add a secondary VNIC to a Linux VM instance, a new interface (that is, an Ethernet device) is added to the instance and automatically recognized by the OS. However, DHCP is not active for the secondary VNIC, and you must configure the interface with the static IP address and default route. The script provided here handles that configuration for you.

Linux Bare Metal Instances

When you add a secondary VNIC to a Linux bare metal instance, the OS does not automatically recognize the secondary VNIC, so you must configure it in the OS. Depending on your requirements, you can configure it as either:

• An SR-IOV virtual function (see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC).
• A VLAN-tagged interface (see the script in the following section).

Configuration Script for Either Linux VM Instances or Linux Bare Metal Instances

The following script works for both VM instances and bare metal instances. It looks at the secondary VNIC information in the instance metadata and configures the OS accordingly. You could run the script periodically to bring the OS configuration up to date with the instance metadata.

For VM instances in particular, the OS automatically recognizes the secondary VNIC's interface, and the script just needs to configure the static IP address and default route.

For bare metal instances in particular, the script creates the interface for the secondary VNIC and configures it with the relevant information. If the instance has two active physical NICs (NIC 0 and NIC 1), the script configures the secondary VNIC to use whichever physical NIC you chose when you added the VNIC to the instance. Note that for NIC 1, if a secondary VNIC has VLAN tag 0, it uses the NIC's interface. The script doesn't create an interface for that secondary VNIC.

Here are some additional notes about how the script works for both VM instances and bare metal instances:

• Default namespace and policy-based routing: By default, this script configures the secondary VNIC in the default namespace and with policy-based routing so applications can communicate through the VNIC with hosts outside the VNIC's subnet. This policy-based routing has effect only if the packets are sourced from the IP address of the secondary VNIC. The ability to bind to a specific source IP address or source interface exists in most tools (such as ssh, ping, and wget) and libraries that initiate connections. For example, the ssh -b <secondary_VNIC_IP_address> <destination_IP_address> lets you bind to the private IP address of the secondary VNIC.

Be aware that if traffic comes in to a service on the instance through a secondary VNIC's interface and the service replies, the reply packets automatically have the VNIC's interface IP address as the source IP address. Policy-based routing is required for that reply to go back out on the same interface and find the correct default gateway.

• A separate namespace: If you're familiar with namespaces, you can instead configure the secondary VNIC in another namespace of your choice by running the script with the -n option. A separate namespace is required when an instance has secondary VNICs that are attached to subnets in different VCNs, and those subnets have overlapping CIDR blocks.

• Secondary private IPs: The instance metadata does not include information about any secondary private IPs assigned to the instance. To include that as part of the script's OS configuration, you must provide the secondary private IP address and OCID at the command line when you run the script.
• **Removal of a secondary VNIC:** After deleting a secondary VNIC from an instance, running the script removes the VNIC's information from the OS configuration.

**Important:**

The script uses a simple configuration process that does not persist if you reboot the instance. If you use the script, make sure to rerun it after each reboot.

Here are basic examples of how to run the script:

• `<script_name> -c`: Configure (adds or deletes) secondary VNIC host IP configuration
• `<script_name> -c -n`: Same but uses separate namespaces
• `<script_name> -d`: Force removes all secondary VNIC host IP configuration

See the script's help for more information.

**Important:**

This script is intended for use in situations where non-hypervisor compute instances need to be assigned an additional VNIC and IP address.

For Kernel-based Virtual Machine (KVM) applications on a bare metal instance, refer to the white paper "Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC."

**Tip:**

Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#linux.

### Windows: Configuring the OS for Secondary VNICS

Secondary VNICS are supported on VM and bare metal instances (except for instances that use previous generation Standard1 and StandardB1 shapes). For bare metal instances, secondary VNICS are supported only on the second physical NIC.

**Tip:**

The first physical NIC is NIC 0, and the second is NIC 1.

You must configure the secondary VNIC within the OS. There's an Oracle-provided PowerShell script that performs configuration. When running the script, you can optionally provide the secondary VNIC's OCID (which you can get from the instance's VNIC metadata):

```
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC OCID>"
```

Otherwise, the script shows a list of the secondary VNICS on the instance and asks you to choose the one you want to configure. Here's generally what the script does:

1. The script checks if the network interface has an IP address and a default route.
2. To enable the OS to recognize the secondary VNIC, the script must overwrite the IP address and default route with static settings (which effectively disables DHCP). The script prompts you with a choice: to overwrite with the static settings, or exit.

**Tip:**

Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#windows.
The overall process for configuration varies slightly depending on the type of instance (VM or bare metal) and how many secondary VNICs you add to the instance.

**Windows VM instances**

Here's the overall process:

1. **Add one or more secondary VNICs** to the instance. Keep each VNIC's OCID handy so you can provide it later when you run the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
3. **Run the script**:
   a. Open PowerShell as an administrator.
   b. Run the script with the secondary VNIC's OCID:
      ```
      .\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
      ```
4. Repeat the preceding step for each additional secondary VNIC.

**Windows bare metal instances: adding the first secondary VNIC**

If you're adding only a single secondary VNIC to the bare metal instance, here's the overall process:

1. **Add the secondary VNIC** to your instance. Keep the VNIC's OCID handy so you can provide it when later running the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
3. **Enable the second physical NIC** on the instance:
   a. Open the Device Manager, and then click **Network adapters**.
   b. Right-click the adapter that corresponds to the instance's second physical NIC, and click **Enable**.
4. **Run the script**:
   a. Open PowerShell as an administrator.
   b. Run the script with the secondary VNIC's OCID:
      ```
      .\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
      ```
   c. When the script prompts you to overwrite the network interface's settings, say yes.

**Windows bare metal instances: adding additional secondary VNICs**

If you have one secondary VNIC on the second physical NIC of a bare metal instance, and you want to one or more additional VNICs, here's the overall process. It includes a task for setting up NIC teaming, which is required if the instance has more than one VNIC on the second physical NIC.

1. **Add one or more additional secondary VNICs** to your instance. Keep each VNIC's OCID and VLAN tag handy so you can provide them when later running the configuration script. You can also get the values from the instance's VNIC metadata.
2. **Connect to the instance** with Remote Desktop.
Networking

3. Set up NIC teaming on the instance:
   a. Open the Server manager, and then click **Local Server**.
   b. In the list of properties, locate **NIC Teaming**, and then click **Disabled** to enable and set up NIC teaming.
   c. In the **Teams** section on the lower-left side of the screen, click **Tasks**, and then click **New Team**.
   d. Enter a name for the team, select the check box for the second physical NIC on the instance, and click **OK**.
      The new team is created and appears in the list of teams in the **Teams** section.
   e. Click the new team so it's selected, and then in the **Adapters and Interfaces** section on the right side of the screen, click the **Team Interfaces** tab.
   f. Click **Tasks**, and then click **Add Interface** (you will create a separate interface for each secondary VNIC on the second physical NIC).
   g. Click the radio button for **Specific VLAN**, and then enter the Oracle-assigned VLAN tag number for the VLAN (for example, 1). You can get the VLAN tag from the Console or the instance's **VNIC metadata**.
   h. Click **OK**.
   i. Repeat the four preceding steps (e-h) for each of the other secondary VNICs. You create a separate interface for each secondary VNIC.

4. Run the script:
   a. Open PowerShell as an administrator.
   b. For the first secondary VNIC, run the script with the secondary VNIC's OCID:

   ```powershell
   .\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
   ```
   c. When the script prompts you to overwrite the network interface's settings, say yes.
   d. Repeat the preceding two steps (b and c) for each of the additional secondary VNICs.

**IP Addresses and DNS in Your VCN**

These topics cover how your instances are assigned private and public IP addresses, and the use of DNS within your cloud network.

- **Private IP Addresses** on page 2864
- **Public IP Addresses** on page 2875
- **Bring Your Own IP** on page 2882
- **IP Pools** on page 2887
- **IPv6 Addresses** on page 2889
- **DNS in Your Virtual Cloud Network** on page 2910

**Private IP Addresses**

This topic describes how to manage the IPv4 addresses assigned to an instance in a virtual cloud network (VCN).

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see **IPv6 Addresses** on page 2889.

**Overview of IP Addresses**

Instances use IP addresses for communication. Each instance has at least one private IP address and optionally one or more public IP addresses. A private IP address enables the instance to communicate with other instances inside the VCN, or with hosts in your on-premises network (via an IPSec VPN or Oracle Cloud Infrastructure FastConnect). A public IP address enables the instance to communicate with hosts on the internet. For more information, see these related topics:

- **Public vs. Private Subnets** on page 2752
- **How IP Addresses Are Assigned** on page 2752
- **Public IP Addresses** on page 2875
About the Private IP Object

The Networking service defines an object called a private IP, which consists of:

- Private IPv4 address, assigned by either you or Oracle.
- Optional hostname for DNS (see DNS in Your Virtual Cloud Network on page 2910).

Each private IP object has an Oracle-assigned OCID (see Resource Identifiers). If you're using the API, you can also assign each private IP object a friendly name.

Each instance receives a primary private IP object during launch. The Networking service uses the Dynamic Host Configuration Protocol (DHCP) to pass the object's private IP address to the instance. This address does not change during the instance's lifetime and cannot be removed from the instance. The private IP object is terminated when the instance is terminated.

If an instance has any secondary VNICs attached, each of those VNICs also has a primary private IP.

A private IP can have a public IP assigned to it at your discretion.

A private IP can be the target of a route rule in your VCN. For more information, see Using a Private IP as a Route Target on page 2924.

About Secondary Private IP Addresses

You can add a secondary private IP to an instance after it's launched. You can add it to either the primary VNIC or a secondary VNIC on the instance. The secondary private IP address must come from the CIDR of the VNIC's subnet.

You can move a secondary private IP from a VNIC on one instance to a VNIC on another instance if both VNICs belong to the same subnet.

Here are a few reasons why you might use secondary private IPs:

- **Instance failover:** You assign a secondary private IP to an instance. Then if the instance has problems, you can easily reassign that secondary private IP to a standby instance in the same subnet. If the secondary private IP has a public IP assigned to it, that public IP moves along with the private IP.
- **Running multiple services or endpoints on a single instance:** For example, you could have multiple container pods running on a single instance, and each uses an IP address from the VCN's CIDR. The containers have direct connectivity to other instances and services in the VCN. Another example: you could run multiple SSL websites with each one using its own IP address.

Here are more details about secondary private IP addresses:

- They're supported for all shapes and OS types, for both bare metal and VM instances.
- A VNIC can have a maximum of 31 secondary private IPs.
- They can be assigned only after the instance is launched (or the secondary VNIC is created/attached).
- A secondary private IP that is assigned to a VNIC in a regional subnet has a null availability domain attribute. Compare this with the VNIC's primary private IP, which always has its availability domain attribute set to the instance's availability domain, regardless of whether the instance's subnet is regional or AD-specific.
- Deleting a secondary private IP from a VNIC returns the address to the pool of available addresses in the subnet.
- They are automatically deleted when you terminate the instance (or detach/delete the secondary VNIC).
- The instance's bandwidth is fixed regardless of the number of private IP addresses attached. You can't specify a bandwidth limit for a particular IP address on an instance.
- A secondary private IP can have a reserved public IP assigned to it at your discretion.

IP Address Information in the Instance Metadata

The instance metadata includes information about the private IP addresses at this URL:

Here's an example response:

```json
[
  {
    "vnicId": "ocid1.vnic.oc1.sea.<unique_ID>",
    "privateIp": "10.0.3.6",
    "vlanTag": 11,
    "macAddr": "00:00:00:00:00:01",
    "virtualRouterIp": "10.0.3.1",
    "subnetCidrBlock": "10.0.3.0/24"
  },
  {
    "vnicId": "ocid1.vnic.oc1.sea.<unique_ID>",
    "privateIp": "10.0.4.3",
    "vlanTag": 12,
    "macAddr": "00:00:00:00:00:01",
    "virtualRouterIp": "10.0.4.1",
    "subnetCidrBlock": "10.0.4.0/24"
  }
]
```

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: see [IAM Policies for Networking](#) on page 2832.

**Using the Console**

*To view an instance's private IPs*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Instances*.
3. Click the instance to view its details.
4. Under *Resources*, click *Attached VNICS*.
   
   The primary VNIC and any secondary VNICS assigned to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under *Resources*, click *IP Addresses*.

   The VNIC's primary private IP and any secondary private IPs are displayed.

*To assign a new secondary private IP to a VNIC*

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Instances*.
3. Click the instance to view its details.
4. Under *Resources*, click *Attached VNICS*.

   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under *Resources*, click *IP Addresses*.

   The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click *Assign Secondary Private IP Address*. 

Networking

8. Enter the following:
   - **Private IP Address**: Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
   - **Unassign if already assigned to another VNIC**: Select this check box to force reassignment of the IP address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a private IP address in the preceding field.
   - **Hostname**: Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See *DNS in Your Virtual Cloud Network* on page 2910.
   - **Public IP Type**: Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See *Public IP Addresses* on page 2875.

9. Click Assign.

The secondary private IP is created and then displayed on the **IP Addresses** page for the VNIC.

10. Configure the IP address:
   - For instances running a variant of Linux, see *Linux: Details about Secondary IP Addresses* on page 2868.
   - For Windows instances, see *Windows: Details about Secondary IP Addresses* on page 2870.

**To move a secondary private IP to another VNIC in the same subnet**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   
The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.
   
The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click **Assign Secondary Private IP Address**.
8. Enter the following:
   - **Private IP Address**: The secondary private IP address you want to move.
   - **Unassign if already assigned to another VNIC**: Select this check box to move the secondary IP address from the VNIC it's currently assigned to.
   - **Hostname**: Optional. The hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See *DNS in Your Virtual Cloud Network* on page 2910.
   - **Public IP Type**: Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See *Public IP Addresses* on page 2875.
9. Click Assign.

The private IP address is moved from the original VNIC to the new VNIC.

**To update the hostname for an existing private IP**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   
The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.
   
The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the IP address you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. Make your changes and click **Update**.
To delete a secondary private IP from a VNIC

**Caution:**
If the private IP is the target of a route rule, deleting it from the VNIC causes the route rule to blackhole and the traffic will be dropped.

Prerequisite: Oracle recommends removing the IP address from the OS configuration before deleting it from the VNIC. See Linux: Details about Secondary IP Addresses on page 2868 or Windows: Details about Secondary IP Addresses on page 2870.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under Resources, click IP Addresses.
   - The VNIC’s primary private IP and any secondary private IPs are displayed.
7. For the private IP you want to delete, click the Actions icon (three dots), and then click Delete Private IP.
8. Confirm when prompted.

The private IP address is returned to the pool of available addresses in the subnet.

To manage tags for a private IP

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under Resources, click IP Addresses.
   - The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click View Tags. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage private IPs on a VNIC, use these operations:

- **GetPrivateIp**: Use this to get a single `privateIp` object by specifying its OCID.
- **ListPrivateIps**: Use this to get a single `privateIp` object by specifying the private IP address (for example, 10.0.3.3) and the subnet's OCID. Or you can list all the `privateIp` objects in a given subnet, or just the ones assigned to a given VNIC.
- **CreatePrivateIp**: Use this to assign a new secondary private IP to a VNIC.
- **UpdatePrivateIp**: Use this to reassign a secondary private IP to a different VNIC in the same subnet, or to update the hostname or display name of a secondary private IP.
- **DeletePrivateIp**: Use this to delete a secondary private IP from a VNIC. The private IP address is returned to the subnet's pool of available addresses.

**Linux: Details about Secondary IP Addresses**

After assigning a secondary private IP to a VNIC, you must configure the OS to use it.
**Basic Commands (Not Persistent Through a Reboot)**

On the instance, run the following command. It works on all variants of Linux, for both bare metal and VM instances:

```
ip addr add <address>/<subnet_prefix_len> dev <phys_dev> label <phys_dev>:<addr_seq_num>
```

where:
- `<address>`: The secondary private IP address.
- `<subnet_prefix_len>`: The subnet's prefix length. For example, if the subnet is 192.168.20.0/24, the subnet prefix length is 24.
- `<phys_dev>`: The interface to add the address to (for example, ens2f0).
- `<addr_seq_num>`: The sequential number in the stack of addresses on the device (for example, 0).

For example:

```
ip addr add 192.168.20.50/24 dev ens2f0 label ens2f0:0
```

Later if you want to delete the address, you can use:

```
ip addr del 192.168.20.50/24 dev ens2f0:0
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

**Note:**
If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**Configuration File (Persistent Through a Reboot)**

You can make the configuration persistent through a reboot by adding the information to a configuration file.

**For Oracle Linux and CentOS**

Create an `ifcfg` file named `/etc/sysconfig/network-scripts/ifcfg-<phys_dev>:<addr_seq_num>`. To continue with the preceding example, the file name would be `/etc/sysconfig/network-scripts/ifcfg-ens2f0:0`, and the contents would be:

```
DEVICE="ens2f0:0"
BOOTPROTO=static
IPADDR=192.168.0.50
NETMASK=255.255.255.0
ONBOOT=yes
```

**Note:**
If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**For Ubuntu**

```
auto <phys_dev>:<addr_seq_num>
iface <phys_dev>:<addr_seq_num> inet static
    address <address>
    netmask <address_netmask>
```
Networking

Where the netmask is not the prefix but the 255.255.x.x. address.

To continue with the earlier example:

```
auto ens2f0:0
iface ens2f0:0 inet static
address 192.168.0.50
netmask 255.255.255.0
```

**Note:**

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

**Windows: Details about Secondary IP Addresses**

After assigning a secondary private IP to a VNIC, you must configure the OS to use it. Here are instructions for using a PowerShell script or the Network and Sharing Center UI.

**Using a PowerShell Script**

You must run PowerShell as an administrator. The script configures two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   ```
ipconfig /all
   ```

3. Note the values for the following items so you can enter them into the script in the next step:
   - Default Gateway
   - DNS Servers
4. Replace the variables in the following PowerShell script with your own values:

   ```powershell
   netadapter = Get-NetAdapter -Name Ethernet
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress <secondary_IP_address> -PrefixLength <subnet_prefix_length> -Type Unicast -DefaultGateway <default_gateway>
   Set-DnsClientServerAddress -InterfaceAlias Ethernet -ServerAddresses <DNS_server>
   ```

   For example:

   ```powershell
   netadapter = Get-NetAdapter -Name Ethernet
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress 192.168.0.14 -PrefixLength 24 -Type Unicast -DefaultGateway 192.168.0.1
   Set-DnsClientServerAddress -InterfaceAlias Ethernet -ServerAddresses 203.0.113.254
   ```
5. Save the script with the name of your choice and a `.ps1` extension, and run it on the instance.

If you run `ipconfig /all` again, you'll see that DHCP has been disabled and the secondary private IP address is included in the list of IP addresses.

Later if you want to delete the address, you can use this command:

```
Remove-NetIPAddress -IPAddress 192.168.11.14 -InterfaceAlias Ethernet
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

**Using the Network and Sharing Center UI**

The following instructions configure two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   `ipconfig /all`

3. Note the values for the following items so you can enter them elsewhere in a later step:
   - IPv4 Address
   - Subnet Mask
   - Default Gateway
   - DNS Servers

4. In the instance's Control Panel, open the Network and Sharing Center (see the image below for the set of dialog boxes you'll see in these steps).
5. For the active networks, click the connection (Ethernet).
6. Click Properties.
7. Click Internet Protocol Version 4 (TCP/IPv4), and then click Properties.
8. Select the radio button for **Use the following IP address**, and then enter the values you noted earlier for the IP address, subnet mask, default gateway, and DNS servers.

9. Click **Advanced....**

10. Under **IP addresses**, click **Add....**
11. Enter the secondary private IP address and the subnet mask you used earlier and click **Add**.

12. Click **OK** until the Network and Sharing Center is closed.
13. Verify the changes by returning to the command prompt and running `ipconfig /all`.

You should now see that DHCP is disabled (static IP addressing is enabled), and the secondary private IP address is in the list of addresses displayed. The address is now configured on the instance and available to use.

![Windows PowerShell](image.png)

**Note:**

You might not see the primary private IP address when you again view the properties for Internet Protocol Version 4 (TCP/IPv4) in the Network and Sharing Center UI. The best way to confirm your changes is to use `ipconfig /all` at the command line.

**Public IP Addresses**

This topic describes how to manage public IPv4 addresses on instances in a virtual cloud network (VCN).

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see [IPv6 Addresses](#) on page 2889.

**Overview of Public IP Addresses**

A public IP address is an IPv4 address that is reachable from the internet. If a resource in your tenancy needs to be directly reachable from the internet, it must have a public IP address. Depending on the type of resource, there might be other requirements.

Certain types of resources in your tenancy are designed to be directly reachable from the internet and therefore automatically come with a public IP address. For example: a NAT gateway or a public load balancer. Other types of resources are directly reachable only if you configure them to be. For example: instances in your VCN.

This topic focuses on these subjects:

- The types of public IP addresses and their characteristics
- How to control whether an instance has a public IP address
For more information about resources that automatically get a public IP address, see Overview of Public IP Addresses on page 2875.

**Instances and Public IP Addresses**

You can assign a public IP address to an instance to enable communication with the internet. The instance is assigned a public IP address from the Oracle Cloud Infrastructure address pool.

The assignment is actually to a private IP object on the instance. The VNIC that the private IP is assigned to must be in a public subnet. A given instance can have multiple secondary VNICs, and a given VNIC can have multiple secondary private IPs. So you can assign a given instance multiple public IPs across one or more VNICs if you like.

For an instance to communicate directly with the internet, all of the following are required:

- The instance must be in a public subnet.
- The instance must have a public IP address.
- The instance's VCN must have an internet gateway.
- The public subnet must have route tables and security lists configured accordingly.

**Tip:**

Oracle Cloud Infrastructure FastConnect public peering lets your on-premises network access the public IP addresses of resources in Oracle Cloud Infrastructure without the traffic traversing the internet. For more information, see FastConnect on page 3173.

**The Public IP Object**

The Networking service defines an object called a public IP, which consists of these items:

- Public IPv4 address (chosen by Oracle)
- Properties that further define the public IP's type and behavior

Each public IP object has an Oracle-assigned OCID (see Resource Identifiers). If you're using the API, you can also assign each public IP object a friendly name.

**Types of Public IPs**

There are two types of public IPs:

- **Ephemeral**: Think of it as temporary and existing for the lifetime of the instance.
- **Reserved**: Think of it as persistent and existing beyond the lifetime of the instance it's assigned to. You can unassign it and then reassign it to another instance whenever you like. Exception: reserved public IPs on public load balancers. See Overview of Public IP Addresses on page 2875.

The following table summarizes the differences between the two types.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Ephemeral Public IPs</th>
<th>Reserved Public IPs</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Allowed assignment</strong></td>
<td>To a VNIC's primary private IP only</td>
<td>To either a primary or secondary private IP</td>
</tr>
<tr>
<td></td>
<td>Limits:</td>
<td>Limit: 32 per VNIC</td>
</tr>
<tr>
<td></td>
<td>• One per VNIC</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Two per VM instance, and 16 per bare metal instance</td>
<td></td>
</tr>
</tbody>
</table>

---

Oracle Cloud Infrastructure User Guide 2876
<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Ephemeral Public IPs</th>
<th>Reserved Public IPs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation</td>
<td>Optionally created and assigned during instance launch or secondary VNIC creation. You can create and assign one later if the VNIC doesn't already have one.</td>
<td>You create one at any time. You can then assign it when you like. Limit: You can create 50 per region</td>
</tr>
<tr>
<td>Unassignment</td>
<td>You can unassign it at any time, which deletes it. You might do this if whoever launched the instance included a public IP, but you don't want the instance to have one. When you stop an instance, its ephemeral public IPs remain assigned to the instance.</td>
<td>You can unassign it at any time, which returns it to your tenancy's pool of reserved public IPs.</td>
</tr>
<tr>
<td>Moving to a different resource</td>
<td>You cannot move an ephemeral public IP to a different private IP.</td>
<td>If assigned to a secondary private IP: If you move the private IP to a different VNIC (must be in the same subnet), the reserved public IP goes with it. You can move it (unassign and then reassign it) at any time to another private IP in the same region. Can be in a different VCN or availability domain.</td>
</tr>
<tr>
<td>Automatic deletion</td>
<td>Its lifetime is tied to the private IP's lifetime. Automatically unassigned and deleted when: • Its private IP is deleted • Its VNIC is detached or terminated • Its instance is terminated</td>
<td>Never. Exists until you delete it.</td>
</tr>
<tr>
<td>Scope</td>
<td>Availability domain</td>
<td>Regional (can be assigned to a private IP in any availability domain in the region)</td>
</tr>
<tr>
<td>Compartment and availability domain</td>
<td>Same as the private IPs</td>
<td>Can be different from the private IPs</td>
</tr>
</tbody>
</table>

When you launch an instance in a public subnet, by default, the instance gets a public IP unless you say otherwise. See To choose whether an ephemeral public IP is assigned when launching an instance on page 2878.

After you create a given public IP, you can't change which type it is. For example, if you launch an instance that is assigned an ephemeral public IP with address 203.0.113.2, you can't convert the ephemeral public IP to a reserved public IP with address 203.0.113.2.

The preceding table notes the public IP limits per VNIC and instance. If you try to perform any operation that assigns or moves a public IP to a VNIC or instance that has already reached its public IP limit, an error is returned. The operations include:

- Assigning a public IP
Networking

- Creating a new secondary VNIC with a public IP
- Moving a private IP with a public IP to another VNIC
- Moving a public IP to another private IP

**Resources That Always Get a Public IP**

As mentioned earlier, certain types of resources are designed to be directly reachable from the internet. Examples: a NAT gateway or a public load balancer. These resources automatically get a public IP address upon creation. Oracle chooses the public IP address from the Oracle pool. You can't remove or change the address.

For public load balancers, the address is a regional reserved public IP that is assigned to a private IP on the load balancer. This public IP appears in the list of your tenancy's reserved public IPs, which you can view in the Console. However, unlike other reserved public IPs that you create, you have no control over this public IP. You can't edit it or unassign it from the load balancer yourself. It's automatically unassigned and deleted from your tenancy when you terminate the load balancer.

For NAT gateways, the address is a regional ephemeral public IP that is assigned to the NAT gateway. Like other ephemeral public IPs, it's automatically unassigned and deleted when you terminate its assigned resource (the NAT gateway). However, unlike other ephemeral public IPs, you can't edit it or unassign it yourself.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

**Ephemeral Public IPs: Using the Console**

To choose whether an ephemeral public IP is assigned when launching an instance

When you launch an instance into a public subnet, there's an Assign a public IPv4 address check box on the Create Compute Instance page. By default, the check box is selected, which means the instance gets an ephemeral public IP.

If you do NOT want an ephemeral public IP assigned, you can either:

- Select the Do not assign a public IPv4 address option
- Delete the ephemeral public IP after instance launch

To assign an ephemeral public IP when creating a secondary VNIC

When you add a secondary VNIC to an instance, you choose whether the primary private IP on the new VNIC gets an ephemeral public IP. This choice is available only if the secondary VNIC is in a public subnet.

In the Create VNIC dialog box, there's an Assign a public IPv4 address check box. By default, the check box is NOT selected, which means the secondary VNIC does not get an ephemeral public IP. You must select the check box.

For instructions, see Connectivity Choices on page 2752.

To assign an ephemeral public IP to an existing primary private IP

Prerequisite: The primary private IP must not have a reserved or ephemeral public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, for **Public IP type**, select the radio button for **Ephemeral Public IP**.

9. In the **Ephemeral Public IP Name** field, enter an optional friendly name for the public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.

10. Click **Update**.

**To delete an ephemeral public IP from an instance**

Deleting an ephemeral public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.

5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.

9. Click **Update**.

**To change the display name for an ephemeral public IP**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

   The primary VNIC and any secondary VNICs attached to the instance are displayed.

5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.

   The VNIC’s primary private IP and any secondary private IPs are displayed.

7. For the VNIC’s primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, edit the **Ephemeral Public IP Name**. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.

9. Click **Update**.

**Reserved Public IPs: Using the Console**

**To view your reserved public IPs**

1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking**, go to **IP Management**, and click **Public IPs**.

   The details of the reserved public IPs in the selected region and compartment are displayed. If the reserved public IP is assigned, there's a link to the relevant VNIC.

**To create a new reserved public IP in your pool**

1. Confirm you're viewing the region and compartment where you want to create the reserved public IP.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking**, go to **IP Management**, and click **Public IPs**.
3. Click **Create Reserved Public IP**.
4. Enter the following:
   - **Name**: An optional friendly name for the reserved public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Compartment**: Leave as is.
   - **IP Pool**: (optional) The IP pool the reserved public IP is drawn from. If you don't select a pool you've created, the default Oracle pool is used.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Reserved Public IP**.

The new reserved public IP is created and displayed on the page. You can now assign it to an existing private IP if you like.

*To delete a reserved public IP from your pool*

The reserved public IP can be in the "Assigned" state. Deleting a reserved public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under Core Infrastructure, go to Networking, go to IP Management, and click Public IPs.
3. For the reserved public IP you want to delete, click the Actions icon (three dots), and then click **Terminate**.
4. Confirm when prompted.

After a few seconds, the reserved public IP is unassigned (if it was assigned) and deleted from your pool.

*To assign a reserved public IP to a private IP*

Prerequisite: The private IP must not have an ephemeral or reserved public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance with the private IP you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.
   
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC that you're interested in.
6. Under Resources, click IP Addresses.

   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the Public IP Type section, select the radio button for Reserved Public IP.
9. For **Reserved Public IP**, enter the reserved public IP you want to assign. You have three choices:
   - Create a new reserved public IP. You can optionally provide a friendly name for it. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Assign a reserved public IP that isn't already assigned.
   - Move a reserved public IP from another private IP.
10. Click **Update**.

*To unassign a reserved public IP and return it to the pool*

1. Confirm you're viewing the compartment that contains the instance with the reserved public IP you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
9. Click **Update**.

The reserved public IP is unassigned and returned to your pool.

*To move a reserved public IP from one private IP to another*

Let's say you want to move a reserved public IP from private IP 1 to private IP 2. In summary: Make sure private IP 2 doesn't have a public IP already assigned to it. Then assign the reserved public IP to private IP 2. It will be automatically unassigned from private IP 1 first. Detailed instructions:

1. Confirm you're viewing the compartment that contains the instance with private IP 2.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICS**.
   The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For private IP 2, click the Actions icon (three dots), and then click **Edit**.
8. If private IP 2 already has a public IP assigned to it:
   a. In the **Public IP Type** section, select the radio button for **No Public IP**.
   b. Click **Update**.
   c. Again for private IP 2, click the Actions icon (three dots), and then click **Edit**.
9. In the **Public IP Type** section, select the radio button for **Reserved Public IP**.
10. In the **Reserved Public IP** list, select the reserved public IP that you want to assign. It will be moved from the public IP it's currently assigned to.
11. Click **Update**.

*To change the display name for a reserved public IP*

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking**, go to **IP Management**, and click **Public IPs**.
3. For the reserved public IP you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. Make your changes to the friendly name. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
5. Click **Save**.

*To manage tags for a reserved public IP*

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking**, go to **IP Management**, and click **Public IPs**.
3. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 211.
To move a reserved public IP to a different compartment

You can move a reserved public IP from one compartment to another. When you move a reserved public IP to a new
compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking, go to IP Management, and click Public IPs.
2. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage public IPs, use these operations:

- **GetPublicIp**: Use this to get a publicIp object by specifying its OCID.
- **GetPublicIpByIpAddress**: Use this to get a publicIp object by specifying its public IP address.
- **GetPublicIpByPrivateIpId**: Use this to get a publicIp object by specifying the OCID of the private IP it's assigned to.
- **ListPublicIps**: Use this to list either your ephemeral or reserved publicIp objects.
- **CreatePublicIp**: Use this to create a new reserved public IP in your pool.
- **UpdatePublicIp**: Use this to assign, reassign, or unassign a reserved public IP, or to update the display name of an ephemeral or reserved public IP. You can also update a reserved public IP's tags.
- **DeletePublicIp**: Use this to delete an ephemeral public IP from its private IP, or delete a reserved public IP from your pool. The operation first unassigns the public IP.
- **ChangePublicIpCompartment**: Use this to move a reserved public IP from one compartment to another. This operation applies only to reserved public IPs. Ephemeral public IPs always belong to the same compartment as their VNIC and move accordingly.

Bring Your Own IP

Oracle Cloud Infrastructure allows you to Bring Your Own IP (BYOIP) address space to use with resources in Oracle Cloud Infrastructure, in addition to using Oracle owned addresses. BYOIP lets you manage your IPv4 CIDR blocks to align with your existing security, management, and deployment policies and achieve:

- **Solution continuity and hardcoded dependencies**: Your VCN is an extension of your public Internet presence, without needing to reinvent policies and management processes. If you have IP addresses hard-coded in devices or built architectural dependencies on specific IP addresses, using BYOIP you have a smooth migration to Oracle Cloud Infrastructure.
- **IP pool management**: Some network administrators require the ability to summarize groups of IP addresses into pools and to create resources for deployment such as load balancers, firewalls, or web servers. IP Pool management provides tools to manage reserved public IP addresses.
- **IP reputation**: Some Internet services rely on a contiguous IP address space (such as a full span of IP addresses from 1 through 255) and act as a trusted contact point between services such as major email service providers and mail delivery systems.

Oracle performs a validation process on imported CIDR blocks, and after validation you are notified that the CIDR block is available for advertisement. You can also create one or many public IP pools from this address space by specifying subranges from the BYOIP CIDR block and use IP pools to allocate specific resources. You can start or stop advertisement of the BYOIP routes when needed.
Networking

Requirements and Preparation

• You must have ownership of the public IPv4 CIDR block you want to import into Oracle Cloud Infrastructure, and the ownership must be registered with a supported Regional Internet Registry (RIR). Oracle validates ownership of your addresses. Only the following registries are supported, and the addresses must have a specified type or status:
  • American Registry for Internet Numbers (ARIN) - "Direct Allocation" and "Direct Assignment" network types
  • Réseaux IP Européens Network Coordination Centre (RIPE NCC) - "ALLOCATED PA," "LEGACY," "ASSIGNED PI," and "ALLOCATED-BY-RIR" allocation statuses
  • Asia-Pacific Network Information Centre (APNIC) – "ALLOCATED PORTABLE" and "ASSIGNED PORTABLE" allocation statuses
• The addresses in the IP address range must have a clean history. We might investigate the reputation of the IP address range and reserve the right to reject an IP address range that contains an IP address that is associated with malicious behavior.

Limits and Quotas

• Your addresses can only be imported to a specific Oracle region.
• You can use BYOIP with a CIDR block that is a minimum of /24 and a maximum of /8.
• You can't bring the same address range to more than one compartment at a time.
• A CIDR block that is /24 or smaller is required for addresses to be advertised to the Internet.
• You can bring up to 10 IPv4 address ranges to your OCI account.
• BYOIP is not available to Oracle Cloud Infrastructure Free Tier or Pay As You Go services.

BYOIP Process Overview

The steps needed for BYOIP in Oracle Cloud Infrastructure require significant time, so plan accordingly. The process is shown in the following diagram:
1. You request to import a public IPv4 CIDR block you own.

2. Oracle issues a verification token.

3. You modify and add the verification token to the information about that public IPv4 CIDR block kept by your RIR service. The details vary depending on the RIR. It can take up to one day for the update to take effect. If you move to the next step before that update takes effect, a day will be added to the total time to complete the process. See To import a BYOIP CIDR block on page 2885 for details.

4. Create a Route Origin Authorization (ROA) with your RIR. As part of the ROA, provide the Oracle BGP ASN (31898 for the commercial cloud). This allows Oracle to advertise the BYOIP CIDR block.

5. Request that Oracle finish the import request, creating a workflow that could take up to 10 days to complete, where Oracle communicates with the RIR and verifies that you own the IP addresses in the CIDR block.
6. Oracle provisions the BYOIP CIDR block to your VCN.
7. At this point, the BYOIP CIDR block is yours to manage in your VCN. You can add addresses to an IP pool, and then use them as reserved IP addresses. You can also advertise the IP addresses to the internet.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

**Limits on IAM Resources**

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Managing BYOIP using the console**

*To import a BYOIP CIDR block*

1. From the BYOIP list page, click Import BYOIP CIDR Block. The Import BYOIP CIDR Block screen appears.
2. In the Import BYOIP CIDR Block screen, enter a name for the BYOIP CIDR Block, choose the compartment, and enter the CIDR block you intend to bring to your tenancy. Avoid entering confidential information.
3. Click Save Changes. The details page for that BYOIP import request appears.
4. In the Next Steps section, make a copy of the validation token. Modify the token slightly, adding the following information as shown. You can use any text editor.

   OCITOKEN::<CIDRblock>::<validation_token>

   The completed token string might look something like: OCITOKEN::10.0.0.0/24:abcdefghij

5. Create a Route Origin Authorization (ROA) object that authorizes Oracle to advertise the BYOIP CIDR block. The Oracle BGP ASN is 31898 for the commercial cloud. For the US Government Cloud, see Oracle's BGP ASN on page 154. Set an expiry date at least 6 months in the future. Follow the instructions appropriate for your RIR.

   - **ARIN**: ROA Requests
   - **RIPE NCC**: Managing ROAs
   - **APNIC**: Route/ROA management

   **Note:**

   If you do not create an ROA, Oracle can't advertise the BYOIP CIDR block. Without being able to advertise the routes, there may be little point in importing them.

6. Now add the modified validation token to the RIR account information associated with your address range. Each RIR uses a slightly different method:

   - **ARIN**: Add the modified token string in the "Public Comments" section associated with your address range.
   - **RIPE NCC**: Add the modified token string as a new "descr" field associated with your address range.
   - **APNIC**: Add the modified token string to the "remarks" field for your address range by emailing it to helpdesk@apnic.net. The email must be sent from the APNIC authorized contact account for the IP address range.

   **Note:**

   The modified validation string must be associated with the address range information. Do not add it to the information for the organization that owns the address range.
7. Wait until both the ROA and the token registration is complete (up to a day) before you click the **Finish Import** button. Otherwise, the process can be delayed up to one day.

8. Return to the details page for the BYOIP request and click **Finish Import**. A confirmation screen appears.

9. Click **Finish Import**, confirming that you would like to validate the BYOIP request. Allow up to 10 days for Oracle to contact your RIR, validate the import, and provision the CIDR block. View the work requests to see the status.

**To view your BYOIP CIDR blocks**

1. Confirm you are viewing the region and compartment you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to **Networking**, go to **IP Management**, and click **BYOIP**.

**To rename a BYOIP CIDR block**

1. In the details page for that BYOIP CIDR block, click **Rename**. A window appears.
2. In the window, enter the new name. Avoid entering confidential information.
3. Click **Save Changes**.

**To remove a BYOIP CIDR block from a pool**

- **Note:**
  
  To successfully remove a BYOIP CIDR block from a pool, there must be no reserved public IP addresses in that address range. You may have to terminate one or more reserved public IP addresses.

1. In the details page for your BYOIP CIDR block, click on the Action Icon corresponding to the subrange you want to remove from a public IP pool, and then click on **Remove from Public IP Pool**. A confirmation window appears.
2. If you are sure you want to delete the BYOIP CIDR block, click **Remove CIDR Block**.

**To delete a BYOIP CIDR block**

To successfully delete a BYOIP CIDR block, it must be in the CREATING, PROVISIONED, ACTIVE, or FAILED state, and it must not have any subranges added to public IP pools.

- **Note:**
  
  If you delete a BYOIP CIDR block, you need to repeat the import process to undo your action.

1. In the details page for your BYOIP CIDR block, click **Delete**. A confirmation window appears.
2. If you are sure you want to delete the BYOIP CIDR block, click **Delete BYOIP CIDR block**.

**To advertise a BYOIP CIDR block**

A BYOIP CIDR block must be provisioned before it can be advertised.

- **Note:**
  
  The BYOIP CIDR block is advertised using a BGP ASN owned by Oracle. Oracle's BGP ASN for the commercial cloud is 31898.

1. In the details page for your BYOIP CIDR block, click **Advertise**. A confirmation window appears.
2. In the confirmation window, click **Advertise**.

**To withdraw a BYOIP CIDR block**

1. In the details page for a BYOIP CIDR block currently being advertised, click **Withdraw**. A confirmation window appears.
2. In the confirmation window, click on **Withdraw**.
To divide a BYOIP CIDR block and assign subranges to a public IP pool

1. From a BYOIP detail page, scroll down to the BYOIP CIDR Block Subranges section and click Manage BYOIP CIDR Block. The Manage BYOIP CIDR Blocks screen appears.
2. Either by entering a number for the CIDR suffix or using the up/down arrows next to the suffix, change the suffix number (often a /24). New rows in the table appear, representing possible subranges within the entire CIDR block.
3. For each of the newly created subranges of the BYOIP CIDR block, check the box in the first column of the table and click Add BYOIP CIDR Blocks to Public IP Pools.
   a. Choose whether to Select an Existing Public IP Pool or Create New Public IP Pool.
      - Select an Existing Public IP Pool: Choose an existing IP pool using the selection list.
      - Create New Public IP Pool: Assign the new pool a name and choose a compartment. You can move the public IP pool to another compartment later. Avoid entering confidential information.
   b. Click Add BYOIP CIDR Blocks to Public IP Pools
4. Repeat the previous step until all subranges of the BYOIP CIDR block are assigned to a public IP pool, then click Submit.

**Note:**
If a subrange of a BYOIP CIDR block is left unassigned to a pool, the table may look different after you click Submit.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage the ByoipRange object, use these operations:
- AdvertiseByoipRange
- ChangeByoipRangeCompartment
- CreateByoipRange
- DeleteByoipRange
- GetByoipRange
- ListByoipRanges
- UpdateByoipRange
- ValidateByoipRange
- WithdrawByoipRange

IP Pools

A public IP pool is simply a set of CIDR blocks allocated to a tenancy. These CIDR blocks can be all or part of a BYOIP CIDR block. Public IP CIDR blocks assigned to a pool are only available for your tenancy. Public IP pools are available as a source for IP allocation when launching a NAT gateway, load balancer, or compute instance. You can add more IP CIDR blocks to a public IP pool at any time. You can also:
- Create a Reserved IP: You can reserve individual IPs from your public IP pools. These reserved IP addresses can be attached to your resources.
- Direct launch from pool: You can launch resources with an IP directly allocated from a public IP pool without previously creating a reserved IP for that resource.
- Delete CIDR blocks and pools: You can delete the entire public IP pool or certain IP CIDR blocks within the pool, provided none of the IP addresses are currently attached or reserved.

Requirements and Preparation
- To use public IP pools with BYOIP addresses, you need to import your addresses.
- To reserve Oracle-supplied public IP addresses, select “Oracle” as the public IP pool when creating the reserved public IP address.
Limits and quotas

- You can create one or up to 10 public IP pools in a compartment.
- A public IP pool can have zero or more IP CIDR ranges assigned to it, with a minimum size of /28 to a maximum size of /24.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

Limits on IAM Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing IP pools using the console

To view your public IP pools

1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Networking, go to IP Management, and click Public IP Pools.

To create a public IP pool

1. From the Public IP Pools list view, click Create Public IP Pool. The Create Public IP Pool screen appears.
2. Give the pool a name. Avoid entering confidential information.
3. Assign the Public IP pool to a compartment.
4. Click Create Public IP Pool.

To delete a public IP pool

1. From the Public IP Pools list view, select a public IP pool from the list and click Delete Public IP Pool. The Delete Public IP Pool verification screen appears.
2. If there are no warnings or errors, click Delete Public IP Pool. If this public IP pool contains reserved public IP addresses currently in use, you can't delete the public IP pool.

To rename a public IP pool

1. From the details view for a public IP pool, click Rename Public IP Pool.
2. Enter a new name for the public IP pool. Avoid entering confidential information.
3. Click Save Changes.

To add CIDR blocks to a public IP pool

1. From the details view for a public IP pool, click Add CIDR Blocks.
2. Choose a named BYOIP CIDR block.
3. Click Add CIDR Blocks.

To remove CIDR blocks from an IP pool

Note:

To successfully remove a BYOIP CIDR block from a public IP pool, there must be no reserved public IP addresses from that address range. You may have to terminate one or more reserved public IP addresses.
Networking

1. In the details page for your BYOIP CIDR block, click the Action Icon corresponding to the subrange you want to remove from a public IP pool, and then click Remove from Public IP Pool. A confirmation window appears.
2. If you are sure you want to delete the BYOIP CIDR block, click Remove CIDR Block.

To reserve a public IP

1. In the details page for a public IP pool, click the Create Reserved Public IP button.
2. Enter a name and specify the compartment for the new reserved public IP address. Avoid entering confidential information.
3. When finished, click Create Reserved Public IP.

To move a public IP pool to another compartment

1. From the details view for an IP pool, click the Move Public IP Pool button. An input screen appears.
2. Choose a new compartment for the public IP pool.
3. Click Move Public IP Pool.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage the Public IP Pool object, use these operations:

- AddPublicIpPoolCapacity
- ChangePublicIpPoolCompartment
- CreatePublicIpPool
- DeletePublicIpPool
- GetPublicIpPool
- ListPublicIpPools
- RemovePublicIpPoolCapacity
- UpdatePublicIpPool

IPv6 Addresses

This topic describes support for IPv6 addressing in your VCN.

Highlights

- IPv6 addressing is currently supported only in the US Government Cloud. See For All US Government Cloud Customers on page 148.
- During VCN creation, you choose whether the VCN is enabled for IPv6. You also choose whether each subnet in an IPv6-enabled VCN is enabled for IPv6. You cannot change whether a VCN or subnet is IPv6-enabled after creation.
- IPv6-enabled VCNs use a /56 IPv6 CIDR block. Oracle assigns a /56 public IPv6 CIDR block to the VCN for internet communication. You can either let the private IPv6 CIDR block be the same as the public CIDR, or provide your own value (in which case it's referred to as a custom IPv6 CIDR). All subnets are /64.
- You also choose whether a given VNIC in an IPv6-enabled subnet has IPv6 addresses (up to 32 maximum per VNIC), and whether each address can be used for internet communication.
- You can choose which particular IPv6 address in the subnet is assigned to a VNIC. This means you can plan how the VCN's private and public address space is allocated within your organization.
- Only these Networking gateways support IPv6 traffic: dynamic routing gateway (DRG) and internet gateway.
- Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network.
- Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported. See other important details in Routing for IPv6 Traffic on page 2896.
- Both FastConnect and IPSec VPN support IPv6 traffic between your VCN and on-premises network. You must configure the FastConnect or IPSec VPN for IPv6.
Overview of IPv6 Addresses

Oracle supports dual-stack IPv4/IPv6 addressing for VCNs. Every VCN always supports IPv4, and you can optionally enable IPv6 during VCN creation. Enabling IPv6 for the VCN means that when you create a subnet, you can optionally enable it to also have IPv6 addresses. Therefore a VCN can have a mix of IPv4-only subnets and IPv6-enabled subnets.

After you create a Compute instance, you may optionally add an IPv6 to the VNIC. You can add up to 32 IPv6s to a given VNIC. You can remove an IPv6 from a VNIC at any time.

CIDRs Assigned to an IPv6-Enabled VCN

An IPv6-enabled VCN has 3 CIDR blocks assigned to it. The following table summarizes them.

<table>
<thead>
<tr>
<th>IPv4 or IPv6</th>
<th>Use and Size</th>
<th>Who Assigns the CIDR Block</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private IPv4 CIDR</td>
<td>Private communication</td>
<td>You</td>
<td>Typically RFC 1918 range</td>
</tr>
<tr>
<td></td>
<td>/16 to /30</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Private IPv6 CIDR*</td>
<td>On-premises communication&lt;br&gt;Only /56</td>
<td>Optionally, you can assign it. If you do, it's referred to in this documentation as a custom IPv6 CIDR. Or, you can let Oracle assign it.</td>
<td>If you assign it, see <a href="#">Overview of IPv6 Addresses</a> on page 2890.</td>
</tr>
<tr>
<td>Public IPv6 CIDR</td>
<td>Internet communication&lt;br&gt;Only /56</td>
<td>Oracle</td>
<td>If you assign the VCN's private IPv6 CIDR, it will be different from the public IPv6 CIDR that Oracle assigns. But if you let Oracle assign the VCN's private IPv6 CIDR, Oracle uses the same CIDR for both the private and public IPv6 CIDRs. That means the private address and public address for a given IPv6 are the same.</td>
</tr>
</tbody>
</table>

* Oracle assigns IPv6 CIDR blocks that are NOT in the IPv6 unique local address (ULA) range. This range is analogous to the IPv4 RFC 1918 private ranges. Therefore, all Oracle-assigned IPv6 CIDRs can be considered public ranges by this definition.
Allowed Custom IPv6 CIDR Ranges

Your custom IPv6 CIDR block can be in these general ranges:

- Global unicast: 2000::/3
- ULA: fc00::/7

But it cannot be in these IANA special registry ranges:

- IETF protocol assignments: 2001::/23
- Documentation: 2001:db8::/32
- 6to4: 2002::/16
- Direct Delegation AS112 Service: 2620:4f:8000::/56

Internet Communication

Regardless of whether you or Oracle assigns the VCN's private IPv6 CIDR, Oracle also assigns the VCN an IPv6 CIDR block for the public IP address space (the public IPv6 CIDR). These addresses are used for internet communication. If you do not assign a custom CIDR, Oracle uses the same Oracle-assigned public IPv6 CIDR for the private address space. This means that a given VNIC might use the same IPv6 IP address for both private and internet communication.

You control whether a given IPv6 address can be used for internet communication. If the IPv6 is in a private subnet, it can never be used for internet communication. If it's in a public subnet, you can enable or disable internet access for that IPv6 at any time. If internet access is enabled, the IPv6 uses its public IPv6 address for communication.

Assignment of IPv6 Addresses to a VNIC

To enable IPv6 for a given VNIC, you assign an IPv6 to the VNIC. You can assign up to 32 IPv6s to a VNIC.

As with IPv4, when assigning an IPv6, you can specify the particular address you want to use, or let Oracle choose one for you. By choosing the IPv6 addresses yourself, you can plan how the VCN's private and public address space is allocated within your organization.

You also choose whether the IPv6 has internet access enabled (it is enabled by default if the VNIC is in a public subnet). A VNIC with an internet-enabled IPv6 is not required to have a public IPv4 address.

You can move an IPv6 address from one VNIC to another in the same subnet.

After adding an IPv6 to a VNIC, you must configure the instance's OS to use the IPv6.

Format of IPv6 Addresses

IPv6 addresses have 128 bits.

An IPv6 CIDR block for a VCN must be /56 in size. The left 56 bits identify the VCN portion of the address. For example:

2001:0db8:0123::/56

An IPv6 CIDR block for a subnet must be /64 in size. The right 16 bits in a subnet's CIDR identify the subnet portion of the address. In the following example, the 1111 is the unique portion for the subnet:

2001:0db8:0123:1111::/64

The right-most 64 bits of an IPv6 address identify the unique portion specific to the particular IPv6 address. For example:

For a given IPv6, those right-most 64 bits are identical for both the private and public address for an IPv6. When you assign an IPv6 to a VNIC, you can specify which specific IPv6 address to use (those 64 bits). Therefore you can control how the private and public address space is allocated within your organization.
**Example 1: You assign a custom CIDR**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle recommends this option if you want instances within the same IPv6-enabled VCN to communicate with each other using public IPv6 addresses. For more information, see Routing for IPv6 Traffic on page 2896.</td>
</tr>
</tbody>
</table>

Let's say you provide this custom IPv6 CIDR: fd00:aaaa:0123::/56.

Oracle assigns a separate CIDR block for the VCN's public CIDR: 2001:0db8:9999::/56.

The following diagram illustrates the VCN and includes two subnets: public subnet 1111 and private subnet 1112.
The VNIC in the public subnet has a primary private IPv4 (10.0.1.4) with an optional public IP address assigned. The VNIC has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.

The VNIC also has two IPv6s. The first one has internet access enabled and therefore has both private and public IPv6 addresses, which are the following:
• Private IPv6 address: fd00:aaaa:0123:1111:abcd:ef01:2345:0006
• Public IPv6 address: 2001:0db8:9999:1111:abcd:ef01:2345:0006

Notice that the right-most 64 bits are the same for both the private and public IP address, as are the subnet's 16 bits. Only the left 48-most bits differ.

The second IPv6 in the public subnet does not have internet access enabled and therefore has only a private IP address, which is fd00:aaaa:0123:1111:abcd:ef01:2345:0007.

The second subnet is private, which means the VNICS can never have public IPv4 or IPv6 addresses. In this case, there's one VNIC that has a primary and secondary IPv4 with addresses 10.0.2.4 and 10.0.2.5, respectively.

The VNIC also has two IPv6s. The first has private address fd00:aaaa:0123:1112:abcd:ef01:2345:0006, and the second IPv6 has private address fd00:aaaa:0123:1112:abcd:ef01:2345:0007.

Example 2: You let Oracle assign the VCN's CIDR

You do not assign a custom CIDR, and Oracle assigns this CIDR: 2001:0db8:0123::/56. Oracle uses this same CIDR for both the private and public IP addresses.

The following diagram illustrates the VCN and includes two subnets: public subnet 1111 and private subnet 1112.
Networking

The VNIC in the public subnet has a primary private IPv4 (10.0.1.4) with an optional public IP address assigned. The VNIC has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.

The VNIC also has two IPv6s. The first one has internet access enabled and therefore has both private and public IPv6 addresses, which are the following:

- **Private IPv6**: 2001:0db8:0123:1111::abcd:ef01:2345:0006
  - **Internet access**: YES
- **Public IPv6**: 2001:0db8:0123:1111::abcd:ef01:2345:0006
- **Private IPv6**: 2001:0db8:0123:1111::abcd:ef01:2345:0007
  - **Internet access**: NO

The VNIC in the public subnet has a primary private IPv4 (10.0.1.4) with an optional public IP address assigned. The VNIC has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.

The VNIC also has two IPv6s. The first one has internet access enabled and therefore has both private and public IPv6 addresses, which are the following:
Networking

Notice that the two addresses are the same.

The second IPv6 does not have internet access enabled and therefore has only a private IP address, which is 2001:0db8:0123:1111:abcd:ef01:2345:0007.

The second subnet is private, which means the VNICs can never have public addresses, IPv4 or IPv6. In this case, there's one VNIC that has a primary and secondary IPv4 with addresses 10.0.2.4 and 10.0.2.5, respectively.

The VNIC also has two IPv6s. The first has private address 2001:0db8:0123:1112:abcd:ef01:2345:0006, and the second IPv6 has private address 2001:0db8:0123:1112:abcd:ef01:2345:0007.

Routing for IPv6 Traffic

Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network.

Here are other important details about routing of IPv6 traffic:

- Currently IPv6 traffic is supported only through these gateways:
  - **Dynamic routing gateway (DRG):** For access to your on-premises network or other networks outside the region. Both Oracle Cloud Infrastructure FastConnect and IPSec VPN support IPv6 traffic. For more details about IPv6 configuration, see the upcoming sections.
  - **Internet gateway:** For access to the internet.
- Traffic between instances on their public IPv6 addresses is supported and must traverse the VCN’s internet gateway. Exception: if the given IPv6 uses the same address for both private and public communication, traffic between instances on their public IPv6 address is not supported. Therefore, if you want instances in the same VCN to communicate with each other using public IPv6 addresses, specify your own private IPv6 CIDR when creating the VCN. This means the private address for an IPv6 in the VCN will be different than its public address. For more information, see Overview of IPv6 Addresses on page 2890.
- Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported.

VCN Route Tables and IPv6

The VCN’s route tables support both IPv4 rules and IPv6 rules that use a DRG or internet gateway as the target. For example, the route table for a given subnet could have these rules:

- Rule to route traffic that matches a certain IPv4 CIDR to the VCN’s attached DRG
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN’s service gateway
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN’s NAT gateway
- Rule to route traffic that matches a certain IPv6 CIDR to the VCN’s attached DRG
- Rule to route traffic that matches a certain IPv6 CIDR to the VCN’s attached internet gateway

Security Rules for IPv6 Traffic

Like route tables, the VCN’s network security groups and security lists Security Rules on page 2833 support both IPv4 and IPv6 rules. For example, a network security group or security list could have these security rules:

- Rule to allow SSH traffic from the on-premises network's IPv4 CIDR
- Rule to allow ping traffic from the on-premises network's IPv4 CIDR
- Rule to allow SSH traffic from the on-premises network's **IPv6** CIDR
- Rule to allow ping traffic from the on-premises network's **IPv6** CIDR

The default security list in an IPv6-enabled VCN includes default IPv4 rules and the following default IPv6 rules:

- **Stateful ingress:** Allow IPv6 TCP traffic on destination port 22 (SSH) from source ::/0 and any source port. This rule makes it easy for you to create a new VCN with a public subnet and internet gateway, create a Linux instance,
add an internet-access-enabled IPv6, and then immediately connect with SSH to that instance without needing to write any security rules yourself.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
</table>
| The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using Windows images, add a stateful ingress rule for TCP traffic on destination port 3389 from source ::/0 and any source port.  
See To enable RDP access for more information. |

- **Stateful ingress**: Allow ICMPv6 traffic type 2 code 0 (Packet Too Big) from source ::/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages.
- **Stateful egress**: Allow all IPv6 traffic. This allows instances to initiate IPv6 traffic of any kind to any destination. Notice that this means the instances with an internet-access-enabled IPv6 can talk to any internet IPv6 address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Stateful Versus Stateless Rules on page 2839.

**FastConnect and IPv6**

If you use *FastConnect*, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. In general, you must ensure that the FastConnect virtual circuit has IPv6 BGP addresses, and update the VCN's routing and security rules for IPv6 traffic.

**About the IPv6 BGP Addresses**

A FastConnect virtual circuit always requires IPv4 BGP addresses, but IPv6 BGP addresses are optional and only required for IPv6 traffic. Depending on how you're using FastConnect, you might be asked to provide all of the virtual circuit's BGP addresses yourself (both IPv4 and IPv6).

The addresses consist of a pair: one for your end of the BGP session, and another for the Oracle end of the BGP session.

When you specify a BGP address pair, you must include a subnet mask that contains both of the addresses. Specifically for IPv6, the allowed subnet masks are:

- /64
- /96
- /126
- /127

For example, you could specify 2001:db8::6/127 for the address at your end of the BGP session, and 2001:db8::7/127 for the Oracle end.

**Process to Enable IPv6**

In general, here's how to enable IPv6 for a FastConnect virtual circuit:

- **Virtual circuit BGP**: Ensure the FastConnect virtual circuit has IPv6 BGP addresses. If you're responsible for providing the BGP IP addresses, when you set up a new virtual circuit or edit an existing one, there's a place for the two IPv4 BGP addresses. There's a separate check box for Enable IPv6 Address Assignment and a place to provide the two IPv6 addresses. Be aware that if you're editing an existing virtual circuit to add support for IPv6, it will go down while it's being reprovisioned to use the new BGP information.

- **VCN route tables**: For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the IPv6 subnets in your on-premises network. For example, the Destination CIDR Block for a route rule would be an IPv6 subnet in your on-premises network, and the Target would be the dynamic routing gateway (DRG) attached to the IPv6-enabled VCN.
• **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow IPv6 traffic between the VCN and your on-premises network. See Security Rules for IPv6 Traffic on page 2896.

If you do not yet have a FastConnect connection, see these topics to get started:
- FastConnect Overview on page 3173
- FastConnect Requirements on page 3181

**VPN Connect and IPv6**

If you use VPN Connect, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. Here’s how to enable IPv6 for the connection:

- **IPSec connection static routes:** Configure the IPSec connection with the IPv6 static routes of your on-premises network. Currently the Oracle IPSec VPN does not support BGP dynamic routing.
- **VCN route tables:** For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the IPv6 subnets in your on-premises network. For example, the Destination CIDR Block for a route rule would be an IPv6 static route for your on-premises network, and the Target would be the dynamic routing gateway (DRG) attached to the IPv6-enabled VCN.
- **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow the wanted IPv6 traffic between the VCN and your on-premises network. See Security Rules for IPv6 Traffic on page 2896.

If you have an existing IPSec VPN that uses static routing, you can update the list of static routes to include ones for IPv6. Be aware that changing the list of static routes causes the IPSec VPN to go down while it's being reprovisioned. See Changing the Static Routes on page 3157.

If you do not yet have an IPSec VPN, see these topics to get started:
- VPN Connect Overview on page 2933
- Setting Up VPN Connect on page 2949
- Working with VPN Connect on page 3156

**DHCP**

Currently DHCPv6 auto-configuration of IP addresses is not supported.

**DNS**

The VCN’s Internet Resolver supports IPv6, which means resources in your VCN can resolve IPv6 addresses of hosts outside the VCN. IPv6 traffic between resources within the VCN is not yet supported, and assignment of a hostname to an IPv6 address is not supported.

**Load Balancers**

When you create a load balancer, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. There is no IPv6 communication between the load balancer and the backend servers.

IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.

**Comparison of IPv4 and IPv6 for Your VCN**

The following table summarizes the differences between IPv4 and IPv6 addressing in a VCN.
<table>
<thead>
<tr>
<th>Characteristic</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Addressing type supported</strong></td>
<td>IPv4 addressing is always required, regardless of whether IPv6 is enabled.</td>
<td>IPv6 addressing is optional per VCN, optional per subnet in an IPv6-enabled VCN, and optional per VNIC in an IPv6-enabled subnet.</td>
</tr>
<tr>
<td><strong>Supported traffic types</strong></td>
<td>IPv4 traffic is supported for all gateways. IPv4 traffic between instances within the VCN is supported (east/west traffic).</td>
<td>IPv6 traffic is supported only with these gateways: internet gateway and DRG. Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network. Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported (east/west traffic). Also see the caveats in Routing for IPv6 Traffic on page 2896.</td>
</tr>
<tr>
<td><strong>VCN size</strong></td>
<td>/16 to /30</td>
<td>/56 only</td>
</tr>
<tr>
<td><strong>Subnet size</strong></td>
<td>/16 to /30, with 3 addresses reserved in each subnet by Oracle (first 2 and last 1).</td>
<td>/64 only, with 8 addresses in the subnet reserved by Oracle (first 4 and last 4).</td>
</tr>
<tr>
<td><strong>Private and public IP address space</strong></td>
<td>Private: A VCN's private IPv4 CIDR can be from an RFC 1918 range or a publicly routable range (in which case, it's treated as private). You must specify the range, unless you use the Console's VCN creation wizard, which always uses 10.0.0.0/16. Public: The VCN does not have a dedicated public IPv4 address space. Any public addresses in your VCN are always chosen by Oracle.</td>
<td>You can specify a /56 from the list of supported ranges for the private IPv6 CIDR (see Overview of IPv6 Addresses on page 2890). If you don't specify a range, Oracle assigns a /56 CIDR that is used for both the private and public IP address space. <strong>Important:</strong> You must assign this value if you want instances in the same VCN to communicate with each other using public IPv6 addresses. For more information, see Routing for IPv6 Traffic on page 2896. Unlike with IPv4, your VCN has a dedicated public IPv6 address space, which is always /56 in size. When you assign an IPv6 to a VNIC, you can choose the address, or you can let Oracle chose it.</td>
</tr>
</tbody>
</table>
### Networking

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IP address assignment</strong></td>
<td>Private: Each VNIC gets a private IPv4 address. You can choose the address or let Oracle choose it. Public: You determine whether the private IPv4 address has a public IP address associated with it (assuming the VNIC is in a public subnet). Oracle chooses the public IP address. From an API standpoint: the PrivateIp object is separate from the PublicIp object. You can remove the public IP address from the private IPv4 address at any time.</td>
<td>You decide whether a VNIC in an IPv6-enabled subnet gets an IPv6. You can choose the private IPv6 address or let Oracle choose it. You also decide whether that IPv6 has internet access enabled (assuming the VNIC is in a public subnet). You can remove the internet access for that IPv6 at any time. When an IPv6 is internet enabled, it has a public IPv6 address. The public IPv6 address always has the same right-most 64 bits as the private IPv6 address. Recall that if Oracle assigns the VCN's private IPv6 CIDR, then the private and public CIDRs for the VCN are the same. In that case, each IPv6 uses the same address (all 128 bits) for both its private IP address and public IP address. From an API standpoint: both the private and public IP addresses are included in the IPv6 object and always exist together.</td>
</tr>
<tr>
<td><strong>Internet access</strong></td>
<td>You control whether a subnet is public or private. You add or remove a public IP address from a private IPv4 address on a VNIC (assuming the VNIC is in a public subnet).</td>
<td>You control whether a subnet is public or private. You do not add or remove a public IP address to or from the VNIC as you do with IPv4. Instead you enable or disable the internet access for a given IPv6 that you've added to a VNIC (assuming the VNIC is in a public subnet).</td>
</tr>
<tr>
<td><strong>Primary and secondary labels</strong></td>
<td>Each VNIC automatically has a primary private IP address, and you can assign up to 31 secondary private IPs per VNIC.</td>
<td>You choose to add an IPv6 to a VNIC. There is no primary or secondary label for it. You can assign up to 32 IPv6s per VNIC.</td>
</tr>
<tr>
<td><strong>Hostnames</strong></td>
<td>You can assign hostnames to IPv4 addresses.</td>
<td>You cannot assign hostnames to IPv6 addresses.</td>
</tr>
<tr>
<td><strong>Route rule limits</strong></td>
<td>See Service Limits on page 215.</td>
<td>IPv4 and IPv6 route rules can reside together in the same route table. IPv6 route rules can target only an internet gateway or DRG. Limit on number of IPv6 route rules in a route table: 8.</td>
</tr>
</tbody>
</table>
### Networking

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security rule limits</td>
<td>See Service Limits on page 215. IPv4 and IPv6 security rules can reside together in same network security group or security list. IPv6 security rules can use only IPv6 CIDR ranges for source or destination, and not a service CIDR label used for a service gateway. Limit on number of IPv6 security rules in a security list: 8 ingress and 8 egress. Limit on number of IPv6 security rules in a network security group: 16 total.</td>
<td>IPv4 and IPv6 security rules can reside together in same network security group or security list. IPv6 security rules can use only IPv6 CIDR ranges for source or destination, and not a service CIDR label used for a service gateway. Limit on number of IPv6 security rules in a security list: 8 ingress and 8 egress. Limit on number of IPv6 security rules in a network security group: 16 total.</td>
</tr>
<tr>
<td>Reserved public IP addresses</td>
<td>Supported.</td>
<td>Not supported.</td>
</tr>
<tr>
<td>Regional or AD-specific</td>
<td>Primary private IPv4 addresses are AD-specific. Secondary private IPv4 addresses are AD-specific unless assigned to a VNIC in a regional subnet. Public IP addresses can be AD-specific or regional depending on the type (ephemeral or reserved). See Public IP Addresses on page 2875.</td>
<td>IPv6 addresses are regional.</td>
</tr>
</tbody>
</table>

### Setting Up an IPv6-Enabled VCN with Internet Access

Use the following process if you want to set up an IPv6-enabled VCN with internet access so you can easily launch an instance and connect to it by using its public IPv6 address.

**Task 1: Create the IPv6-enabled VCN**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.
3. Click Create Virtual Cloud Network.
4. Enter the following:
   - **Name**: A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: Leave as is.
   - **CIDR Block**: A single, contiguous IPv4 CIDR block for the VCN. For example: 172.16.0.0/16. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment**: Select the check box and optionally provide the private IPv6 CIDR in the field labeled Private IPv6 CIDR Block. You must provide the value if you want the instances in this IPv6-enabled VCN to communicate with each other using their public IP addresses. Leave the field blank if you want Oracle to assign the private IPv6 CIDR for you. You cannot later disable IPv6 for the VCN or change the CIDR. All IPv6-enabled VCNs are always /56 in size.
   - **Use DNS Hostnames in this VCN** (supported for IPv4 only): Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the
Networking

VCN (<VCN DNS label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.

- **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.

5. Click **Create Virtual Cloud Network**.

The VCN is then created and displayed on the Virtual Cloud Networks page in the compartment you chose.

**Task 2: Create a regional IPv6-enabled public subnet**

1. While still viewing the VCN, click **Create Subnet**.
2. Enter the following:

   - **Name**: A descriptive name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and you can change it later. Avoid entering confidential information.

   - **Regional or Availability Domain-specific subnet**: Oracle recommends creating only **regional subnets**, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose **Availability Domain-Specific** (the only kind of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.

   - **CIDR Block**: A single, contiguous IPv4 CIDR block for the subnet (for example, 172.16.0.0/24). The address block must be within the VCN's IPv4 CIDR block and not overlap any other subnets. You **cannot** change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.

   - **Enable IPv6 Address Assignment**: Select the check box and provide your choice of 16 bits for the subnet (example: 1111). You **cannot** later disable IPv6 for the subnet or change the CIDR. All IPv6-enabled subnets are always /64 in size. For more information about IPv6 address format, see Overview of IPv6 Addresses on page 2890.

   - **Route Table**: Select the default route table.

   - **Private or public subnet**: Select **Public Subnet**, which means instances in the subnet can optionally have public IP addresses. For more information, see Access to the Internet on page 2752.

   - **Use DNS Hostnames in this Subnet** (supported for IPv4 only): This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network on page 2910.

   - **DHCP Options**: Select the default set of DHCP options.

   - **Security Lists**: Select the default security list.

   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.

3. Click **Create Subnet**.

   The subnet is then created and displayed on the Subnets page.

**Task 3: Create the internet gateway**

1. Under **Resources**, click **Internet Gateways**.
2. Click **Create Internet Gateway**.
3. Enter the following:

   - **Name**: A descriptive name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

   - **Create in Compartment**: Leave as is.

   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.

4. Click **Create Internet Gateway**.

   Your internet gateway is created and displayed on the Internet Gateways page. It's already enabled, but you must add route rules that allow IPv4 and IPv6 traffic to flow to the gateway.
Task 4: Update the default route table to use the internet gateway

The default route table starts out with no rules. Here you add rules that route all IPv4 and IPv6 traffic destined for addresses outside the VCN to the internet gateway. The existence of these rules also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security rules to control the types of traffic that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required in order to route traffic within the VCN itself.

1. Under Resources, click Route Tables.
2. Click the default route table to view its details.
3. Click Add Route Rules.
4. Enter the following:
   - **Target Type**: Internet Gateway
   - **Destination CIDR block**: 0.0.0.0/0 (which means that all IPv4 non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
   - **Compartment**: The compartment where the internet gateway is located.
   - **Target**: The internet gateway you created.
   - **Description**: An optional description of the rule.
5. Click + Additional Route Rule.
6. Enter the following:
   - **Target Type**: Internet Gateway
   - **Destination CIDR block**: ::/0 (for the IPv6 traffic).
   - **Compartment**: The compartment where the internet gateway is located.
   - **Target**: The internet gateway you created.
   - **Description**: An optional description of the rule.
7. Click Add Route Rules.

The default route table now has two rules for the internet gateway, one for IPv4 traffic and one for IPv6 traffic. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.

Task 5: Update the default security list (optional)

**Note:**

This task is about configuring security rules to allow traffic to and from your instances. Although this task uses a security list to implement those rules, you can also use network security groups to implement security rules.

Earlier you set up the subnet to use the VCN's default security list. This list already includes basic rules that allow essential IPv4 and IPv6 traffic. In this task, you add any additional security rules that allow the types of connections that the instances in the VCN will need.

For example: This is a public subnet with an internet gateway, so the instances you create might need to receive inbound HTTPS connections from the internet (if they're web servers). Here's how to add another rule to the default security list to enable that traffic:

2. Click the default security list to view its details. By default, you land on the Ingress Rules page.
3. Click Add Ingress Rule.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - **Stateless**: Unselected (this is a stateful rule)
   - **Source Type**: CIDR
   - **Source CIDR**: 0.0.0.0/0 (or ::/0 if you want to enable IPv6 traffic with this rule)
   - **IP Protocol**: TCP
   - **Source Port Range**: All
   - **Destination Port Range**: 443
   - **Description**: An optional description of the rule.

5. Click **Add Ingress Rule**.

   **Important:**

   Security List Rule for Windows Instances

   If you're going to create Windows instances, you need to add a security rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 (and a separate rule with ::/0 for IPv6 traffic) and any source port.

   For more information, see [Security Rules](#page-2833) on page 2833.

For a production VCN, you typically set up one or more custom security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages for IPv4.

**Task 6: Create an instance**

Your next step is to create an instance in the subnet. When you create the instance, you choose the availability domain, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IPv4 address. When you create an instance in a public subnet, you choose whether the instance gets a public IP address. A public IPv4 address is NOT required for public IPv6 traffic. But if you want to connect to the instance from an IPv4 host, you must give the instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

For more information and instructions, see [Launching an Instance](#page-2835).

**Task 7: Add an internet-enabled IPv6 to the instance**

1. While viewing the instance you just created, click **Attached VNICs**.
2. Click the VNIC.
3. Under Resources, click **IPv6 Addresses**.
4. Click **Assign Private IPv6 Address**.
5. Enter the following:
   - **Private IPv6 Address**: Optional. An available private IPv6 address of your choice from the subnet's private IPv6 CIDR (otherwise the private IP address is automatically assigned).
   - **Unassign if already assigned to another VNIC**: Leave this check box as is (cleared). Use this only to force reassignment of an IPv6 address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a private IP address in the preceding field.
   - **Enable Internet Access**: Select this check box. This enables internet access and assigns the IPv6 a public address (if it's in a public subnet, which is the case here). See [Overview of IPv6 Addresses](#page-2890) on page 2890.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see [Resource Tags](#page-211) on page 211.
6. Click **Assign**.

   The IPv6 is created and then displayed on the **IPv6 Addresses** page for the VNIC. Notice that it has both a private and public IPv6 address.
Task 8: Configure the instance's OS to use the IPv6

You must configure the instance's OS to use the IPv6. For more information, see Configuring the OS to Use an IPv6 on page 2907.

After performing this task, you can connect to the instance over the internet with SSH or RDP from your on-premises network or a location on the internet. The host connecting to the instance must be using a public IPv6 address.

Managing IPv6s in the Console

This section includes basic tasks for working with IPv6-related resources.

To create an IPv6-enabled VCN

Important:
You can't enable IPv6 for an existing VCN. You can only enable IPv6 when creating a VCN. After enabling IPv6 for a VCN, you cannot disable it.

See the instructions in Task 1: Create the IPv6-enabled VCN on page 2901.

To create an IPv6-enabled subnet

Important:
After enabling IPv6 for a subnet, you cannot disable it.

Summary: Creating an IPv6-enabled subnet is similar to creating an IPv4 subnet. The only difference is that you must select the check box for Enable IPv6 Address Assignment and provide 16 bits for the subnet's portion of the IPv6 CIDR. See Overview of IPv6 Addresses on page 2890.

For general instructions, see Task 2: Create a regional IPv6-enabled public subnet on page 2902. If you want a private subnet, select the radio button for Private Subnet when creating the subnet.

To assign an IPv6 to a VNIC

The process for adding an IPv6 to a VNIC is similar to adding a secondary private IPv4 address. You can specify the particular IPv6 address to use or let Oracle choose it from the subnet. You can enable internet access if you like. The resulting public IPv6 address uses the same right-most 64 bits as the private IPv6 address. In certain situations, the entire IPv6 address is the same. For more information, see Overview of IPv6 Addresses on page 2890. After assigning the IPv6 to the VNIC, you must configure the OS to use the IPv6.

1. Assign the IPv6. For general instructions, see Task 7: Add an internet-enabled IPv6 to the instance on page 2904. If you want an IPv6 without internet access, do not select the check box for Enable Internet Access when assigning the IPv6.
2. Configure the OS to use the IPv6 address. For more information, see Configuring the OS to Use an IPv6 on page 2907.

To move an IPv6 to another VNIC in the subnet

The process is similar to moving a secondary private IPv4 address from one VNIC to another (let's call them the original VNIC and the new VNIC). You assign the IPv6 to the new VNIC, specify the private IPv6 address, and select the check box for Unassign if already assigned to another VNIC. Oracle automatically unassigns it from original VNIC and assigns it to the new VNIC. The public address for the IPv6 stays the same regardless of which VNIC the IPv6 is assigned to.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICs.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
7. Click Assign Private IP Address.
8. Enter the following:
   - **Private IPv6 Address**: The private IPv6 address that you want to move.
   - **Unassign if already assigned to another VNIC**: Select this check box to move the IPv6 address from the VNIC it's currently assigned to.
   - **Enable Internet Access**: Whether to assign a public IPv6 address. Available only if the VNIC is in a public subnet. See Overview of IPv6 Addresses on page 2890.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

9. Click **Assign**.

The private IP address is moved from the original VNIC to the new VNIC.

**To delete an IPv6 from a VNIC**

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
7. For the IPv6 you want to delete, click the Actions icon (three dots), and then click Delete IPv6.
8. Confirm when prompted.

The IPv6 address is returned to the pool of available addresses in the subnet.

**To enable or disable internet access for an IPv6**

Internet access for an IPv6 is controlled by the IPv6's Enable Internet Access check box. When you enable internet access, the IPv6 is assigned a public IPv6 address. That address's right-most 64 bits are the same as the private IPv6 address. In certain situations, the entire IPv6 address is the same. For more information, see Overview of IPv6 Addresses on page 2890.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click the instance to view its details.
4. Under Resources, click Attached VNICS.
   - The primary VNIC and any secondary VNICS attached to the instance are displayed.
5. Click the VNIC you're interested in.
7. For the IPv6 you're interested in, click the Actions icon (three dots), and then click Edit.
8. Either select or clear the check box for Enable Internet Access.
9. Click Update.

When you disable internet access, the public IPv6 address becomes null. If you re-enable internet access, the public IPv6 address is again assigned to the IPv6.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For IPv6 addressing, there's an Ipv6 object with the following operations:

- ListIpv6s
- GetIpv6
Networking

- UpdateIpv6
- CreateIpv6
- DeleteIpv6

**Configuring the OS to Use an IPv6**

After assigning an IPv6 to a VNIC, you must configure the OS to use the IPv6.

**Getting the IPv6 Virtual Router IP (Default Gateway)**

You need the IPv6 virtual router IP (called the default gateway in Windows), which is included in the instance metadata available at the following URL:

```
```

Here's an example response:

```
[
   {
      "vnicId": "ocid1.vnic.oc1.phx.examplevq7kncmdtfr23dznohkd2cywjcem33eg3dxa",
      "privateIp": "10.0.3.7",
      "vlanTag": 3396,
      "macAddr": "00:00:17:01:14:0C",
      "virtualRouterIp": "10.0.3.1",
      "subnetCidrBlock": "10.0.3.0/24",
      "ipv6SubnetCidrBlock": "2001:0db8:95f4::/64",
      "ipv6VirtualRouterIp": "2001:0db8::200:17ff:fee3:c491"
   }
]
```

**Oracle Linux Configuration**

The following commands are for Oracle Linux 8 and Oracle Linux 7. They are NOT persistent through a reboot. You need the IPv6 virtual router IP from the instance metadata (see the previous section).

```
sysctl net.ipv6.conf.all.disable_ipv6=0
ip -6 addr add <private_IPv6_address>/64 dev <interface_name>
ip -6 route add default via <IPv6_virtual_router_IP> dev <interface_name>
```

For example:

```
sysctl net.ipv6.conf.all.disable_ipv6=0
ip -6 addr add 2001:0db8:95f4::abcd:1234/64 dev ens3
ip -6 route add default via 2001:0db8::200:17ff:fee3:c491 dev ens3
```

If you haven't yet, ensure that the VCN's route table and security rules are configured for the wanted IPv6 traffic. See Routing for IPv6 Traffic on page 2896 and Security Rules for IPv6 Traffic on page 2896.

**Windows Configuration**

You can use a command line or the Network Connections UI.

**Command Line**

If you use PowerShell, you must run it as an administrator. The following configuration persists through a reboot of the instance.
1. In your browser, go to the Console, and note the private IPv6 address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:
   
   ```
   ```
3. Note the value for the `ipv6VirtualRouterIp`, which is the `<default_gateway>` to use in the next step.
4. Run the following 2 commands:
   
   ```
   netsh interface ipv6 add address interface="Ethernet" 
   address=<private_IPv6_address>/64 
   netsh interface ipv6 add route prefix=::/0 interface="Ethernet" 
   nexthop=<default_gateway> publish=Yes
   ```
   
   For example:
   
   ```
   netsh interface ipv6 add address interface="Ethernet" 
   address=2001:0db8:95f4::abcd:1234/64 
   netsh interface ipv6 add route prefix=::/0 interface="Ethernet" 
   nexthop=2001:0db8::200:17ff:fee3:c491 publish=Yes
   ```
   
   If you haven’t yet, ensure that the VCN’s route table and security rules are configured for the wanted IPv6 traffic. See Routing for IPv6 Traffic on page 2896 and Security Rules for IPv6 Traffic on page 2896.

   You can run the following command to see that the IPv6 address has been configured for the interface:
   
   ```
   netsh interface ipv6 show addresses
   ```
   
   Later if you want to delete the address, you can use this command:
   
   ```
   netsh interface ipv6 delete address interface="Ethernet" 
   address=<private_IPv6_address>
   ```
   
   For example:
   
   ```
   netsh interface ipv6 delete address interface="Ethernet" 
   address=2001:0db8:95f4::abcd:1234
   ```
   
   Also delete the IPv6 from the VNIC. You can do that before or after executing the earlier command to delete the address from the OS configuration.

   **Network Connections UI**

   The following configuration persists through a reboot of the instance.

   1. In your browser, go to the Console, and note the private IPv6 address that you want to configure on the instance.
   2. Connect to the instance, and run the following command at a command prompt:
      
      ```
      ```
   3. Note the value for the `ipv6VirtualRouterIp`, which is the default gateway to use in a later step.
   4. In the instance’s Control Panel, go to Network and Internet, and view your network connections (see the image that follows for the set of dialog boxes you see in these steps).
   5. For the active networks, click the connection (Ethernet).
   6. Click Properties.
7. Click **Internet Protocol Version 6 (TCP/IPv6)**, and then click **Properties**.

8. Select the radio button for **Use the following IP address**, and then enter the values you noted earlier for the private IPv6 address and default gateway. Use 64 for the subnet prefix length.

9. Click **OK** until the dialog boxes are closed.

If you haven't yet, ensure that the VCN's route table and security rules are configured for the wanted IPv6 traffic. See **Routing for IPv6 Traffic** on page 2896 and **Security Rules for IPv6 Traffic** on page 2896.
**DNS in Your Virtual Cloud Network**

The Domain Name System (DNS) lets computers use hostnames instead of IP addresses to communicate with each other.

**Choices for DNS in Your VCN**

Following are the choices for DNS name resolution for the instances in your VCN. You make this choice for *each subnet* in the VCN, using the subnet's set of DHCP options. This is similar to how you configure which route table and security lists are associated with each subnet. For more information, see [DHCP Options](#) on page 2917.

**Note:**

You use the Domain Name Server DHCP option to specify the DNS Type for the associated subnet. If you change the option's value, either restart the DHCP client on the instance or reboot the instance. Otherwise, the change does not get picked up until the DHCP client refreshes the lease (within 24 hours).

**DEFAULT CHOICE: INTERNET AND VCN RESOLVER**

This is an Oracle-provided option that includes two parts:

- **Internet Resolver:** Lets instances resolve hostnames that are publicly published on the internet. The instances do not need to have internet access by way of either an internet gateway or a connection to your on-premises network (such as an IPSec VPN connection through a DRG).
- **VCN Resolver:** Lets instances resolve hostnames (which you can assign) of other instances in the same VCN. For more information, see [About the DNS Domains and Hostnames](#) on page 2910.

By default, new VCNs you create use the Internet and VCN Resolver. If you're using the Networking API, this choice refers to the `VcnLocalPlusInternet` enum in the `DhcpDnsOption` object.

**Note:**

By default, the Internet and VCN Resolver does not let instances resolve the hostnames of hosts in your on-premises network connected to your VCN by IPSec VPN connection or FastConnect. That functionality can be achieved either by using a custom resolver or by configuring the VCN's private DNS resolver.

**CUSTOM RESOLVER**

Use DNS servers of your choice for resolution (maximum three). They could be DNS servers that are:

- Available through the internet. For example, 216.146.35.35 for Dyn's Internet Guide.
- In your VCN.
- In your on-premises network, which is connected to your VCN by way of an IPSec VPN connection or FastConnect (through a DRG).

**About the DNS Domains and Hostnames**

When you initially create a VCN and subnets, you may specify DNS labels for each. Subnet DNS labels can only be set if the VCN itself is created with a DNS label. The labels, along with the parent domain of `oraclevcn.com` form the VCN domain name and subnet domain name:

- **VCN domain name:** `<VCN DNS label>.oraclevcn.com`
- **Subnet domain name:** `<subnet DNS label>.<VCN DNS label>.oraclevcn.com`

When you then launch an instance, you may assign a hostname. It's assigned to the VNIC that's automatically created during instance launch (that is, the *primary VNIC*). Along with the subnet domain name, the hostname forms the instance's fully qualified domain name (FQDN):

- **Instance FQDN:** `<hostname>.<subnet DNS label>.<VCN DNS label>.oraclevcn.com`

For example: `database1.privatesubnet1.abccorpcvn1.oraclevcn.com`
The FQDN resolves to the instance's private IP address. The Internet and VCN Resolver also enables reverse DNS lookup, which lets you determine the hostname corresponding to the private IP address.

If you add a secondary VNIC to an instance, you can specify a hostname. The resulting FQDN resolves to the VNIC's private IP address (that is, the primary private IP).

If you add a secondary private IP to a VNIC, you can specify a hostname. The resulting FQDN resolves to that private IP address.

Important:

Oracle recommends that you always use the instance FQDN when sending messages to a host, or alternately specify only the hostname for messages sent within a VCN.

Requirements for DNS Labels and Hostnames

- VCN and subnet labels: Max 15 alphanumeric characters and must start with a letter. Notice that hyphens and underscores are NOT allowed. The value cannot be changed later.
- Hostnames: Max 63 characters and must be compliant with RFCs 952 and 1123. The value can be changed later.

Important:

The Networking service allows hostnames up to 63 characters. However, some older operating systems enforce shorter hostnames. In Linux, here's how to determine the maximum allowed hostname length:

```
getconf HOST_NAME_MAX
```

If an instance has a hostname longer than the OS-specific maximum, the instance's FQDN is not resolvable within the VCN. You can use the Networking service to update the VNIC and change the hostname to a shorter value.

Uniqueness:

- VCN DNS label should be unique across your VCNs (not required, but a best practice)
- Subnet DNS labels must be unique within the VCN
- Hostnames must be unique within the subnet

Tip:

Don't confuse the DNS label or hostname with the friendly name you can assign to the object (that is, the display name), which doesn't have to be unique.

Validation and Generation of the Hostname

If you've set DNS labels for the VCN and subnets, Oracle validates the hostname for DNS compliance and uniqueness during instance launch. If either of these requirements isn't met, the launch request fails.

If you don't specify a hostname during instance launch, Oracle tries to use the instance's display name as the hostname. If the display name does not pass the validation, Oracle automatically generates a DNS-compliant hostname that's unique across the subnet. You can see the generated hostname on the instance's page in the Console. In the API, the hostname is part of the VNIC object.

If you don't provide a hostname or display name during instance launch using the SDK or CLI, Oracle does not generate a display name or hostname. This means the instance won't be resolvable using the Internet and VCN Resolver.

If you don't provide a hostname or display name during instance launch using the Console, Oracle will auto-generate a display name and a corresponding DNS record, provided the Subnet has a valid DNS label associated with it.
**Note:**

The Linux OS hostname on the instance is automatically set to the hostname you set during instance launch (or the one generated by Oracle). If you change the hostname directly on the instance, the FQDN of the instance does not get updated.

If you add a secondary VNIC to an instance, or add a secondary private IP to a VNIC, Oracle never tries to generate a hostname. Provide a valid hostname if you want the private IP address to be resolvable using the Internet and VCN Resolver.

**DHCP Options for DNS**

Two DHCP options are related to DNS in your VCN:

- **Domain Name Server:** To specify your choice for DNS type (either Internet and VCN Resolver, or Custom Resolver).
- **Default value in the default set of DHCP options:** Internet and VCN Resolver
- **Search Domain:** To specify a single search domain. When resolving a DNS query, the OS appends this search domain to the value being queried. You can specify only one search domain for the set of DHCP options.
- **Default value in the default set of DHCP options:** The VCN domain name (\(<VCN\ DNS label>\).oraclevcn.com), if you specified a DNS label for the VCN during creation but did not specify a search domain value. If you specified a search domain value, then that value is used for the Search Domain option. If you did NOT specify a DNS label, the default set of DHCP options does not include a Search Domain option.

**Caution:**

Oracle recommends that you always use the instance FQDN when sending messages to a host in another subnet/VCN and do not rely on the DNS search domain.

**Important:**

In general, when *any* set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name (\(<VCN\ DNS label>\).oraclevcn.com) if *all of these are true*:

- The VCN has a DNS label
- DNS Type = Internet and VCN Resolver
- You did NOT specify a search domain of your choice during creation of the set of DHCP options

After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value.

**How to Enable DNS Hostnames in Your VCN**

Only new VCNs created after the release of the Internet and VCN Resolver feature have automatic access to it. How to enable DNS hostnames for a new VCN depends on which interface you're using.

*If you create a VCN and subnets with the Console*

1. When creating the VCN:
   - Check the check box for **Use DNS Hostnames in this VCN**
   - Specify a DNS label of your choice for the VCN. If you check the check box but don't specify a DNS label, the Console assumes that you want to use the Internet and VCN Resolver in your VCN and automatically generates a DNS label for the VCN. The Console takes the VCN name you provided, removes non-
alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15 characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the DNS Label field. See About the DNS Domains and Hostnames on page 2910.

2. When creating the subnets:
   • Again, check the check box for Use DNS Hostnames in this Subnet
   • Specify a DNS label of your choice for each subnet. If you check the check box but don't specify the DNS label for a given subnet, the Console assumes you want to use the Internet and VCN Resolver for the subnet and automatically generates a DNS label for the subnet. The Console takes the subnet name you provided, removes non-alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15 characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the DNS Label field. See About the DNS Domains and Hostnames on page 2910.

   **Note:**
   Subnet DNS labels can only be set if the VCN itself is created with a DNS label.

   • Associate any set of DHCP options that has DNS type = Internet and VCN Resolver. The default set of DHCP options in the VCN uses the Internet and VCN Resolver by default.

3. When launching instances:
   • Specify a hostname (or at least a display name) for each instance. For more information, see About the DNS Domains and Hostnames on page 2910.

   If you don't check the check box for Use DNS Hostnames in this VCN when creating the VCN, you can't set the DNS label for the VCN or subnets, and you can't specify a hostname during instance launch.

   **Note:**
   The previous procedure assumes you create the VCN and subnets one at a time in the Console. The Console has a feature that automatically creates a VCN with subnets and an internet gateway all at the same time. If you use that feature to create the VCN and subnets, the Console automatically generates DNS labels for them.

If you create a VCN and subnets with the API

1. When creating the VCN:
   • Specify a DNS label for the VCN. See About the DNS Domains and Hostnames on page 2910. If you don't set a value (if it's null), Oracle assumes that you don't want to use the Internet and VCN Resolver, even if the DHCP options have Dhcpi\n   DnsOption serverType = VcnLocalPlusInternet.

2. When creating the subnets:
   • Specify a DNS label for each subnet. See About the DNS Domains and Hostnames on page 2910. If you specified a DNS label for the VCN, but you don't specify a DNS label for the subnet, Oracle assumes that you don't want the instances in the subnet to use the Internet and VCN Resolver and the ability to use hostnames to communicate with instances in the VCN is no longer available.

   **Note:**
   Subnet DNS labels can only be set if the VCN itself was created with a DNS label.

   • Associate any set of DHCP options that has Dhcpi\n   DnsOption serverType = VcnLocalPlusInternet, which is the default DHCP option in the VCN.

3. When launching instances:
   • Specify a hostname (or at least a display name) for each instance. For more information, see About the DNS Domains and Hostnames on page 2910.

   If you don't specify a DNS label when creating the VCN, you can't:
- Set the DNS label for the subnets (causing the CreateSubnet call to fail)
- Specify a hostname during instance launch (causing the LaunchInstance call to fail)
- Assign a hostname to a secondary VNIC or a secondary private IP

**Scenario 1: Use Internet and VCN Resolver with DNS Hostnames Across the VCN**

The typical scenario is to enable the Internet and VCN Resolver across your entire VCN, which allows all instances in the VCN to communicate with each other without knowing their IP addresses. To do that, follow the instructions in About the DNS Domains and Hostnames on page 2910, and assign a DNS label to the VCN and every subnet. Then assign every instance a hostname (or at least a display name) at launch. If you add a secondary VNIC or secondary private IP, also assign it a hostname. The instances can then communicate with each other using FQDNs instead of IP addresses.

**Scenario 2: Use a Private DNS Resolver to Resolve DNS Hostnames**

You can use a private DNS resolver to answer DNS queries for a VCN using a configuration you create. The resolver listens on 169.254.169.254 by default, but also allows you to define endpoints for listening for queries and forwarding them to other resolvers in other VCNs, a customer’s on-premises network, or other private network. For more information, see Private DNS resolvers.

**Scenario 3: Use Different DHCP Options Per Subnet**

**Scenario 1** assumes you want to use the Internet and VCN Resolver the same way across all subnets, and thus all instances in the VCN. You could, however, configure different DNS settings for each subnet, because the DHCP options are configured at the subnet level. The important thing to understand is: the subnet where you want to generate the DNS query is where you need to configure the corresponding Internet and VCN Resolver settings.

For example, if you want instance A in subnet A to resolve the hostname of instance B in subnet B, you must configure subnet A to use the Internet and VCN Resolver. Conversely, if you want instance B to resolve the hostname of instance A, you must configure subnet B to use the Internet and VCN Resolver.

You can configure a different set of DHCP options for each subnet. For example, you could set subnet A’s Search Domain to subneta.vcn1.oraclevcn.com, which means all instances in subnet A could use just hostnames to communicate with each other. You could similarly set subnet B’s Search domain to subnetb.vcn1.oraclevcn.com to enable Subnet B’s instances to communicate with each other with just hostnames.

**Private DNS resolvers**

A private DNS resolver answers DNS queries for a VCN per a configuration you create.

When you create a VCN and select the Use DNS hostnames in this VCN option, this choice creates a dedicated private DNS resolver and a default private view with system-managed zones. A private DNS resolver also handles internal DNS queries for your VCN based on private views and the private zones that you have created and the rules you create for the resolver. A private DNS zone has capabilities similar to an internet DNS zone, but only provides responses for clients that can reach it through a VCN. The default view is only used if the resolver does not get a match from the other attached private views, if there are any. A private resolver can be configured to use views and zones as well as conditional forwarding rules to define how to respond to DNS queries. To better understand views and zones, refer to Private DNS on page 1698.

You can create your own custom domains to use in addition to the system-generated names based on VCNs and subnets, and you can do VCN to VCN and VCN to on-premises resolution.

**To add a private view to a private resolver**

1. From the Virtual Cloud Network Details screen for your VCN, look in the VCN Information tab and click the name of the DNS resolver for the VCN. The Private Resolver Details screen appears.
2. From the Private Resolver Details screen, click Manage Private Views. The Manage Private Views screen appears.
3. Select a previously created private view from the drop down menu in the numbered Private view list.
4. To associate another view, click Additional Private View select another view.
5. When you are finished, click Save Changes.
Views created automatically by Oracle are available in addition to views you create.

**To remove a private view from a private resolver**

1. From the Private Resolver Details screen, click the check box next to the private view you want to remove from the resolver. Remove turns red, and can now be clicked. You can select other private views if necessary.
2. Click Remove.

**Note:**
You can also remove a private view from the Manage Private Views screen by clicking the red button labeled - and then clicking Save Changes.

**To rename a private resolver**

1. From the Private Resolver Details screen, click Edit.
2. Enter the new name for the resolver. Avoid entering confidential information. Then, click Save Changes.

**To manage DNS zones and views**

See Managing DNS Service Zones on page 1679.

**Resolver Endpoints**

A DNS forwarding resolver endpoint is required before you can create a resolver rule. Resolver endpoints are attached to a VCN or a subnet. No listening endpoint is required for compute instances sending queries to 169.254.169.254. Two types of endpoint are used:

- **Listening** - A listening endpoint receives queries from these sources: within the VCN, other VCN Resolvers, or your on-premises network's DNS. Once created, no further configuration is needed for a listening endpoint.
- **Forwarding** - A forwarding endpoint forwards DNS queries to the Listening endpoint for resolvers in other peered VCNs or your on-premises network's DNS. Decisions about where to forward queries are based on resolver rules that you define.

An endpoint can only be configured to either forward or listen.

**Note:**
Network security groups (NSGs) act as a virtual firewall for your DNS resolver endpoints. An NSG consists of a set of ingress and egress security rules that apply only to the associated DNS resolver endpoints.

**To create a resolver endpoint**

1. From the Virtual Cloud Network Details screen for your VCN, look in the VCN Information tab and click the name of the DNS resolver for the VCN. The Private Resolver Details screen appears.
2. From the Private Resolver Details screen, click Endpoints in the left-hand navigation.
3. Click Create Endpoint. The Create Endpoint screen appears.
4. Make choices for the following settings:
   - Select a name for the endpoint. The name can use any combination of letters and numbers, but the only supported special character is an underscore.
   - Select a subnet for the endpoint from the pull-down list.
   - Select the endpoint type, which can be either Listening or Forwarding. When you make this choice, you provide an IP address, or allow Oracle to assign one for the endpoint. This IP address is used by the resolver to forward DNS queries, or to listen for DNS queries from other systems. The IP address must be in the same CIDR block used by the VCN or subnet associated with the resolver.
   - Optional: Use a Network Security Group to control traffic. To use this feature, select an NSG to use with the endpoint. You can also add an NSG after the endpoint is created.
To delete a resolver endpoint

1. From the Private Resolver Details screen, click the Action button to the right of the endpoint you want to delete, and then click Delete.
2. Confirm the deletion by clicking Delete.

To add an NSG to a resolver endpoint

1. From the Private Resolver Details screen, click the name of the endpoint you want to associate with a Network Security group. The Endpoint Details screen appears.
2. Click Add Network Security Groups, and select up to five security groups to associate with the endpoint.

To remove an NSG from a resolver endpoint

1. From the Private Resolver Details screen, click the name of the endpoint you want to de-associate with a Network Security group. The Endpoint Details screen appears.
2. Click the X button to the right of the listed NSG. You could change to a different NSG if necessary.

Resolver Rules

Rules are used to answer queries that aren't answered by a resolver's views. They are checked in order, and each can optionally have conditions that limit which queries they apply to. Queries not matched by any view or rule are resolved from internet DNS. You can have up to 10 rules per resolver.

Note:
Endpoints are used in the rule, and they must exist before you create a resolver rule.

Use case

The most common application is to have one or more rules that follow this general form:

If <query domain> is <example.com>, forward using <forwarding-endpoint> to IP address X.X.X.X.

Followed by a final rule that follows this form:

If <anything else>, forward using <forwarding-endpoint> to IP address Y.Y.Y.Y.

So if the query is looking for example.com, the resolver internally forwards it to X.X.X.X through the specified forwarding endpoint and responds with the answer it receives. For any other query, it forwards to Y.Y.Y.Y through the same forwarding endpoint and responds with that answer it gets from Y.Y.Y.Y.

To create resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column. Click Manage Rules. The Manage Rules screen appears.
2. You can have up to 10 rules per resolver. For each rule, select:
   - **Rule condition**: Determines whether routing decisions are made based on the query's originating CIDR Block or Domain (up to 10 hostnames), or neither (Select None to match any CIDR Block or Domain).
   - **Client CIDR blocks or Domains**: Up to 10 CIDR blocks or domains.
   - **Rule action**: This field is read-only. Forward is the only option.
   - **Source endpoint**: The private endpoint used to forward queries when the rule condition is met.
   - **Destination IP address**: The address to forward the query to if the rule condition is met.
3. Click +Additional Rule to create another rule if necessary.
4. Click Save Changes when finished.
To edit resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column.
2. Click Manage Rules. The Manage Rules screen appears.
3. Make changes based on your intended design. These changes can include changing options in a rule, changing the order of rules, and removing rules altogether.
4. When finished, click Save Changes.

To remove resolver rules

1. From the Private Resolver Details screen, click Rules in the Resources column.
2. Click the check box in the row for the rule or rules you want to delete. Click Remove. The Confirm Removal screen appears.
3. Click Remove.

Reverse DNS (PTR)

A reverse DNS record, also known as a pointer record (PTR), resolves an IP address back to a fully qualified domain name (FQDN). It functions in the opposite way of an A (IPv4) or AAAA (IPv6) forward record. For example:
192.0.2.5 # myhost.mydomain.com

You can request that a PTR record be established for your cloud IP addresses:

1. Create an A (IPv4) or AAAA (IPv6) forward record that points the fully qualified domain name to the IP prior to opening the request. You can create the record using the Oracle Cloud Infrastructure DNS service, or a third-party DNS provider.
2. Open a service request and include the following information:
   a. The IP address and fully qualified domain name (FQDN) you want in the PTR.
   b. The FQDN of the forward record that you created in step 1.

After the service request is received, the forward (A or AAAA) record information is validated to be sure it can be successfully resolved, and Oracle creates the PTR record on your behalf.

Using the API

Use the following operations to manage resolvers and resolver endpoints:

- ListResolvers
- GetResolver
- UpdateResolver
- ChangeResolverCompartment
- ListResolverEndpoints
- CreateResolverEndpoint
- GetResolverEndpoint
- UpdateResolverEndpoint
- DeleteResolverEndpoint

DHCP Options

This topic describes how to manage the Dynamic Host Configuration Protocol (DHCP) options in a virtual cloud network (VCN).

Overview of DHCP Options

The Networking service uses DHCP to automatically provide configuration information to instances when they boot up. Although DHCP lets you change some settings dynamically, others are static and never change. For example, when you launch an instance, either you or Oracle specifies the instance's private IP address. Each time the instance
boots up or you restart the instance's DHCP client, DHCP passes that same private IP address to the instance. The address never changes during the instance's lifetime.

The Networking service provides **DHCP options** to let you control certain types of configuration on the instances in your VCN. You can change the values of these options at your discretion, unlike the static information that DHCP provides to the instance. The changes take effect the next time you restart a given instance's DHCP client or reboot the instance. For more details, see [Important Notes about Your Instances and DHCP Options](#) on page 2919.

Each subnet in a VCN can have a single set of DHCP options associated with it. That set of options applies to all instances in the subnet. Each VCN comes with a **default set of DHCP options** with initial values that you can change. If you don't specify otherwise, every subnet uses the VCN's default set of DHCP options.

The following table summarizes the available DHCP options you can configure.

<table>
<thead>
<tr>
<th>DHCP Option</th>
<th>Possible Values</th>
<th>Initial Value in the Default DHCP Options</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Domain Name Server</strong></td>
<td>DNS Type: • Internet and VCN Resolver • Custom Resolver</td>
<td>DNS Type = Internet and VCN resolver. For more information, see <a href="#">Choices for DNS in Your VCN</a> on page 2910.</td>
<td>If you set DNS Type = Custom Resolver, you can specify up to three DNS servers of your choice. For more information, see <a href="#">Choices for DNS in Your VCN</a> on page 2910.</td>
</tr>
</tbody>
</table>
| **Search Domain** | A single search domain                                                      | If you've set up your VCN with a DNS label, the default value for the Search Domain option is the VCN domain name (`<VCN DNS label>.oraclevcn.com`). Otherwise, the Search Domain option is not present in the default set of DHCP options. | In general, when any set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name (`<VCN DNS label>.oraclevcn.com`) if all of these are true:  
- The VCN has a DNS label  
- DNS Type = Internet and VCN Resolver  
- You did NOT specify a search domain of your choice during creation of the set of DHCP options.  
After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value.  
You can specify only a single search domain in a set of DHCP options. |
**Working with DHCP Options**

When you create a subnet, you specify which set of DHCP options to associate with the subnet. If you don't, the default set of DHCP options for the VCN is used. You can change which set of DHCP options the subnet uses at any time.

When creating a new set of DHCP options, you may optionally assign it a friendly name. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the set of options a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can change the values of an individual DHCP option in a set, but notice that when you use the REST API to update a single option in a set, the new set of options replaces the entire existing set.

To delete a set of DHCP options, it must not be associated with a subnet yet. You can't delete a VCN's default set of DHCP options.

For information about the maximum number of DHCP options allowed, see Service Limits on page 215.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

**Important Notes about Your Instances and DHCP Options**

Whenever you change the value of one of the DHCP options, you must do one of the following for the change to take effect on existing instances in the subnets associated with that set of DHCP options: either restart the DHCP client on the instance, or reboot the instance.

Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

Any changes you make to the `/etc/resolv.conf` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted.

Changes you make to the `/etc/hosts` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted. To persist your changes to the `/etc/hosts` file in Oracle Linux or CentOS instances, add the following line to `/etc/oci-hostname.conf`:

```
PRESERVE_HOSTINFO=2
```

If the `/etc/oci-hostname.conf` file does not exist, create it.

**Using the Console**

**To view a VCN's set of default DHCP options**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.

   The default set and its details are displayed in the list.
To update options in an existing set of DHCP options

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click Edit:
   - For DNS Type: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select Internet and VCN Resolver. Or to use a DNS server of your choice, select Custom Resolver and then enter the server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - For Search Domain: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. If the Search Domain option is already set to the VCN domain name and you're not sure why, see the details in Overview of DHCP Options on page 2917.
5. When you're done, click Save Changes.
6. If you have any existing instances in a subnet that uses this set of DHCP options, make sure to restart the DHCP client on each affected instance, or reboot the instance itself so that it picks up the new setting.

To create a new set of DHCP options

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. Click Create DHCP Options.
5. Enter the following:
   - Name: A friendly name for the set of options. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Create in Compartment: The compartment where you want to create the set of DHCP options, if different from the compartment you're currently working in.
   - DNS Type: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select Internet and VCN Resolver. Or to use a DNS server of your choice, select Custom Resolver and then enter the server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - Search Domain: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. Be aware that the Networking service automatically sets the Search Domain option in certain situations. See the details in Overview of DHCP Options on page 2917.
   - Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
6. When you're done, click Create DHCP Options.

The set of options is created and then displayed on the DHCP Options page of the compartment you chose. You can now specify this set of options when creating or updating a subnet.

To change which set of DHCP options a subnet uses

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Subnets.
4. Click the subnet you're interested in.
5. Click Edit.
6. In the DHCP Options section, select the new set of DHCP options you want the subnet to use.
7. Click Save Changes.

    The changes take effect within a few seconds.
To delete a set of DHCP options

Prerequisite: To delete a set of DHCP options, it must not be associated with a subnet yet. You can't delete the default set of DHCP options in a VCN.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you want to delete, click the Actions icon (three dots), and then click Terminate.
5. Confirm when prompted.

To manage tags for a set of DHCP options

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click View Tags. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 211.

To move a set of DHCP options to a different compartment

You can move a set of DHCP options from one compartment to another. When you move a set of DHCP options to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click DHCP Options.
4. For the set you're interested in, click the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage a VCN's DHCP options, use these operations:

- ListDhcpOptions
- GetDhcpOptions
- UpdateDhcpOptions
- CreateDhcpOptions
- DeleteDhcpOptions
- ChangeDhcpOptionsCompartment

Route Tables

This topic describes how to manage the route tables in a virtual cloud network (VCN).

Overview of Routing for Your VCN

Your VCN uses virtual route tables to send traffic out of the VCN (for example, to the internet, to your on-premises network, or to a peered VCN). These virtual route tables have rules that look and act like traditional network route rules you might already be familiar with. Each rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR.
Here are basics about routing in your VCN:

- The primary routing scenario is for sending a subnet's traffic to destinations outside the VCN. A subnet has a single route table of your choice associated with it. All VNICs in that subnet are subject to the rules in the route table. The rules govern how the traffic leaving the subnet is routed.

- Traffic within the VCN is automatically handled by the VCN local routing. No route rules are required to enable that traffic. And in general: for any route table that belongs to a given VCN, you can't create a rule that lists that VCN's CIDR (or a sub-section) as the rule's destination. Oracle uses a subnet's route table only if the destination IP address is not within the VCN's CIDR block.

- If a route table has overlapping rules, Oracle uses the most specific rule in the table to route the traffic (that is, the rule with the longest prefix match).

- If there is no route rule that matches the network traffic you intend to route outside the VCN, the traffic is dropped (blackholed).

- IPv6 addressing and routing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

For important details about routing between your VCN and on-premises network, see Routing Details for Connections to Your On-Premises Network on page 2942.

### Working with Route Tables and Route Rules

Each VCN automatically comes with a default route table that has no rules. If you don't specify otherwise, every subnet uses the VCN's default route table. When you add route rules to your VCN, you can simply add them to the default table if that suits your needs. However, if you need both a public subnet and a private subnet (for example, see Scenario C: Public and Private Subnets with a VPN on page 2769), you instead create a separate (custom) route table for each subnet.

Each subnet in a VCN uses a single route table. When you create the subnet, you specify which one to use. You can change which route table the subnet uses at any time. You can also edit a route table's rules, or remove all the rules from the table.

You may optionally assign a descriptive name to a custom route table during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the route table a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

A route rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR. Here are the allowed types of targets for a route rule:

- **dynamic routing gateway (DRG):** For subnets that need private access to networks connected to your VCN (for example, your on-premises network connected with an IPSec VPN or FastConnect, or a peered VCN in another region).
- **internet gateway:** For public subnets that need direct access to the internet.
- **NAT gateway:** For subnets with instances that do not have public IP addresses but need outbound access to the internet.
- **service gateway:** For subnets that need private access to Oracle services such as Object Storage.
- **local peering gateway (LPG):** For subnets that need private access to a peered VCN in the same region.
- **private IP:** For subnets that need to route traffic to an instance in the VCN. For more information, see Using a Private IP as a Route Target on page 2924. Also see Overview of Routing for Your VCN on page 2921.

### Note:

You can't delete a particular resource if it's the target in a route rule. For example, you can't delete an internet gateway that has traffic routed to it. You must first delete all rules (in all route tables) with that internet gateway as the target.

When adding a route rule to a route table, you provide the destination CIDR block and target (plus the compartment where the target resides). Exception: if the target is a service gateway, instead of a destination CIDR block, you
specify an Oracle-provided string that represents the public endpoints for the service of interest. That way you don't need to know all the service's CIDR blocks, which might change over time.

If you misconfigure a rule (for example, enter the wrong destination CIDR block), the network traffic you intended to route might be dropped (blackholed) or sent to an unintended target.

You can move route tables from one compartment to another. Moving a route table doesn't affect its attachment to VCNs or subnets. When you move a route table to a new compartment, inherent policies apply immediately and affect access to the route table. For more information, see Access Control on page 2831.

You can't delete a VCN's default route table. To delete a custom route table, it must not be associated with a subnet yet. Or, in the advanced scenario of transit routing, it must not be associated with a DRG attachment or LPG in the VCN.

For information about the maximum number of route tables and route rules, see Service Limits on page 215.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

**Advanced Scenarios: Transit Routing**

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See scenarios A, B, and C in Networking Scenarios on page 2756.

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then transits through the VCN to its destination. See these topics:

- **Transit Routing: Access to Multiple VCNs in the Same Region** on page 2780: Your on-premises network has access to multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke topology, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- **Transit Routing: Private Access to Oracle Services** on page 2803: Your on-premises network has private access to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's service gateway. The traffic does not go over the internet.

Both of the transit routing scenarios involve creating route tables that you associate with a gateway instead of a subnet.

For example:

- For **Transit Routing: Access to Multiple VCNs in the Same Region** on page 2780, you create a route table for a DRG attachment, and then multiple route tables, each for different LPGs.
- For **Transit Routing: Private Access to Oracle Services** on page 2803, you create a route table for a DRG attachment and a route table for a service gateway.

The Networking service imposes restrictions on how the route tables can be used:

- DRG attachment: If you associate a route table with the DRG attachment on a VCN, the route table can contain only rules that use an LPG on the VCN, a service gateway on the VCN, or a private IP in the VCN as the target.
- LPG or service gateway: If you associate a route table with an LPG or a service gateway, the route table can contain only rules that use the VCN's attached DRG or a private IP in the VCN as the target.
A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table’s rules, or delete some or all of the rules.

### Using a Private IP as a Route Target

If you’re not familiar with the definition of a private IP, see [Private IP Addresses](#) on page 2864. In short: a private IP is an object that contains a private IP address and related properties and has its own **OCID**.

### General Use Cases

As mentioned earlier, Oracle uses a given subnet's route table only for traffic with a destination IP address outside the VCN. Typically you set up one or more rules to route that traffic to a gateway on the VCN (for example, a DRG connected to your on-premises network, or an internet gateway connected to the internet). However, you might want to route that traffic (going to destinations outside the VCN) through an instance in the VCN first. In that case, you can use a private IP in the VCN as the target instead of a gateway on the VCN. Here are a few reasons you might do this:

- To implement a virtual network appliance (NVA) such as a firewall or intrusion detection that filters outgoing traffic from instances.
- To manage an overlay network on the VCN, which lets you run container orchestration workloads.
- To implement Network Address Translation (NAT) in the VCN. Note that Oracle instead recommends using a **NAT gateway** with your VCN. In general, NAT enables outbound internet access for instances that don't have direct internet connectivity.

To implement these use cases, there's more to do than simply route traffic to the instance. There's also configuration required on the instance itself.

**Tip:**

You can enable high availability of the private IP route target by using a **secondary private IP address**. In the event of a failure, you can move the secondary private IP from an existing VNIC to another VNIC in the same subnet. See [Using the Console](#) on page 2866 (Console instructions) and [UpdatePrivateIp](#) (API instructions).

### Requirements for Using a Private IP as a Target

- The private IP must be in the same VCN as the route table.
- The private IP's VNIC must be configured to skip the source/destination check so that the VNIC can forward traffic. By default, VNICs are configured to perform the check. For more information, see [Overview of VNICs and Physical NICs](#) on page 2856.
- You must configure the instance itself to forward packets.
- The route rule must specify the OCID of the private IP as the target, and not the IP address itself. Exception: If you use the Console, you can instead specify the private IP address itself as the target, and the Console determines and uses the corresponding OCID in the rule.

**Important:**

A route rule with a private IP target can result in blackholing in these cases:

- The instance the private IP is assigned to is stopped or terminated
- The VNIC the private IP is assigned to is updated to enable the source/destination check or is deleted
- The private IP is unassigned from the VNIC

When a target private IP is terminated, in the Console, the route rule displays a note that the target OCID no longer exists.
Networking

For failover: If your target instance is terminated before you can move the secondary private IP to a standby, you must update the route rule to use the OCID of the new target private IP on the standby. The rule uses the target's OCID and not the private IP address itself.

General Setup Process

1. Determine which instance will receive and forward the traffic (the NAT instance, for example).
2. Choose a private IP on the instance (can be on the instance's primary VNIC or a secondary VNIC). If you want to implement failover, set up a secondary private IP on one of the VNICs on the instance.
3. Disable the source/destination check on the private IP's VNIC. See Overview of VNICs and Physical NICs on page 2856.
4. Get the OCID for the private IP. If you're using the Console, you can get either the OCID or the private IP address itself, along with the name of the private IP's compartment.
5. For the subnet that needs to route traffic to the private IP, view the subnet's route table. If the table already has a rule with the same destination CIDR but a different target, delete that rule.
6. Add a route rule with the following:
   
   • Target type: Private IP.
   • Destination CIDR block: If all traffic leaving the subnet needs to go to the private IP, use 0.0.0.0/0.
   • Compartment: The compartment of the private IP.
   • Target: The OCID of the private IP. If you're using the Console and instead enter the private IP address itself, the Console determines the corresponding OCID and uses it as the target for the route rule.
   
   • Description: An optional description of the rule.

As mentioned earlier, you must configure the instance itself to forward packets.

Using the Console

To view a VCN's default route table

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.

   The default route table is displayed in the list of tables.

4. Click the default route table to view its details.

To update rules in an existing route table

You can add, edit, or delete rules.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.
4. Click the route table you're interested in.
5. If you want to create a new route rule, click Add Route Rule and enter the following:

   • Target Type: See the list of target types in Overview of Routing for Your VCN on page 2921. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify
the target yourself. If the target is a private IP, make sure you've first disabled the source/destination check on
the private IP's VNIC. For more information, see Using a Private IP as a Route Target on page 2924.

- **Destination CIDR Block**: Only if the target is not a service gateway. The value is the destination CIDR block
  for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other
  rules in the route table will go to the target specified in this rule.
- **Destination Service**: Only if the target is a service gateway. The value is the service CIDR label that you're
  interested in.
- **Compartment**: The compartment where the target is located.
- **Target**: The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in
  which case the Console determines the corresponding OCID and uses it as the target for the route rule.
- **Description**: An optional description of the rule.

6. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
7. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

**To create a route table**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click **Route Tables**.
4. Click **Create Route Table**.
5. Enter the following:
   - **Name**: A friendly name for the route table. The name doesn't have to be unique, and it cannot be changed later
     in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment**: The compartment where you want to create the route table, if different from the
     compartment you're currently working in.

6. Optionally, click **Additional Route Rule** to add one or more route rules, each with the following information
   (remember, a route table can exist with no rules until you're ready to add them):
   - **Target Type**: See the list of target types in Overview of Routing for Your VCN on page 2921. If the target
     type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify
     the target yourself. If the target is a private IP, make sure you've first disabled the source/destination check on
     the private IP's VNIC. For more information, see Using a Private IP as a Route Target on page 2924.
   - **Destination CIDR Block**: Only if the target is not a service gateway. The value is the destination CIDR block
     for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other
     rules in the route table will go to the target specified in this rule.
   - **Destination Service**: Only if the target is a service gateway. The value is the service CIDR label that you're
     interested in.
   - **Compartment**: The compartment where the target is located.
   - **Target**: The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in
     which case the Console determines the corresponding OCID and uses it as the target for the route rule.
   - **Description**: An optional description of the rule.

7. **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to
   that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
   about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option
   (you can apply tags later) or ask your administrator.

8. Click **Create Route Table**.

   The route table is created and then displayed on the **Route Tables** page in the compartment you chose. You can
   now specify this route table when creating or updating a subnet.

**To change which route table a subnet uses**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in
Networking

5. Click Edit.
6. In the Route Table section, select the new route table you want the subnet to use.
7. Click Save Changes.

The changes take effect within a few seconds.

To move a route table to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Route Tables.
4. Find the route table in the list, click the the Actions icon (three dots), and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To delete a route table

Prerequisite: To delete a route table, it must not be associated with a subnet yet. You can't delete the default route table in a VCN.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.
4. Click the route table you're interested in.
5. Click Terminate.
6. Confirm when prompted.

To manage tags for a route table

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Route Tables.
4. Click the route table you're interested in.
5. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage a VCN's route tables, use these operations:

- ListRouteTables
- GetRouteTable
- UpdateRouteTable
- CreateRouteTable
- DeleteRouteTable
- ChangeRouteTableCompartment

Dynamic Routing Gateways (DRGs)

This topic describes how to manage a dynamic routing gateway (DRG). This topic uses the terms dynamic routing gateway and DRG interchangeably. The Console uses the term Dynamic Routing Gateway, whereas for brevity the API uses DRG.

You use a DRG when connecting your existing on-premises network to your virtual cloud network (VCN) with one (or both) of these:

- IPSec VPN
Networking

- Oracle Cloud Infrastructure FastConnect

You also use a DRG when peering a VCN with a VCN in a different region:
- Remote VCN Peering (Across Regions) on page 3280

**Overview of Dynamic Routing Gateways**

You can think of a DRG as a virtual router that provides a path for private traffic (that is, traffic that uses private IPv4 addresses) between your VCN and networks outside the VCN's region.

For example, if you use an IPSec VPN or Oracle Cloud Infrastructure FastConnect (or both) to connect your on-premises network to your VCN, that private IPv4 address traffic goes through a DRG that you create and attach to your VCN. For scenarios for using a DRG to connect a VCN to your on-premises network, see Networking Scenarios on page 2756. For important details about routing to your on-premises network, see Routing Details for Connections to Your On-Premises Network on page 2942.

Also, if you decide to peer your VCN with a VCN in another region, your VCN's DRG routes traffic to the other VCN over a private backbone that connects the regions (without traffic traversing the internet). For information about connecting VCNs in different regions, see Remote VCN Peering (Across Regions) on page 3280.

**Working with DRGs and DRG Attachments**

For the purposes of access control, when creating a DRG, you must specify the compartment where you want the DRG to reside. If you're not sure which compartment to use, put the DRG in the same compartment as the VCN. For more information, see Access Control on page 2831.

You may optionally assign a friendly name to the DRG. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the DRG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

A DRG is a standalone object. To use it, you must attach it to a VCN. A VCN can be attached to only one DRG at a time, and a DRG can be attached to only one VCN at a time. You can detach a DRG and reattach it at any time. In the API, the process of attaching creates a DrgAttachment object with its own OCID. To detach the DRG, you delete that attachment object.

After attaching a DRG, you must update the routing in the VCN to use the DRG. Otherwise, traffic from the VCN will not flow to the DRG. See To route a subnet's traffic to a DRG on page 2930.

To delete a DRG, it must not be attached to a VCN or connected to another network by way of IPSec VPN, Oracle Cloud Infrastructure FastConnect, or remote VCN peering. Also, there must not be a route rule that lists that DRG as a target.

For information about the number of DRGs you can have, see Service Limits on page 215.

**Routing a Subnet's Traffic to a DRG**

The basic routing scenario sends traffic from a subnet in the VCN to the DRG. For example, if you're sending traffic from the subnet to your on-premises network, you set up a rule in the subnet's route table. The rule's destination CIDR is the CIDR for the on-premises network (or a subnet within), and the rule's target is the DRG. For more information, see Route Tables on page 2921.

**Advanced Scenarios: Transit Routing**

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See scenarios A, B, and C in Networking Scenarios on page 2756.

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then transits through the VCN to its destination. See these topics:
• **Transit Routing: Access to Multiple VCNs in the Same Region** on page 2780: Your on-premises network has access to *multiple* VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke topology, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.

• **Transit Routing: Private Access to Oracle Services** on page 2803: Your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's *service gateway*. The traffic does not go over the internet.

In the transit routing scenarios, the VCN has a route table associated with its **DRG attachment** (typically route tables are associated with a VCN's subnets). That route table lets you manage routing of traffic through the VCN that is connected to the on-premises network.

When you attach a DRG to a VCN, you can optionally associate a route table with the attachment. Or if you already have a DRG attachment, you can associate a route table with it. The route table must belong to the attached VCN. A route table associated with a DRG attachment can contain only rules that use one of the following as a target:

- A **local peering gateway** (LPG) on the attached VCN
- A **service gateway** on the attached VCN
- A **private IP** in the attached VCN

A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a **different** route table. You can also edit the table's rules, or delete some or all of the rules.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: see **IAM Policies for Networking** on page 2832.

**Using the Console**

In general, to use a DRG, you must complete these steps:

1. Create the DRG.
2. Attach the DRG to your VCN.
3. Route subnet traffic to the DRG. This involves updating the route table associated with each subnet that must send traffic to the DRG. If all the subnets use the VCN's default route table, you must only update that one table.

**To create a DRG**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see **Access Control** on page 2831.
3. Click **Create Dynamic Routing Gateway**.
4. Enter the following items:

   - **Create in Compartment**: The compartment where you want to create the DRG, if different from the compartment you're currently working in.
   - **Name**: A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
5. Click **Create Dynamic Routing Gateway**.

The resource is created and then displayed on the **Dynamic Routing Gateways** page of the compartment you chose. It will be in the "Provisioning" state for a short period. You can connect it to other parts of your network only after provisioning is complete.

**To update a DRG's name**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click **Edit**.
4. Edit the name. Avoid entering confidential information. Then click **Save Changes**.

**To attach a DRG to a VCN**

**Note:** A VCN can be attached to only one DRG at a time, and a DRG can be attached to only one VCN at a time. The attachment is automatically created in the compartment that holds the VCN.

The following instructions have you navigate to the DRG and then choose which VCN to attach. You could instead navigate to the VCN and then choose which DRG to attach.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you want to attach.
3. Under **Resources**, click **Virtual Cloud Networks**. If you want to attach the DRG to a VCN in a different compartment than the one you're working in, choose that compartment from the list on the left side of the page.
4. Click **Attach to Virtual Cloud Network**.
5. Select the VCN.
6. (Optional) Only if you're setting up an advanced scenario for transit routing, you can associate a route table with the DRG attachment (you can do this later if you want to):
   a. Click **Show Advanced Options**.
   b. Select the route table that you want to associate with the DRG attachment.
7. Click **Attach to Virtual Cloud Network**.

The attachment will be in the "Attaching" state for a short period before it's ready.

After it's ready, make sure to create a route rule that directs subnet traffic to this DRG. See **To route a subnet's traffic to a DRG** on page 2930.

**To route a subnet's traffic to a DRG**

For each subnet that must send traffic to the DRG, you must add a route rule to the route table associated with that subnet. If all the subnets in the VCN use the default route table, you must add a rule to only that one table.

If all non-intra-VCN traffic that's not covered by another rule in the table must be routed to the DRG, then this is the new rule to add:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
- **Destination CIDR Block** = 0.0.0.0/0. If you want to limit the rule to a specific network (for example, your on-premises network), then use that network's CIDR instead of 0.0.0.0/0.

For step-by-step instructions, see **To update rules in an existing route table** on page 2925.

**To associate a route table with an existing DRG attachment**

**Important:**

Perform this task only if you're setting up an advanced scenario for transit routing. See **Transit Routing: Access to Multiple VCNs in the Same Region**
A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

**Prerequisites:** The route table must exist and belong to the VCN that the DRG is already attached to.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG that is attached to the VCN that has the route table.
3. Click the Actions icon (three dots), and then click either:
   - **Associate Route Table:** If the DRG attachment has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the DRG attachment.
4. Select the route table.
5. Click **Associate Route Table**.

The route table is associated with the DRG attachment.

**To detach a DRG from a VCN**

**Note:** You do not need to remove the route rule that routes traffic to the DRG before you detach the DRG from the VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you want to detach.
3. Under **Resources**, click **Virtual Cloud Networks** to see the VCN the DRG is attached to. If the VCN is in a different compartment than the one you're working in, choose that compartment from the list on the left side of the page.
4. Click the Actions icon (three dots), and then click **Detach**.
5. Confirm when prompted.

The attachment will be in the "Detaching" state for a short period.

**To delete a DRG**

**Prerequisites:**

- The DRG must not be attached to a VCN.
- The DRG must not be connected to another network by way of an IPSec VPN, FastConnect, or remote VCN peering.
- There must not be a route rule that lists the DRG as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click **Terminate**.
4. Confirm when prompted.

The DRG will be in the "Terminating" state for a short period while it's being deleted.

**To manage tags for a DRG**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see **Resource Tags** on page 211.
To move a dynamic routing gateway to a different compartment

You can move a dynamic routing gateway from one compartment to another. When you move a dynamic routing gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.
2. Click the DRG you're interested in.
3. Find the DRG in the list, click the the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your DRGs, use these operations:

- ListDrgs
- CreateDrg
- GetDrg
- UpdateDrg
- DeleteDrg
- ChangeDrgCompartment
- ListDrgAttachments
- CreateDrgAttachment: This attaches a DRG to a VCN and results in a DrgAttachment object with its own OCID. You may optionally specify a route table if you're setting up the advanced routing scenario called transit routing.
- GetDrgAttachment
- UpdateDrgAttachment: Among other things, this associates a route table with an existing DRG attachment for transit routing.
- DeleteDrgAttachment: This detaches a DRG from a VCN by deleting the DrgAttachment.

For information about route table operations, see Route Tables on page 2921.

VPN Connect

VPN Connect provides a site-to-site IPSec VPN between your on-premises network and your virtual cloud network (VCN).

Create a service request Ask the community
Networking

**VPN Connect Overview**
The VPN connection uses industry-standard IPSec protocols. The Oracle service that provides site-to-site connectivity is named VPN Connect (also referred to as an IPSec VPN). VPN Connect provides a site-to-site IPSec VPN between your on-premises network and your virtual cloud network (VCN). The IPSec protocol suite encrypts IP traffic before the packets are transferred from the source to the destination and decrypts the traffic when it arrives.

Other secure VPN solutions include OpenVPN, a Client VPN solution that can be accessed in the Oracle Marketplace. OpenVPN connects individual devices to your VCN, but not whole sites or networks.

This topic gives an overview of a site-to-site IPSec VPN for your VCN. For scenarios that include an IPSec VPN, see Scenario B: Private Subnet with a VPN on page 2761 and Scenario C: Public and Private Subnets with a VPN on page 2769.

**Required Personnel and Knowledge**
Typically the following types of personnel are involved in setting up an IPSec VPN with Oracle Cloud Infrastructure:

- **Dev Ops team member** (or similar function) who uses the Oracle Cloud Infrastructure Console to set up the cloud components required for the virtual network and IPSec VPN.
- **Network engineer** (or similar function) who configures the customer-premises equipment (CPE) device with information provided by the Dev Ops team member.

**Tip:**
The Dev Ops team member must have the required permission to create and manage the cloud components. If the person is the default administrator for your Oracle Cloud Infrastructure tenancy or a member of the Administrators group, then they have the required permission. For information about

---

**Use cases**

**Securely connect to Oracle Cloud**
Securely connect your existing infrastructure to the cloud by using industry-standard encryption algorithms.

**Connect multiple locations to the cloud**
Connect your headquarters, branch locations, and private data centers to Oracle Cloud so all of your offices can access applications.

**Connect to other public clouds**
Securely connect to workloads in other providers’ cloud services.

**Build redundant connectivity for Oracle FastConnect**
Already have Oracle FastConnect? VPN Connect can provide a redundant connection to Oracle Cloud Infrastructure.
restricting access to your networking components, see Access Control on page 2831.

The personnel should be familiar with the following concepts and definitions:

- The fundamentals of Oracle Cloud Infrastructure
- The basic Networking service components
- General IPSec VPN tunnel functionality

**CLOUD RESOURCES**

Anything you provision on a cloud platform. For example, with Oracle Cloud Infrastructure, a cloud resource can refer to a VCN, compute instance, user, compartment, load balancer, or any other service component on the platform.

**ON-PREMISES**

A widely used term in cloud technologies that refers to your traditional data center environments. On-premises can refer to a colocation scenario, a dedicated floor space, a dedicated data center building, or a desktop running under your desk.

**ORACLE CLOUD IDENTIFIER (OCID)**

A unique identifier assigned to each resource that you provision on Oracle Cloud Infrastructure. The OCID is a long string that Oracle automatically generates. You can't choose the value for an OCID or change a resource's OCID. For more information, see Resource Identifiers on page 197.

**About the Oracle IPSec VPN**

In general, IPSec can be configured in the following modes:

- **Transport mode:** IPSec encrypts and authenticates only the actual payload of the packet, and the header information stays intact.
- **Tunnel mode (supported by Oracle):** IPSec encrypts and authenticates the entire packet. After encryption, the packet is then encapsulated to form a new IP packet that has different header information.

Oracle Cloud Infrastructure supports only the tunnel mode for IPSec VPNs.

Each Oracle IPSec VPN consists of multiple redundant IPSec tunnels. For a given tunnel, you can use either Border Gateway Protocol (BGP) dynamic routing or static routing to route that tunnel's traffic. More details about routing follow.

IPSec VPN site-to-site tunnels offer the following advantages:

- Public internet lines are used to transmit data, so dedicated, expensive lease lines from one site to another aren't necessary.
- The internal IP addresses of the participating networks and nodes are hidden from external users.
- The entire communication between the source and destination sites is encrypted, significantly lowering the chances of information theft.

**Note:**
IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

**Routing for the Oracle IPSec VPN**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE device to use both tunnels (if your device supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
• **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

**Important Routing Details for an Oracle IPSec VPN**

Here are important details to understand about routing for your IPSec VPN:

**Routing choices:**

- Originally, the Oracle IPSec VPN supported only static routing, and you were required to provide at least one static route for the overall IPSec connection.
- Now two different types of routing are available (BGP and static routing), and you configure the routing type per tunnel. *Only one type of routing at a time is supported for a given tunnel.*
- In general, Oracle encourages you to use the same routing type for all tunnels in your IPSec connection. Exception: if you're in the process of transitioning between static routing and BGP, then one tunnel might temporarily still use static routing while the other has already been switched to BGP.
- When you create an IPSec connection, static routing is the default type of routing for all tunnels *unless you explicitly configure each tunnel to use BGP.*

**Routing information required:**

- If you choose BGP, for each tunnel you must provide two IP addresses (one for each of the two BGP speakers in the tunnel's BGP session). The addresses must be in the encryption domain for the IPSec connection. You must also provide the BGP autonomous system number (BGP ASN) for your network.
- If you choose static routing, you must provide at least one static route (maximum 10). The static routes are configured with the *overall IPSec connection,* so the same set of static routes are used for *all* tunnels in the IPSec connection that are configured to use static routing. You can change the static routes at any time after creating the IPSec connection. If you're doing PAT between your CPE device and VCN, the static route for the IPSec connection is the PAT IP address. See Example Layout with PAT on page 2966.
- If you choose static routing, you may optionally provide an IP address for each end of the tunnel for the purposes of tunnel troubleshooting or monitoring.
- If the tunnel is configured to use BGP, the IPSec connection's static routes are ignored. Any static routes associated with the IPSec connection are used for routing a given tunnel's traffic *only if that tunnel is configured to use static routing.* This is especially relevant if you have an IPSec VPN that uses static routing, but want to switch to using BGP.

**Changing the routing:**

- If you want to change a tunnel from BGP to static routing, you must first ensure that the IPSec connection itself has at least one static route associated with it.
- You can change an existing tunnel's routing type at any time (unless the tunnel is currently being provisioned by Oracle). While you change the routing, the tunnel remains up (its IPSec status does not change). However, traffic flowing through the tunnel is disrupted temporarily during re provisioning and while you reconfigure your CPE device. For information about making changes to an existing IPSec VPN, see Working with VPN Connect on page 3156.
- Because you configure the routing type separately for each tunnel, if you want to switch your IPSec VPN from static routing to BGP, you can do it one tunnel at a time. This avoids the entire IPSec VPN being down. For instructions, see Changing from Static Routing to BGP Dynamic Routing on page 3160.

**Route Advertisements and Path Preferences When You Have Multiple Connections**

When you use BGP, the DRG attached to your VCN advertises routes to your CPE.

If you set up multiple connections between your on-premises network and VCN, you must understand what routes the DRG advertises and how to set path preferences to use your desired connection.

For important information, see Routing Details for Connections to Your On-Premises Network on page 2942.
Preferring a Specific Tunnel in the IPSec VPN

Within an IPSec VPN, you can influence which tunnel is preferred. Here are items you can configure:

- **Your CPE's BGP local preference**: If you use BGP, you can configure the BGP local preference attribute on your CPE device to control which tunnel is preferred for connections initiated from your on-premises network to your VCN. Because Oracle generally uses asymmetric routing, you must configure other attributes if you want Oracle to respond on that same tunnel. See the next two items.

- **More specific routes on the preferred tunnel**: You can configure your CPE to advertise more specific routes for the tunnel that you want to prefer. Oracle uses the route with the longest prefix match when responding to or initiating connections.

- **AS path prepending**: BGP prefers the shortest AS path, so if you use BGP, you can use AS path prepending to control which tunnel has the shortest path for a given route. Oracle uses the shortest AS path when responding to or initiating connections.

Overview of the IPSec VPN Components

If you're not already familiar with the basic Networking service components, see Networking on page 2746 before proceeding.

When you set up an IPSec VPN for your VCN, you must create several Networking components. You can create the components with either the Console or the API. See the following diagram and description of the components.

**cpe object**

At your end of the IPSec VPN is the actual device in your on-premises network (whether hardware or software). The term *customer-premises equipment (CPE)* is commonly used in some industries to refer to this type of on-premises equipment. When setting up the VPN, you must create a virtual representation of the device. Oracle calls the virtual representation a CPE, but this documentation typically uses the term *CPE object* to help distinguish the virtual representation from the actual CPE device. The CPE object contains basic information about your device that Oracle needs.
**DYNAMIC ROUTING GATEWAY (DRG)**

At Oracle’s end of the IPSec VPN is a virtual router called a dynamic routing gateway, which is the gateway into your VCN from your on-premises network. Whether you’re using an IPSec VPN or Oracle Cloud Infrastructure FastConnect private virtual circuits to connect your on-premises network and VCN, the traffic goes through the DRG. For more information, see Dynamic Routing Gateways (DRGs) on page 2927.

A network engineer might think of the DRG as the **VPN headend**. After creating a DRG, you must **attach** it to your VCN, using either the Console or API. You must also add one or more route rules that route traffic from the VCN to the DRG. Without that DRG attachment and the route rules, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining VPN components. You can then reattach the DRG, or attach it to another VCN.

**ipsec connection**

After creating the CPE object and DRG, you connect them by creating an IPSec connection, which you can think of as a parent object that represents the overall IPSec VPN. The IPSec connection has its own **OCID**. When you create this component, you configure the type of routing to use for each tunnel, and you provide any related routing information.

**TUNNEL**

An IPSec tunnel is used to encrypt traffic between secure IPSec endpoints. Oracle creates two tunnels in each IPSec connection for redundancy. Each tunnel has its own **OCID**. Oracle recommends that you configure your CPE device to support both tunnels in case one fails or Oracle takes one offline for maintenance. Each tunnel has configuration information that your network engineer needs when configuring your CPE device. This information includes an IP address and shared secret, as well as ISAKMP and IPSec parameters. You can use the CPE Configuration Helper to gather the information that the network engineer needs. For more information, see Supported IPSec Parameters on page 2945 and Verified CPE Devices on page 2969.

**Access Control for the Components**

For the purposes of access control, when you set up the IPSec VPN, you must specify the compartment where you want each of the components to reside. If you’re not sure which compartment to use, put all the components in the same compartment as the VCN. Note that the IPSec tunnels always reside in the same compartment as the parent IPSec connection. For information about compartments and restricting access to your networking components, see Access Control on page 2831.

**Component Names and Identifiers**

You can optionally assign a descriptive name to each of the components when you create them. These names don't have to be unique, although it's a best practice to use unique names across your tenancy. Avoid entering confidential information. Oracle automatically assigns each component an OCID. For more information, see Resource Identifiers.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's **public** IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's **private** IP address, as show in the following diagram.
Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

About the Tunnel Shared Secret

Each tunnel has a shared secret. By default, Oracle assigns the shared secret to the tunnel unless you provide a shared secret yourself. You can provide a shared secret for each tunnel when you create the IPSec connection, or later after the tunnels are created. For the shared secret, only letters, numbers, and spaces are allowed. If you change an existing tunnel's shared secret, the tunnel goes down while it is being reprovisioned.

For instructions, see Changing the Shared Secret That an IPSec Tunnel Uses on page 3159.

Resources for Configuring the CPE

Your network engineer must configure the CPE at your end of the IPSec connection. To make it easier, Oracle provides these resources:

- **CPE Configuration Helper**: A tool in the Oracle Console that generates a set of content that the network engineer can use when configuring the CPE.
- **A list of verified CPE devices**: For each device, Oracle provides configuration instructions.
- **A list of supported IPSec parameters**: If your CPE is not on the list of verified devices, you can use this list of parameters to configure your CPE.

For more information, also see CPE Configuration on page 2967.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring your connection, VPN Connect Metrics on page 3164.

What’s Next?

See these related topics:

- **VPN Connect Quickstart** on page 2939
- **Setting Up VPN Connect** on page 2949
- **Supported IPSec Parameters** on page 2945
The VPN Connect workflow is the quickest way to set up a site-to-site VPN between your on-premises network and your virtual cloud network (VCN). The workflow is a guided, step-by-step process in the Console that sets up the VPN plus related Networking service components.

Other secure VPN solutions include OpenVPN, a Client VPN solution that can be accessed in the Oracle Marketplace. OpenVPN connects individual devices to your VCN, but not whole sites or networks.

**Purpose of the Workflow**

VPN Connect involves setting up and configuring several Networking service components. The workflow sets up those components for you. In general, the workflow does the following:

- Uses a template with assumptions that will help you get started.
- Asks you for some basic network information.
- Sets up the Networking service components for you.
- Lets you generate configuration content for a network engineer to use when configuring your customer-premises equipment (CPE) device.

The workflow is a task within the overall process of setting up VPN Connect, which is illustrated in the following diagram. The workflow is the shaded box.

Notice that the overall process includes work by a network engineer in your organization. That engineer provides information that you, in turn, must supply during the workflow. The workflow returns information that the network engineer needs when configuring your CPE device. You can use the CPE Configuration Helper to consolidate the necessary information into an organized template for the network engineer.

The following short sections summarize each task.

**Task 1: Information to get from your network engineer**

- CPE device's public IP address.
- If the CPE is behind a NAT device, get the CPE IKE identifier. For more information, see Overview of the IPSec VPN Components on page 2936.
- On-premises network routes.
- If you use BGP dynamic routing with the VPN:
  - Your network's BGP ASN
  - For each of the two IPSec tunnels that will be created, the pair of BGP IP addresses (with subnet mask) that you want to use for the inside tunnel interfaces at the ends of each tunnel. For example:
    - Tunnel 1: Inside tunnel interface - CPE: 10.0.0.8/31
    - Tunnel 1: Inside tunnel interface - Oracle: 10.0.0.9/31
    - Tunnel 2: Inside tunnel interface - CPE: 10.0.0.16/31
    - Tunnel 2: Inside tunnel interface - Oracle: 10.0.0.17/31
• If you don't already have a VCN: The CIDR to use for the new VCN that will be created. For the workflow, the allowed VCN size is /16 to /24. The CIDR must not overlap with your on-premises network.

Task 2: Workflow
You walk through the workflow in the Console. For more information, see these sections:
• Where to Access the Workflow in the Console on page 2942
• What the Workflow Creates for You on page 2940

Task 3: Information to give to your network engineer
You use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

The content includes these items:
• For each IPSec tunnel, the Oracle VPN IP address and shared secret.
• The supported IPSec parameter values.
• Information about the VCN.
• CPE-specific configuration information.

Task 4: CPE configuration
Your network engineer takes the information you provide and configures your CPE device.

Task 5: Testing
You and the network engineer test the connection and confirm that traffic is flowing.

Alternative to the Workflow
If you prefer, you can manually set up VPN Connect yourself. For step-by-step instructions, see Setting Up VPN Connect on page 2949.

What the Workflow Creates for You
Most Oracle customers who set up a VPN Connect already have a VCN to connect to their on-premises network. In that case, the workflow creates the numbered components in the following diagram. The table describes each component.

<table>
<thead>
<tr>
<th>Number</th>
<th>Component</th>
<th>Description</th>
<th>Can Use Existing One or Create New One?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CPE</td>
<td>A CPE is a virtual representation of your actual CPE device. This virtual representation contains basic information such as the CPE device's public IP address.</td>
<td>Yes, you can either use an existing CPE or the workflow creates a new one.</td>
</tr>
<tr>

<tr>
<td>2</td>
<td>Dynamic routing gateway (DRG)</td>
<td>A DRG is a <em>virtual representation</em> of the actual router at the Oracle end of your VPN Connect.</td>
<td>Yes. If you use an existing one, it must not already be attached to a VCN.</td>
</tr>
<tr>
<td>3</td>
<td>VCN Connect IPSec tunnels</td>
<td>The workflow creates two <em>IPSec tunnels</em>, each with specific configuration information that you must provide to your network engineer. Note: The workflow uses IKEv1 for the tunnels. If you want to use IKEv2 instead, after creating the IPSec connection, edit each tunnel in the Oracle Console to use IKEv2. Then configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For more information, see Using IKEv2 on page 3158.</td>
<td>No. The workflow automatically creates the tunnels.</td>
</tr>
</tbody>
</table>
• Default security list. The workflow configures the subnet to use this security list, which automatically comes with default rules to enable basic traffic flow. The workflow also adds these rules:
  • One or more rules to allow all types of traffic from your on-premises network. There's one rule per on-premises network route that you provide in the workflow. Notice that the security list does not include rules to allow ping.

After the workflow completes, you can modify the VCN's configuration in any way you want. For example, you could edit the route rules and security list rules, add more subnets, remove the internet gateway, and so on.

After the workflow completes, you can also use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

**Where to Access the Workflow in the Console**

**Option 1:**
1. In the Console, click the Oracle Cloud icon at the top of the page to go to the Console home page.

   The page has a Quick Actions section to take you directly to common tasks.
2. Click the quick action for Networking: Set up a network with a wizard.
3. Select VCN with VPN Connect and Internet Connectivity, and then click Start Workflow.

**Option 2:**
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click Networking Quickstart.
3. Select VCN with VPN Connect and Internet Connectivity, and then click Start Workflow.

**Routing Details for Connections to Your On-Premises Network**

You might use multiple site-to-site connections between your on-premises network and virtual cloud network (VCN) for redundancy or other reasons.

For example, you might use both FastConnect private peering and VPN Connect to the dynamic routing gateway (DRG) attached to your VCN. Or perhaps you use redundant VPN Connect connections to the DRG (for an example scenario, see Example Layout with Multiple Geographic Areas on page 2965). Or perhaps you use FastConnect public peering, FastConnect private peering, and VPN Connect.

This topic covers important details about route advertisement and path preferences when you have multiple connections.

**DRG Route Advertisements to Your On-Premises Network**

FastConnect private peering and VPN Connect provide your on-premises network with private access to a VCN. Both types of connections terminate on a single DRG that is attached to the VCN. Remember that VPN Connect can use either Border Gateway Protocol (BGP) or static routing, or a combination. FastConnect always uses BGP for route advertisements.

The DRG advertises the routes for the individual subnets in the DRG's attached VCN. A DRG can be attached to only a single VCN, and a VCN can be attached to only a single DRG.
If you set up transit routing to multiple VCNs for your on-premises network, the DRG advertises other routes. Transit routing is an advanced routing scenario that involves a single FastConnect or VPN Connect and multiple peered VCNs in a hub-and-spoke layout. With transit routing, the DRG also advertises routes for the VCNs that are peered with the DRG's attached VCN (the hub).

If you set up your on-premises network with private access to Oracle services through the VCN's service gateway, the DRG advertises more routes. They are routes for the Oracle Services Network, which is available with the service gateway. For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

Important:
If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

Routing Preferences for Traffic from Oracle to Your On-Premises Network
This section describes how Oracle chooses which path to use when sending traffic to your on-premises network. The traffic can be for responding to a request or initiating new connections.

Routers generally prefer to use the most specific route (the one with the longest prefix match).

However, if the routes for the different paths are the same, Oracle uses the shortest AS path when sending traffic to your on-premises network, regardless of which path was used to initiate the connection to Oracle. Therefore asymmetric routing is allowed. Asymmetric routing here means that Oracle's response to a request can follow a different path than the request. For example, depending on how your edge device (also called your customer-premises equipment, or CPE) is configured, you could send a request over VPN Connect, but the Oracle response could come back over FastConnect. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections.

Oracle implements AS path prepending to establish preference on which path to use if your edge device advertises the same route and routing attributes over multiple different connection types between your on-premises network and VCN. The details are summarized in the following table. Unless you're influencing routing in some way, when the same route is advertised over multiple paths to the DRG at the Oracle end of the connections, Oracle prefers the paths in the following order:

<table>
<thead>
<tr>
<th>Oracle preference</th>
<th>Path</th>
<th>Details of how Oracle prefers the path</th>
<th>Resulting AS path for the route</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FastConnect</td>
<td>Oracle prepends no ASNs to the routes that your edge device advertises, for a total AS path length of 1.</td>
<td>Your ASN</td>
</tr>
<tr>
<td>2</td>
<td>VPN Connect with BGP routing</td>
<td>Oracle prepends a single private ASN on all the routes that your edge device advertises over VPN Connect with BGP, for a total AS path length of 2.</td>
<td>Private ASN, Your ASN</td>
</tr>
</tbody>
</table>
If you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, **Oracle prefers the oldest continuously advertised route** when responding to requests or initiating connections.

The above table above assumes you are sending a single autonomous system number in your AS path. Oracle honors the complete AS path you send. If you use static routing, and also send an AS path that has "Your ASN" plus 2 or more other ASNs, it can cause unexpected behavior because Oracle's routing preference may change accordingly.

While static policy-based VPN routing behavior is documented above, Oracle also recommends that if you use FastConnect connections with VPN backup, you employ BGP on your IPSEC route-based VPN. This strategy allows you to have full control of failover behavior.

**Routing Preferences for Traffic from Your On-Premises Network to Oracle**

You can configure your edge device to prefer a specific path when sending traffic from your on-premises network to Oracle. The following section describes a particular situation where you must do that to ensure a consistent traffic path if your on-premises hosts use Oracle services.

Your on-premises network can access public Oracle Services Network services such as Object Storage over multiple paths. You can use public paths, such as the internet or FastConnect public peering. With these public paths, the on-premises hosts communicate with Oracle services by using public IP addresses.

You can also set up your on-premises network with private access to Oracle services through the VCN's service gateway. A service gateway lets hosts in your on-premises network use any of the services listed in Service Gateway: Supported Cloud Services in Oracle Services Network and communicate with those Oracle services from your private IP addresses.

If you've configured your on-premises network with multiple connection paths to Oracle services, your edge device may receive route advertisement of the Oracle services' public IP address routes over multiple paths. Here are the possible paths you can use with your on-premises network:

- Public access paths:
  - Internet service provider (ISP)
  - FastConnect public peering
- Private access paths by way of the VCN's DRG and service gateway:
  - FastConnect private peering
  - VPN Connect

Your edge device receives route advertisements from the DRG and possibly from routers over public paths. Most of the routes for Oracle services that the DRG advertises have a longer prefix (they are more specific) than the routes for Oracle services that are advertised over the public access paths. Therefore, if you set up your network with both public access and private access to Oracle services, **you must configure your edge device to prefer the private access path to the DRG** for traffic from the on-premises network to Oracle services. Setting up both public and private access ensures a consistent path for access to Oracle services.

For a list of the public IP ranges advertised over FastConnect public peering, see [FastConnect Public Peering Advertised Routes](#) on page 3219.
For a list of the regional public IP ranges advertised over the private paths (for a VCN with a service gateway), see Public IP Addresses for VCNs and the Oracle Services Network on page 193.

- VPN Connect Best Practices (PDF)
- FastConnect Redundancy Best Practices on page 3185

**Supported IPSec Parameters**

This topic lists the supported phase 1 (ISAKMP) and phase 2 (IPSec) configuration parameters for VPN Connect. Oracle chose these values to maximize security and to cover a wide range of CPE devices. If your CPE device is not on the list of verified devices, use the information here to configure your device.

You can also use the CPE Configuration Helper to gather information that a network engineer uses when configuring the CPE device.

**Important:**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

**Supported Encryption Domain or Proxy ID**

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 2948.

**Supported Parameters for the Commercial Cloud**

This section lists the supported parameters if your VPN Connect is for the commercial cloud. For a list of the commercial cloud regions, see Regions and Availability Domains on page 180.

For some parameters, Oracle supports multiple values, and the recommended one is noted.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

**Supported Parameters for the Government Cloud**

This section lists the supported parameters if your VPN Connect is for the Government Cloud. For more information, see For All US Government Cloud Customers on page 148.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in **bold text**.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

Networking

**Supported Encryption Domain or Proxy ID**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

![Note:

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.](image)

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domains for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.
Networking

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

Setting Up VPN Connect

This topic gives instructions for constructing a site-to-site VPN Connect link to your VCN. For general information about IPSec VPNs, see VPN Connect Overview on page 2933.

Before You Get Started

To prepare, do these things first:

- Read this section: Routing for the Oracle IPSec VPN on page 2934
- Answer these questions:

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is your VCN’s CIDR?</td>
<td></td>
</tr>
<tr>
<td>What is the public IP address of your CPE device? If you have multiple devices for redundancy, get the IP address for each.</td>
<td></td>
</tr>
<tr>
<td>Note: If your CPE device is behind a NAT device, see Overview of the IPSec VPN Components on page 2936 and also Requirements and Prerequisites on page 2968.</td>
<td></td>
</tr>
</tbody>
</table>
Networking

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Will you use port address translation (PAT) between each CPE device and your VCN?</td>
<td></td>
</tr>
<tr>
<td>What type of routing do you plan to use? If you want BGP dynamic routing, list the BGP session IP addresses to use and the ASN of your network. The IP addresses must be part of the IPSec VPN's encryption domain. If you want static routing, what are the static routes for your on-premises network? See Routing for the Oracle IPSec VPN on page 2934. Do you plan to use policy based routing or multiple encryption domains? See Encryption domains for policy-based tunnels on page 2948. Do you want to provide each tunnel's shared secret or let Oracle assign them? See Overview of the IPSec VPN Components on page 2936.</td>
<td></td>
</tr>
<tr>
<td>• Draw a diagram of your network layout (for examples, see the first task in Example: Setting Up a Proof of Concept IPSec VPN on page 2951). Think about which parts of your on-premises network need to communicate with your VCN, and the reverse. Map out the routing and security rules that you need for your VCN.</td>
<td></td>
</tr>
<tr>
<td><strong>Tip:</strong> If you have an existing Oracle IPSec VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.</td>
<td></td>
</tr>
</tbody>
</table>

**Overall Process**

Here's the overall process for setting up an IPSec VPN:

1. **Complete the tasks listed in Before You Get Started on page 2949.**
2. **Set up the IPSec VPN components** (instructions in Example: Setting Up a Proof of Concept IPSec VPN on page 2951):
   a. Create your VCN.
   b. Create a DRG.
   c. Attach the DRG to your VCN.
   d. Create a route table and route rule for the DRG.
   e. Create a security list and required rules.
   f. Create a subnet in the VCN.
   g. Create a CPE object and provide your CPE device's public IP address.
   h. Create an IPSec connection to the CPE object and provide required routing information.
3. **Use the CPE Configuration Helper:** Your network engineer must configure your CPE device with information that Oracle provides during the previous steps. The CPE Configuration Helper generates the information for your network engineer. For more information, see Using the CPE Configuration Helper on page 2970 and also CPE Configuration on page 2967.
4. **Have your network engineer configure your CPE device.**
5. **Validate connectivity.**
   If you plan to set up redundant connections, see the Connectivity Redundancy Guide.
**Example: Setting Up a Proof of Concept IPSec VPN**

**Tip:**
Oracle offers a quickstart workflow to make it easier to set up VPN Connect. For more information, see [VPN Connect Quickstart](#) on page 2939.

This example scenario shows how to set up a single IPSec VPN with a simple layout that you might use for a proof of concept (POC). It follows tasks 1 and 2 in [Overall Process](#) on page 2950 and shows each component in the layout being created. For each task, there's a corresponding screenshot from the Console to help you understand what information is needed. For more complex layouts, see [Example Layout with Multiple Geographic Areas](#) on page 2965 or [Example Layout with PAT](#) on page 2966.

**Task 1: Gather information**

<table>

</table>
Here’s an example diagram for task 1 that uses BGP dynamic routing:

Here’s an example diagram for task 1 that uses static routing:

Here’s an example diagram for task 1 that uses policy-based routing:

Task 2a: Create the VCN
If you already have a VCN, skip to the next task.

Tip:
When you use the Console to create a VCN, you can create only the VCN, or you can create the VCN with several related resources. This task creates only the VCN, and the subsequent tasks create the other required resources.
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control on page 2831.

3. Click Create Virtual Cloud Network.

4. Enter the following values:
   - **Name**: A descriptive name for the cloud network. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **CIDR Block**: A single, contiguous CIDR block for the cloud network (for example, 172.16.0.0/16). You can’t change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, use a CIDR calculator.
   - **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

5. You can provide values for the rest of the options, or you can ignore them:
   - **DNS Resolution**: Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the Internet and VCN Resolver). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding DNS Domain Name for the VCN (VCN DNS label). For more information, see DNS in Your Virtual Cloud Network on page 2910.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. Click Create Virtual Cloud Network.

The VCN is created and displayed on the page. Ensure that it's done being provisioned before continuing.
Task 2b: Create the DRG

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.
2. Click Create Dynamic Routing Gateway.
3. Enter the following values:
   - **Create in Compartment**: Leave as is (the VCN's compartment).
   - **Name**: A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.
4. Click Create Dynamic Routing Gateway.

The DRG is created and displayed on the page. Ensure that it's done being provisioned before continuing.

Tip:

You could also use this DRG as the gateway for Oracle Cloud Infrastructure FastConnect, which is an alternative way to connect your on-premises network to your VCN.

Task 2c: Attach the DRG to the VCN

1. Click the name of the DRG you created.
2. Under Resources, click Virtual Cloud Networks.
3. Click Attach to Virtual Cloud Network.
4. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called transit routing, which is not relevant here.

5. Click Attach.

The attachment is in the Attaching state for a short period before it's ready.

Task 2d: Create a route table and route rule for the DRG

Although the VCN comes with a default route table (without any rules), in this task you create a custom route table with a route rule for the DRG. In this example, your on-premises network is 10.0.0.0/16. You create a route rule that takes any traffic destined for 10.0.0.0/16 and routes it to the DRG. When you create a subnet in task 2f, you associate this custom route table with the subnet.

If you already have an existing VCN with a subnet, you don’t need to create a route table or subnet. Instead you can update the existing subnet’s route table to include the route rule for the DRG.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click your VCN.
3. Click Route Tables to see your VCN's route tables.
4. Click Create Route Table.
5. Enter the following values:
   - Name: A descriptive name for the route table (for example, MyExampleRouteTable). The name doesn’t have to be unique, and it can’t be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
   - Create in compartment: Leave as is.
   - Click + Additional Route Rule, and enter the following:
     - Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
     - Destination CIDR Block: The CIDR for your on-premises network (10.0.0.0/16 in this example).
     - Description: An optional description of the rule.
     - Tags: Leave the tag information as is.
6. Click Create Route Table.

The route table is created and displayed on the page. However, the route table doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).
Task 2e: Create a security list

By default, incoming traffic to the instances in your VCN is set to DENY on all ports and all protocols. In this task, you set up two ingress rules and one egress rule to allow basic required network traffic. Your VCN comes with a default security list with a set of default rules. However, in this task you create a separate security list with a more restrictive set of rules focused on traffic with your on-premises network. When you create a subnet in task 2f, you associate this security list with the subnet.

Tip:

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

Important:

In the following procedure, ensure that the on-premises CIDR that you specify in the security list rules is the same (or smaller) than the CIDR that you specified in the route rule in the preceding task. Otherwise, traffic will be blocked by the security lists.

1. While still viewing your VCN, click Security Lists on the left side of the page.
2. Click Create Security List.
3. Enter the following values:
   - Name: A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
   - Create in compartment: Leave as is.
4. In the Allow Rules for Ingress section, click Add Ingress Rule and enter the following values for the ingress rule, which allows incoming SSH on TCP port 22 from your on-premises network:
   - Source Type: CIDR
   - Source CIDR: The CIDR for your on-premises network (10.0.0.0/16 in this example)
   - IP Protocol: TCP.
   - Source Port Range: Leave as is (the default All).
   - Destination Port Range: 22 (for SSH traffic).
   - Description: An optional description of the rule.

5. In the Allow Rules for Egress section, click Add Egress Rule enter the following values for the egress rule, which allows outgoing TCP traffic on all ports to your on-premises network:
   - Destination Type: CIDR
   - Destination CIDR: The CIDR for your on-premises network (10.0.0.0/16 in this example).
   - IP Protocol: TCP.
   - Source Port Range: Leave as is (the default All).
   - Destination Port Range: Leave as is (the default All).
   - Description: An optional description of the rule.

6. Leave the tag information as is.

7. Click Create Security List.

The security list is created and displayed on the page. However, the security list doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).

**Task 2f: Create a subnet**

In this task, you create a subnet in the VCN. Typically a subnet has a CIDR block smaller than the VCN's CIDR. Any instances that you create in this subnet have access to your on-premises network. Oracle recommends using regional subnets. Here you create a regional private subnet.

1. While still viewing your VCN, click Subnets on the left side of the page.
2. Click Create Subnet.
3. Enter the following values:

- **Name**: A descriptive name for the subnet. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Regional or AD-specific subnet**: Select the radio button for **Regional**. Oracle recommends using regional subnets.
- **CIDR Block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). It must be within the cloud network's CIDR block and can't overlap with any other subnets. You can't change this value later. See [Allowed VCN Size and Address Ranges](#) on page 2750. For reference, use a CIDR calculator.
- **Enable IPv6 Address Assignment**: This option is available only if the VCN is in the US Government Cloud. For more information, see [IPv6 Addresses](#) on page 2889.
- **Route Table**: The route table that you created earlier.
- **Private Subnet**: Select this option. For more information, see [Access to the Internet](#) on page 2752.
- **Use DNS Hostnames in this Subnet**: Leave as is (selected).
- **DHCP Options**: The set of DHCP options to associate with the subnet. Select the default set of DHCP options for the VCN.
- **Security Lists**: The security list that you created earlier.
- **Tags**: Leave as is. You can add tags later if you want. For more information, see [Resource Tags](#) on page 211.

4. Click **Create Subnet**.

The subnet is created and displayed on the page. The basic VCN in this example is now set up, and you're ready to create the remaining components for the IPSec VPN.

**Task 2g: Create a CPE object and provide your CPE device's public IP address**

In this task, you create the CPE object, which is a virtual representation of your CPE device.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
2. Click **Create Customer-Premises Equipment**.
3. Enter the following values:
   - **Create in Compartment**: Leave as is (the VCN's compartment).
   - **Name**: A descriptive name for the CPE object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **IP Address**: The public IP address of the CPE device at your end of the VPN (see the list of information to gather in [Before You Get Started](#) on page 2949).
   - **Tags**: Leave as is. You can add tags later if you want. For more information, see [Resource Tags](#) on page 211.
4. Click **Create**.

The CPE object is created and displayed on the page.
Task 2h: Create an IPSec connection to the CPE object

In this task, you create the IPSec tunnels and configure the type of routing for them (BGP dynamic routing or static routing).

**Tip:**

If you have an existing Oracle IPSec VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.

For BGP dynamic routing

In this example, you configure both tunnels to use BGP dynamic routing.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
2. Click Create IPSec Connection.
3. Enter the following values:
   - **Create in Compartment:** Leave as is (the VCN's compartment).
   - **Name:** Enter a descriptive name for the IPSec connection. It doesn’t have to be unique, and you can change it later. Avoid entering confidential information.
   - **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
   - **Customer-Premises Equipment:** Select the CPE object that you created earlier.
   - **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
   - **Dynamic Routing Gateway:** Select the DRG that you created earlier.
   - **Static Route CIDR:** Leave empty because this IPSec connection uses BGP dynamic routing. You configure the two tunnels to use BGP in subsequent steps.
4. Click Show Advanced Options.
5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.

6. On the **Tunnel 1** tab (required):
   - **Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Select the radio button for **BGP Dynamic Routing**.
   - **BGP ASN**: Enter your network's ASN.
   - **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31. The IP address must be part of the IPSec VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31. The IP address must be part of the IPSec VPN's encryption domain.

7. On the **Tunnel 2** tab (required):
   - **Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Select the radio button for **BGP Dynamic Routing**.
   - **BGP ASN**: Enter your network's ASN.
   - **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of the IPSec VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of the IPSec VPN's encryption domain.

8. On the **Tags** tab (optional): Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.

9. Click **Create IPSec Connection**.
   
   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

   The displayed tunnel information includes:
   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.
   - The tunnel's BGP status. At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.

10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure your CPE device.

    You can view this tunnel information here in the Console at any time.
You have now created all the components required for the IPSec VPN. But your network engineer must configure your CPE device before network traffic can flow between your on-premises network and VCN.

For static routing

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
2. Click Create IPSec Connection.
3. Enter the following values:
   - Create in Compartment: Leave as is (the VCN's compartment).
   - Name: Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Customer-Premises Equipment Compartment: Leave as is (the VCN's compartment).
   - Customer-Premises Equipment: Select the CPE object that you created earlier.
   - Dynamic Routing Gateway Compartment: Leave as is (the VCN's compartment).
   - Dynamic Routing Gateway: Select the DRG that you created earlier.
   - Static Route CIDR: Enter at least one static route CIDR (see the list of information to gather in Before You Get Started on page 2949). For this example, enter 10.0.0.0/16. You can enter up to 10 static routes, and you can change the static routes later.
4. Click Show Advanced Options.
5. On the CPE IKE Identifier tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
6. On the **Tunnel 1** tab (optional):

   - **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Leave the radio button for *Static Routing* selected.
   - **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of the IPSec VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of the IPSec VPN's encryption domain.

7. On the **Tunnel 2** tab (optional):

   - **Tunnel Name**: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version**: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type**: Leave the radio button for *Static Routing* selected.
   - **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of the IPSec VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of the IPSec VPN's encryption domain.

8. **Tags**: Leave as is. You can add tags later if you want. For more information, see *Resource Tags* on page 211.

9. Click **Create IPSec Connection**.

   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

   The displayed tunnel information includes:

   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.

10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the CPE device.

   You can view this tunnel information here in the Console at any time.

   You have now created all the components required for the IPSec VPN. But your network engineer must configure the CPE device before network traffic can flow between your on-premises network and VCN.

   For more information, see *CPE Configuration* on page 2967.

For policy-based routing

   Set up **VPN Connect with policy-based routing**.
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

2. Click Create IPSec Connection.

3. Enter the following values:
   - Create in Compartment: Leave as is (the VCN's compartment).
   - Name: Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Customer-Premises Equipment Compartment: Leave as is (the VCN's compartment).
   - Dynamic Routing Gateway Compartment: Leave as is (the VCN's compartment).
   - Static Route CIDR: Enter at least one static route CIDR (see the list of information to gather in Before You Get Started on page 2949). For this example, enter 10.0.0.0/16. You can enter up to 10 static routes, and you can change the static routes later.

4. Click Show Advanced Options.

5. On the CPE IKE Identifier tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.

6. On the Tunnel 1 tab (optional):
   - Tunnel Name: Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - Provide custom shared secret (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - IKE Version: The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - Routing Type: Select the radio button for Policy-based routing.
   - On-premises: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your on-premises network, with routing determined by the CPE device policies.

   Note:

   See Encryption domains for policy-based tunnels on page 2948 for limitations on how many IPv4 or IPv6 CIDR blocks can be used.

   - Oracle Cloud: You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your VCN.

   Note:

   See Encryption domains for policy-based tunnels on page 2948 for limitations on how many IPv4 or IPv6 CIDR blocks can be used.

   - Inside Tunnel Interface - CPE (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of one of the IPSec VPN's encryption domains.

   - Inside Tunnel Interface - Oracle (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of one of the IPSec VPN's encryption domains.
7. On the **Tunnel 2** tab (optional):

- **Tunnel Name:** Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
- **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
- **IKE Version:** The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type:** Select the radio button for **Policy-based** routing.
- **On-premises:** You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your on-premises network, with routing determined by the CPE device policies.
  
  **Note:** See Encryption domains for policy-based tunnels on page 2948 for limitations.

- **Oracle Cloud:** You can provide multiple IPv4 or IPv6 CIDR blocks used by resources in your VCN.
  
  **Note:** See Encryption domains for policy-based tunnels on page 2948 for limitations.

- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of one of the IPSec VPN's encryption domains.
- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of one of the IPSec VPN's encryption domains.

8. **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags on page 211.

9. **Click Create IPSec Connection.**

   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

   The displayed tunnel information includes:

   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.

10. **Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location, then deliver it to the network engineer who configures the CPE device.**

   You can view this tunnel information here in the Console at any time.

   You have now created all the components required for the IPSec VPN. But your network engineer must configure the CPE device before network traffic can flow between your on-premises network and VCN.

   For more information, see CPE Configuration on page 2967.

**Task 3: Use the CPE Configuration Helper**

Use the CPE Configuration Helper to generate configuration content that your network engineer can use to configure the CPE.

The content includes these items:

- For each IPSec tunnel, the Oracle VPN IP address and shared secret.
- The supported IPSec parameter values.
- Information about the VCN.
- CPE-specific configuration information.
For more information, see Using the CPE Configuration Helper on page 2970.

**Task 4: Have your network engineer configure your CPE**

Provide your network engineer with the following items:

- The content generated by the CPE Configuration Helper.
- The general IPSec parameters that Oracle supports.

**Important:**
Be sure to have your network engineer configure your CPE device to support both of the tunnels in case one fails or Oracle takes one down for maintenance. If you're using BGP, see Routing for the Oracle IPSec VPN on page 2934.

**Task 5: Validate connectivity**

After the network engineer configures your CPE device, you can confirm that the tunnel's IPSec status is Up and green. Next, you can create a Linux instance in the subnet in your VCN. You should then be able to use SSH to connect to the instance's private IP address from a host in your on-premises network. For more information, see Creating an Instance on page 695.

**Example Layout with Multiple Geographic Areas**

The following diagram shows an example with this configuration:

- Two networks in separate geographical areas that each connect to your VCN
- A single CPE device in each area
- Two IPSec VPNs (one for each CPE device)

Notice that each IPSec VPN has two routes associated with it: one for the particular geographical area's subnet, and a default 0.0.0.0/0 route. Oracle learns about the available routes for each tunnel either through BGP (if the tunnels use BGP), or because you've set them as static routes for the IPSec connection (if the tunnels use static routing).
Following are some examples of situations in which the 0.0.0.0/0 route can provide flexibility:

- Assume that the CPE 1 device goes down (see the next diagram). If Subnet 1 and Subnet 2 can communicate with each other, your VCN could still reach the systems in Subnet 1 because of the 0.0.0.0/0 route that goes to CPE 2.

- Assume that your organization adds a new geographical area with Subnet 3 and initially just connects it to Subnet 2 (see the next diagram). If you added a route rule to your VCN’s route table for Subnet 3, the VCN could reach systems in Subnet 3 because of the 0.0.0.0/0 route that goes to CPE 2.

**Example Layout with PAT**

The following diagram shows an example with this configuration:

- Two networks in separate geographical areas that each connect to your VCN
- Redundant CPE devices (two in each geographical area)
- Four IPSec VPNs (one for each CPE device)
- Port address translation (PAT) for each CPE device

For each of the four connections, the route that Oracle needs to know about is the PAT IP address for the specific CPE device. Oracle learns about the PAT IP address route for each tunnel either through BGP (if the tunnels use
BGP), or because you've set the relevant address as a static route for the IPSec connection (if the tunnels use static routing).

When you set up the route rules for the VCN, you specify a rule for each PAT IP address (or an aggregate CIDR that covers them all) with your DRG as the rule's target.

**CPE Configuration**

This topic is for network engineers. It explains how to configure the on-premises device (the customer-premises equipment, or CPE) at your end of the IPSec VPN so traffic can flow between your on-premises network and virtual cloud network (VCN). See these related topics:

- [Networking](#) on page 2746: For general information about the parts of a VCN
- [VPN Connect](#) on page 2932: For various topics about IPSec VPNs
- [Verified CPE Devices](#) on page 2969: For a list of CPE devices Oracle has verified
The following figure shows the basic layout of the IPSec VPN connection.

Requirements and Prerequisites
There are several requirements and prerequisites to be aware of before moving forward.

Routing Considerations
For important details about routing for your IPSec VPN see Routing for the Oracle IPSec VPN on page 2934.

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

If you use BGP dynamic routing with your IPSec VPN, you can configure routing so that Oracle prefers one tunnel over the other.

Note that the Cisco ASA policy-based configuration uses a single tunnel.

Creation of Cloud Network Components
You or someone in your organization must have already used the Oracle Console to create a VCN and an IPSec connection, which consists of multiple IPSec tunnels for redundancy. You must gather the following information about those components:

- VCN OCID: The VCN OCID is a unique Oracle Cloud Infrastructure identifier that has a UUID at the end. You can use this UUID or any other string that helps you identify this VCN in the device configuration and doesn't conflict with other object-group or access-list names.
- VCN CIDR
- VCN CIDR subnet mask
- For each IPSec tunnel:
  - The IP address of the Oracle IPSec tunnel endpoint (the VPN headend)
  - The shared secret

Information About Your CPE Device
You also need some basic information about the inside and outside interfaces of your on-premises device (your CPE). For a list of the required information for your particular CPE, see the links in this list: Verified CPE Devices on page 2969.

Oracle recommends that you disable NAT-T at your CPE when establishing IPSec tunnels with Oracle Cloud Infrastructure. Unless you have multiple CPEs sharing the same NAT IP, NAT-T is not required.

If your CPE is behind a NAT device, you can provide Oracle with your CPE's IKE identifier. For more information, see Overview of the IPSec VPN Components on page 2936.
Route-Based Versus Policy-Based IPSec

The Oracle VPN headends use route-based tunnels, but can work with policy-based tunnels with some caveats. See Encryption domains for policy-based tunnels on page 2948 for full details.

IPSec VPN Best Practices

- **Configure all tunnels for every IPSec connection:** Oracle deploys multiple IPSec headends for all your connections to provide high availability for your mission-critical workloads. Configuring all the available tunnels is a key part of the "Design for Failure" philosophy. (Exception: Cisco ASA policy-based configuration, which uses a single tunnel.)

- **Have redundant CPEs in your on-premises locations:** Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant CPE devices. You add each CPE to the Oracle Cloud Infrastructure Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. Oracle may use any tunnel that is "up" to send traffic back to your on-premises network. For more information, see Routing for the Oracle IPSec VPN on page 2934.

- **Consider backup aggregate routes:** If you have multiple sites connected via IPSec VPNs to Oracle Cloud Infrastructure, and those sites are connected to your on-premises backbone routers, consider configuring your IPSec connection routes with both the local site aggregate route as well as a default route.

  Note that the DRG routes learned from the IPSec connections are only used by traffic you route from your VCN to your DRG. The default route will only be used by traffic sent to your DRG whose destination IP address does not match the more specific routes of any of your tunnels.

Confirming the Status of the Connection

After you configure the IPSec connection, you can test the connection by launching an instance into the VCN and then pinging it from your on-premises network. For information about launching an instance, see Launching an Instance. To ping the instance, the VCN's security rules must allow ping traffic.

You can get the status of the IPSec tunnels in the API or Console. For instructions, see To view the status and configuration information for the IPSec tunnels on page 3157.

Device Configurations

For links to the specific configuration information for each verified CPE device, see Verified CPE Devices on page 2969.

Verified CPE Devices

The following devices or software have been verified for use with VPN Connect.

**Note:**

Oracle provides configuration instructions for the vendors and devices in the following table. Make sure to use the configuration instructions for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the following table, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

**Using the CPE Configuration Helper**

After you set up VPN Connect, your network engineer must configure the customer-premises equipment (CPE) at your end of the connection (for example, a router). The configuration includes details about your virtual cloud network (VCN) and the IPSec tunnels in the VPN Connect. This topic describes how to use the CPE Configuration Helper in the Oracle Console to generate information that a network engineer uses to configure the CPE. Notice that the CPE Configuration Helper is also referred to as the Helper.

**Overview of the Helper**

For the IPSec tunnels in a VPN Connect to work, your network engineer must configure your CPE with specific information. The information comes from different sources. Oracle provides some of it in several places within the Oracle Console. The Helper collects the necessary information in one place and then organizes it to make CPE configuration easier for the network engineer. You can copy or download the resulting content to a file.
The configuration information that the network engineer needs depends on which vendor makes the CPE. To ensure that the Helper can produce vendor-specific content, you specify which vendor makes your CPE. See the one-time prerequisite in Using the Helper on page 2971.

In some cases, the Helper might ask for information about your network and include it in the content. If you don't know the answers, you can leave them blank. The resulting content then uses placeholder variables to show where the network engineer needs to provide the answers.

The content that the Helper produces includes these items:

- The Oracle VPN headend for the tunnel (the IP address at the Oracle end)
- The shared secret (pre-shared key) for the tunnel
- Your VCN's CIDR
- BGP information (if you're using BGP dynamic routing for the tunnel)
- The IPSec parameters that Oracle supports
- Other relevant information

**Using the Helper**

One-time prerequisite: Specify the CPE vendor

Edit the CPE and select the vendor. If you're not sure which vendor makes your CPE, or it's not in the list, select Other.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Customer-Premises Equipment.
2. Select the CPE you're interested in, and then click Edit.
3. For Vendor, select your CPE vendor from the list. If you're not sure which vendor makes your CPE, or it's not in the list, select Other.
4. If prompted, select a value for Platform/Version. Here are guidelines:
   - Oracle recommends using a route-based configuration if possible.
   - If you do not see your specific CPE platform or version in the list, choose the closest platform/version that predates your CPE version.
5. Click Save Changes.

Open the Helper from one of three locations

You can access the Helper from three different locations in the Oracle Console. Where you access the Helper controls the scope of the content it produces:

- **The CPE page:** The Helper produces content for all IPSec connections that terminate on the CPE. Notice that there could be IPSec connections in compartments that you do not have access to. If you don't have permission to view a particular IPSec connection, it is not included in the content.
- **An IPSec connection page:** The Helper produces content for one individual IPSec connection (all tunnels within the connection).
- **A tunnel's page:** The Helper produces content for one tunnel in an IPSec connection.

1. Under Core Infrastructure, go to Networking and navigate to the resource page you're interested in:
   - The CPE page
   - The IPSec connection page
   - The tunnel page
2. Click Open CPE Configuration Helper.

   The Helper opens on the right side of the page.

   It shows basic information such as the CPE's public IP address and vendor.

Generate the content

The Helper has a Create Content button at the bottom. After you click it and the content is produced, there are buttons to copy or download the content to a file. Give the content to your network engineer, along with the link to
the configuration topic for your CPE type (see Verified CPE Devices on page 2969). You can return to the Helper at any time and again generate the configuration content.

**Tip:**

For certain CPE vendors, the Helper displays fields for vendor-specific information that is used for CPE configuration. The fields might be blank or already have values. You can fill in the blank fields or leave them as is. For blank fields, the resulting content displays placeholder variables to show where the network engineer needs to fill in the values.

**Instructions:**

1. Review the template of information in the Helper. Optionally fill in any blank fields.
2. Click **Create Content** at the bottom of the Helper.
   
   The Helper generates the content.

   **Note:**
   
   See this known issue if you instead see an error that says *The CPE is missing the vendor information (the device type). Update the CPE and add the vendor information.*

3. Click either **Copy Configuration to Clipboard** or **Download Configuration** (to download it to a file).
4. Click **Close**.
5. Give the following items to your network engineer:
   - A link to the configuration topic for your CPE type. See Verified CPE Devices on page 2969.
   - The Helper content that you generated.

**If You Update Your VPN Connect**

You could change aspects of your VPN Connect, and after you do, you might want to generate the Helper content again. For example, imagine that you have an IPSec connection that uses static routing, and you decide to change it to use BGP dynamic routing. After updating the Oracle Console with the new routing information, you can generate the Helper content again for the IPSec connection. You can then give that new content to your network engineer to configure the CPE accordingly.

**Related Topics**

**Check Point Configuration Options**

Choose the configuration that suits your situation:

- Check Point: Route-Based on page 2972
- Check Point: Policy-Based on page 2997

**Check Point: Route-Based**

This topic provides a route-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.
Networking

This topic is for route-based (VTI-based) configuration. If you instead want policy-based configuration, see Check Point: Policy-Based on page 2997.

Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

![Diagram of a basic IPSec connection to Oracle Cloud Infrastructure](image)

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
Networking

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI), or traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
• **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
Networking

- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

![Diagram showing CPE configuration behind a NAT device](image)

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see [Changing the CPE IKE Identifier That Oracle Uses](#) on page 3158.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see [Supported IPSec Parameters](#) on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see [Required VPN Connect Parameters for Government Cloud](#) on page 152 and also [Oracle's BGP ASN](#) on page 154. For the United Kingdom Government Cloud, see [Oracle's BGP ASN](#) on page 171.

**CPE Configuration (Route-Based)**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
The following figure shows the basic layout of the IPSec connection.

![Diagram of IPSec connection]

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

If you want to use IKEv2, there’s a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select IKEv2 only for the encryption method.

**Configuration Process**

**Redundancy with BGP Over IPSec**

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see Routing Details for Connections to Your On-Premises Network on page 2942.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of the IPSec VPN’s encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

Oracle’s BGP ASN in commercial regions is 31898. If you’re configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle’s BGP ASN on page 154.

For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

**Task 1: Install IPSec VPN on Check Point CloudGuard Security Gateway**

**Prerequisite:** Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.
1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.

2. Click OK to save your changes.

Task 2: Create the VTI interface from GAIA

In this task, you configure a VTI interface that passes traffic by using routing rules from the VTI interface to the newly created IPSec tunnel.

1. Log in to the GAIA portal using the Check Point CloudGuard Security Gateway public or private IP address.
2. On the GAIA portal, select the Advanced view.
3. Under Network Management, go to Network Interfaces.
4. Click **Add**, and then click **VPN Tunnel**.
5. Specify the following items:

- **VPN Tunnel ID:** A number that will be added to the VTI interface called vpnt*, where the asterisk is the VPN tunnel ID number specified. For VPN tunnel ID = 1, the interface is labeled vpnt1.
- **Peer:** The name of the interoperable device that you created earlier for the IPSec tunnel. In this case, the name is OCI-VPN_BGP1.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the name you specify here does not match the name of the interoperable device, traffic does not flow through the IPSec tunnel.</td>
</tr>
</tbody>
</table>

- **Numbered:** Select **Numbered** to create a numbered interface.
- **Local Address:** The local IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - CPE.**
- **Remote Address:** The remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle.**

6. Click **OK.**

7. Under **Network Management,** go to **IPv4 Static Routes.**

8. Specify the following items:

- **Static route for the Oracle IP address:** Add an IP address with /32 mask for the remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle.**
- **Static routes to the VCN subnets:** If you're using static routing for this IPSec connection to Oracle, add at least one subnet for the Oracle VCN to be reached through the IPSec tunnel. The following screenshot shows
Networking

a static route to 172.31.2.0/26. If you're using BGP for this IPSec connection to Oracle, skip this item because those routes are learned through BGP (see the next section).

Now all traffic with a specific destination learned from a static route will pass through the newly created IPSec tunnel.

9. Get the interfaces and verify that the VPN tunnel is in the list:
   a. In the Smart Console, go to **Gateways & Servers**.
   b. Select the **Check Point Security Gateways**, and double-click.
   c. Under **General Properties**, on the **Network Management** page, select **Get Interfaces**.

   The VPN tunnel interface should appear in the list.

10. To force a route-based VPN to take priority, create an empty group and assign it to the VPN domain:
   a. On the **VPN Domain** page, select **Manually defined**, and then select **Create empty group**.
   b. Click **New**, select **Group**, and then select **Simple Group**.
   c. Enter an **Object Name**, and then click **OK**. Do not assign any objects to this empty group.

---

Task 3: Create an interoperable device

Later, you will create a VPN Community. Before you can, you must create an **Interoperable Device** that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.
1. Create the new interoperable device.
2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.

![Image of Interoperable Device - OCI-VPN_BGP1](image)

3. To force the route-based VPN to take priority, you must create an empty group and assign it to the VPN domain. To do that, on the **Topology** page, in the **VPN Domain** section, select **Manually defined**, and select the empty group.
4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN Communities created.

Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.
5. On the **Link Selection** page, under **Always use this IP address**, select **Main address**, which was the address you specified when creating the interoperable device. If necessary, you can use a specific IP address that will be used as the IKE ID.
6. On the VPN Advanced page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2 parameters.

7. Click **OK** to save your changes.

Task 4: Create a VPN community

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a **Star Community**.

3. For the star community, add a name.
4. On the Gateways page, select the values for Center Gateways and Satellite Gateways. This star community acts as a settings template for the interoperable devices you specify in Center Gateways and Satellite Gateways.

- Center Gateways: For the Check Point CloudGuard Security Gateway.
- Satellite Gateways: For the CPE that connects to the Oracle DRG for each IPSec tunnel.
5. To allow traffic, go to **Global Properties**, and then **VPN**, and then **Advanced**.
6. Select the check box for **Enable VPN Directional Match in VPN Column**. Later you will create a security policy that uses a directional match condition to allow traffic to pass based on routing rules.

7. Click **OK**.
8. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see [Supported IPSec Parameters](#) on page 2945.

If you're configuring VPN Connect for the Government Cloud, see [Required VPN Connect Parameters for Government Cloud](#) on page 152.

Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.
9. On the Tunnel Management page, select **Set Permanent Tunnels**. Oracle recommends that you:

- Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.
- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an encryption domain).

**Important:**

The Oracle VPN headend can support multiple encryption domains, but there are limitations. See Encryption domains for policy-based tunnels on page 2948 for full details.

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see Supported Encryption Domain or Proxy ID on page 2948.
10. On the Shared Secret page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.

![Shared Secret page](image)

11. Click **OK** to save your changes.

Task 5: Create a security policy

1. Go to **Access Control**, and then the **Policy** tab. Create specific security policies by using **Directional Match Condition**, which allows traffic to pass based on routing tables. Set up the condition with these settings:
   - **Internal_Clear > VPN Community created**
   - **VPN Community created > VPN Community created**
   - **VPN Community created > Internal_Clear**

   In this case, the **VPN Community** is **OCI-DRG-BGP** and the **Internal_Clear** is predefined by Check Point.

![Policy tab](image)

2. Click **OK** to save your changes.
3. Click **Install Policy** to apply the configuration.

Task 1: Enable BGP

Perform the following steps for each tunnel.

1. Go to **Advanced Routing**, and then **BGP**.
2. Under BGP Global Settings, click Change Global Settings, and then add a router ID and local ASN.

3. Click Save.

Task 2: Redistribute routes into BGP

1. Go to Advanced Routing, and then Route Distribution.
2. Click **Add Redistribution From**, and then select **Interface**, which is for adding all connected subnets.

![Add Redistribution From Interface](image)

3. In the **Add Redistribution from Interface** dialog, configure the following items:
   - **To Protocol**: Select **BGP AS 31898**, which is the Oracle ASN for commercial regions. If you're configuring VPN Connect for the Government Cloud, see Oracle's **BGP ASN** on page 154.
   - **Interface**: Select **all** to advertise all connected subnets.

![Add Redistribution from Interface Configuration](image)

4. Click **Save**.
Networking

Now the BGP session should be up and advertising and receiving subnets.

**Verification**

The following CLI command verifies BGP peers and routing.

```
show bgp peers
```

The following command verifies that you're receiving BGP routes.

```
show route bgp
```

The following command verifies the routes that are being advertised. In this example, replace `<remote_IP_address>` with the remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle**

```
show bgp peer <remote_IP_address> advertise
```

The following command verifies the routes that are being received.

```
show bgp peer <remote_IP_address> received
```

Use options 2 and 4 in the following command to verify security associations (SAs).

```
vpn tunnelutil

***********     Select Option     ***********

(1)   List all IKE SAs
(2)   * List all IPsec SAs
(3)   List all IKE SAs for a given peer (GW) or user (Client)
(4)   * List all IPsec SAs for a given peer (GW) or user (Client)
(5)   Delete all IPsec SAs for a given peer (GW)
(6)   Delete all IPsec SAs for a given User (Client)
(7)   Delete all IPsec+IKE SAs for a given peer (GW)
(8)   Delete all IPsec+IKE SAs for a given User (Client)
(9)   Delete all IPsec SAs for ALL peers and users
(0)   Delete all IPsec+IKE SAs for ALL peers and users

* To list data for a specific CoreXL instance, append "-i <instance number>" to your selection.

(Q)   Quit

******************************************************************************
```

A **Monitoring service** is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see **VPN Connect Metrics** on page 3164.

If you have issues, see **VPN Connect Troubleshooting** on page 3166.

**Check Point: Policy-Based**

This topic provides a policy-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.

This topic is for policy-based configuration. If you instead want route-based (VTI-based) configuration, see **Check Point: Route-Based** on page 2972.
Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

---

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).
Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
• **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
Networking

- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

CPE Configuration (Policy-Based)

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.
Networking

The following figure shows the basic layout of the IPSec connection.

![IPSec Connection Diagram]

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

If you want to use IKEv2, there’s a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select **IKEv2 only** for the encryption method.

**Configuration Process**

Task 1: Install IPSec VPN on Check Point CloudGuard Security Gateway

**Prerequisite:** Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.

</tbody>
</table>
1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.

2. Click OK to save your changes.

Task 2: Configure IPSec settings for Check Point CloudGuard Security Gateway

This task covers the most important options used for an IPSec tunnel with Oracle Cloud Infrastructure.

1. On the Network Management page, import all the interfaces. You can do this by clicking Get Interfaces, which contains options for Get Interfaces With Topology and Get Interfaces Without Topology. This example uses
Get Interfaces Without Topology so that you can define the purpose of each interface as an external or internal network.

All of these interfaces will be used in the VPN Domain as subnets advertised by Check Point CloudGuard Security Gateway in the IPSec encryption domain.
2. On the **VPN Domain** page, Oracle recommends that you select the option **for All IP Addresses behind Gateway are based on Topology information**. This option adds all the subnets discovered in **Network Management** to the IPSec Encryption Domain.

You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec encryption domain.
3. If your Check Point CloudGuard Security Gateway uses 1:1 NAT to map private IP addresses to public IP addresses: On the Link Selection page, under Always use this IP address, select Statically NATed IP and specify the IP address that you want to use as your IKE ID.

If you don’t want to use a public IP address as the local IKE ID, you can use another value (such as a private IP address), but the value will not match the one expected on the Oracle DRG. To resolve this, you can change the value that Oracle uses in the Oracle Console (see the instructions that follow).

**To change the CPE IKE identifier that Oracle uses (Oracle Console)**

a. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

A list of the IPSec connections in the compartment that you’re viewing is displayed. If you don’t see the one you’re looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

b. For the IPSec connection you’re interested in, click the Actions icon (three dots), and then click Edit.

The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.

c. Enter your new values for CPE IKE Identifier Type and CPE IKE Identifier, and then click Save Changes.

4. Click OK to save your changes.

**Task 3: Create an interoperable device**

Later, you will create a VPN Community. Before you can, you must create an Interoperable Device that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.
1. Create the new interoperable device.
2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.
3. On the **Topology** page, Oracle recommends that you create a new topology by clicking **New** and then adding the Oracle VCN subnets to be used for the tunnel.

You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec Encryption Domain.
4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN Communities created.

Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.
5. On the Link Selection page, under Always use this IP address, select Main address, which is the address that you specified when creating the interoperable device. If necessary, you can use a specific IP address that will be used as the IKE ID.
6. On the **VPN Advanced** page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2 parameters.

7. Click **OK** to save your changes.

Task 4: Create a VPN community

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a **Star Community**.

3. For the star community, add a name.
4. On the **Gateways** page, select the values for **Center Gateways** and **Satellite Gateways**. This star community acts as a settings template for the interoperable devices you specify in **Center Gateways** and **Satellite Gateways**.

- **Center Gateways**: For the Check Point CloudGuard Security Gateway.
- **Satellite Gateways**: For the CPE that connects to the Oracle DRG for each IPSec tunnel.

5. If this is a proof of concept (POC) scenario: On the **Encrypted Traffic** page, select the check box for **Accept all encrypted traffic on**. The default value for this setting allows the traffic between both center and satellite gateways. This setting is appropriate for a POC scenario. However, for a production scenario, Oracle recommends
that you instead create specific security policies under **Access Control** and on the **Policy** tab. That is covered in the final task in this process.
6. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see [Supported IPSec Parameters](#) on page 2945.

If you're configuring VPN Connect for the Government Cloud, see [Required VPN Connect Parameters for Government Cloud](#) on page 152.

Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.
7. On the **Tunnel Management** page, select **Set Permanent Tunnels**. Oracle recommends that you:

- Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.
- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an *encryption domain*).

**Important:**

The Oracle VPN headend can support multiple encryption domains, but there are limitations. See Encryption domains for policy-based tunnels on page 2948 for full details.

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see Supported Encryption Domain or Proxy ID on page 2948.
8. On the **Shared Secret** page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.

9. Click **OK** to save your changes.

Task 5: Create a security policy (recommended for a production scenario)

If this is a proof of concept (POC) scenario, earlier you selected **Accept all encrypted traffic** on the **Encrypted Traffic** page. If this is instead a production scenario, Oracle recommends creating security policies.

1. Under Security Policies, click Access Control, and then select the Policy tab.
2. Configure the required values.

3. Click **OK** to save your changes.
4. Click **Install Policy** to apply the configuration.

The IPSec tunnel should now be up.

**Verification**

Use options 2 and 4 in the following command to verify security associations (SAs).

```bash
vpn tunnelutil

**********  Select Option  **********

(1)     List all IKE SAs
(2)     * List all IPsec SAs
```
Networking

(3) List all IKE SAs for a given peer (GW) or user (Client)
(4) * List all IPsec SAs for a given peer (GW) or user (Client)
(5) Delete all IPsec SAs for a given peer (GW)
(6) Delete all IPsec SAs for a given User (Client)
(7) Delete all IPsec+IKE SAs for a given peer (GW)
(8) Delete all IPsec+IKE SAs for a given User (Client)
(9) Delete all IPsec SAs for ALL peers and users
(0) Delete all IPsec+IKE SAs for ALL peers and users

* To list data for a specific CoreXL instance, append "-i <instance number>" to your selection.

(Q) Quit

*******************************************

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

Cisco ASA Configuration Options

Choose the configuration based on the ASA software version:

- **9.7.1 or newer:** Route-based configuration
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

**Important:**

Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

**Cisco ASA: Route-Based**

This topic provides a route-based configuration for a Cisco ASA that is running software version 9.7.1 (or newer).

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer:** Route-based configuration (this topic)
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still
Networking

work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.

Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.
Networking

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Specific to Cisco ASA: Caveats and Limitations

This section covers important characteristics and limitations that are specific to Cisco ASA.

Tunnel MTU and Path MTU Discovery

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- Option 1: TCP MSS adjustment on page 3022
- Option 2: Clear/set the Don't Fragment bit on page 3022

Option 1: TCP MSS adjustment

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration on page 3038 section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```
sysopt connection tcpmss 1387
```

Option 2: Clear/set the Don't Fragment bit

Path MTU discovery requires that all TCP packets have the Don't Fragment (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- Set the DF bit (recommended): Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.
  
  ```
  crypto ipsec df-bit set-df ${outsideInterface}
  ```

- Clear the DF bit: The DF bit is cleared in the packet's IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

  ```
  crypto ipsec df-bit clear-df ${outsideInterface}
  ```

- Ignore (copy) the DF bit: The ASA looks at the original packet's IP header information and copies the DF bit setting.

  ```
  crypto ipsec df-bit copy-df ${outsideInterface}
  ```

VPN Traffic Might Enter One Tunnel and Exit Another
Networking

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration on page 3038 section.

```text
same-security-traffic permit inter-interface
```

**General Caveats and Limitations**

This section covers general characteristics and limitations of VPN Connect.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

**Route-Based or Policy-Based IPSec VPN**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

**Encryption domain for route-based tunnels**

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4
If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

**CPE Configuration**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Cisco router running Cisco ASA 9.7.1 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.
The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your ASA and your Oracle VCN.
- Identify the IPSec profile used (the following configuration template references this group policy as `oracle-vcn-vpn-policy`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vcn-transform`).
- Identify the virtual tunnel interface names used (the following configuration template references these as variables `${tunnelInterfaceName1}` and `${tunnelInterfaceName2}`).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names or numbers
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

Oracle provides a separate configuration template for IKEv1 versus IKEv2.

Oracle also provides a tool that can generate the template for you, with some of the information automatically filled in. For more information, see Using the CPE Configuration Helper on page 2970.

**IKEv1 Configuration Template**

```bash
!------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! ISAKMP Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! VTI Interface Configuration
! IP Routing (BGP or Static)
!------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template has various parameters that you must define before applying the configuration.

Oracle Cloud Infrastructure User Guide 3026
Networking

! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.

! ${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.

! ${bgpASN} = Your BGP ASN

! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface

! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.

! ${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.

! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.

! ${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.

! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.

! ${tunnelInterfaceName1} = The name of the first VTI used on your ASA.

! ${tunnelInterfaceName2} = The name of the second VTI used on your ASA.

! ${cpeInsideTunnelIpAddress1} = The CPE's inside tunnel IP for the first tunnel.

! ${cpeInsideTunnelIpAddress2} = The CPE's inside tunnel IP for the second tunnel.

! ${cpeInsideTunnelNetmask1} = The CPE's inside tunnel netmask for the first tunnel.

! ${cpeInsideTunnelNetmask2} = The CPE's inside tunnel netmask for the second tunnel.

! ${vcnCidrNetwork} = VCN IP range

! ${vcnCidrNetmask} = Subnet mask for VCN

! ${onPremCidrNetwork} = On-premises IP range

! ${onPremCidrNetmask} = ON-premises subnet mask

----------------------------------------------------------------------------------------------

! ISAKMP Policy

! ISAKMP Phase 1 configuration.

IKEv1 is enabled on the outside interface.

IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).

If different parameters are required, modify this template before applying the configuration.

WARNING: The IKEv1 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev1 enable ${outsideInterface}

crypto ikev1 policy 10
  authentication pre-share
  encryption aes-256
  hash sha
  group 5
  lifetime 28800

! IPSec Configuration

Create an IKEv1 transform set named 'oracle-vcn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication.

If different parameters are required, modify this template before applying the configuration.
crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-hmac

! A IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created transform set is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle-vcn-vpn-policy
  set ikev1 transform-set oracle-vcn-transform
  set pfs group5
  set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group defines the pre-shared key used for each respective tunnel.

tunnel-group $(oracleHeadend1) type ipsec-l2l
  ikev1 pre-shared-key $(sharedSecret1)

tunnel-group $(oracleHeadend2) type ipsec-l2l
  ikev1 pre-shared-key $(sharedSecret2)

! VTI Interface Configuration

! A virtual tunnel interface (VTI) is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Two VTIs are created representing two tunnels, one to each Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.
! All traffic routed to a VTI will be encrypted and sent across the tunnel towards Oracle Cloud Infrastructure.
! Each VTI configuration also references the previously created IPSec profile 'oracle-vcn-vpn-policy' for its IPSec parameters.

interface ${tunnelInterfaceName1}
  nameif ORACLE-VPN1
  ip address $(cpeInsideTunnelIpAddress1) $(cpeInsideTunnelNetmask1)
  tunnel source interface $(outsideInterface)
  tunnel destination $(oracleHeadend1)
  tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

interface ${tunnelInterfaceName2}
  nameif ORACLE-VPN2
  ip address $(cpeInsideTunnelIpAddress2) $(cpeInsideTunnelNetmask2)
  tunnel source interface $(outsideInterface)
  tunnel destination $(oracleHeadend2)
  tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
address-family ipv4 unicast
neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
neighbor ${OracleInsideTunnelIpAddress1} activate
neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
neighbor ${OracleInsideTunnelIpAddress2} activate
network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
no auto-summary
no synchronization
exit-address-family

Static Route Configuration
Each static route references the other VTI by its name if value.
 Uncomment below line if you want to use static routing.

route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask}
${OracleInsideTunnelIpAddress1} 1 track
route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask}
${OracleInsideTunnelIpAddress2} 100

Configuration for Tunnel Failover
 Uncomment the below IP SLA lines if using static routing.
 Use this IP SLA configuration for static route failover This IP SLA
 configuration is used for static route failover between the two tunnels.
 Make sure that the SLA monitor and tracking numbers used do not conflict
 with any existing configuration on your ASA.

sla monitor 10
! type echo protocol ipIcmpEcho ${oracleHeadend1} interface outside
! frequency 5
! sla monitor schedule 10 life forever start-time now
! track 1 rtr 10 reachability

IKEv2 Configuration Template

IKEv2 Configuration Template
The configuration consists of two IPSec tunnels. Oracle highly recommends
that you configure both tunnels for maximum redundancy.

The configuration template involves setting up the following:
IKEv2 Policy
IPSec Configuration
IPSec Tunnel Group Configuration
VTI Interface Configuration
IP Routing (BGP or Static)

The configuration template has various parameters that you must define
before applying the configuration.

PARAMETERS REFERENCED:
${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side
for the first tunnel. You provide these values when creating the IPSec
connection in the Oracle Console.
${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side
for the second tunnel. You provide these values when creating the IPSec
connection in the Oracle Console.
${bgpASN} = Your BGP ASN
${cpePublicIpAddress} = The public IP address for the CPE. This is the IP
address of your outside interface
${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle
Console.
Networking

! ${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! ${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
! ${tunnelInterfaceName1} = The name of the first VTI used on your ASA.
! ${tunnelInterfaceName2} = The name of the second VTI used on your ASA.
! ${cpeInsideTunnelIpAddress1} = The CPE's inside tunnel IP for the first tunnel.
! ${cpeInsideTunnelIpAddress2} = The CPE's inside tunnel IP for the second tunnel.
! ${cpeInsideTunnelNetmask1} = The CPE's inside tunnel netmask for the first tunnel.
! ${cpeInsideTunnelNetmask2} = The CPE's inside tunnel netmask for the second tunnel.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask

! IKEv2 Policy

! IKEv2 is enabled on the outside interface.
! IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev2 enable ${outsideInterface}
crypto ikev2 policy 10
  encryption aes-256
  integrity sha
  group 5
  prf sha
  lifetime seconds 28800

! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which defines AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
  protocol esp encryption aes-256
  protocol esp integrity sha-1

! An IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created IPSec proposal is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle-vcn-vpn-policy
  set ikev2 ipsec-proposal oracle_v2_ipsec_proposal
  set pfs group5
set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

group-policy oracle_v2_group_policy internal
group-policy oracle_v2_group_policy attributes
vpn-tunnel-protocol ikev2

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group defines the pre-shared key used for each respective tunnel.
tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
default-group-policy oracle_v2_group_policy
tunnel-group ${oracleHeadend1} ipsec-attributes
   ikev2 local-authentication pre-shared-key ${sharedSecret1}
   ikev2 remote-authentication pre-shared-key ${sharedSecret1}

tunnel-group ${oracleHeadend2} type ipsec-l2l
tunnel-group ${oracleHeadend2} general-attributes
default-group-policy oracle_v2_group_policy
tunnel-group ${oracleHeadend2} ipsec-attributes
   ikev2 local-authentication pre-shared-key ${sharedSecret2}
   ikev2 remote-authentication pre-shared-key ${sharedSecret2}

! VTI Interface Configuration

! A virtual tunnel interface (VTI) is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Two VTIs are created representing two tunnels, one to each Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.
! All traffic routed to a VTI will be encrypted and sent across the tunnel towards Oracle Cloud Infrastructure.
! Each VTI configuration also references the previously created IPSec profile 'oracle-vcn-vpn-policy' for its IPSec parameters.

interface ${tunnelInterfaceName1}
   nameif ORACLE-VPN1
   ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
   tunnel source interface ${outsideInterface}
   tunnel destination ${oracleHeadend1}
   tunnel mode ipsec ipv4
   tunnel protection ipsec profile oracle-vcn-vpn-policy

interface ${tunnelInterfaceName2}
   nameif ORACLE-VPN2
   ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
   tunnel source interface ${outsideInterface}
   tunnel destination ${oracleHeadend2}
   tunnel mode ipsec ipv4
   tunnel protection ipsec profile oracle-vcn-vpn-policy

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
!   address-family ipv4 unicast
!     neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
!     neighbor ${OracleInsideTunnelIpAddress1} activate
Networking

! neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
! neighbor ${OracleInsideTunnelIpAddress2} activate
! network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
! no auto-summary
! no synchronization
! exit-address-family

! Static Route Configuration
! Each static route references the other VTI by its nameif value.
! Uncomment below line if you want to use static routing.

! route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask}
${OracleInsideTunnelIpAddress1} 1 track
! route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask}
${OracleInsideTunnelIpAddress2} 100

! Configuration for Tunnel Failover

! Uncomment the below IP SLA lines if using static routing.
! Use this IP SLA configuration for static route failover This IP SLA configuration is used for static route failover between the two tunnels.
! Make sure that the SLA monitor and tracking numbers used do not conflict with any existing configuration on your ASA.

! sla monitor 10
! type echo protocol ipIcmpEcho ${oracleHeadend1} interface outside
! frequency 5
! sla monitor schedule 10 life forever start-time now
! track 1 rtr 10 reachability

Verification

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to Cisco’s IPSec Troubleshooting document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

`show crypto isakmp sa`

Use the following command to verify the status of all your BGP connections.

`show bgp summary`

Use the following command to verify the ASA’s route table.

`show route`

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

Cisco ASA: Policy-Based

This topic provides a policy-based configuration for a Cisco ASA that is running software version 8.5 to 9.7.0.

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer**: Route-based configuration
- **8.5 to 9.7.0**: Policy-based configuration (this topic)
- **Older than 8.5**: Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.
Important:

Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.

Important:

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you’re already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor’s documentation for assistance.

Best Practices

This section covers best practices and considerations for using VPN Connect.

Specific to Cisco ASA: VPN filters

VPN filters let you further filter traffic either before it enters or after it exits a tunnel. Use VPN filters if you need additional granularity for filtering different traffic types or source/destination flows. For more information, see Cisco’s VPN Filter documentation.

VPN filter configuration is not included in the configuration template that appears in the CPE Configuration on page 3038 section. To use VPN filters, add the following configuration items manually.
• **Access control list (ACL)**: Create an ACL that the VPN filter can use to restrict the traffic permitted through the tunnels. If you have an ACL already used for a VPN filter, do not also use it for an interface access group.

```
access-list ${vpnFilterAclName} extended permit ip ${VcnCidrNetwork} ${VcnCidrNetmask} ${onPremCidrNetwork} ${onPremCidrNetmask}
```

• **Group policy**: Apply the VPN filter to your group policy.

```
group-policy oracle-vcn-vpn-policy attributes
    vpn-filter value ${vpnFilterAclName}
```

• **Tunnel group**: Apply the group policy to your tunnel group.

```
tunnel-group ${oracleHeadend1} general-attributes
default-group-policy oracle-vcn-vpn-policy
```

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

• **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.

• **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

**Specific to Cisco ASA: Caveats and Limitations**

This section covers important characteristics and limitations that are specific to Cisco ASA.
**Tunnel MTU and Path MTU Discovery**

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- **Option 1: TCP MSS adjustment** on page 3035
- **Option 2: Clear/set the Don’t Fragment bit** on page 3035

**Option 1: TCP MSS adjustment**

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration on page 3038 section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```bash
sysopt connection tcpmss 1387
```

**Option 2: Clear/set the Don’t Fragment bit**

Path MTU discovery requires that all TCP packets have the **Don’t Fragment** (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- **Set the DF bit (recommended):** Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.
  ```bash
  crypto ipsec df-bit set-df ${outsideInterface}
  ```

- **Clear the DF bit:** The DF bit is cleared in the packet's IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.
  ```bash
  crypto ipsec df-bit clear-df ${outsideInterface}
  ```

- **Ignore (copy) the DF bit:** The ASA looks at the original packet's IP header information and copies the DF bit setting.
  ```bash
  crypto ipsec df-bit copy-df ${outsideInterface}
  ```

**VPN Traffic Might Enter One Tunnel and Exit Another**

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration on page 3038 section.

```bash
same-security-traffic permit inter-interface
```

**General Caveats and Limitations**

This section covers general characteristics and limitations of VPN Connect.
Networking

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.
Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE’s public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE’s private IP address, as shown in the following diagram.
Networking

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle’s BGP ASN on page 171.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor’s support directly.

The following figure shows the basic layout of the IPSec connection.

![Basic Layout of IPSec Connection](image)

The configuration template provided is for a Cisco ASA running version 8.5 software (or later).

**Note:**

Cisco ASA versions 9.7.1 and newer support route-based configuration, which is the recommended method to avoid interoperability issues.

If you want tunnel redundancy with a single Cisco ASA device, you must use the route-based configuration. With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your ASA and your Oracle VCN (the following configuration template references this access list with the variable \$\{outboundAclName\}).
- Identify the internal VPN group policy (the following configuration template references this group policy as oracle-vcn-vpn-policy).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as oracle-vcn-transform).
- Identify the crypto map name and sequence number (the following configuration template references the map name as oracle-vpn-map-v1 and sequence number 1).
- Identify the operation number for IP SLA continuous ping (the following configuration template uses operation number 1).

### Important:

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. The syntax for each CPE device configuration may be different and depends on the model and software versions. Be sure to compare your CPE model and version to the appropriate configuration template.

Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure that the following values are unique:

- Policy names or numbers
- Crypto map names and sequence numbers
- Interface names
- Access list names or numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see [Supported IPSec Parameters](#) on page 2945.

Oracle also provides a separate configuration template for IKEv1 versus IKEv2.

Oracle provides a tool that can generate the template for you, with some of the information automatically filled in. For more information, see [Using the CPE Configuration Helper](#) on page 2970.

### IKEv1 Configuration Template

```plaintext
! Ikev1 Configuration Template
! The configuration consists of a single IPSec tunnel.
! The configuration template involves setting up the following:
! Access Lists
! ISAKMP Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
```

---
Networking

The configuration template has various parameters that you must define before applying the configuration.

PARAMETERS REFERENCED:

${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.

${bgpASN} = Your BGP ASN

${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface

${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces

${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.

${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.

${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.

${vcnCidrNetwork} = VCN IP range

${vcnCidrNetmask} = Subnet mask for VCN

${onPremCidrNetwork} = On-premises IP range

${onPremCidrNetmask} = ON-premises subnet mask

${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.

${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.

Access Lists

Permit Traffic Between Your ASA and Your Oracle VCN

Assuming there is an access-list controlling traffic in and out of your Internet facing interface, you will need to permit traffic between your CPE and the Oracle VPN Headend

WARNING: The new ACL entry you add to permit the traffic between your ASA and VPN headend needs to be above any deny statements you might have in your existing access-list

access-list ${outboundAclName} extended permit ip host ${oracleHeadend1}
host ${cpePublicIpAddress}

Crypto ACL

Create an ACL named ${cryptoMapAclName} which will later be associated with the IPSec security association using the 'crypto-map' command. This will define which source/destination traffic needs to be encrypted and sent across the VPN tunnel.

Keep this ACL to a single entry. In a policy based configuration each ACL line will establish a separate encryption domain.

The encryption domain used in this configuration sample will have a source/destination of any/VCN CIDR. Refer to the 'Encryption domain for policy-based tunnels' subsection for supported alternatives.

access-list ${cryptoMapAclName} extended permit ip any ${vcnCidrNetwork}
${vcnCidrNetmask}

ISAKMP Policy

ISAKMP Phase 1 configuration.
IKEv1 is enabled on the outside interface.
IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv1 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev1 enable outside
crypto ikev1 policy 10
  authentication pre-share
  encryption aes-256
  hash sha
  group 5
  lifetime 28800

! Base VPN Policy

! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to define some basic VPN tunnel settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and tunnel protocol is set to IKEv1

group-policy oracle-vcn-vpn-policy internal
group-policy oracle-vcn-vpn-policy attributes
  vpn-idle-timeout none
  vpn-session-timeout none
  vpn-tunnel-protocol ikev1

! IPSec Configuration

! Create an IKEv1 transform set named 'oracle-vcn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-hmac

! A crypto map is used to tie together the important traffic that needs encryption (via crypto map ACL) with defined security policies (from the transform set along with other crypto map statements), and the destination of the traffic to a specific crypto peer.
! In this configuration example, a single crypto map is created named 'oracle-vcn-map-v1' This crypto map references the previously created crypto map ACL, the 'oracle-vcn-transform' transform set and further defines PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! WARNING: Make sure your crypto map name and sequence numbers do not overlap with existing crypto maps.
! WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels:
crypto map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vcn-map-v1 1 match address ${cryptoMapAclName}
crypto map oracle-vcn-map-v1 1 set pfs group5
crypto map oracle-vcn-map-v1 1 set peer ${oracleHeadend1}
crypto map oracle-vcn-map-v1 1 set ikev1 transform-set oracle-vcn-transform
crypto map oracle-vcn-map-v1 1 set security-association lifetime seconds 3600

! WARNING: The below command will apply the 'oracle-vcn-map-v1' crypto map to the outside interface. The Cisco ASA supports a single crypto map per interface. Make sure no other crypto map is applied to the outside interface before using this command.
crypto map oracle-vcn-map-v1 1 apply interface outside
crypto map oracle-vpn-map-v1 interface outside

! IPSec Tunnel Group Configuration

! This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend endpoint.
! The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
default-group-policy oracle-vcn-vpn-policy
tunnel-group ${oracleHeadend1} ipsec-attributes
ikev1 pre-shared-key ${sharedSecret1}

! IP SLA Configuration

! The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the tunnel.
! You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all times.
! You must allow ICMP on the outside interface.
! Make sure that the SLA monitor number used is unique.

sla monitor 1
type echo protocol ipIcmpEcho ${vcnHostIp} interface outside
frequency 5
sla monitor schedule 1 life forever start-time now
icmp permit any ${outsideInterface}

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
! address-family ipv4 unicast
! neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
! neighbor ${OracleInsideTunnelIpAddress1} activate
! network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
! no auto-summary
! no synchronization
! exit-address-family

! Static Route Configuration
! Uncomment below line if you want to use static routing.

! route outside ${VcnCidrNetwork} ${VcnCidrNetmask}
${OracleInsideTunnelIpAddress1}

! Disable NAT for VPN Traffic

! If you are using NAT for traffic between your inside and outside interfaces, you might need to disable NAT for traffic between your on-premises network and the Oracle VCN.
! Two objects are created for this NAT exemption. 'obj-OnPrem' represents the on-premises network as a default route, and 'obj-oracle-vcn-1' represents the VCN CIDR block used in Oracle Cloud Infrastructure.
! If different address ranges are required, modify this template before applying the configuration.
Networking

! object network obj-onprem
! subnet 0.0.0.0 0.0.0.0
! object network obj-oracle-vcn-1
! subnet ${vcnCidrNetwork} ${vcnCidrNetmask}
! nat (inside, outside) source static obj-onprem obj-onprem destination
static obj-oracle-vcn-1 obj-oracle-vcn-1

IKEv2 Configuration Template

!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of a single IPSec tunnel.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! Access Lists
! IKEv2 Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template has various parameters that you must define before applying the configuration.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface
! ${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
! ${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.
! ${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------

! Access Lists

! Permit Traffic Between Your ASA and Your Oracle VCN
! Assuming there is an access-list controlling traffic in and out of your Internet facing interface, you will need to permit traffic between your CPE and the Oracle VPN Headend
! WARNING: The new ACL entry you add to permit the traffic between your ASA and VPN headend needs to be above any deny statements you might have in your existing access-list

access-list ${outboundAclName} extended permit ip host ${oracleHeadend1}
host ${cpePublicIpAddress}

Oracle Cloud Infrastructure User Guide

3043
Networking

! Crypto ACL

! Create an ACL named `${cryptoMapAclName}` which will later be associated with the IPSec security association using the 'crypto-map' command. This will define which source/destination traffic needs to be encrypted and sent across the VPN tunnel.
! Keep this ACL to a single entry. In a policy based configuration each ACL line will establish a separate encryption domain.
! The encryption domain used in this configuration sample will have a source/destination of any/VCN CIDR. Refer to the 'Encryption domain for policy-based tunnels' subsection for supported alternatives.

access-list `${cryptoMapAclName}` extended permit ip any `${vcnCidrNetwork}`

! IKEv2 Policy

! IKEv2 is enabled on the outside interface.
! IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5, and a lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration on your ASA.

crypto ikev2 enable outside
crypto ikev2 policy 10
   encryption aes-256
   integrity sha384
   group 5
   prf sha
   lifetime seconds 28800

! Base VPN Policy

! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to define some basic VPN tunnel settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and tunnel protocol is set to IKEv2

group-policy oracle-vcn-vpn-policy internal
group-policy oracle-vcn-vpn-policy-policy attributes
   vpn-idle-timeout none
   vpn-session-timeout none
   vpn-tunnel-protocol ikev2

! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which defines AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
   protocol esp encryption aes-256
   protocol esp integrity sha-1

! A crypto map is used to tie together the important traffic that needs encryption (via crypto map ACL) with defined security policies (from the IPSec proposal along with other crypto map statements), and the destination of the traffic to a specific crypto peer.
! In this configuration example, a single crypto map is created named 'oracle-vpn-map-v2'. This crypto map references the previously created crypto map ACL, the 'oracle_v2_ipsec_proposal' IPSec proposal and further
Networking

defines PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).

! WARNING: Make sure your crypto map name and sequence numbers do not overlap with existing crypto maps.

! WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels:
crypto map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vpn-map-v2 1 match address $\{cryptoMapAclName\}
crypto map oracle-vpn-map-v2 1 set pfs group5
crypto map oracle-vpn-map-v2 1 set peer $\{oracleHeadend1\}
crypto map oracle-vpn-map-v2 1 set ikev2 ipsec-proposal
oracle_v2_ipsec_proposal
crypto map oracle-vpn-map-v2 1 set security-association lifetime seconds 3600

! WARNING: The below command will apply the 'oracle-vpn-map-v2' crypto map to the outside interface. The Cisco ASA supports a single crypto map per interface. Make sure no other crypto map is applied to the outside interface before using this command.
crypto map oracle-vpn-map-v2 interface outside

! IPSec Tunnel Group Configuration

! This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend endpoint.
! The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.
tunnel-group $\{oracleHeadend1\} type ipsec-l2l
tunnel-group $\{oracleHeadend1\} general-attributes
default-group-policy oracle-vcn-vpn-policy
tunnel-group $\{oracleHeadend1\} ipsec-attributes
ikev2 local-authentication pre-shared-key $\{sharedSecret1\}
ikev2 remote-authentication pre-shared-key $\{sharedSecret1\}

! IP SLA Configuration

! The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the tunnel.
! You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all times.
! You must allow ICMP on the outside interface.
! Make sure that the SLA monitor number used is unique.
sla monitor 1
type echo protocol ipIcmpEcho $\{vcnHostIp\} interface outside
frequency 5
sla monitor schedule 1 life forever start-time now
icmp permit any $\{outsideInterface\}

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp $\{bgpASN\}
! address-family ipv4 unicast
Networking

! neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
! neighbor ${OracleInsideTunnelIpAddress1} activate
! network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
! no auto-summary
! no synchronization
! exit-address-family

! Static Route Configuration
! Uncomment below line if you want to use static routing.

! route outside ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress1}

! Disable NAT for VPN Traffic

! If you are using NAT for traffic between your inside and outside interfaces, you might need to disable NAT for traffic between your on-premises network and the Oracle VCN.
! Two objects are created for this NAT exemption. 'obj-OnPrem' represents the on-premises network as a default route, and 'obj-oracle-vcn-1' represents the VCN CIDR block used in Oracle Cloud Infrastructure.
! If different address ranges are required, modify this template before applying the configuration.

! object network obj-onprem
! subnet 0.0.0.0 0.0.0.0
! object network obj-oracle-vcn-1
! subnet ${vcnCidrNetwork} ${vcnCidrNetmask}
! nat (inside,outside) source static obj-onprem obj-onprem destination static obj-oracle-vcn-1 obj-oracle-vcn-1

Verification

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to Cisco's IPSec Troubleshooting document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections.

```
show bgp summary
```

Use the following command to verify the ASA's route table.

```
show route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

Cisco IOS

This topic provides a route-based configuration for a Cisco IOS device. The configuration was validated using a Cisco 2921 running IOS version 15.4(3)M3.

| Important: |
| Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor. |
If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
• **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see *Routing for the Oracle IPSec VPN* on page 2934.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see *Routing for the Oracle IPSec VPN* on page 2934.

**Route-Based or Policy-Based IPSec VPN**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

• **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

• **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.
Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as show in the following diagram.
Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

**CPE Configuration**

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template was validated using a Cisco 2921 running IOS version 15.4(3)M3. The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.
The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your CPE and your Oracle VCN.
- Identify the IPSec profile used (the following configuration template references this group policy as `oracle-vpn`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vpn-transform`).

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Keyrings
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

There's a separate configuration template for IKEv1 versus IKEv2.

**IKEv1 Configuration Template**

```
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! Keyring (Pre-Shared Key)
! Basic ISAKMP Options
! ISAKMP and IPSec Policy Configuration
! IPSec Peers
! Virtual Tunnel Interfaces
! IP Routing (BGP or Static)
! Update Any Internet Facing Access List to Allow IPSec and ISAKMP Packets
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template has various parameters that you must define before applying the configuration.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! PARAMETERS REFERENCED:
! `${OracleInsideTunnelIpAddress1}` = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
```
$\{OracleInsideTunnelIpAddress2\} = \text{Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.}$

$\{bgpASN\} = \text{Your BGP ASN}$

$\{cpePublicIpAddress\} = \text{The public IP address for the CPE. This is the IP address of your outside interface}$

$\{oracleHeadend1\} = \text{Oracle public IP endpoint obtained from the Oracle Console.}$

$\{oracleHeadend2\} = \text{Oracle public IP endpoint obtained from the Oracle Console.}$

$\{sharedSecret1\} = \text{You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.}$

$\{sharedSecret2\} = \text{You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.}$

$\{outsideInterface\} = \text{The public interface or outside of tunnel interface which is configured with the CPE public IP address.}$

$\{vcnCidrNetwork\} = \text{VCN IP range}$

$\{vcnCidrNetmask\} = \text{Subnet mask for VCN}$

$\{onPremCidrNetwork\} = \text{On-premises IP range}$

$\{onPremCidrNetmask\} = \text{ON-premises subnet mask}$

---

### Keyring (Pre-Shared Key)

For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.

Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.

```plaintext
crypto keyring oracle-vpn-$\{oracleHeadend1\}
   local-address $\{cpePublicIpAddress\}
   pre-shared-key address $\{oracleHeadend1\} key $\{sharedSecret1\}
crypto keyring oracle-vpn-$\{oracleHeadend2\}
   local-address $\{cpePublicIpAddress\}
   pre-shared-key address $\{oracleHeadend2\} key $\{sharedSecret2\}
```

### Basic ISAKMP Options

Optional IPSec settings are included here.

All optional settings included are recommended by Oracle. Remove or comment out any unneeded commands prior to applying this configuration.

WARNING: These settings are global and may impact other IPSec connections

- Enables fragmentation of IKE packets prior to encryption.
  ```plaintext
crypto isakmp fragmentation
```

- Enables Dead Peer Detection (DPD)
  ```plaintext
crypto isakmp keepalive 10 10
```

The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

```plaintext
crypto ipsec df-bit clear
```

- Increases security association anti-replay window. An increased window size is helpful for scenarios where packets are regularly being dropped due to delays.
  ```plaintext
crypto ipsec security-association replay window-size 128
```

### ISAKMP and IPSec Policy Configuration

An ISAKMP policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA384, Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
If different parameters are required, modify this template before applying the configuration.

**WARNING:** The ISAKMP group policy is created with a priority of 10. Make sure this doesn't conflict with any pre-existing configuration before applying.

```plaintext
crypto isakmp policy 10
  encr aes 256
  hash sha384
  authentication pre-share
  group 5
  lifetime 28800
```

Create an IPSec transform set named 'oracle-vpn-transform' which defines a combination of IPSec (Phase 2) policy options. Specifically, AES256 for encryption and SHA1 for authentication. This is also where tunnel mode is set for IPSec.

If different parameters are required, modify this template before applying the configuration.

```plaintext
crypto ipsec transform-set oracle-vpn-transform esp-aes 256 esp-sha-hmac
  mode tunnel
```

A IPSec profile named 'oracle-vpn' is created.

The previously created transform set is added to this policy along with settings for enabling PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).

If different parameters are required, modify this template before applying the configuration.

```plaintext
crypto ipsec profile oracle-vpn
  set pfs group5
  set security-association lifetime seconds 3600
  set transform-set oracle-vpn-transform
```

**IPSec Peers**

Two ISAKMP profiles are created for each Oracle VPN Headend.

An ISAKMP profile is used as a repository for various Phase 1 commands tied to a specific IPSec peer. In this case, we match the previously created keyrings to an Oracle VPN headend.

```plaintext
crypto isakmp profile oracle-vpn-`{oracleHeadend1}`
  keyring oracle-vpn-`{oracleHeadend1}`
  self-identity address
  match identity address `{oracleHeadend1}` 255.255.255.255

crypto isakmp profile oracle-vpn-`{oracleHeadend2}`
  keyring oracle-vpn-`{oracleHeadend2}`
  self-identity address
  match identity address `{oracleHeadend2}` 255.255.255.255
```

**Virtual Tunnel Interfaces**

Each tunnel interface is a logical interface representing the local end of a VPN tunnel to a remote VPN peer. Each tunnel interface represents a single tunnel to a different Oracle VPN Headend. The IP address of each VPN headend is provided when you create your IPSec connection in Oracle Console.

All traffic routed to a tunnel interface will be encrypted and sent across the tunnel towards Oracle Cloud Infrastructure.

Each tunnel interface configuration also references the previously created IPSec profile 'oracle-vpn' for its IPSec parameters.

**WARNING:** When doing static routing you do NOT have to set IPs on the tunnel interfaces unless you have pre-configured inside tunnel interfaces.
in Oracle Console when creating your IPSec connection. Inside tunnel interfaces are required if using BGP.

```bash
interface Tunnel${tunnelNumber1}
 ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
tunnel source ${cpePublicIpAddress}
tunnel mode ipsec ipv4
tunnel destination ${oracleHeadend1}
tunnel protection ipsec profile oracle-vpn

interface Tunnel${tunnelNumber2}
 ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
tunnel source ${cpePublicIpAddress}
tunnel mode ipsec ipv4
tunnel destination ${oracleHeadend2}
tunnel protection ipsec profile oracle-vpn
```

```
! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! ip access-group INTERNET-INGRESS in
```

**IKEv2 Configuration Template**

```
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! Keyring (Pre-Shared Key)
```
Networking

IKEv2 and IPSec Policy Configuration
IPSec Peers
Virtual Tunnel Interfaces
IP Routing (BGP or Static)
Update Any Internet Facing Access List to Allow IPSec and ISAKMP Packets

The configuration template has various parameters that you must define before applying the configuration.

PARAMETERS REFERENCED:
${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
${bgpASN} = Your BGP ASN
${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside interface
${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
${outsideInterface} = The public interface or outside of tunnel interface which is configured with the CPE public IP address.
${vcnCidrNetwork} = VCN IP range
${vcnCidrNetmask} = Subnet mask for VCN
${onPremCidrNetwork} = On-premises IP range
${onPremCidrNetmask} = ON-premises subnet mask

Keyring (Pre-Shared Key)

For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.
Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.

crypto ikev2 keyring oracle-vpn-\${oracleHeadend1}
peer oracle_vpn
  address \${oracleHeadend1}
  pre-shared-key local \${sharedSecret1}
  pre-shared-key remote \${sharedSecret1}

crypto ikev2 keyring oracle-vpn-\${oracleHeadend2}
peer oracle_vpn
  address \${oracleHeadend2}
  pre-shared-key local \${sharedSecret2}
  pre-shared-key remote \${sharedSecret2}

Optional IPSec settings are included here.
All optional settings included are recommended by Oracle. Remove or comment out any unneeded commands prior to applying this configuration.
WARNING: These settings are global and may impact other IPSec connections

The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.
crypto ipsec df-bit clear

Oracle Cloud Infrastructure User Guide
! Increases security association anti-replay window. An increased window size is helpful for scenarios where packets are regularly being dropped due to delays.
crypto ipsec security-association replay window-size 128

! IKEv2 and IPSec Policy Configuration

! An IKEv2 proposal is created and specifies use of a Pre-Shared Key, AES256, SHA384, and Diffie-Hellman Group 5.
! If different parameters are required, modify this template before applying the configuration.

! permit icmp any any echo-reply
! permit icmp any any unreachable

! interface ${outsideInterface}
! ip address ${cpePublicIpAddress} $(netmask)
! ip access-group INTERNET-INGRESS in

**Verification**

The following IOS commands are included for basic troubleshooting.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```bash
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections or neighbors.

```bash
show ip bgp summary
show ip bgp neighbors
```

Use the following command to verify the route table.

```bash
show ip route
```

A **Monitoring service** is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see **VPN Connect Metrics** on page 3164.

If you have issues, see **VPN Connect Troubleshooting** on page 3166.

**FortiGate**

This topic provides configuration for a FortiGate that is running software version 6.0.4.

FortiGate experience is recommended. For more details on how to use FortiGate products, visit their official site. For FortiGate documentation for high availability (HA) or manual deployment, see the **Fortinet Document Library**.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.</td>
</tr>
</tbody>
</table>

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you’re already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor’s documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.
Networking

Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.
Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR
Networking

blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

• VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
• Policy-based routing is not available in all ADs. The release notes list available ADs.
• Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
• The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
• An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as show in the following diagram.
**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

By default, FortiGate provisions the IPSec tunnel in route-based mode. This topic focuses on FortiGate with a route-based VPN configuration.

If necessary, you can have FortiGate provision the IPSec tunnel in policy-based mode. To enable the feature, go to System, and then to Feature Visibility. Under Additional Features, enable the Policy-based IPsec VPN feature.
About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

If you want to use IKEv2, there’s a variation on one of the tasks presented in the next section. Specifically, in task 2, when configuring authentication, select IKE version 2.

Configuration Process

**Important:*******

Before starting, ensure you have a valid license or trial license to configure FortiGate.

Task 1: Use the wizard to create the VPN

1. Go to VPN, and then to **IPsec Wizard** to create a new VPN tunnel.
2. On the **VPN Creation Wizard** page, specify the following items:
   - **Name:** Description used to identify the IPSec tunnel. Avoid entering confidential information.
   - **Template Type:** Site to Site
   - **Remote Device Type:** Cisco
   - **NAT Configuration:** No NAT between sites

3. Click **Next**.

4. On the **Authentication** page, specify the following items:
   - **Remote Device:** IP Address
   - **IP Address:** IP address for the Oracle VPN headend. Oracle generated this value when creating the IPSec tunnel.
   - **Outgoing Interface:** The WAN interface configured for external traffic.
   - **Authentication Method:** Pre-shared Key. Oracle supports only shared secret keys.
   - **Pre-shared Key:** The shared secret. Oracle generated this value when creating the IPSec tunnel.

5. Click **Next**.

6. On the **Policy & Routing** page, specify the following items:
   - **Local Interface:** The LAN interface configured for internal traffic.
   - **Local Subnets:** The subnet used for internal traffic.
   - **Remote Subnets:** The Oracle VCN subnets that will be used for the IPSec tunnel.
   - **Internet Access:** None
7. Click Create.

A summary message is shown with details about the configuration. Notice that the wizard automatically creates security policies with the subnets that you specified and adds the required static routes.

![VPN Creation Wizard](image)

Task 2: Add Phase 1 and Phase 2 parameters to each IPSec tunnel

You must convert each newly created IPSec tunnel into a custom tunnel to add the recommended parameters for Phase 1 and Phase 2.

Perform the following steps for each tunnel.

1. Go to VPN, and then click IPsec Tunnels.
2. Select the tunnel and click Edit to view the Edit VPN Tunnel page.
3. Click **Convert to Custom Tunnel**.

![Networking Diagram]

- **ROI**: Remote Gateway: Static IP Address (129.213.6.50), Interface: port1
- **Authentication**
  - Authentication Method: Pre-shared Key
  - IKE Version: 1, Mode: Main (ID protection)
- **Phase 1 Proposal**
  - Algorithms: AES256-SHA384
  - Diffie-Hellman Group: 5
- **XAUTH**
  - Type: Disabled
- **Phase 2 Selectors**
  - Name | Local Address | Remote Address
  - OCI-DRG-CPE1 | OCI-DRG-CPE1_local | OCI-DRG-CPE1_remote
4. Edit the relevant sections to match the required settings shown in the following screenshots. Remember to click the check mark icon in the top-right corner of each section after making your changes.

The IP address shown in the first screenshot is an example address.

Notice that if you want to use IKEv2, on the Authentication screen, instead select IKE Version 2.
5. After configuring all sections, click **OK** to save and close the dialogs.

Task 3: Verify the IPSec connection

At this point, the IPSec tunnel will not be established by default because FortiGate uses the IP address assigned on the WAN interface. In this case, this IP address is a private IP address because Oracle does 1:1 NAT. This private IP address will be used as the local IKE ID and will not match the one expected on the Oracle DRG. To resolve this, you can manually change the local IKE ID on your FortiGate by using the CPE's CLI, or you can change the value that Oracle uses in the Oracle Console (see the instructions that follow). Either way, this fixes the incompatibility and brings up the IPSec tunnel.

To change the CPE IKE identifier that Oracle uses (Oracle Console)
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

   A list of the IPSec connections in the compartment that you’re viewing is displayed. If you don’t see the one you’re looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. For the IPSec connection you’re interested in, click the Actions icon (three dots), and then click Edit.

   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.

3. Enter your new values for CPE IKE Identifier Type and CPE IKE Identifier, and then click Save Changes.

Redundancy with BGP Over IPSec

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see Routing Details for Connections to Your On-Premises Network on page 2942.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of the IPSec VPN’s encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

Oracle’s BGP ASN in commercial regions is 31898. If you’re configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle’s BGP ASN on page 154.

For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

Task 1: Edit the tunnel interface

In the first task, you add the BGP IP address to the newly created FortiGate tunnel interface.

Perform the following steps for each tunnel.

1. Go to Network, and then Interface.

2. Select the interface you’re interested in and click Edit.

   ![FortiGate VM64-OPC Interface Configuration](image)

3. Configure the following items:
   - **IP**: Enter the BGP IP address that you assigned to the FortiGate end of the tunnel interface. The following screenshot shows an example value of 192.168.66.2.
   - **Remote IP/Network Mask**: Add the BGP IP address that you assigned to the Oracle end of the tunnel interface. Include either a /30 or /31 mask, depending on how you specified the addresses in the Oracle
Networking

Console. In the following screenshot, 192.168.66.0/30 was used, where 192.168.66.2 is assigned to the FortiGate end, and 192.168.66.1 is assigned to the Oracle end.

- **Ping access** (recommended): In the **Administrative Access** section, enable ping access.

![Edit Interface](image)

**Task 2: Add a static route for the Oracle IP address**

For each tunnel, add a /32 static route towards the Oracle IP address through the tunnel, as shown in the following screenshot.

![Static Routes](image)

**Task 3: Configure BGP**

Perform the following steps for each tunnel.

1. Go to **Network**, and then **BGP**.
2. Enter the following items:

- **Local AS**: Your BGP ASN. You can use a private ASN. Private ASNs are in the range 64512–65534.
- **Router ID**: A value to provide a unique identity for this BGP router among its peers.
- **Neighbors**: Click Create New and enter the BGP IP address for the Oracle end of the tunnel, and the Oracle BGP ASN (31898 for commercial regions). If you're configuring VPN Connect for connecting to the Government Cloud, see Oracle's BGP ASN on page 154.
- **Networks**: Optionally use this field to advertise a specific subnet over BGP. You can also advertise subnets by using the Redistribute section in the Advanced Options section.

3. Click OK.
**Verification**

The following CLI command is useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the encryption domain (SPI) identifier, and so on. This kind of information can be critical for determining an issue with the VPN.

```plaintext
diagnose vpn tunnel list
```

The following command indicates a lack of firewall policy, a lack of forwarding route, and policy ordering issues. If there are no communication issues, this command returns blank output.

```plaintext
diagnose debug flow
```

The following command verifies BGP neighbor status information. Remember that an "Active" state doesn't mean that the BGP session is up. "Active" refers to a BGP state message. For more information, see BGP Background and Concepts in the FortiGate documentation.

```plaintext
get router info bgp summary
```

The following command provides more detailed information about a BGP neighbor.

```plaintext
get router info bgp neighbors
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

**Furukawa Electric**

This configuration was validated using a Furukawa Electric series FITELnet-F220/F221 running Firmware 01.00(00) [0]00.00.0 [2019/07/05 15:00].

> **Important:**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

**Before Starting**

Before configuring your CPE, ensure that you:

- Configure your internet provider settings.
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

**Supported Encryption Domain or Proxy ID**

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 2948.

**Parameters from API or Console**

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

```plaintext
${vpn-ip#}
```

- Oracle VPN headend IPSec tunnel endpoints. There is one value for each tunnel.
- Example values: 129.146.12.52, 129.146.13.52
Networking

${sharedSecret#}
• The IPSec ISAKMP pre-shared-key. There is one value for each tunnel.
• Example value: EXAMPLEDPfAMkD7nTH3SWr6OFabdT6exXn6enSlsKbE

${cpePublicIpAddress}
• The public IP address for the CPE (previously made available to Oracle via the Console).

${VcnCidrBlock}
• When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.
• Example Value: 10.0.0.0/20

Parameters Based on Current CPE Configuration and State
The following parameters are based on your current CPE configuration.

${tunnelNumber#}
• An interface number to identify the specific tunnel. You need one unused unit number per tunnel.
• Example value: 1, 2

${isakmpPolicy}
• The ISAKMP policy name.
• Example value: isakmp-policy

${ipsecPolicy#}
• The IPSec policy name.
• Example value: ipsec-policy

${isakmpProfile#}
• The ISAKMP profile name. You need one unused ISAKMP profile name per tunnel.
• Example values: OCI-VPN-profile1, OCI-VPN-profile2

${selector}
• The selector name.
• Example value: OCI-VPN-selector

${map#}
• The map name. You need one unused map name per tunnel.
• Example values: OCI-VPN-MAP1, OCI-VPN-MAP2

${customer-bgp-asn}
• Your BGP ASN.
• Example value: 65000

${oracle-bgp-asn#}
• Oracle's BGP ASN.
• Example value: 31898

${customer-interface-ip#}
• The inside tunnel interface for CPE.
• Example value: 10.0.0.16/31

${oracle-interface-ip#}
• The inside tunnel interface for ORACLE.
• Example value: 10.0.0.17/31
$\{router-id\}

- The BGP router ID.
- Example value: 10.0.0.16

**Config Template Parameter Summary**

Each region has multiple Oracle IPSec headends. The following template allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the following table, "User" is you/your company.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Source</th>

Juniper MX

This topic provides configuration for a Juniper MX that is running software version JunOS 15.0 (or newer).

Important:
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.
If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you’re already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor’s documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
• **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see *Routing for the Oracle IPSec VPN* on page 2934.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor’s support.

*Caveats and Limitations*

This section covers general important characteristics and limitations of VPN Connect to be aware of.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see *Routing for the Oracle IPSec VPN* on page 2934.

**Route-Based or Policy-Based IPSec VPN**

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

**Note:**

Other vendors or industry documentation might use the term *proxy ID*, *security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

• **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

• **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.
Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

**Encryption domain for policy-based tunnels**

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an *encryption domain*.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as shown in the following diagram.
Note:
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

CPE Configuration

Important:
The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Juniper MX router running JunOS 15.0 (or newer). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.
The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure the Juniper MX public interface (the CPE public IP address is bound to this interface).
- Configure internal routing that routes traffic between the CPE and your local network.
- Configure the tunnel interfaces. See the next section for more information.

### About the Tunnel Interfaces

In the following configuration template, the tunnel interfaces are referred to with the following variables:

- **msInterface#** - one per tunnel
  - These interfaces correspond to one of the four encryption ASICs on the MS-MPC card.
  - You can distribute load across the ASICs by spreading your tunnels across them.
  - Example values: ms-2/3/0, ms-2/3/1
- **insideMsUnit#** and **outsideMsUnit#** - one pair per tunnel
  - For every tunnel, you need an ms-mpc interface pair of units.
  - One represents the outside of the IPSec tunnel. The other represents the inside of the tunnel.
  - The router forwards packets from your on-premises network to your VCN into the inside unit.
    - The encryption ASIC then encrypts the packets based on the rules and policies.
    - Then the encrypted packet egresses out the outside unit as an ESP packet, ready to be forwarded to the Oracle VPN headend routers.
  - There are over 16,000 possible values for unit numbers.
    - One way to allocate the units is to offset them by 8,000.
    - You can pick values between 0 - 7999 for insideMsUnit# and 8000-15999 for outsideMsUnit#.

**Important:**

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword USER_DEFINED in the template.

### About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see [Supported IPSec Parameters](#) on page 2945.
You specify the IKE version when defining the IKE policy. In the following configuration, there's a comment showing how to configure the IKE policy for IKEv1 versus IKEv2.

**Configuration Template**

```bash
# Configuration Template
# The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.

# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE TUNNEL INTERFACES FOR ORACLE
# SETTING THE SERVICES FOR ORACLE.
# SETTING BGP/STATIC ROUTING
# SETTING ROUTING-INSTANCES FOR ORACLE (OPTIONAL).

# The configuration template has various parameters that you must define before applying the configuration.
# Search in the template for the keyword "USER_DEFINED" to find those parameters.

# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle Console.
# connection_presharedkey_1 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# cpe_public_ip_address = The internet-routable IP address that is assigned to the public interface on the CPE. You provide this when creating the CPE object in the Oracle Console.
# cpe_public_interface = The name of the Juniper interface where the CPE IP address is configured. Eg: ge-0/0/1.0
# msInterface1 = The interface correspond to one of the four encryption ASICs on the MS-MPC card. Eg: ms-2/3/0, ms-2/3/1
# msInterface2 = Second tunnel interface that needs to be configured. Eg: ms-2/3/0, ms-2/3/1
# insideMsUnit1 = The inside interface of the MS-MPC interface pair for tunnel_1
# insideMsUnit2 = The inside interface of the MS-MPC interface pair for tunnel_2
# outsideMsUnit1 = The outside interface of the MS-MPC interface pair for tunnel_1
# outsideMsUnit2 = The outside interface of the MS-MPC interface pair for tunnel_2
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these when creating the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address between the MX and Oracle end points of the inside tunnel interface.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range

# OPTIONAL PARAMETERS:
# customer_on-prem_to_oracle = Name of the routing instance to be defined on the CPE for the tunnel interfaces connecting to the Oracle headends.
```
Networking

# internet_routing_instance = Name of the routing instance to be defined on the CPE for the tunnel interfaces that are connected to the Internet.

# #5b: Static Route Configuration

# USER_DEFINED: Replace the parameters in the section below as needed
# In case you plan to use static routing to get traffic through the IPSec
tunnels, you can point the routes down to the tunnel interfaces. You should
redistribute these routes into your on-premises network. Configuration for CPE to VCN static routes:

```
set routing-options static route <vcn_range> next-hop <msInterface2>.<insideMsUnit2>
```

## 6: Routing Instances Configuration (Optional)

### USER_DEFINED: Replace the parameters in the section below as needed.

If you are using routing-instances on your CPE, you need to make sure you account for them in your configuration. Merge the following configuration into the template provided above.

```
set routing-instances <customer_on-prem_to_oracle>
  interface <msInterface2>.<insideMsUnit2>
set routing-instances <internet_routing_instance>
  interface <msInterface2>.<outsideMsUnit2>
set services service-set oracle-vpn-tunnel-tunnel_2 ipsec-vpn-options local-gateway <cpe_public_ip_address> routing-instance <internet_routing_instance>
```

**Verification**

Use the following command to verify security associations (SAs).

```
show services ipsec-vpn ipsec security-associations detail
```

Use the following command to check the BGP status.

```
show bgp summary
```

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure. If you’ve configured the CPE to use routing instances, use the commands with `table <table-name>` at the end.

```
show route advertising-protocol bgp <neighbor-address>
show route receive-protocol bgp <neighbor-address>
show route advertising-protocol bgp <neighbor-address> table <table-name>
show route receive-protocol bgp <neighbor-address> table <table-name>
```

A **Monitoring service** is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see [VPN Connect Metrics](#) on page 3164.

If you have issues, see [VPN Connect Troubleshooting](#) on page 3166.

**Juniper SRX**

This topic provides configuration for a Juniper SRX that is running software version JunOS 11.0 (or newer).

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor’s documentation and make any necessary adjustments.
If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.

![Diagram of IPSec connection to Oracle Cloud Infrastructure](image)

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.

**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.
Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called *next-hop-based tunnels*. A route table lookup is performed on a packet’s destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.
Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

---

Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can’t overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

---

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE’s private IP address, as show in the following diagram.
Note:
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

CPE Configuration

Important:
The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for a Juniper SRX router running JunOS 11.0 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.
The configuration template refers to these items that you must provide:

- **CPE public IP address**: The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.

- **Inside tunnel interface (required if using BGP)**: The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.

- **BGP ASN (required if using BGP)**: Your BGP ASN.

In addition, you must:

- Configure the outside tunnel interface (the CPE public IP address is bound to this interface).
- Configure the tunnel interface IDs (referred to as st0.1 and st0.2 in the following configuration template). You need multiple tunnel unit numbers per IPSec connection.
- Configure internal routing that routes traffic between the CPE and your local network.
- Identify the security zone for the outside interface (the following configuration template references this zone as `internet_untrust`).
- Identify the security zone for the inside interface (the following configuration template references this zone as `oracle_trust`).
- Identify the security zone for the tunnel interface (the following configuration template references this zone as `oracle_vpn`).

### Important:

This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword `USER_DEFINED` in the template.

### About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

You specify the IKE version when defining the IKE gateway. In the following configuration, there's a comment showing how to configure the IKE gateway for IKEv1 versus IKEv2.

### Configuration Template

```bash
# Configuration Template
# The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.

# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE SECURITY ZONES FOR ORACLE
# SETTING THE SECURITY POLICIES FOR ORACLE
```
# SETTING THE SECURITY SETTING FOR ORACLE

# SETTING BGP/STATIC ROUTING

# The configuration template has various parameters that you must define before applying the configuration.
# Search in the template for the keyword "USER_DEFINED" to find those parameters.

# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle Console.
# connection_presharedkey_1 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
# outside_public_interface = The public interface or outside of tunnel interface which is configured with the CPE public IP address. Example: ge-0/0/1.0
# cpe_public_ip_address = The internet-routable IP address that is assigned to the public interface on the CPE. You provide this when creating the CPE object in the Oracle Console.
# inside_tunnel_interface = The internal-facing interface for the on-premises network behind the SRX that needs to reach the Oracle VCN. Example: ge-0/0/0.0
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these when creating the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address between the SRX and Oracle end points of the inside tunnel interface.
# internal_network_ip_range = Internal on-premise network behind the SRX that needs to reach resources in the Oracle VCN.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range

# IPSec Tunnel 1
# #1: Internet Key Exchange (IKE) Configuration (Phase 1)
# Defining the IKE Proposal for Oracle
# This IKE (Phase 1) configuration template uses AES256, SHA384, Diffie-Hellman Group 5, and 28800 second (8 hours) IKE session key lifetime.
# If different parameters are required, modify this template before applying the configuration.

**Verification**

Use the following command to verify security associations (SAs).

`show security ipsec security-associations`

Use the following command to check the BGP status.

`show bgp summary`

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure.

`show route advertising-protocol bgp <neighbor-address>`
`show route receive-protocol bgp <neighbor-address>`

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

**Libreswan**

Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. For an example of setting up a Libreswan host in another cloud provider to connect to your Oracle Cloud Infrastructure virtual cloud network (VCN), see Access to Other Clouds with Libreswan on page 3310.

This topic provides configuration for CPE that is running Libreswan. Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are an example only.
Networking

Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.
Networking

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR
blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can’t overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE’s public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE’s private IP address, as show in the following diagram.
Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

CPE Configuration

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

Default Libreswan Configuration Files

The default Libreswan installation creates the following files:

- `etc/ipsec.conf`: The root of the Libreswan configuration.
- `/etc/ipsec.secrets`: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- `/etc/ipsec.d/`: A directory for storing the `.conf` and `.secrets` files for your Oracle Cloud Infrastructure tunnels (for example: `oci-ipsec.conf` and `oci-ipsec.secrets`). Libreswan encourages you to create these files in this folder.

The default `etc/ipsec.conf` file includes this line:

```plaintext
include /etc/ipsec.d/* .conf
```
Networking

The default etc/ipsec.secrets file includes this line:

```
include /etc/ipsec.d/*.secrets
```

The preceding lines automatically merge all the .conf and .secrets files in the /etc/ipsec.d directory into the main configuration and secrets files that Libreswan uses.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

You specify the IKE version when setting up the IPSec configuration file in task 3 in the next section. In that example file, there’s a comment showing how to configure IKEv1 versus IKEv2.

Configuration Process

Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

For details about the specific parameters used in this document, see Supported IPSec Parameters on page 2945.

Task 1: Prepare the Libreswan instance

Depending on the Linux distribution you're using, you might need to enable IP forwarding on your interface to allow clients to send and receive traffic through Libreswan. In the /etc/sysctl.conf file, set the following values and apply the updates with sudo sysctl -p.

If you're using an interface other than eth0, change eth0 in the following example to your interface (lines 5 and 7).

```
net.ipv4.ip_forward=1
net.ipv4.conf.all.accept_redirects = 0
net.ipv4.conf.all.send_redirects = 0
net.ipv4.conf.default.send_redirects = 0
net.ipv4.conf.eth0.send_redirects = 0
net.ipv4.conf.default.accept_redirects = 0
net.ipv4.conf.eth0.accept_redirects = 0
```

Task 2: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- `${cpeLocalIP}`: The IP address of your Libreswan device.
- `${cpePublicIpAddress}`: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from `${cpeLocalIP}`.
- `${oracleHeadend1}`: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${oracleHeadend2}`: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${vti1}`: The name of the first VTI used. For example, vti1.
- `${vti2}`: The name of the second VTI used. For example, vti2.
- `${sharedSecret1}`: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${sharedSecret2}`: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${vcnCidrNetwork}`: The VCN IP range.

Task 3: Set up the configuration file: /etc/ipsec.d/oci-ipsec.conf
Networking

Libreswan configuration uses the concept of left and right to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the conn in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **left**: Your local Libreswan CPE
- **right**: The Oracle VPN headend

Use the following template for your /etc/ipsec.d/oci-ipsec.conf file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.

```plaintext
conn oracle-tunnel-1
left=${cpeLocalIP}
    # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
right=${oracleHeadend1}
authby=secret
leftsubnet=0.0.0.0/0
rightsubnet=0.0.0.0/0
auto=start
mark=5/0xffffffff # Needs to be unique across all tunnels
vti-interface=${vti1}
vti-routing=no
ikev2=no # To use IKEv2, change to ikev2=insist
ike=aes_cbc256-sha2_384;modp1536
phase2alg=aes_gcm256;modp1536
encapsulation=yes
ike_lifetime=28800s
salifetime=3600s

conn oracle-tunnel-2
left=${cpeLocalIP}
    # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
right=${oracleHeadend2}
authby=secret
leftsubnet=0.0.0.0/0
rightsubnet=0.0.0.0/0
auto=start
mark=6/0xffffffff # Needs to be unique across all tunnels
vti-interface=${vti2}
vti-routing=no
ikev2=no # To use IKEv2, change to ikev2=insist
ike=aes_cbc256-sha2_384;modp1536
phase2alg=aes_gcm256;modp1536
encapsulation=yes
ike_lifetime=28800s
salifetime=3600s
```

Task 4: Set up the secrets file: /etc/ipsec.d/oci-ipsec.secrets

Use the following template for your /etc/ipsec.d/oci-ipsec.secrets file. It contains two lines per IPSec connection (one line per tunnel).

```plaintext
${cpePublicIpAddress} ${oracleHeadend1}: PSK "${sharedSecret1}"
${cpePublicIpAddress} ${oracleHeadend2}: PSK "${sharedSecret2}"
```

Task 5: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service.
Networking

**Important:**

Restarting the Libreswan service may impact existing tunnels.

The following command rereads the config file and restarts the Libreswan service.

```
service ipsec restart
```

Task 6: Configure IP routing

Use the following `ip` command to create static routes that send traffic to your VCN through the IPSec tunnels. If you're logged in with an unprivileged user account, you might need to use `sudo` before the command.

**Important:**

Static routes created with the `ip route` command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.

```
ip route add ${VcnCidrBlock} nexthop dev ${vti1} nexthop dev ${vti2}
ip route show
```

**Verification**

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see [VPN Connect Metrics](#) on page 3164.

If you have issues, see [VPN Connect Troubleshooting](#) on page 3166.

**Checking the Libreswan Status**

Check the current state of your Libreswan tunnels by using the following command.

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you're using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

**Checking the Tunnel Interface Status**

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as `tcpdump` with the interfaces.

Here's an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>
vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
    inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
tunnel txqueuelen 1000 (IPIP Tunnel)
    RX packets 0 bytes 0 (0.0 B)
    RX errors 0 dropped 0 overruns 0 frame 0
```
Here's an example of the `ip link show` output:

```bash
ip link show
<output trimmed>
9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
   state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.0.0.2 peer 129.213.240.52
10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
   state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.0.0.2 peer 129.213.240.51
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.

**NEC IX Series**

This topic provides a route-based IPSec VPN configuration for NEC IX Series devices. This configuration was validated using an IX3315 running Firmware Ver.10.2.16 and IX2106 running Firmware Ver.10.2.16.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.
Networking

Best Practices
This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection
Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations
Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations
When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

Other Important CPE Configurations
Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR
Networking blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.

**Important:**

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can't overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

**If Your CPE Is Behind a NAT Device**

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's private IP address, as shown in the following diagram.
Networking

**Note:**

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as `cpe.example.com`. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

**Supported IPSec Parameters**

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

**CPE Configuration**

**Important:**

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

The configuration template provided is for an IX3315 running Firmware Ver.10.2.16 or IX2106 running Firmware Ver.10.2.16 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing for traffic between the CPE and your local network.
- Ensure that you permit traffic between your NEC IX Series and your Oracle VCN.
- Identify the IKE policy used (the following configuration template references this IKE policy as `$<ikePolicy1>` and `$<ikePolicy2>`).
• Identify the IPSec policy used (the following configuration template references this IPSec policy as $<ipsecPolicy1>$ and $<ipsecPolicy2>$).
• Identify the virtual tunnel interface names used (the following configuration template references these as variables $<tunnelInterfaceNumber1>$ and $<tunnelInterfaceNumber2>$).

Important:
This following configuration template from Oracle Cloud Infrastructure is a starting point for what you need to apply to your CPE. Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

• Policy names or numbers
• Interface names
• Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword USER_DEFINED in the template.

About Using IKEv2
Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

You specify the IKE version when defining the IKE gateway. In the following configuration, there's a comment showing how to configure the IKE gateway for IKEv1 versus IKEv2.

IKEv1 Configuration Template

!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------

! The configuration template involves setting up the following:
! Configure ISAKMPv1 and IPSec Policies
! Configure Keepalive Setting of ICMP
! Configure Virtual Tunnel Interfaces
! IP Routing (BGP or Static)

!-------------------------------------------------------------------------------------------------------------------------------------------------------------

! The configuration template has various parameters that you must define before applying the configuration.

!-------------------------------------------------------------------------------------------------------------------------------------------------------------

! PARAMETERS REFERENCED:
! $<OracleHeadendIpAddress1>$ = Oracle public IP endpoint obtained from the Oracle Console.
! $<OracleHeadendIpAddress2>$ = Oracle public IP endpoint obtained from the Oracle Console.
! $<sharedSecret1>$ = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! $<sharedSecret2>$ = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
! $<cpePublicIpAddress>$ = The public IP address for the CPE. This is the IP address of your outside interface.
! $<vcnCidrBlock>$ = VCN CIDR block. For example, 10.0.0.0/20.
! $<tunnelInterfaceNumber1>$ = The number of your tunnel interface for the first tunnel. For example, 1.
! $<tunnelInterfaceNumber2> = The number of your tunnel interface for the second tunnel. For example, 2.
! $<ikePolicy1> = The name of your IKE Policy. For example, ike-policy1.
! $<ikePolicy2> = The name of your IKE Policy. For example, ike-policy2.
! $<ipsecPolicy1> = The name of your IPSec Policy. For example, ipsec-policy1.
! $<ipsecPolicy2> = The name of your IPSec Policy. For example, ipsec-policy2.
! $<lanInterfaceNumber> = The number of your LAN interface. For example, 1.0.
! $<lanIpAddress> = The IP address of the LAN interface for your CPE.
! $<OracleInsideTunnelIpAddress1> = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! $<OracleInsideTunnelIpAddress2> = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
! $<cpeInsideTunnelIpAddress1> = The CPE's inside tunnel IP for the first tunnel.
! $<cpeInsideTunnelIpAddress2> = The CPE's inside tunnel IP for the second tunnel.
! $<bgpASN> = Your BGP ASN.

! Configure ISAKMPv1 and IPSec Policies

    ip access-list sec-list permit ip src any dest any
    ike nat-traversal
    ike proposal ike-prop encryption aes-256 hash sha2-256 group 1536-bit
    ike policy $<ikePolicy1> peer $<OracleHeadendIpAddress1> key $<sharedSecret1>
    ike policy $<ikePolicy2> peer $<OracleHeadendIpAddress2> key $<sharedSecret2>

IKEv2 Configuration Template

!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
! The configuration template involves setting up the following:
! Keyring (Pre-Shared Key)
! Configure ISAKMP and IPSec Policies
! Configure Virtual Tunnel Interfaces
! IP Routing (BGP or Static)
!-------------------------------------------------------------------------------------------------------------------------------------------------------------
```
The configuration template has various parameters that you must define before applying the configuration.

**PARAMETERS REFERENCED:**

- $<OracleHeadendIpAddress1>$ = Oracle public IP endpoint obtained from the Oracle Console.
- $<OracleHeadendIpAddress2>$ = Oracle public IP endpoint obtained from the Oracle Console.
- $<sharedSecret1>$ = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
- $<sharedSecret2>$ = You provide when you set up the IPSec connection in the Oracle Console, or you can use the default Oracle-provided value.
- $<cpePublicIpAddress>$ = The public IP address for the CPE. This is the IP address of your outside interface.
- $<vcnCidrBlock>$ = VCN CIDR block. For example, 10.0.0.0/20.
- $<tunnelInterfaceNumber1>$ = The number of your tunnel interface for the first tunnel. For example, 1.
- $<tunnelInterfaceNumber2>$ = The number of your tunnel interface for the second tunnel. For example, 2.
- $<lanInterfaceNumber>$ = The number of your LAN interface. For example, 1.0.
- $<wanInterfaceNumber>$ = The WAN interface or outside of tunnel interface which is configured with the CPE public IP address. For example, 0.1.
- $<OracleInsideTunnelIpAddress1>$ = Inside tunnel IP address of Oracle-side for the first tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
- $<OracleInsideTunnelIpAddress2>$ = Inside tunnel IP address of Oracle-side for the second tunnel. You provide these values when creating the IPSec connection in the Oracle Console.
- $<cpeInsideTunnelIpAddress1>$ = The CPE's inside tunnel IP for the first tunnel.
- $<cpeInsideTunnelIpAddress2>$ = The CPE's inside tunnel IP for the second tunnel.
- $<bgpASN>$ = Your BGP ASN.

**Keyring (Pre-Shared Key)**

For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.

Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.

```bash
ikev2 authentication psk id ipv4 $<OracleHeadendIpAddress1> key char $<sharedSecret1>
ikev2 authentication psk id ipv4 $<OracleHeadendIpAddress2> key char $<sharedSecret2>
```

Configure ISAKMP and IPSec Policies

```bash
ikev2 default-profile
dpd interval 10
source-address GigaEthernet$<wanInterfaceNumber>
child-pfs 1536-bit
child-proposal enc aes-cbc-256
child-proposal integrity sha1
sa-proposal enc aes-cbc-256
sa-proposal integrity sha2-384
sa-proposal dh 1536-bit
```

Configure Virtual Tunnel Interfaces

```bash
interface Tunnel$<tunnelInterfaceNumber1>
tunnel mode ipsec-iKEv2
ip address $<cpeInsideTunnelIpAddress1>
```
Networking

```
ip tcp adjust-mss auto
ikey2 connect-type auto
ikey2 ipsec pre-fragment
ikey2 outgoing-interface GigaEthernet<$wanInterfaceNumber>
ikey2 peer $<OracleHeadendIpAddress1> authentication psk id ipv4
$<OracleHeadendIpAddress1>
n0 shutdown

interface Tunnel<$tunnelInterfaceNumber2>
tunnel mode ipsec-ikey2
ip address $<cpeInsideTunnelIpAddress2>
ip tcp adjust-mss auto
ikey2 connect-type auto
ikey2 ipsec pre-fragment
ikey2 outgoing-interface GigaEthernet<$wanInterfaceNumber>
ikey2 peer $<OracleHeadendIpAddress2> authentication psk id ipv4
$<OracleHeadendIpAddress2>
n0 shutdown

```

Openswan

If you want to use Openswan to create an IPSec VPN to Oracle Cloud Infrastructure, see Libreswan on page 3102.

How Openswan and Libreswan Are Related

Openswan is a well-known IPSec implementation for Linux. It began as a fork of the now-defunct FreeS/WAN project in 2003. Unlike the FreeS/WAN project, it didn't exclusively target the GNU/Linux operation system, but
Networking

expanded its use to other operating systems. In 2012, FreeS/WAN renamed itself to The Libreswan Project because of a lawsuit over a trademark of the name openswan.

As a result, when you try to install or query the Openswan package on Oracle Linux, by default the Libreswan package is installed or shown instead. The following yum search query command illustrates this behavior:

```bash
$ sudo yum search openswan
Loaded plugins: langpacks, ulninfo
Matched: openswan ============================================
NetworkManager--libreswan.x86_64 : NetworkManager VPN plugin for libreswan
NetworkManager--libreswan-gnome.x86_64 : NetworkManager VPN plugin for libreswan-GNOME files
libreswan.x86_64 : IPsec implementation with IKEv1 and IKEv2 keying protocols
```

Libreswan is maintained by The Libreswan Project and has been under active development for over 15 years, going back to the FreeS/WAN Project. For more information, see the project's history.

**Palo Alto**

This topic provides configuration for a Palo Alto device. The configuration was validated using PAN-OS version 8.0.0.

Palo Alto experience is required.

**Important:**

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are only examples.

**Best Practices**

This section covers general best practices and considerations for using VPN Connect.
**Configure All Tunnels for Every IPSec Connection**

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two heads are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

**Have Redundant CPEs in Your On-Premises Network Locations**

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

**Routing Protocol Considerations**

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing**: The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing**: When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN on page 2934.

**Other Important CPE Configurations**

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

**Caveats and Limitations**

This section covers general important characteristics and limitations of VPN Connect to be aware of.

**Asymmetric Routing**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Routing for the Oracle IPSec VPN on page 2934.
Networking

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note:

Other vendors or industry documentation might use the term proxy ID, security parameter index (SPI), or traffic selector when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels**: Also called next-hop-based tunnels. A route table lookup is performed on a packet's destination IP address. If that route’s egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels**: The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address**: Any (0.0.0.0/0)
- **Destination IP address**: Any (0.0.0.0/0)
- **Protocol**: IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

When you use policy-based tunnels, every policy entry (a CIDR block on one side of the IPSec connection) that you define generates an IPSec security association (SA) with every eligible entry on the other end of the tunnel. This pair is referred to as an encryption domain.

In this diagram, the Oracle DRG end of the IPSec tunnel has policy entries for three IPv4 CIDR blocks and one IPv6 CIDR block. The on-premises CPE end of the tunnel has policy entries two IPv4 CIDR blocks and two IPv6 CIDR blocks. Each entry generates an encryption domain with all possible entries on the other end of the tunnel. Both sides of an SA pair must use the same version of IP. The result is a total of eight encryption domains.
Important:

If your CPE supports only policy-based tunnels, be aware of the following restrictions.

- VPN Connect supports multiple encryption domains, but has an upper limit of 50 encryption domains.
- Policy-based routing is not available in all ADs. The release notes list available ADs.
- Depending on when your tunnel was created you might not be able to edit an existing tunnel to use policy-based routing and might need to replace the tunnel with a new IPSec tunnel.
- The CIDR blocks used on the Oracle DRG end of the tunnel can’t overlap the CIDR blocks used on the on-premises CPE end of the tunnel.
- An encryption domain must always be between two CIDR blocks of the same IP version.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE’s public IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE’s private IP address, as shown in the following diagram.
Networking

Note:

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

CPE Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.

Important Details About the Configuration Instructions

- **Commits**: For PAN to activate the configuration, you must perform the commit action after any configuration change.
- **Example IP addresses**: The example configuration uses IP addresses from class A 10.0.0.0/8 (RFC1918) and 198.51.100.0/24 (RFC5735). When you perform the configuration on the CPE, use the correct IP addressing plan for your networking topology.

The example configuration uses the following variables and values:

- **Inside tunnel1 interface - CPE**: 198.51.100.1/30
- **Inside tunnel2 interface - CPE**: 198.51.100.5/30
- **Inside tunnel1 interface - Oracle**: 198.51.100.2/30
- **Inside tunnel2 interface - Oracle**: 198.51.100.6/30
- **CPE ASN**: 64511
- **On-premises network**: 10.200.1.0/24
- **VCN CIDR block**: 10.200.0.0/24
• CPE public IP address: 10.100.0.100/24
• Oracle VPN headend (DRG) IP address 1: 10.150.128.1/32
• Oracle VPN headend (DRG) IP address 2: 10.150.127.1/32
• Tunnel number 1: tunnel.1
• Tunnel number 2: tunnel.2
• Exit interface: ethernet1/1

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

If you want to use IKEv2, there are special variations of some steps presented in the next section. Here is a summary of the special steps:

• For task 2 (defining the ISAKMP peers), when you add the IKE gateway:
  • On the General tab, for the Version, select IKEv2 only mode.
  • On the Advanced Options tab, select the IKE crypto profile associated with the IKEv2 tunnel.
• For task 5 (configuring the IPSec sessions), configure the proxy ID.

Configuration Process

The following process includes BGP configuration for the IPSec connection. If you instead want to use static routing, perform tasks 1–5, and then skip to CPE Configuration on page 3124.

Task 1: Configure the ISAKMP Phase 1 policy

In this example, the same ISAKMP policy is used for both tunnels.

1. Go to Network, to IKE Crypto, and then click Add.
2. Configure the parameters as shown in the next screenshot. For a list of the values, see Supported IPSec Parameters on page 2945. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152.

The next screenshot shows the final result for this task:

Task 2: Define the ISAKMP peers
1. Go to **Network**, to **IKE Gateways**, and then click **Add**.
Networking

2. For peer 1, configure the parameters as shown in the next screenshots.

   a. On the **General** tab:
      - **Version**: For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2 only mode**. Notice that if you're using IKEv2, later in task 5 you also add proxy IDs.
      - **Interface**: The interface that owns the public IP address on the CPE. Change **ethernet1/1** to the particular value for your networking topology.
      - **Peer IP addresses**: The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your first tunnel.
      - **Pre-shared Key**: The shared secret that Oracle automatically assigned during IPSec tunnel creation. If you want, you can specify a different value. Enter the same value here and in the Oracle Console.
      - **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE's public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the first tunnel.

   ![IKE Gateway Configuration Screenshot](image)

   b. On the **Advanced Options** tab, ensure that the values are set for the first peer according to the following screenshot.
If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.
3. For peer 2, configure the parameters as shown in the next screenshots.

   a. On the General tab:

      • **Version**: For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2 only mode**. For IKEv2, notice that you also need to provide a proxy ID later in task 5.
      • **Interface**: The interface that owns the public IP address on the CPE. Change `ethernet1/1` to the particular value for your networking topology.
      • **Peer IP addresses**: The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your second tunnel.
      • **Pre-shared Key**: The shared secret that Oracle automatically assigned during IPSec tunnel creation. If you want, you can specify a different value. Enter the same value here and in the Oracle Console.
      • **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE's public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the second tunnel.

   ![IKE Gateway Configuration](image)

   b. On the Advanced Options tab, ensure that the values are set for the second peer according to this screenshot:
Networking

If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.

The next screenshot shows the final result for this task:

Task 3: Define the IPSec Phase 2 policy

In this example, the same IPSec crypto profile is used for both tunnels.
1. Go to **Network**, to **IPSec Crypto**, and then click **Add**.
2. Configure the parameters as shown in the next screenshot.

![IPSec Crypto Profile](image)

The next screenshot shows the final result for this task:

![Virtual Tunnel Interfaces](image)

**Task 4: Configure the virtual tunnel interfaces**

1. Go to **Network**, to **Interfaces**, to **Tunnel**, and then click **Add**.
2. For peer 1, configure the parameters as shown in the next screenshots.
   
   a. On the Config tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_tunnel security zone are used.
   
   ![Tunnel Interface Configuration](image1.png)
   
   b. On the IPv4 tab, ensure that the values are set for the first peer according to the following screenshot. In this example, the IP address for the tunnel interface is ipsec_address_static1 = 198.51.100.1/30. Configure your tunnel IP address according to your networking IP addressing plan.
   
   ![Tunnel Interface IPv4 Configuration](image2.png)
3. For peer 2, configure the parameters as shown in the next screenshots.

a. On the **Config** tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_tunnel security zone are used.

![Tunnel Interface](image)

b. On the **IPv4** tab, ensure that the values are set for the second peer according to the following screenshot. In this example, the IP address for the tunnel interface is ipsec_address_static2 = 198.51.100.5/30. Configure your tunnel IP address according to your networking IP addressing plan.

![Tunnel Interface](image)

The next screenshot shows the final result for this task:

![Tunnel Interface](image)

Task 5: Configure the IPSec sessions

1. Go to **Network**, to **IPSec Tunnels**, and then click **Add**.
2. For peer 1, configure the parameters on the **General** tab as shown in the next screenshot.

Notice that if you're using IKEv1, you do not need to add specific proxy IDs to the **Proxy IDs** tab. They are not needed for an IKEv1 route-based VPN configuration.

However, for IKEv2, do add proxy IDs to the **Proxy IDs** tab for better interoperability. Ensure that you also configured the IKE gateway to use IKEv2 earlier in task 2.

3. For peer 2, configure the parameters on the **General** tab as shown in the next screenshot.

If you are using IKEv2, also add proxy IDs on the **Proxy IDs** tab.

![General Tab Configuration](image)

Task 6: Configure BGP over IPSec

**Note:**

If you want to use static routing instead of BGP, skip task 6 and go to **Configuring Static Routing** on page 3148.

BGP over IPSec requires IP addresses on the tunnel interfaces on both ends.

The screenshots in this example use these subnets for the tunnel interfaces:

- 198.51.100.0/30
- CPE: 198.51.100.1/30
- DRG: 198.51.100.2/30
- 198.51.100.4/30
- CPE: 198.51.100.5/30
- DRG: 198.51.100.6/30

Replace the example values with the BGP IP addresses you specified in the Oracle Console for the inside tunnel interfaces.
This task consists of three subtasks, each with multiple steps.

Subtask 6-a: Configure the BGP parameters

1. Go to **Network**, to **Virtual Routers**, to **default**, and then to **BGP**. This example uses the default virtual router. Also, the example uses 10.200.1.10 for the router ID and 64511 for the ASN. Use the correct virtual router based on your networking configuration, and use the correct router ID and ASN for your environment.

2. On the **General** tab, configure the parameters as shown in the next screenshot.

3. On the **Advanced** tab, configure the parameters as shown in the next screenshot.
4. On the **Peer Group** tab:

a. Add the first Peer Group, and under the **Peer Group Name**, add the first session. Add the BGP session with the DRG.

![Peer Group Configuration](image1)

b. For the first tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot. Oracle's BGP ASN in commercial regions is 31898. If you're configuring VPN Connect for the Government Cloud, see Oracle's BGP ASN on page 154.

![Addressing Configuration](image2)

c. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.
d. On the **Advanced** tab, configure the parameters as shown in the next screenshot.
e. On the **Peer Group** tab, add the second Peer Group, and under the **Peer Group Name**, add the second session. Add the BGP session with the DRG.

f. For the second tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot.
g. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.
h. On the Advanced tab, configure the parameters as shown in the next screenshot.
The next screenshot shows the final Peer Group configuration:

<table>
<thead>
<tr>
<th>Name</th>
<th>Route</th>
<th>Type</th>
<th>Peer AS</th>
<th>Peer AS No</th>
<th>Peer Address</th>
<th>Local Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>DRG1</td>
<td>Yes</td>
<td>mtp</td>
<td>31898</td>
<td>199.10.100.2</td>
<td>peer_address_dr1</td>
<td></td>
</tr>
<tr>
<td>DRG2</td>
<td>Yes</td>
<td>mtp</td>
<td>31898</td>
<td>199.10.100.6</td>
<td>peer_address_dr2</td>
<td></td>
</tr>
</tbody>
</table>

Network
5. On the **Import** tab, configure the parameters as shown in the next screenshots. Here you configure tunnel.1 as the primary and tunnel.2 as the backup for the VCN route received from the DRG by way of BGP (10.200.0.0/24). From the BGP perspective, both tunnels are in the Established state.

a. For the first rule, on the **General** tab, configure the parameters as shown in the next screenshot.

![Virtual Router - BGP - Import Rule](image)

b. On the **Match** tab, configure the parameters as shown in the next screenshot.

![Virtual Router - BGP - Import Rule](image)

c. On the **Action** tab, configure the parameters as shown in the next screenshot.
Networking

d. For the second rule, on the **General** tab, configure the parameters as shown in the next screenshot.

![General tab configuration screenshot](image)

e. On the **Match** tab, configure the parameters as shown in the next screenshot.

![Match tab configuration screenshot](image)
f. On the **Action** tab, configure the parameters as shown in the next screenshot.
6. On the **Export** tab, configure the parameters as shown in the next screenshots. Here you configure a policy to force the DRG to prefer tunnel.1 for the returning path to the on-premises network CIDR (10.200.1.0/24).

   a. On the **General** tab, configure the parameters as shown in the next screenshot.

   ![General Tab Screenshot]

   b. On the **Match** tab, configure the parameters as shown in the next screenshot.

   ![Match Tab Screenshot]

   c. On the **Action** tab, configure the parameters as shown in the next screenshot.
The next screenshot shows the final Export configuration:

Notice that no configuration is required for the **Conditional Adv** or **Aggregate** tabs.
7. On the **Redist Rules** tab, configure the parameters as shown in the next screenshot. Here you announce the on-premises network CIDR in BGP.

Subtask 6-b: Wait for the BGP sessions to establish and then check the BGP status

1. Go to **Network**, to **IPSec Tunnels**, to the **Virtual Router** column, and then click **Show Routes**.

2. Go to **BGP**, and then to the **Peer** tab to verify that the BGP session is established. Any other value means that the BGP session has not been established successfully and route exchange will not occur.
3. On the **Local RIB** tab: The prefixes are received from the DRG, with tunnel.1 being preferred.

![Virtual Router - default](image)

4. On the **RIB Out** tab: The on-premises network CIDR is sent by way of BGP to DRG1 with as_path of 64511, and for DRG2, with an as_path of 64511, 64511. In this way, based on the BGP Best Path Algorithm, the route preferred by the DRG to reach the on-premises network CIDR uses the connection over tunnel.1.

![Virtual Router - default](image)

Subtask 6-c: Confirm that the BGP routes have been inserted in the routing table

To view the routes, go to **Routing**, and then to the **Route Table** tab.

![Virtual Router - default](image)

**Configuring Static Routing**

Use the instructions here if your CPE does not support BGP over IPSec, or you do not want to use BGP over IPSec.

In this task, you configure static routes to direct traffic through the tunnel interfaces to reach the DRG and finally the VCN hosts.

1. Follow tasks 1–5 in the preceding section.
2. Configure static routes:
   a. Go to Network, to Virtual Routers, to default, to Static Routes, and then click Add.
   b. For Route 1, configure the parameters as shown in the next image.
   c. For Route 2, configure the parameters as shown in the next image.
3. (Recommended) Enable ECMP for traffic sent through the two tunnels. The metric for both routes is set to 10. Here are some important notes about enabling ECMP:

- First check to see if your networking design allows for ECMP.
- Enabling or disabling ECMP on an existing virtual router causes the system to restart the virtual router. The restart might cause existing sessions to be terminated.
- This example uses the default virtual router. Use the correct virtual router for your network environment.

To enable ECMP, go to Network, to Virtual Routers, to default, to Router Settings, to ECMP, and then select the check box for Enable.

Here are screenshots that show the final configuration after this task is complete:

Changing the IKE Identifier

If the CPE is behind a NAT device with a private IP address on the exit interface that the tunnel interfaces use as the source, you must specify the public IP address of the NAT device as the local IKE ID. You can do this by setting the Local Identification value in the IKE Gateway configuration:
Verifying IPSec Tunnel Status

Use this command to verify the IKE SA:

```
show vpn ike-sa
```

Use this command to verify the IPSec tunnel configuration:

```
show vpn tunnel name <tunnel_name>
```

To verify the BGP status, look for **Established:**
To verify the BGP status from the command line:

```
show routing protocol bgp peer peer-name <name>
```

To verify that the routes are installed in the routing table:

```
show routing route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics on page 3164.

If you have issues, see VPN Connect Troubleshooting on page 3166.

**WatchGuard**

You can configure a WatchGuard Firebox as your CPE device for an IPSec VPN.

To download the configuration instructions, go to the WatchGuard knowledge base article.

**Yamaha RTX Series**

This configuration was validated using an RTX1210 running Firmware Rev.14.01.28 and RTX830 running Firmware Rev.15.02.03.

---

**Important:**

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

---

**Before Starting**

Before configuring your CPE:

- Configure your internet provider settings.
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

**Supported Encryption Domain or Proxy ID**

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID on page 2948.

**Parameters from API or Console**

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

- `$(ipAddress#)`
  - Oracle VPN headend IPSec tunnel endpoints. There is one value for each tunnel.
  - Example value: 129.146.12.52

- `$(sharedSecret#)`
  - The IPSec IKE pre-shared-key. There is one value for each tunnel.
  - Example value: EXAMPLEDPfAMkD7nTH3SWr6OFabdT6exXn6enSlsKbE

- `$(cpePublicIpAddress)`
  - The public IP address for the CPE (previously made available to Oracle via the Console).

- `$(VcnCidrBlock)`
When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.

Example Value: 10.0.0.0/20

**Parameters Based on Current CPE Configuration and State**

The following parameters are based on your current CPE configuration.

`${tunnelInterface#}`

- An interface number to identify the specific tunnel.
- Example value: 1

`${ipsecPolicy#}`

- The SA policy to be used for the selected inline interface.
- Example value: 1

`${localAddress}`

- The public IP address of your CPE.
- Example value: 146.56.2.52

**Config Template Parameter Summary**

Each region has multiple Oracle IPSec headends. The following template allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the table, "User" is you/your company.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Source</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${ipAddress1}</code></td>
<td>Console/API</td>
<td>129.146.12.52</td>

Working with VPN Connect

This topic contains some details about working with VPN Connect and the related components. Also see these topics:

- [VPN Connect Overview](#) on page 2933
- [VPN Connect Quickstart](#) on page 2939
- [Setting Up VPN Connect](#) on page 2949
- [CPE Configuration](#) on page 2967
- [Using the CPE Configuration Helper](#) on page 2970
- [VPN Connect FAQ](#)
- [VPN Connect Metrics](#) on page 3164
- [VPN Connect Troubleshooting](#) on page 3166

Updated VPN Connect service

VPN Connect v2 improves availability and reliability of IPSec connections and makes possible new functionality. Regions that can provide VPN Connect v2 are listed in [VPN Connect v2 availability](#) on page 3156. Where available, all newly created IPSec connections are created using VPN Connect v2. The process for setting up VPN Connect v2 is identical to setting up VPN Connect v1.

New functions that depend on VPN Connect v2 include:

- [Multiple encryption domains](#)
- [Logging for VPN Connect](#)

Regions that support VPN Connect v2 will continue to support VPN Connect v1. If you have VPN Connect in one of these regions and want to use one of the added features available for VPN Connect v2, you will need to create a new connection and end the older connection. There is no migration path to change a v1 connection to a v2 connection currently.

VPN Connect v2 availability

VPN Connect v2 is available in the following regions:

<table>
<thead>
<tr>
<th>Commercial Regions</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia East (Sydney)</td>
<td>Available</td>
</tr>
<tr>
<td>Australia Southeast (Melbourne)</td>

</tr>
</tbody>
</table>

### Viewing Tunnel Status and Configuration

When you successfully create the IPSec connection, Oracle produces important configuration information for each of the resulting IPSec tunnels. For an example, see task 2h in the overall setup process. You can view that information and the status of the tunnels at any time. This includes the BGP status if the tunnel is configured to use BGP dynamic routing.

**To view the status and configuration information for the IPSec tunnels**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.

   A list of the IPSec connections in the compartment that you’re viewing is displayed. If you don’t see the one you’re looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

   Each tunnel's details are displayed, including the IPSec status, the BGP status (if the tunnel uses BGP dynamic routing), and the Oracle VPN IP address (the VPN headend).

3. To view a tunnel's shared secret:
   a. Click the tunnel you're interested in.
   b. Next to the **Shared Secret** field, click **Show**.

### Using the CPE Configuration Helper

After you set up VPN Connect, your network engineer must configure the customer-premises equipment (CPE) at your end of the connection. The configuration includes details about your virtual cloud network (VCN) and the IPSec tunnels in the VPN Connect. The CPE Configuration Helper generates the information for your network engineer. For more information, see Using the CPE Configuration Helper on page 2970.

### Changing the Static Routes

You can change the static routes for an existing IPSec connection. You can provide up to 10 static routes.

Remember that an IPSec connection can use either static routing or BGP dynamic routing. You associate the static routes with the overall IPSec connection and not the individual tunnels. If an IPSec connection has static routes associated with it, Oracle uses them for routing a tunnel's traffic only if the tunnel itself is configured to use static routing. If it's configured to use BGP dynamic routing, the IPSec connection's static routes are ignored.

**Important:**

The IPSec connection goes down while it is reprovisioned with your static route changes.
To edit the static routes

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click Edit.

   The current static routes are displayed.

3. Make your changes and click Save Changes.

Changing the CPE IKE Identifier That Oracle Uses

If your CPE is behind a NAT device, you might need to give Oracle your CPE IKE identifier. You can either specify it when you create the IPSec connection, or later edit the IPSec connection and change the value. Oracle expects the value to be an IP address or fully qualified domain name (FQDN). When you specify the value, you also specify which type it is.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The IPSec connection goes down while it is reprovisioned to use your CPE IKE identifier.</td>
</tr>
</tbody>
</table>

To change the CPE IKE identifier that Oracle uses

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click Edit.

   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.

3. Enter your new values for CPE IKE Identifier Type and CPE IKE Identifier, and then click Save Changes.

Using IKEv2

Oracle supports Internet Key Exchange (IKE) version 1 and version 2 (IKEv2).

If you want to use IKEv2 and your CPE supports it, you must:

- Configure each IPSec tunnel to use IKEv2 in the Oracle Console. See the following procedures.
- Configure your CPE to use IKEv2 encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see Supported IPSec Parameters on page 2945.

New IPSec connection: using IKEv2

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you create a new IPSec connection manually, you can specify IKEv2 when you create the IPSec connection in the Oracle Console. See the procedure that immediately follows.</td>
</tr>
<tr>
<td>If you instead use the VPN quickstart workflow, the IPSec connection is configured to use IKEv1 only. However, after the workflow is complete, you can edit the resulting IPSec tunnels in the Oracle Console and change them to use IKEv2.</td>
</tr>
</tbody>
</table>

To manually set up a new IPSec connection that uses IKEv2:

1. While creating the IPSec connection in the Oracle Console, in the Advanced Options section, click the Tunnel 1 tab.
2. From the IKE Version menu, select IKEv2.
3. Repeat the preceding step for the Tunnel 2 tab.
4. Later when configuring your CPE, configure it to use only IKEv2 and related IKEv2 encryption parameters that the CPE supports.

**Existing IPSec connection: upgrading to IKEv2**

**Important:**

Oracle recommends performing the following process for one tunnel at a time to avoid disruption in your overall connection. If your connection is not redundant (for example, does not have multiple tunnels), expect downtime while you upgrade to IKEv2.

1. Change the tunnel's IKE version in the Oracle Console:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.
   b. Click the IPSec connection you're interested in.
   c. Click the tunnel to view its details.
   d. Click **Edit**.
   e. From the **IKE Version** menu, select IKEv2.
   f. Click **Save Changes**.

2. Update your CPE configuration for the tunnel to use IKEv2 and the related encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see **Supported IPSec Parameters** on page 2945.

3. If the security associations did not rekey immediately, force a rekey for that tunnel on your CPE. In other words, clear the phase 1 and phase 2 security associations and do not wait for them to expire. Some CPE devices wait for the SAs to expire before rekeying. Forcing the rekey lets you confirm immediately that the IKE version configuration is correct.

4. To verify, ensure that the security associations for the tunnel rekey correctly. If they don't, confirm that the correct IKE version is set in the Oracle Console and on your CPE, and that the CPE is using the desired parameters.

After you've confirmed the first tunnel is up and running again, repeat the preceding steps for the second tunnel.

**Changing the Shared Secret That an IPSec Tunnel Uses**

When you set up an IPSec VPN, by default Oracle provides each tunnel's shared secret (also called the pre-shared key). You might have a particular shared secret that you want to use instead. You can specify each tunnel's shared secret when you create the IPSec connection, or you can edit the tunnels and provide each new shared secret then. For the shared secret, only numbers, letters, and spaces are allowed. Oracle recommends using a different shared secret for each tunnel.

**Important:**

When you change a tunnel's shared secret, both the overall IPSec connection and the tunnel go into the Provisioning state while the tunnel is reprovisioned with the new shared secret. The other tunnel in the IPSec connection remains in the Available state. However, while the first tunnel is being reprovisioned, you cannot change the second tunnel's configuration.

**To change the shared secret that an IPSec tunnel uses**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

3. Click the tunnel you're interested in.

4. Next to the **Shared Secret** field, click **Edit**.

5. Enter your new value. Only numbers, letters, and spaces are allowed.

6. Click **Save Changes**.
Changing from Static Routing to BGP Dynamic Routing

If you want to change an existing IPSec VPN from using static routing to using BGP dynamic routing, follow the process in this section.

**Caution:**

When you change a tunnel's routing type, the tunnel's IPsec status does not change during reprovisioning. However, routing through the tunnel is affected. Traffic is temporarily disrupted until your network engineer configures your CPE device in accordance with the routing type change. **If your existing IPSec VPN is currently configured to use only a single tunnel, this process will disrupt your connection to Oracle.** If your IPSec VPN instead uses multiple tunnels, Oracle recommends reconfiguring one tunnel at a time to avoid disrupting your connection to Oracle.

**To change from static routing to BGP dynamic routing**

**Prerequisites:**
- You've read this section: Routing for the Oracle IPSec VPN on page 2934
- You've gathered the necessary BGP routing information:
  - Your network's ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 154.
  - For each tunnel: The BGP IP address for each end of the tunnel (the two addresses for a given tunnel must be a pair from a /30 or /31 subnet, and they must be part of the IPSec VPN's encryption domain)

Repeat the following process for each tunnel in the IPSec connection:

1. Reconfigure the tunnel's routing type from static routing to BGP dynamic routing:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.
   b. Click the IPSec connection you're interested in.
      The tunnels are listed, and the status for each tunnel is shown. The **BGP Status** for the tunnel you're interested in should show only a hyphen (no value), which means that the tunnel is currently configured to use static routing.
   c. Click the tunnel to view all of its details.
   d. Click **Edit**.
   e. Do the following:
      - **Routing Type**: Select the radio button for **BGP Dynamic Routing**.
      - **BGP ASN**: Enter your network's BGP ASN.
      - **Inside Tunnel Interface - CPE**: Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31.
      - **Inside Tunnel Interface - Oracle**: Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31.
   f. Click **Save Changes**.
      The tunnel's **BGP Status** changes to Down.
2. Have your network engineer update your CPE device's tunnel configuration to use BGP.
3. On your side of the connection, confirm that the tunnel's BGP session is in an established state. If it is not, make sure you've configured the correct IP addresses for the tunnel in the Oracle Console and also for your CPE device.
4. In the Oracle Console, confirm that the tunnel's **BGP Status** is now Up.
5. Confirm that your CPE device is learning routes from Oracle, and your CPE device is advertising routes to Oracle.
   If you want to re-advertise the Oracle routes from BGP back to your on-premises network, make sure your CPE device is configured accordingly. Your existing policy to advertise the static routes to your on-premises network may not work for the BGP learned routes.
6. Ping the Oracle BGP IP address from your side of the connection to confirm that traffic is flowing.
After you've confirmed the first tunnel is up and running with BGP, repeat the process for the second tunnel.

**Important:**

As noted in Routing for the Oracle IPSec VPN on page 2934, the static routes that are still configured for the overall IPSec connection do NOT override the BGP routing. Those static routes are ignored when Oracle routes traffic through a tunnel that is configured to use BGP.

Also, you can change a tunnel's routing type back to static routing if necessary. You might do this if the scheduled downtime window for the CPE device is ending soon and you're having trouble establishing the BGP session. When you switch back to static routing, make sure the overall IPSec connection still has your desired static routes configured.

**Monitoring Your IPSec VPN**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring your connection, see VPN Connect Metrics on page 3164.

**Viewing Your VPN Connect Log Messages**

Access the log messages for VPN Connect.

You can view the log messages generated for various operational aspects of VPN Connect such as the negotiations that occur in bringing an IPSec tunnel UP. Enabling and accessing the VPN Connect log messages can be done via VPN Connect or the Logging Service.

- For an overview of the Logging Service in general, refer to Logging Overview on page 2574
- For details on enabling and accessing the VPN Connect log messages via the Logging service, refer to Service Logs on page 2591
- For details on the VPN Connect log message schema, refer to Details for VPN Connect on page 2615

**To enable message logging**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
2. A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
3. For the IPSec connection you're interested in, click the name of the connection.
   The details page for the connection is displayed.
4. On the left side of the screen under Resources, click on Logs.
   If you do not see this option, the connection has the older VPN Connect v1 type. Message logging requires VPN Connect v2.
   Details for the options on the screen are at Enabling Logging for a Resource on page 2591. Logs are handled the same regardless of the resource type generating the log.
6. Click Enable Log.
   The Log detail page is displayed, and the log will be in the process of being created (a "Creating log" message is displayed).

**To view log messages**

You must already have logging enabled to view the message log. To view the message log:

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
2. A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

3. On the left side of the screen under Resources, click on Logs.

   If you do not see this option, the connection has the older VPN Connect v1 type. Message logging requires VPN Connect v2.

4. Click on the Log Name of the log you are interested in. This will open a new browser tab showing the requested log.

See To view the contents of logs on page 2581 for details on using the log display screen.

Disabling or Terminating the IPSec VPN

If you want to disable the IPSec VPN between your on-premises network and VCN, you can simply detach the DRG from the VCN instead of deleting the IPSec connection. If you're also using the DRG with FastConnect, detaching the DRG would also interrupt the flow of traffic over FastConnect.

You can delete the IPSec connection. However, if you later want to re-establish it, your network engineer would have to configure your CPE device again with a new set of tunnel configuration information from Oracle.

If you want to permanently delete the entire IPSec VPN, you must first terminate the IPSec connection. Then you can delete the CPE object. If you're not using the DRG for another connection to your on-premises network, you can detach it from the VCN and then delete it.

To delete an IPSec connection

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

   A list of the IPSec connections in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

3. Click Terminate.

4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

To delete a CPE object

Prerequisite: There must not be an IPSec connection between the CPE object and a DRG.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Customer-Premises Equipment.

   A list of the CPE objects in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. For the CPE object that you want to delete, click the Actions icon (three dots), and then click Delete.

3. Confirm the deletion when prompted.

The object will be in the Terminating state for a short period while it's being deleted.

Managing Tags for an IPSec Connection or CPE Object

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

To manage tags for an IPSec connection

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.

   A list of the IPSec connections in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

3. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.
To manage tags for a CPE object

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Customer-Premises Equipment.

   A list of the CPE objects in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the CPE object you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

Moving an IPSec Connection or CPE Object to a Different Compartment

You can move your resources from one compartment to another. After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. Moving the CPE object to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Working with Compartments on page 2432.

To move a CPE object to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Customer-Premises Equipment.
2. Find the CPE object in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.

Managing Your DRG

For tasks related to DRGs, see Dynamic Routing Gateways (DRGs) on page 2927.

Using the API for VPN Connect

This topic lists the Networking service API operations for managing VPN Connect components.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your VCN and subnets, use these operations:

- ListVcns
- CreateVcn
- GetVcn
- UpdateVcn
- DeleteVcn
- ChangeVcnCompartment
- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

To manage your DRG, use these operations:

- ListDrgs
- CreateDrg
- GetDrg
- UpdateDrg
- DeleteDrg
- ListDrgAttachments
• **CreateDrgAttachment**: This operation attaches a DRG to a VCN and results in a `DrgAttachment` object with its own OCID.
• **GetDrgAttachment**
• **UpdateDrgAttachment**
• **DeleteDrgAttachment**: This operation detaches a DRG from a VCN by deleting the `DrgAttachment` object.

To manage routing for your VCN, use these operations:
• **ListRouteTables**
• **GetRouteTable**
• **UpdateRouteTable**
• **CreateRouteTable**
• **DeleteRouteTable**

To manage security lists for your VCN, use these operations:
• **ListSecurityLists**
• **GetSecurityList**
• **UpdateSecurityList**
• **CreateSecurityList**
• **DeleteSecurityList**

To manage your CPEs, use these operations:
• **ListCpes**
• **CreateCpe**
• **GetCpe**
• **UpdateCpe**
• **DeleteCpe**
• **ChangeCpeCompartment**

To manage your IPSec connections, use these operations:
• **ListIPSecConnections**
• **CreateIPSecConnection**: Use this operation to get the configuration information for each tunnel, including the IP address of the DRG (the VPN headend) and the shared secret. See [CPE Configuration](#) on page 2967.
• **GetIPSecConnection**
• **UpdateIPSecConnection**
• **DeleteIPSecConnection**
• **ChangeIPSecConnectionCompartment**
• **GetIPSecConnectionDeviceStatus**: Use this operation to determine the status of the IPSec tunnels (up or down).
• **GetIPSecConnectionDeviceConfig**: Use this operation to get the configuration information for each tunnel.

### VPN Connect Metrics

You can monitor the health, capacity, and performance of your **VPN Connect** by using metrics, alarms, and notifications. For more information, see [Monitoring Overview](#) on page 2660 and [Notifications Overview](#) on page 3350.

This topic describes the metrics emitted by the metric namespace `oci_vpn`.

Resources: IPSec connections.

**Overview of Metrics: oci_vpn**

The available metrics help you determine quickly if your **VPN Connect** is up, how much data is flowing over the connection, and if packets are being dropped for unexpected errors.

A VPN Connect includes these resources:
• An IPSec connection, which you can think of as the parent resource (identified by parentResourceId in the following discussion).

• One or more individual tunnels associated with that IPSec connection (each identified by the tunnel's publicIp in the following discussion).

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_vpn

The metrics listed in the following table are automatically available for any VPN Connect that you create. You do not need to enable monitoring on the resource to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

PARENTRESOURCEID

The OCID of the IPSec connection (the parent resource). The connection has multiple individual tunnels.

PUBLICIP

Although each tunnel has its own OCID, it can be easier to use the publicIp dimension to identify a specific IPSec tunnel in the connection. The value is the public IP address of the Oracle end of the tunnel (also known as the Oracle VPN headend).

<td>Number of packets dropped at the Oracle end of the connection. Dropped packets indicate a misconfiguration in some part of the overall system. Check if there's been a change to the configuration of your VCN, the IPSec VPN, or your CPE.</td>
<td></td>
</tr>
</tbody>
</table>

#### Using the Console

To view default metrics charts for an individual tunnel in an IPSec connection

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click VPN Connections.
2. Click the IPSec connection to view its details.
3. Click the tunnel you're interested in to view its details and default metrics charts.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for all IPSec connections in a compartment

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the IPSec connection you're interested in.
3. For Metric Namespace, select oci_vpn.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Each IPSec tunnel is a single line in a given chart. The tunnel is identified in the chart by the public IP address of the Oracle end of the tunnel.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

#### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

#### VPN Connect Troubleshooting

Create a service request Ask the community

This topic covers the most common troubleshooting issues for VPN Connect. Some suggestions assume that you are a network engineer with access to your CPE device's configuration.
Log Messages

Viewing log messages generated for various operational aspects of VPN Connect can be a valuable aid in troubleshooting many of the issues presented during operation. Enabling and accessing the VPN Connect log messages can be done via VPN Connect or the Logging Service.

- For an overview of the Logging Service in general, refer to Logging Overview on page 2574
- For details on enabling and accessing the VPN Connect log messages via the logging service, refer to Service Logs on page 2591
- For details on enabling and accessing the VPN Connect log messages via the Networking service, refer to Viewing Your VPN Connect Log Messages on page 3161
- For details on the VPN Connect log message schema, refer to Details for VPN Connect on page 2615

Tunnel Flapping

Interesting traffic at all times: In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

Multiple IPSEC Connections: You can use two IPSec connections for redundancy. If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

Encryption Domain: The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Local IKE identifier: Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Maximum Transmission Unit (MTU): The standard internet MTU size is 1500 bytes. For more information on how to determine your MTU please see Overview of MTU on page 3329.

CPE Configuration

Local IKE identifier: Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as cpe.example.com. For instructions, see Changing the CPE IKE Identifier That Oracle Uses on page 3158.

Cisco ASA: Policy Based: Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

Multiple Tunnels If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.
**Encryption Domain Issues**

The Oracle VPN headends use route-based tunnels, but can work with policy-based tunnels with some caveats. See Encryption domains for policy-based tunnels on page 2948 for full details.

**Stateful security list rules:** If you're using stateful security list rules (for TCP, UDP, or ICMP traffic), you don't need to ensure that your security list has an explicit rule to allow ICMP type 3 code 4 messages because the Networking service tracks the connections and automatically allows those messages. Stateless rules require an explicit ingress security list rule for ICMP type 3 code 4 messages. Confirm that the instance firewalls are set up correctly.

**General VPN Connect Issues**

**IPSec tunnel is DOWN**

Check these items:

- **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:
  
  List of configurations
  
  - Verified CPE Devices on page 2969
  - Using the CPE Configuration Helper on page 2970
  - Checkpoint:
    - Check Point: Route-Based on page 2972
    - Check Point: Policy-Based on page 2997
  - Cisco ASA:
    - Cisco ASA: Route-Based on page 3020
    - Cisco ASA: Policy-Based on page 3032
  - Cisco IOS on page 3046
  - FortiGate on page 3058
  - Furukawa Electric on page 3072
  - Juniper MX on page 3076
  - Juniper SRX on page 3089
  - Libreswan on page 3102
  - NEC IX Series on page 3110
  - Openswan on page 3119
  - Palo Alto on page 3120
  - WatchGuard on page 3153
  - Yamaha RTX Series on page 3153

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

- **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see Overview of the IPSec VPN Components on page 2936.
**IPSec tunnel is UP, but no traffic is passing through**

Check these items:

- **Phase 2 (IPSec) configuration:** Confirm that the phase 2 (IPSec) parameters are configured correctly on your CPE device. See the configuration appropriate for your CPE device:
  
  List of configurations
  
  - Verified CPE Devices on page 2969
  - Using the CPE Configuration Helper on page 2970
  - Checkpoint:
    - Check Point: Route-Based on page 2972
    - Check Point: Policy-Based on page 2997
  - Cisco ASA:
    - Cisco ASA: Route-Based on page 3020
    - Cisco ASA: Policy-Based on page 3032
  - Cisco IOS on page 3046
  - FortiGate on page 3058
  - Furukawa Electric on page 3072
  - Juniper MX on page 3076
  - Juniper SRX on page 3089
  - Libreswan on page 3102
  - NEC IX Series on page 3110
  - Openswan on page 3119
  - Palo Alto on page 3120
  - WatchGuard on page 3153
  - Yamaha RTX Series on page 3153
  - **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
  - **Firewall rules:** Ensure that your firewall rules allow both ingress and egress traffic with the Oracle VPN headend IPs and the VCN CIDR block.
  - **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.
  - **Cisco ASA:** Do not use the originate-only option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels:
    ```
    crypto map <map name> <sequence number> set connection-type originate-only
    ```

**IPSec tunnel is UP, but traffic is passing in only one direction**

Check these items:

- **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.
  - **Single tunnel preferred:** If you want to use only one of the tunnels, ensure that you have the proper policy or routing in place on the CPE to prefer that tunnel.
  - **Multiple IPSec connections:** If you have multiple IPSec connections with Oracle, make sure to specify more specific static routes for the preferred IPSec connection.
  - **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
• **Firewall rules:** Ensure that your firewall rules allow traffic in both directions with the Oracle VPN headend IPs and the VCN CIDR block.

**Troubleshooting an IPSec VPN with a Policy-Based Configuration**

**IPSec tunnel is DOWN**

Check these items:

• **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

  List of configurations
  
  • **Verified CPE Devices** on page 2969
  • **Using the CPE Configuration Helper** on page 2970
  • **Checkpoint:**
    • **Check Point: Route-Based** on page 2972
    • **Check Point: Policy-Based** on page 2997
  • **Cisco ASA:**
    • **Cisco ASA: Route-Based** on page 3020
    • **Cisco ASA: Policy-Based** on page 3032
  • **Cisco IOS** on page 3046
  • **FortiGate** on page 3058
  • **Furukawa Electric** on page 3072
  • **Juniper MX** on page 3076
  • **Juniper SRX** on page 3089
  • **Libreswan** on page 3102
  • **NEC IX Series** on page 3110
  • **Openswan** on page 3119
  • **Palo Alto** on page 3120
  • **WatchGuard** on page 3153
  • **Yamaha RTX Series** on page 3153

• **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

• **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see **Overview of the IPSec VPN Components** on page 2936.

• **Cisco ASA:** Do not use the `originate-only` option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels: `crypto map <map name> <sequence number> set connection-type originate-only`
IPSec tunnel is UP but keeps flapping

Check these items:

- **Initiation of connection**: Ensure that your CPE device is initiating the connection.
- **Local and remote proxy IDs**: If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

- **Interesting traffic at all times**: In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

IPSec tunnel is UP but traffic is unsteady

Check these items:

- **Local and remote proxy IDs**: If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Local Proxy ID</th>
<th>Remote Proxy ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANY (or 0.0.0.0/0)</td>
<td>ANY (or 0.0.0.0/0)</td>
</tr>
<tr>
<td>2</td>
<td>On-premises CIDR (an aggregate that covers all the subnets of interest)</td>
<td>VCN's CIDR</td>
</tr>
</tbody>
</table>

- **Interesting traffic at all times**: In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it. Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

BGP Session Troubleshooting for VPN Connect

**BGP status is DOWN**

Check these items:

- **IPSec status**: For the BGP session to be up, the IPSec tunnel itself must be up.
- **BGP address**: Verify that both ends of the tunnel are configured with the correct BGP peering IP address.
- **ASN**: Verify that both ends of the tunnel are configured with the correct BGP local ASN and Oracle BGP ASN. Oracle’s BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle’s BGP ASN on page 154.
- **MD5**: Verify that MD5 authentication is disabled or not configured on your CPE device. The Oracle IPSec VPN does not support MD5 authentication.
• **Firewalls**: Verify that your on-premises firewall or access control lists are not blocking the following ports:
  - TCP port 179 (BGP)
  - UDP port 500 (IKE)
  - IP protocol port 50 (ESP)

If your CPE device's firewall is blocking TCP port 179 (BGP), the BGP neighborship state will always be down. Traffic cannot flow through the tunnel because the CPE device and Oracle router do not have any routes.

### BGP status is flapping

Check these items:

- **IPSec status**: For the BGP session to be up and not flapping, the IPSec tunnel itself must be up and not flapping.
- **Maximum prefixes**: Verify that you are advertising no more than 2000 prefixes. If you're advertising more, BGP won't be established.

### BGP status is UP, but no traffic is passing through

Check these items:

- **VCN security lists**: Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
- **Correct routes on both ends**: Verify that you have received the correct VCN routes from Oracle and the CPE device is using those routes. Likewise, verify that you are advertising the correct on-premises network routes over the IPSec VPN, and the VCN route tables use those routes.

### BGP status is UP, but traffic is passing in only one direction

Check these items:

- **VCN security lists**: Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
- **Firewalls**: Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.
- **Asymmetric routing**: Oracle uses asymmetric routing. If you have multiple IPSec connections, ensure that your CPE device is configured for asymmetric route processing.
- **Redundant connections**: If you have redundant IPSec connections, ensure that they're both advertising the same routes.

### Troubleshooting Redundant VPN Connections

Remember these important notes:

- FastConnect uses BGP dynamic routing. IPSec connections can use either static routing or BGP, or a combination.
- For important details about routing and preferred routes when using redundant connections, see [Routing for the Oracle IPSec VPN](#) on page 2934.
- You can use two IPSec connections for redundancy. If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

### IPSec and FastConnect are both set up, but traffic is only passing through IPSec

Ensure that you use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in [Routing for the Oracle IPSec VPN](#) on page 2934.
Two on-premises data centers each have an IPSec connection to Oracle, but only one is passing traffic

Verify that both IPSec connections are up and ensure that you have asymmetric route processing enabled on the CPE.

If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

For more information about this type of setup, see Example Layout with Multiple Geographic Areas on page 2965.

FastConnect

The following topics have information about setting up Oracle Cloud Infrastructure FastConnect between your on-premises network and virtual cloud network (VCN):

- FastConnect Overview on page 3173
- FastConnect Requirements on page 3181
- FastConnect Redundancy Best Practices on page 3185
- Routing Details for Connections to Your On-Premises Network on page 2942
- FastConnect: With an Oracle Partner on page 3192
- FastConnect: With a Third-Party Provider on page 3200
- FastConnect: Colocation with Oracle on page 3210
- FastConnect Metrics on page 3236
- FastConnect Troubleshooting on page 3241

FastConnect Overview

Oracle Cloud Infrastructure FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

Uses for FastConnect

With FastConnect, you can choose to use private peering, public peering, or both.

- **Private peering**: To extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud, or a lift and shift scenario). Communication across the connection is with IPv4 private addresses (typically RFC 1918).
- **Public peering**: To access public services in Oracle Cloud Infrastructure without using the internet. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, or public load balancers in your VCN. Communication across the connection is with IPv4 public IP addresses. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection. For a list of the services available with public peering, see FastConnect Supported Cloud Services. For a list of the public IP address ranges (routes) that Oracle advertises, see FastConnect Public Peering Advertised Routes on page 3219.

In general it's assumed you'll use private peering, and you might also use public peering. Most of this documentation is relevant to both, with specific details called out for private versus public.

If you choose to have multiple paths from your on-premises network to Oracle, see Routing Details for Connections to Your On-Premises Network on page 2942.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
How and Where to Connect

With FastConnect, there are different connectivity models to choose from.

Oracle Partners

- List of Oracle Cloud Infrastructure FastConnect partners
- Port speeds in 1-Gbps and 10-Gbps increments
- Instructions for integrating: FastConnect: With an Oracle Partner on page 3192

Third-Party Provider

- Port speed of 1 Gbps or 10 Gbps per cross-connect
- Instructions for integrating: FastConnect: With a Third-Party Provider on page 3200

Colocation with Oracle in an Oracle Cloud Infrastructure FastConnect Location

- List of Oracle Cloud Infrastructure FastConnect locations
- Port speed of 1 Gbps or 10 Gbps per cross-connect
- Instructions for integrating: FastConnect: Colocation with Oracle on page 3210

The following table summarizes several important requirements for each connectivity model.

<table>
<thead>
<tr>
<th>Requirement</th>

**Networking**

**Concepts**

Here are some important concepts to understand (also see the following diagrams):

**FastConnect**

The general concept of a connection between your existing network and Oracle Cloud Infrastructure over a private physical network instead of the internet.

**FastConnect location**

A specific Oracle data center where you can connect to Oracle Cloud Infrastructure.

**METRO AREA**

A geographical area (for example, Ashburn) with multiple FastConnect locations. All locations in a metro area connect to the same set of availability domains for resiliency if there is failure in a single location.

**ORACLE PARTNER**

A network service provider that has integrated with Oracle in a FastConnect location. See the list of the Oracle partners in How and Where to Connect on page 3174. If your provider is in the list, see FastConnect: With an Oracle Partner on page 3192.

**THIRD-PARTY PROVIDER**

A network service provider that is NOT on the list of Oracle partners in How and Where to Connect on page 3174. If you have a third-party provider and want to use FastConnect, see FastConnect: With a Third-Party Provider on page 3200.

**COLOCATION**

The situation where your equipment is deployed into a FastConnect location. If your network service provider is not on the list of Oracle partners in How and Where to Connect on page 3174, you must colocate.

**CROSS-CONNECT**

In a colocation or third-party provider scenario, this is the physical cable connecting your existing network to Oracle in the FastConnect location.

**CROSS-CONNECT GROUP**

In a colocation or third-party provider scenario, this is a link aggregation group (LAG) that contains at least one cross-connect. You can add more cross-connects to a cross-connect group as your bandwidth needs increase. This is applicable only for colocation.

**VIRTUAL CLOUD NETWORK (VCN)**

Your virtual network in Oracle Cloud Infrastructure. You can use a VCN to extend your infrastructure into the cloud. For more information, see VCNs and Subnets on page 2821.

**DYNAMIC ROUTING GATEWAY (DRG)**

A virtual edge router attached to your VCN. Necessary for private peering. The DRG is a single point of entry for private traffic coming in to your VCN, whether it's over FastConnect or a VPN Connect link. After creating the DRG, you must attach it to your VCN and add a route for the DRG in the VCN's route table to enable traffic flow. Instructions for everything are included in the sections that follow.

**VIRTUAL CIRCUIT**

An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure. Private virtual circuits support private peering, and public virtual circuits support public peering (see Uses for FastConnect on page 3173). Each virtual circuit is made up of information shared between you and Oracle (and also a partner if you're connecting through an Oracle partner). You could have multiple private virtual...
circuits, for example, to isolate traffic from different parts of your organization (one virtual circuit for 10.0.1.0/24; another for 172.16.0.0/16), or to provide redundancy.

**Basic Network Diagrams**

The diagrams in this section introduce the basic logical and physical connections involved in FastConnect. Details specific to private versus public peering are called out.

**General Concept of FastConnect**

The following diagram illustrates the two ways to connect to Oracle with FastConnect: either through colocation with Oracle in the FastConnect location, or through an Oracle partner. In both cases, the connection goes between the edge of your existing network and Oracle.

**Physical Connection**

The next two diagrams give more detail about the physical connections. They also show the metro area that contains the FastConnect location, and a VCN within an Oracle Cloud Infrastructure region.
The first diagram shows the colocation scenario, with your physical connection to Oracle within the FastConnect location.

The next diagram shows a scenario with either an Oracle partner or third-party provider. It shows your physical connection to the provider, and the provider's physical connection to Oracle within the FastConnect location.

**Logical Connection: Private Virtual Circuit**

The next two diagrams show a private virtual circuit, which is a single, logical connection between your edge and Oracle Cloud Infrastructure by way of your DRG. Traffic is destined for private IP addresses in your VCN.
The first diagram shows the colocation scenario.

![First Diagram]

The next diagram shows the scenario with either an Oracle partner or third-party provider.

![Second Diagram]

**Logical Connection: Public Virtual Circuit**

A public virtual circuit gives your existing network access to Oracle services in Oracle Cloud Infrastructure. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, and public load balancers in your VCN. All communication across a public virtual circuit uses public IP addresses. For a list of services available with FastConnect public peering, see [FastConnect Supported Cloud Services](#). For a list of the public IP address ranges (routes) that Oracle advertises, see [FastConnect Public Peering Advertised Routes](#) on page 3219.
The first diagram shows the colocation scenario with both a private virtual circuit and a public virtual circuit. Notice that the DRG is not involved with the public virtual circuit, only the private virtual circuit.

Here are a few basics to know about public virtual circuits:

- You choose which of your organization's public IP prefixes you want to use with the virtual circuit. All prefix sizes are allowed. Oracle verifies your organization's ownership of each prefix before sending any traffic for it across the connection. Oracle's verification for a given prefix can take up to three business days. You can get the status of the verification of each prefix in the Oracle Console or API. **Oracle begins advertising the Oracle Cloud Infrastructure public IP addresses across the connection only after successfully verifying at least one of your public prefixes.**
- Configure your firewall rules to allow traffic coming from the Oracle public IP addresses.
- Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private...
access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 2942.

- You can add or remove public IP prefixes at any time by editing the virtual circuit. If you add a prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

**Oracle Partner Scenario: BGP Session to Either Oracle or the Oracle Partner**

This section is applicable if you're using FastConnect through an Oracle partner. A Border Gateway Protocol (BGP) session is established from your edge, but where it goes depends on which Oracle partner you use.

**Tip:**

For simplicity, the following diagrams show only a private virtual circuit. However, the location of the BGP session is the same for a public virtual circuit.

**To Oracle:** With some of the Oracle partners, the BGP session goes from your edge to Oracle, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are asked to provide basic BGP peering information (see General Requirements on page 3182).

**To the Oracle partner:** With other Oracle partners, your BGP session goes from your edge to the partner's, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are NOT asked for any BGP session information. Instead, you share BGP information with your Oracle partner. Notice that there's a separate BGP session that the partner establishes with Oracle.
To use FastConnect if you do not own a Public ASN or Public IP Address

If you use a Public ASN or Public IP Address loaned or leased from a third-party source, your third-party source must provide a Letter of Authorization (LOA) on your behalf before Oracle can allow the completion of FastConnect configuration.

The following additional steps are required to obtain approval when configuring public peering virtual connections:

1. Obtain an LOA from the third-party source that authorizes the Customer to use the Public ASN and or Public IP address. The LOA must contain:
   - Customer Name approved to the use the Public IP Address and Public ASN
   - The range of the Public IP Addresses and or the Public ASN must be explicitly listed
   - The third-party source who owns the Public IP Addresses and or the Public ASN
   - Third-party source authorization authority signatory
   - Contact email, phone number and address of third-party source
   - Your enterprise's contact email and phone number
   - Date of authorization and validity

2. Using the Console, open a service request on the tenancy and region where you wish to use the third-party provided Public ASN and Public IP Address.

3. Attach the LOA to the service request.

Once the service request is opened and the LOA is approved, Oracle will authorize the use of the Public ASN and or Public IP Address.

FastConnect with Access to Multiple VCNs

You can use a single FastConnect to access multiple VCNs. Different network scenarios are available depending on your needs and which FastConnect connectivity model you use. For more information, see these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region on page 2780: This scenario can be used with either FastConnect or VPN Connect. It involves a single DRG, and multiple VCNs in a hub-and-spoke layout.
- FastConnect with Multiple DRGs and VCNs on page 2816: This scenario can be used only with FastConnect, and only if you're using a third-party provider or colocated with Oracle. It involves multiple DRGs and private virtual circuits.

What's Next?

See these topics to get started:

- FastConnect Requirements on page 3181
- FastConnect Redundancy Best Practices on page 3185
- Routing Details for Connections to Your On-Premises Network on page 2942
- FastConnect: With an Oracle Partner on page 3192
- FastConnect: With a Third-Party Provider on page 3200
- FastConnect: Colocation with Oracle on page 3210

FastConnect Requirements

This topic covers the requirements for implementing FastConnect.

For general information about FastConnect, see the articles listed for FastConnect on page 3173.

Before Getting Started: Learn and Plan

Here are basic things you need to do before getting started with FastConnect:

- **FastConnect concepts:** Be familiar with the basic concepts covered in FastConnect Concepts.
- **Limits increase:** If you are colocated with Oracle, you must ask Oracle to increase your account limits for cross-connects. By default, these limits are initially set to 0, and a request to create a cross-connect will fail. For instructions, see Requesting a Service Limit Increase on page 217. In your request, indicate the region where you need the resources. It can take a couple of business days for the limit increase to take effect.
Networking

- **Hardware and routing requirements**: Review the hardware and routing requirements.
- **Tenancy setup and compartment design**: If you haven't yet, set up your tenancy. Think about who needs access to Oracle Cloud Infrastructure and how. For more information, see “Setting Up Your Tenancy” in the Oracle Cloud Infrastructure Getting Started Guide. Specifically for FastConnect, see Required IAM Policy on page 3184 to understand the policy required to work with FastConnect components.
- **Cloud network design**: Design your virtual cloud network (VCN), including how you want to allocate your VCN's subnets, define security list rules, define route tables, set up load balancers, and so on. For more information, see Networking on page 2746.
- **Redundancy**: Think through your overall redundancy model to ensure your network can handle planned maintenance by Oracle or your organization, and unexpected failures of the various components. For best practices, see FastConnect Redundancy Best Practices on page 3185.
- **Public IP prefixes**: If you plan to set up a public virtual circuit, get the list of the public IP prefixes that you want to use with the connection. Oracle must validate your organization's ownership of each of the prefixes before advertising each one over the connection.
- **Cloud network setup**: Set up your VCN, subnets, DRG, security lists, IAM policies, and so on, according to your design.

**General Requirements**

Before getting started with FastConnect, ensure that you meet the following requirements:

- Oracle Cloud Infrastructure account, with at least one user with appropriate Oracle Cloud Infrastructure Identity and Access Management (IAM) permissions (for example, a user in the Administrators group).
- Network equipment that supports Layer 3 routing using BGP.
- For colocation with Oracle: Ability to connect using single mode fiber in your selected FastConnect location. Also see Hardware and Routing Requirements on page 3182.
- For connection to an Oracle partner: At least one physical network connection with the partner. Also see Hardware and Routing Requirements on page 3182.
- For connection to a third-party provider: At least one physical connection with the provider. Also see Hardware and Routing Requirements on page 3182.
- For private peering only: At least one existing DRG set up for your VCN.
- For public peering only: The list of public IP address prefixes that you want to use with the connection. Oracle will validate your ownership of each prefix.

**Important:**

If you intend to colocate with Oracle, you must ask Oracle to increase your account limits for cross-connects. These default limits are initially set to 0, and a without a specific request for a limit increase you won’t be able to create a valid cross-connect. For instructions on placing this request, see Requesting a Service Limit Increase on page 217. In your request, indicate the region where you need the resources. It can take a couple of business days for the limit increase to take effect.

**Hardware and Routing Requirements**

*If you're using an Oracle partner*

Here are general routing requirements for FastConnect. These are particularly relevant if your BGP session is between your edge and Oracle.

- **IP addressing supported**: IPv4. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.
- **P2P IP addresses**:
  - For public virtual circuits, Oracle specifies the IP addresses.
  - For private virtual circuits where your BGP session is between your edge and Oracle, you specify these addresses (/30 or /31, and one pair per virtual circuit). If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.
• **Maximum IP MTU:** 9000
• **Routing protocol:** BGPv4
• **BGP prefix limit:** For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.
• **BGP ASN:** 2-byte or 4-byte ASNs are supported, except for those listed in *Special-Purpose Autonomous System (AS) Numbers*. Public virtual circuits require a public ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the US Government Cloud, see Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171. BGP ASN 65534 is not available for you to use with FastConnect and VPN. All other private ASNs in the 64512 - 65533 (inclusive) range defined in RFC-6996 can be used normally.
• **BGP MD5 authentication:** Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
• **BGP keep-alive interval:** 60s
• **BGP hold-time interval:** 180s

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.</td>
</tr>
</tbody>
</table>

*If you’re colocating in a FastConnect location or using a third-party provider*

For the cross-connect group and cross-connects:

• **Bandwidth (three choices):**
  • 1 Gbps:
    • 1000Base-LX, 10-km range, 1310 nm
    • **You must configure your edge device so that auto-negotiation is OFF**
    • Minimum Rx level > -15 dBm
  • 10 Gbps:
    • 10 GbE, LR (10-km range), 1310 nm
    • Minimum Rx level > -12 dBm
  • 100 Gbps:
    • 100GBASE, LR4 QSFP28 (10-km range), WDM optics
    • CrossConnect Groups (LAG/LACP) are not currently supported
    • Minimum Rx level > -12 dBm on each of four lanes

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 Gbps speeds are available to select customers only. Please work with your account representative to gain access to these ports.</td>
</tr>
</tbody>
</table>

• **General:**
  • Single Mode Fiber
  • Duplex LC connectors

• **Redundancy:**
  • Device redundancy highly recommended
  • In some regions, location redundancy is available and recommended

• **Capacity:**
  • 1 GbE: Minimum 1, Maximum 8
  • 10 GbE: Minimum 1, Maximum 8
  • 100 GbE: 1 only

• **LAG protocol:** LACP with short timers (3 @ 1s). If your router doesn't support LAG, you can set up a single non-LAG cross-connect.
• **VLAN tagging**: 802.1q (single tag)
• **VLAN range**: 100-4094 (you assign the VLANs)
• **Maximum interface MTU**: 9196 (include 4-byte FCS trailer)

For routing:

• **IP addressing supported**: IPv4. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses on page 2889.

• **P2P IP addresses**:
  • For public virtual circuits, Oracle specifies the IP addresses.
  • For private virtual circuits, you specify the addresses (a /30 or /31). You need one pair of IP addresses per private virtual circuit. If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.

• **Maximum IP MTU**: 9000
• **Routing protocol**: BGPv4
• **BGP prefix limit**: For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.
• **BGP ASN**: 2-byte or 4-byte ASNs are supported, except for those listed in Special-Purpose Autonomous System (AS) Numbers. Public virtual circuits require a public ASN. Oracle's BGP ASN is 31898. For the US Government Cloud, see Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171. BGP ASN 65534 is not available for you to use with FastConnect and VPN. All other private ASNs in the 64512 - 65533 (inclusive) range defined in RFC-6996 can be used normally.

• **BGP MD5 authentication**: Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
• **BGP keep-alive interval**: 60s
• **BGP hold-time interval**: 180s

**Tip:**
By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

**Required IAM Policy**

*If you're using an Oracle partner*

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, and virtual circuits, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions below. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```bash
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To only create and manage a virtual circuit, you would need a policy like this:

```bash
Allow group VirtualCircuitAdmins to manage drgs in tenancy
Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

*If you're colocating in a FastConnect location or using a third-party provider*

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, virtual circuits, and cross-connects, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions below. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```bash
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To only create and manage a virtual circuit, you would need a policy like this:

```bash
Allow group VirtualCircuitAdmins to manage drgs in tenancy
Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.
policy) to perform all the instructions that follow. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To only create and manage cross-connects, cross-connect groups, and virtual circuits, you would need a policy like this:

```
Allow group FastConnectAdmins to manage drgs in tenancy
Allow group FastConnectAdmins to manage cross-connects in tenancy
Allow group FastConnectAdmins to manage cross-connect-groups in tenancy
Allow group FastConnectAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Identifiers for Your FastConnect Resources**

Your resources have several identifiers:

- **Name for the overall connection:** When you create a new FastConnect connection, you can give it a descriptive name of your choice. If you don't specify one, Oracle automatically assigns a name to the connection.

- **Reference name for each cross-connect:** Each cross-connect has an optional reference name. If you set up a cross-connect, Oracle recommends that you fill in the reference name with the identifier for the cross-connect's physical fiber cable. That makes it easier for Oracle to help if future troubleshooting is required for the connection. After cabling is done and you have the identifier from the data center, you can add it to the cross-connect's information in the Oracle Console.

- **OCID for each resource:** Each cross-connect group, cross-connect, and virtual circuit has its own unique Oracle-assigned identifier called an OCID.

**What's Next?**

**FastConnect Redundancy Best Practices**

This topic covers best practices for redundancy when implementing FastConnect.

For general information about FastConnect, see FastConnect on page 3173.

**Overview**

In general, you should design your network to achieve high availability (HA). In addition, you should be prepared for these types of disruptions:

- Regularly scheduled maintenance by your organization, your provider (if you're using one), or Oracle.
- Unexpected failures on the part of your networking components, your provider, or Oracle. Failures are rare, but you should plan for them.

For redundancy, Oracle provides:

- Multiple providers for each region
• Two **FastConnect locations** for each of the following regions (all other regions have a single FastConnect location)
  - Germany Central (Frankfurt)
  - UK South (London)
  - US East (Ashburn)
  - US West (Phoenix)
• Two routers in each FastConnect location
• Multiple physical connections between each Oracle partner and Oracle (for a given region)

The redundancy best practices depend on which connectivity model you use. Also see How and Where to Connect on page 3174.

**If You Use an Oracle Partner**

Connectivity model:
• **FastConnect: With an Oracle Partner** on page 3192

Oracle handles redundancy of the physical connections between the partner and Oracle, and the redundancy of routers in the FastConnect locations. You should handle redundancy of the physical connection between your existing network and the Oracle partner.

The remaining best practices depend on the partner you're using, and details of the BGP session from your edge:
• For some partners, the BGP session from your edge goes to Oracle. For redundancy best practices, see the next section.
• For other partners, the BGP session from your edge goes to the Oracle partner. For redundancy best practices, see Oracle Partner Scenario: Your BGP Session Is to the Oracle Partner on page 3187.

For information about the two scenarios, see Basic Network Diagrams on page 3176.

**Oracle Partner Scenario: Your BGP Session Is to Oracle**

At a minimum, each Oracle partner has two separate physical connections to Oracle. Set up one virtual circuit on one physical connection (as primary), and the other virtual circuit on another physical connection (as secondary). The following diagram illustrates two virtual circuits, each going to a different router in a single FastConnect location. If the region has a second location, your partner's second physical connection might instead go to that location.

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of two virtual circuits with the same Oracle partner, but in a second FastConnect location in a nearby region. Notice that you must have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
If you also want provider diversity, repeat your entire setup with another provider in each region that you're using.

**Oracle Partner Scenario: Your BGP Session Is to the Oracle Partner**

In this scenario, the BGP session *from your edge* goes to the Oracle partner (as shown in the following diagram). Separate from your BGP session, the Oracle partner has *its own* BGP sessions with Oracle (between the partner's edge and Oracle's edge). The virtual circuit is a logical connection that goes from your edge to the Oracle edge.

The partner has two separate physical connections to Oracle. You create one virtual circuit with the partner. In this scenario, the virtual circuit is automatically designed to be redundant and diverse. The virtual circuit has two separate BGP sessions between the partner and Oracle, each on a different physical connection. The following diagram shows the two separate BGP sessions for the single virtual circuit as dotted lines.
Separately, you must ensure that the connection between your edge and the partner is redundant and diverse.

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of a virtual circuit with the same Oracle partner, but in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
If You Use a Third-Party Provider or Colocate with Oracle

Connectivity models:

- FastConnect: With a Third-Party Provider on page 3200
- FastConnect: Colocation with Oracle on page 3210

Oracle handles redundancy of the Oracle routers in the FastConnect locations. You should handle redundancy of the physical connection between your existing network and Oracle.

To do this, create two physical connections to Oracle, one for each FastConnect location that serves the region. This means that in the Oracle Console, you set up two separate FastConnect connections. You then create two virtual circuits. Set up the first one on the first physical connection (the first FastConnect connection), and the second one on the second physical connection. The following diagram shows the general setup.
Networking

You might prefer to connect to only a single FastConnect location because of cost concerns, or if the region has only a single FastConnect location. In that case, create two physical connections and ensure each goes to a different Oracle router in that FastConnect location. You can do this in the Oracle Console when you set up the second physical connection. You can specify the proximity of that connection to other FastConnect connections in that location. For example, the following image shows how to request that your second physical connection (which is a cross-connect group) is created on a different router than your first connection in that FastConnect location (called MyConnection-1).

You must scale the bandwidth of both physical connections evenly, and by using a cross-connect group (LAG) for each connection. Imagine that you have two individual 10 Gbps cross-connects in a single FastConnect location (each to a different Oracle router for redundancy and diversity). If you need to have 20-Gbps bandwidth at a given time, you must ensure that each of your physical connections consists of a cross-connect group (LAG) to contain the cross-connect. Then you need to add another 10 Gbps cross-connect to each LAG, so that each redundant physical connection has two 10 Gbps cross-connects. FastConnect currently does not support equal-cost multi-path routing (ECMP).

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat your setup in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.
VPN Connect as Backup for FastConnect

Oracle recommends using VPN Connect as a backup for your FastConnect connection. If you do, ensure that the VPN Connect tunnels are configured to use BGP routing with a route-based VPN. Within your existing on-premises network, manipulate the routing to prefer routes learned through FastConnect over routes learned through VPN Connect. For example, use AS_Path Prepend to influence egress traffic from Oracle, and use local preference to influence egress traffic from your network.

If you are using VPN backup, review Oracle's BGP routing behavior in the table shown in Routing Preferences for Traffic from Oracle to Your On-Premises Network on page 2943.

The following diagram shows a setup with redundant FastConnect virtual circuits and redundant VPN Connect tunnels.

What’s Next?

Choose the topic that suits your situation:

- FastConnect: With an Oracle Partner on page 3192
- FastConnect: With a Third-Party Provider on page 3200
- FastConnect: Colocation with Oracle on page 3210

FastConnect: With an Oracle Partner

This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to an Oracle partner. For a summary of the different ways to connect, see the connectivity models.

If you instead want to use a network provider that is not on the list of Oracle partners, see FastConnect: With a Third-Party Provider on page 3200. Or if you want to use FastConnect by collocating with Oracle, see FastConnect: Colocation with Oracle on page 3210.

For general information about FastConnect, see FastConnect on page 3173.
Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.

Also see the sequence diagram in To get the status of your virtual circuit on page 3197.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan on page 3181. Also see FastConnect Redundancy Best Practices on page 3185.

Task 2: Set up connection to the Oracle partner

If you haven't already, start the process of ordering the connection from the Oracle partner, setting it up, and then testing it with the partner. It can take some time, depending on the partner.

Task 3: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:

- To create a DRG on page 2929
- To attach a DRG to a VCN on page 2930
• To update rules in an existing route table on page 2925

Task 4: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. If your network design includes more than one virtual circuit, complete the following steps for each one.

Instructions:
Repeat the following steps for each virtual circuit you want to create.

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). The choice of compartment, along with a corresponding IAM policy, controls who has access to the virtual circuit you're about to create.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection.
3. Click Create FastConnect.
4. Select FastConnect Partner and choose the partner from the list.
5. Click Next.
6. Enter the following for your virtual circuit:
   - Name: A friendly name that helps you track your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - Create in Compartment: Leave as is (the compartment you're currently working in).
7. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering.
Networking

(where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 3173.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway:** Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth:** Choose a value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3198).

If your BGP session goes to Oracle (see Basic Network Diagrams on page 3176), the dialog box includes other fields for the BGP session:

- **Customer BGP IP Address:** The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
- **Oracle BGP IP Address:** The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
- **Enable IPv6 Address Assignment:** Available only in the Government Cloud. For more information, see FastConnect and IPv6 on page 2897.
- **Customer BGP ASN:** The public or private ASN for your network.
- **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth:** Choose a value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3198).
  - **Public IP Prefixes:** The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
  - **Customer BGP ASN:** The public ASN for your network. Present only if your BGP session goes to Oracle (see Basic Network Diagrams on page 3176). Oracle specifies the BGP IP addresses for a public virtual circuit.
  - **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

8. **Click Create.**

The virtual circuit is created. Its OCID and a link to the partner's portal are displayed in the resulting confirmation box at the top of the page. The OCID is also available with the other virtual circuit details.

9. **Copy and paste the OCID to another location. You give it to your partner in the next task.**

The virtual circuit is listed on the FastConnect page.

Until you complete the next task and the partner does their provisioning work, the virtual circuit's Lifecycle State is PENDING PROVIDER and the BGP state is DOWN. After the partner does their work, the Lifecycle State switches to PROVISIONED. When the BGP session is established and working, the BGP state changes to UP.

**Tip:**

For a virtual circuit where your BGP session goes to the Oracle partner, the BGP state for the virtual circuit reflects the status of the separate BGP session between the Oracle partner and Oracle. For reference, see Basic Network Diagrams on page 3176.

Also see the diagram in To get the status of your virtual circuit on page 3197.

**Task 5: Give the partner information about the virtual circuit**

Contact the partner and give the OCID of each virtual circuit that you created, along with any other information the partner requests. Depending on the partner, you might do this in the partner's portal, or over the phone. The partner then configures each virtual circuit on their end to complete the connectivity.

If your partner is AT&T: After AT&T gives you the service key for your virtual circuit, create a ticket at My Oracle Support to request provisioning, and give Oracle the service key.
Task 6: Configure your edge

If your BGP session goes to Oracle: (see Basic Network Diagrams on page 3176), configure your edge (your CPE) to use the BGP peering information (see General Requirements on page 3182). Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 154. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time. Also configure the router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices on page 3185). After you successfully configure the BGP session, the virtual circuit's BGP session state changes to UP.

If your BGP session instead goes to the Oracle partner: You still need to configure your router if you haven't already. You may need to contact your partner to get the required BGP peering information. This BGP session must be up and running for FastConnect to work. Also configure your edge router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices on page 3185).

Important:

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 2942.

Task 7: Check light levels

Confirm that the light levels are good for each of your physical network connections to the partner. Don't proceed until they are.

Task 8: Confirm your interfaces are up

Confirm your side of the interfaces for the connections to the partner are up. Don't proceed until they are.

BGP Session Goes to Oracle

Task 9a: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

Task 9b: Confirm that the BGP session is established

For each virtual circuit, confirm that the BGP session is in an established state. When it is, the connection is ready to test (see Task 11: Test the connection on page 3197).

BGP Session Goes to the Partner

Task 10a: Ping the partner's edge

For each virtual circuit, ping the partner's edge. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping the partner's edge without errors.

Task 10b: Confirm the BGP session is established

Confirm the BGP session you have with the partner is in an established state. Don't proceed until it is.

Task 10c: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address (which you can get from the partner). Check the error counters and look for any dropped packets. When you can successfully ping this IP address without errors, the connection is ready to test.
Networking

Task 11: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance on page 695. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified at least one of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that only the public prefixes that Oracle has successfully verified so far are advertised on the connection.

Managing Your Virtual Circuit

To get the status of your virtual circuit

1. In the Console, go to Networking, and then click FastConnect to view your list of connections.
2. Click the virtual circuit you're interested in to view its details.

The following diagram shows the different states of the virtual circuit when you're setting it up.
To edit a virtual circuit

You can change these items for a virtual circuit:

- The name
- The bandwidth
- Which DRG it uses (for a private virtual circuit)
- The public IP prefixes (for a public virtual circuit)
- Depending on the situation, you might also have access to the BGP session information for the virtual circuit and thus can change it.
Important:

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Edit and make your changes. Avoid entering confidential information.
4. Click Save Changes.

To terminate a virtual circuit

Important:

Also terminate the connection with the partner, or else the partner may continue to bill you.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.

The virtual circuit's Lifecycle State changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Basic Network Diagrams on page 3176.

You can specify your public IP prefixes when you create the virtual circuit. See Task 4: Set up your virtual circuit on page 3194.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 3198. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving a Compartment to a Different Parent Compartment on page 2435.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 2737 for more information.

**Monitoring Your Connection**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring your connection, see FastConnect Metrics on page 3236.

**Troubleshooting**

See FastConnect Troubleshooting on page 3241.

**FastConnect: With a Third-Party Provider**

This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to a third-party network provider of their choice, and not an Oracle partner. For a summary of the different ways to connect, see the connectivity models.

If you are using an Oracle partner, see FastConnect: With an Oracle Partner on page 3192. Or, if you want to use FastConnect by colocating with Oracle, see FastConnect: Colocation with Oracle on page 3210.

For general information about FastConnect, see FastConnect on page 3173.

**Important Points and Responsibilities**

- You can use FastConnect by working with a third-party network service provider or carrier of your choice. The network provider must be capable of connecting to the Oracle routers in one of the FastConnect data center locations over single-mode fiber. For more detailed technical requirements, see Hardware and Routing Requirements on page 3182.

- Your overall connection with the third-party provider includes two parts, as illustrated in the following diagram:
  - **Part 1**: Your physical connection to the third-party provider. The rest of this topic assumes you’ve already set up this part of the overall connection.
  - **Part 2**: The physical fiber connection (cross-connect) that the third-party provider sets up in the FastConnect location data center on your behalf.

  ![Diagram](https://example.com/diagram.png)

- To obtain the Letter of Authorization (LOA) for the cross-connect, you must use the Oracle Console to **set up a cross-connect or cross-connect group**. The resulting LOA from Oracle covers part 2 of the connection in the preceding diagram.
- You must forward the LOA to your third-party provider, who is responsible for working with the data center to set up the physical cross-connect on your behalf.
• The third-party provider issues a cross-connect order with the data center facility to run fiber optics to complete the connection from the third-party provider's cage to Oracle's patch panel as described in the LOA. Typically the data center colocation staff are the ones who run the fiber optics to complete the connection.

• Each LOA is valid for only a limited time. If the physical cross-connect is not set up before the LOA's expiration, the LOA is revoked.

• **The third-party provider is responsible for charging you for the entire connection (both parts 1 and 2).** Oracle does not set up this cross-connect in the data center, does not pay for it, and does not include it in your FastConnect charges.

• The LOA specifies an Oracle demarcation point. If your network provider is located at a different demarcation point in the data center cage, they must set up the cross-connect from their demarcation point to the Oracle demarcation point.

**Getting Started with FastConnect**

The following flow chart shows the overall process of setting up FastConnect.

**Note:**

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.
Task 1: Learn and plan

If you haven’t yet, walk through the planning in Before Getting Started: Learn and Plan on page 3181. Also see FastConnect Redundancy Best Practices on page 3185.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven’t already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It’s easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:
- To create a DRG on page 2929
- To attach a DRG to a VCN on page 2930
- To update rules in an existing route table on page 2925

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.

You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).
Instructions:

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.

2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.

   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection and its components.

3. Click Create FastConnect.

4. Select Colocate with Oracle and click Next. Select this option even though a third-party provider will set up the physical connection to Oracle in the FastConnect location.

5. Enter the following items:
   - **Name:** A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).
   - **Compartment:** Leave as is (the compartment you're currently working in).
   - **Cross-Connect Type:**
     - If your router supports LAG, select Cross-Connect Group. You will create a cross-connect group (a LAG) with at least one cross-connect.
     - If your router does not support link aggregation (LAG), select Single Cross-Connect. You will create a single non-LAG cross-connect with no cross-connect group.
   - **Reference Name:** The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. You might need to get this value from your third-party provider. If you don't have it, you can add it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.
   - **Number of cross-connects:** Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
   - **Port speed:** 1 Gbps, 10 Gbps, or 100 Gbps.

   **Note:**

   100 Gbps speeds are available to select customers only. Please work with your account representative to gain access to these ports.

   - **Physical location:** The FastConnect location for this connection.
   - **Specify Router Proximity:** Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.

6. Click Create.

   The new connection is created and listed on the FastConnect page.

7. Click the new connection to see its details.

8. **Print the LOA for each cross-connect:** Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect's details, and then view and print the cross-connect's LOA. In the next task, you forward
Networking

it to your third-party provider so they can request cabling at the FastConnect location. The cross-connect's status is PENDING CUSTOMER until you complete the next few tasks.

Task 4: Forward the LOA to your third-party provider

Forward the LOA or LOAs from the preceding task to your third-party network provider so they can request cabling at the FastConnect location. Each LOA is valid for a limited time. The details are printed on the LOA.

Task 5: Check light levels

After the third-party provider completes setup of the physical cross-connect in the FastConnect location, confirm from your side that the light levels for each physical connection (cross-connect) are good (> -15 dBm). Don’t proceed until they are.

In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:

If they are not good, contact your third-party network provider.

Task 6: Confirm that your interfaces are up

For each cross-connect’s physical fiber cable, confirm your side of the interfaces are up. Don’t proceed until they are.

In the Console, you can see the status of Oracle’s side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).

If the interfaces are not up, contact your third-party network provider.
**Task 7: Activate each cross-connect**

**Summary:** When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

**Instructions:**
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click Activate.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click Edit and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time. After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

**Task 8: Set up your virtual circuit**

**Summary:** Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

**Important:**

If you want to use a single FastConnect to connect your existing network to multiple DRGs and VCNs, you must set up a different private virtual circuit for each VCN. Each virtual circuit must have a different VLAN and a different set of BGP IP addresses. For more information, see FastConnect with Multiple DRGs and VCNs on page 2816.

**Instructions:**
1. In the Console, return to the connection you created earlier. Under Resources, click Virtual Circuits.
2. Click Add Virtual Circuit.
3. Enter the following for your virtual circuit:
   - **Name:** A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment:** Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.
4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering.
Networking

(where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 3173.

• For a private virtual circuit, enter the following:

  - **Dynamic Routing Gateway**: Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3217).
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP IP Address**: The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address**: The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment**: Available only in the US Government Cloud. For more information, see FastConnect and IPv6 on page 2897.
  - **Customer BGP ASN**: The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

• For a public virtual circuit, enter the following:

  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3217).
  - **Public IP Prefixes**: The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP ASN**: The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click **Create**.

The virtual circuit is created.

The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

**Task 9: Configure your edge**

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 154. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

**Important:**

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 2942.
If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.
- If the third-party provider is performing any media conversion, LACP must be configured on the provider's device instead of your device.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

**Task 10: Ping the Oracle BGP IP address**

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

**Task 11: Confirm that the BGP session is established**

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

**Task 12: Test the connection**

**For a private virtual circuit:** You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See [Creating an Instance](page-695) on page 695. If you can, your FastConnect private virtual circuit is ready to use.

**For a public virtual circuit:**

1. Make sure that Oracle has successfully verified *at least one* of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that *only the public prefixes that Oracle has successfully verified so far* are advertised on the connection.

**Managing Your Connection**

**To get the status of your connection**

Look at the icon for the particular part of the connection that you're interested in (cross-connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

**Cross-Connect: PENDING CUSTOMER**

- You need to forward the LOA to your third-party provider so they can request cabling at the FastConnect location. See [Task 4: Forward the LOA to your third-party provider](page-3204) on page 3204.
- Or, you need to activate a cross-connect after confirming it's ready to use. See [Task 7: Activate each cross-connect](page-3205) on page 3205, but make sure you've performed tasks 5 and 6 first.

**Virtual circuit: DOWN**

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:

- You need to configure your edge. See [Task 9: Configure your edge](page-3206) on page 3206.
- Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).
The following table summarizes the different states of each component involved in the connection at different points during setup:

<table>
<thead>
<tr>
<th>Task in Setup Process</th>
<th>CCG Icon</th>
<th>CC Icon</th>
<th>VC Icon</th>
</tr>
</thead>
<tbody>

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection to view its details.
   c. Click Add Cross-Connect.
   d. Enter the following items:
      • **Name:** A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.
      • **Reference Name:** Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.
   e. Click Add.
      The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.
   f. Print the new cross-connect's LOA. You forward it to your third-party provider in the next step.
2. Perform tasks 4-7 in Getting Started with FastConnect on page 3201. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:

• The name
• The bandwidth
• Which DRG it uses (for a private virtual circuit)
• Which VLAN it uses
• The BGP session information
• The public IP prefixes (for a public virtual circuit)

**Important:**

Notes About Editing a Virtual Circuit
If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Edit and make your changes. Avoid entering confidential information.
5. Click Save Changes.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

Important:
Also terminate the connection with the data center or third-party provider, or else they may continue to bill you.

To terminate a virtual circuit

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Delete.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the last provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Cross-Connects, and then click the cross-connect to view its details.
4. Click Delete.
5. Confirm when prompted.

The cross-connect's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect group

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.
The cross-connect group's status changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Basic Network Diagrams on page 3176.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit on page 3214.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 3217. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see To move a resource to a different compartment on page 2444.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 2737 for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring your connection, see FastConnect Metrics on page 3236.

Troubleshooting

See FastConnect Troubleshooting on page 3241.

FastConnect: Colocation with Oracle

This topic is for customers who are colocated with Oracle in a FastConnect location. For a summary of the different ways to connect, see the connectivity models.

If you instead have a relationship with an Oracle partner, see FastConnect: With an Oracle Partner on page 3192. Or if you have a relationship with a third-party provider, see FastConnect: With a Third-Party Provider on page 3200.

For general information about FastConnect, see FastConnect on page 3173.
Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.

Note:

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan on page 3181. Also see FastConnect Redundancy Best Practices on page 3185.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.
Instructions:

- To create a DRG on page 2929
- To attach a DRG to a VCN on page 2930
- To update rules in an existing route table on page 2925

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.

You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).

Instructions:

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.

2. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.

   The resulting FastConnect page is where you'll create a new connection and later return to when you need to manage the connection and its components.

3. Click Create FastConnect.

4. Select Colocate with Oracle and click Next.

5. Enter the following items:

   - Name: A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).
   - Compartment: Leave as is (the compartment you're currently working in).
   - Cross-Connect Type:
     - If your router supports LAG, select Cross-Connect Group. You will create a cross-connect group (a LAG) with at least one cross-connect.
     - If your router does not support link aggregation (LAG), select Single Cross-Connect. You will create a single non-LAG cross-connect with no cross-connect group.
   - Reference Name: The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. If you don't have it, you can add it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.
   - Number of cross-connects: Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
   - Port speed: 1 Gbps, 10 Gbps, or 100 Gbps.

   **Note:**

   100 Gbps speeds are available to select customers only. Please work with your account representative to gain access to these ports.

   - Physical location: The FastConnect location for this connection.
   - Specify Router Proximity: Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.
6. Click **Create**.

   The new connection is created and listed on the FastConnect page.

7. Click the new connection to see its details.

8. **Print the LOA for each cross-connect**: Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect’s details, and then view and print the cross-connect’s LOA. In the next task, you submit it with your cabling request at the FastConnect location. The cross-connect’s status is PENDING CUSTOMER until you complete the next few tasks.

![MyConnection](image)

**Task 4: Submit LOA and request cabling in the FastConnect location**

At the FastConnect location, submit each LOA from the preceding task and request cabling for each cross-connect. Each LOA is valid for a limited time. The details are printed on the LOA.

**Task 5: Check light levels**

For each cross-connect’s physical fiber cable, confirm from your side that the light levels are good (> -15 dBm). Don’t proceed until they are.

In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:

![MyConnection](image)

**Task 6: Confirm that your interfaces are up**

For each cross-connect’s physical fiber cable, confirm your side of the interfaces are up. Don’t proceed until they are.

In the Console, you can see the status of Oracle’s side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).
Task 7: Activate each cross-connect

Summary: When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

Instructions:
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click Activate.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click Edit and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time. After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

Task 8: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

Instructions:
1. In the Console, return to the connection you created earlier. Under Resources, click Virtual Circuits.
2. Click Add Virtual Circuit.
3. Enter the following for your virtual circuit:
   - **Name**: A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment**: Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.
4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering.
Networking

(where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect on page 3173.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway**: Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3217).
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP IP Address**: The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address**: The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment**: Available only in the US Government Cloud. For more information, see FastConnect and IPv6 on page 2897.
  - **Customer BGP ASN**: The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth**: Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit on page 3217).
  - **Public IP Prefixes**: The public IP prefixes that you want Oracle to receive over the connection. All prefix sizes are allowed. You can enter a comma-separated list of prefixes, or one per line.
  - **VLAN**: The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP ASN**: The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
  - **Use a BGP MD5 Authentication Key (optional)**: Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click Create.

The virtual circuit is created.

The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

**Task 9: Configure your edge**

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 154. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

**Important:**

For a public virtual circuit: Your existing network can receive advertisements for Oracle’s public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give FastConnect higher preference than your ISP. You must configure your edge appropriately so that traffic uses your desired path to receive the benefits of FastConnect. This is particularly important if you decide to also set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network on page 2942.
If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.
- If the third-party provider is performing any media conversion, LACP must be configured on the provider's device instead of your device.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

**Task 10: Ping the Oracle BGP IP address**

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

**Task 11: Confirm that the BGP session is established**

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

**Task 12: Test the connection**

**For a private virtual circuit:** You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance on page 695. If you can, your FastConnect private virtual circuit is ready to use.

**For a public virtual circuit:**

1. Make sure that Oracle has successfully verified at least one of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that only the public prefixes that Oracle has successfully verified so far are advertised on the connection.

**Managing Your Connection**

**To get the status of your connection**

Look at the icon for the particular part of the connection that you're interested in (cross-connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

**Cross-Connect: PENDING CUSTOMER**

- You need to submit the LOA and request cabling at the FastConnect location. See Task 4: Submit LOA and request cabling in the FastConnect location on page 3213.
- Or, you need to activate a cross-connect after confirming it's ready to use. See Task 7: Activate each cross-connect on page 3214, but make sure you've performed tasks 5 and 6 first.

**Virtual circuit: DOWN**

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:

- You need to configure your edge. See Task 9: Configure your edge on page 3215.
- Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).
The following table summarizes the different states of each component involved in the connection at different points during setup:

<table>
<thead>
<tr>
<th>Task in Setup Process</th>

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection to view its details.
   c. Click Add Cross-Connect.
   d. Enter the following items:
      • **Name**: A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.
      • **Reference Name**: Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.
   e. Click Add.
      The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.
   f. Print the new cross-connect's LOA. You submit it with your cabling order in the next step.
2. Perform tasks 4-7 in Getting Started with FastConnect on page 3211. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:
- The name
- The bandwidth
- Which DRG it uses (for a private virtual circuit)
- Which VLAN it uses
- The BGP session information
- The public IP prefixes (for a public virtual circuit)

**Important:**

Notes About Editing a Virtual Circuit
If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and may cause the related BGP session to go down. After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Edit and make your changes. Avoid entering confidential information.
5. Click Save Changes.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

Important:

Also terminate the connection with the data center or third-party provider, or else they may continue to bill you.

To terminate a virtual circuit

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Virtual Circuits, and then click the virtual circuit to view its details.
4. Click Delete.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the last provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Cross-Connects, and then click the cross-connect to view its details.
4. Click Delete.
5. Confirm when prompted.

The cross-connect's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect group

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click Delete.
4. Confirm when prompted.
The cross-connect group's status changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Basic Network Diagrams on page 3176.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit on page 3214.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit on page 3217. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress**: Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed**: Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed**: Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see To move a resource to a different compartment on page 2444.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Find the connection in the list, click the the Actions icon (three dots), and then click Move Resource.
3. Choose the destination compartment from the list.
4. Click Move Resource.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 2737 for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about monitoring your connection, see FastConnect Metrics on page 3236.

Troubleshooting

See FastConnect Troubleshooting on page 3241.

FastConnect Public Peering Advertised Routes

This topic lists the public IP address ranges (routes) that are advertised to your on-premises network by way of FastConnect public peering (a public virtual circuit).

When you connect with FastConnect to Oracle Cloud Infrastructure in a particular region, the routes advertised over the public virtual circuit may include routes for other Oracle Cloud Infrastructure regions, and for specific Oracle Cloud Infrastructure Classic regions. If you do not own a Public ASN or Public IP Address, you may need to review To use FastConnect if you do not own a Public ASN or Public IP Address on page 3181. The following sections list the regional routes that are advertised over the public virtual circuit.
<table>
<thead>

FastConnect Metrics

You can monitor the health, capacity, and performance of your FastConnect connection by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

This topic describes the metrics emitted by the metric namespace oci_fastconnect.

Resources: cross-connect groups, virtual circuits
Overview of Metrics: **oci_fastconnect**

Metrics are available for multiple resources in the FastConnect connection. The metrics help you determine quickly whether your FastConnect connection is up, how much data is flowing over the connection, and whether packets are being dropped for unexpected errors.

FastConnect offers different **connectivity models:**

- **Connect with an Oracle partner:** Metrics are available for virtual circuits in the connection.
- **Connect with a third-party provider:** Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.
- **Colocate with Oracle:** Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.

A cross-connect group (LAG) contains one or more cross-connects. If there are multiple and one goes down, the cross-connect group stays up, but the group might experience a lower overall bandwidth.

**Required IAM Policy**

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_fastconnect**

The metrics listed in the following table are automatically available for each virtual circuit or cross-connect group that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

**COMPONENT**

Possible values are crossconnectgroup and virtualcircuit. If you connect through an Oracle partner, only the virtualcircuit component is available.

**RESOURCEID**

The OCID of the resource (either a cross-connect group or virtual circuit).
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectionState</td>
<td>Connection State</td>
<td>Binary (1 or 0)</td>
<td>The values are up (1) or down (0). For a virtual circuit, the operational state of the virtual circuit's interface. For a cross-connect group, this reflects the overall operational state of the cross-connects that make up the cross-connect group (LAG). If at least one of the cross-connects is up, this value is up (1). If all the cross-connects in the group are down, this value is down (0).</td>
<td>component resourceId</td>
</tr>
<tr>
<td>PacketsReceived</td>
<td>Packets Received</td>
<td>Packets</td>
<td>Number of packets received on the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.</td>
<td></td>
</tr>
<tr>
<td>BytesReceived</td>
<td>Bytes Received</td>
<td>Bytes</td>
<td>Number of bytes received on the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.</td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------</td>
<td>------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>PacketsSent</td>
<td>Packets Sent</td>
<td>Packets</td>
<td>Number of packets sent from the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.</td>
<td></td>
</tr>
<tr>
<td>BytesSent</td>
<td>Bytes Sent</td>
<td>Bytes</td>
<td>Number of bytes sent from the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.</td>
<td></td>
</tr>
<tr>
<td>PacketsError</td>
<td>Packets with Errors</td>
<td>Packets</td>
<td>Number of packets dropped at the Oracle end of the connection. Dropped packets indicate a misconfiguration in some part of the overall system. Check if there's been a change to the configuration of your VCN, the virtual circuit, or your CPE. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

The instructions depend on which FastConnect connectivity model you use.

**If You Use an Oracle Partner**

*To view default metric charts for a single FastConnect connection*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Click the connection you're interested in.
3. The default metrics charts for the connection's virtual circuit are displayed on the resulting page.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**To view default metric charts for all FastConnect connections in a compartment**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that you're interested in.
3. For Metric Namespace, select oci_fastconnect.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

If there are multiple FastConnect connections in the compartment, by default the charts show a separate line for each one (each virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**If You Use a Third-Party Provider or Colocate with Oracle**

In this situation, you manage both the physical connection (cross-connects) and logical connection (virtual circuit).

For the physical connection, metrics are available for the cross-connect group (LAG), but not the individual cross-connects. If you are using only a single cross-connect with no cross-connect group, then no metrics are available for the physical connection.

For the logical connection, metrics are available for each virtual circuit.

**To view default metric charts for a single FastConnect connection**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Click the connection you're interested in.
3. View the metrics for the resource you're interested in:
   - For a cross-connect group: Under Resources, click Metrics. The default metrics charts are displayed on the resulting page.
   - For a virtual circuit:
      a. Under Resources, click Virtual Circuits.
      b. Click the virtual circuit you're interested in. If it's a private virtual circuit, the default metrics charts are displayed on the resulting page. If it's a public virtual circuit, click Metrics to view the charts.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**To view default metric charts for all FastConnect connections in a compartment**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that you're interested in.
3. For Metric Namespace, select oci_fastconnect.

   The Service Metrics page dynamically updates the page to show charts for each metric emitted by the selected metric namespace.

By default the charts show a separate line for each resource in the compartment (each cross-connect group and virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

FastConnect Troubleshooting

This topic covers troubleshooting techniques for a FastConnect connection that has issues.

Some of the troubleshooting techniques assume that you are a network engineer with access to your CPE's configuration.

Microsoft Azure Connection Issues

Problems terminating the Azure connection

The connection components must be terminated in a specific order. If you don't follow this order, the FastConnect virtual circuit switches to a "Failed" state and cannot be deleted.

To fix a virtual circuit in the "Failed" state, go to the Azure portal and confirm the following items:

- The ExpressRoute circuit is not in the "Failed" state. If it is, click the ExpressRoute circuit's Refresh button. The circuit should return to its normal state.
- The ExpressRoute circuit has no connections. Delete all its connections and then retry terminating the connection.

After you've confirmed the preceding items, you can continue with the termination process in the following steps:

1. In the Oracle Console, delete your FastConnect virtual circuit. Ensure that it is deleted before proceeding.
2. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not Provisioned".
3. In the Azure portal, delete the ExpressRoute circuit.

General Issues

Cross-connect and physical connection (layer 1)

Check these items:

- **Port allocation**: Verify that your connection is using the correct port, and the port is UP and activated.
- **Optical signal**: Verify that your connection is using the correct optics and transceiver, and the port is sending and receiving an optimal signal. For more information, see FastConnect Requirements on page 3181.
- **Fiber strands**: Try rolling or flipping the Tx/Rx fiber strands.
- **End-to-end physical connectivity**: Verify the end-to-end physical connectivity. Also verify the Tx/Rx optic signal between your CPE, the provider's network device (if you're working with a provider), and the Oracle FastConnect router.

Data-link (layer 2)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

- **BGP address**: Verify that the router is configured with the correct BGP peering IP address under the correct VLAN on the interface.

Important:

If you're working with an Oracle partner or a third-party provider, contact both the provider and Oracle to help troubleshoot the issue. If you're colocated with Oracle, contact Oracle.
• **MAC address:** Verify that the router is receiving the MAC address from the Oracle FastConnect router, and that the MAC address has an entry in the router’s address resolution protocol (ARP) table.

• **LAG and LACP:** Verify that the router has LAG configured and LACP is enabled on the interface (the Oracle FastConnect router requires both). For more information, see FastConnect Requirements on page 3181.

Network and transport (layers 3 and 4)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

• **BGP address:** Verify that the router is configured with the correct BGP peering IP address.

• **ASN:** Verify that the router is configured with the correct BGP local ASN and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN on page 154.

• **MD5:** If you're using MD5 authentication, verify that the authentication string (the password) is correct.

• **Maximum prefixes:** Verify that you are advertising less than the maximum allowed number of prefixes for virtual circuits. If you're advertising more prefixes than allowed, BGP establishment fails. Here are the limits:
  - Public virtual circuits: maximum 200 prefixes
  - Private virtual circuits: maximum 2000 prefixes

• **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking TCP port 179 (BGP) or any high-numbered TCP ports.

*FastConnect virtual circuit is UP, but BGP session is DOWN*

The Oracle Console displays an alert if the virtual circuit is in the PROVISIONED state, but the BGP session is DOWN.

Typically, the alert indicates one of the following issues:

• You have not yet configured your CPE with the required information for the FastConnect connection. After you configure the CPE, the alert should no longer appear.

• You have configured your CPE with incorrect information. Verify that your CPE is configured with the correct information.

The CPE configuration information includes these items:

• BGP address for each side of the connection

• ASN for your network and for Oracle's network

• MD5 authentication string (if you're using MD5 authentication)

• Maximum number of allowed prefixes

For more details, see the preceding information shown for network and transport (layers 3 and 4) in FastConnect is DOWN on page 3241.

**Exception:** The preceding information is not relevant if you're using an Oracle partner, and the BGP session from your CPE goes to that partner and not Oracle. In that case, contact your provider to confirm that the BGP session they have with Oracle is configured correctly.

*FastConnect virtual circuit is UP, but no traffic is passing through*

Check these items:

• **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.

• **Correct routes on both ends:** Verify that you have received the correct VCN routes from FastConnect and the CPE is using those routes. Likewise, verify that you are advertising the correct on-premises network routes to FastConnect and the VCN route tables use those routes.

*FastConnect virtual circuit is UP, but traffic is passing in only one direction*

Check these items:

• **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
Networking

- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.
- **Asymmetric routing:** Oracle uses asymmetric routing. If you have multiple virtual circuits, ensure that your CPE is configured for asymmetric route processing.
- **Redundant connections:** If you have redundant FastConnect virtual circuits, ensure that they're both advertising the same routes.

**Redundant Connections**
Remember that FastConnect uses BGP dynamic routing, and IPSec connections can use either static routing or BGP, or a combination.

*IPSec and FastConnect are both set up, but traffic is only passing through IPSec*

Verify that the route tables use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in Routing for the Oracle IPSec VPN on page 2934.

**Access to the Internet**
See these topics for how to give your virtual cloud network (VCN) access to the internet:
- **Internet Gateway** on page 3243: For public resources that need to be reached from the internet
- **NAT Gateway** on page 3247: For resources that need to reach the internet but are not reachable from the internet

**Internet Gateway**
This topic describes how to set up and manage an internet gateway to give your VCN internet access.

| Tip: |
| Oracle also offers a **NAT gateway**, which is recommended for subnets in your VCN that do not require ingress connections from the internet. |

**Highlights**
- An internet gateway is an optional virtual router you can add to your VCN to enable direct connectivity to the internet.
- The gateway supports connections initiated from within the VCN (egress) and connections initiated from the internet (ingress).
- Resources that need to use the gateway for internet access must be in a public subnet and have public IP addresses. Resources that have private IP addresses can instead use a NAT gateway to initiate connections to the internet.
- Each public subnet that needs to use the internet gateway must have a route table rule that specifies the gateway as the target.
- You use security rules to control the types of traffic allowed in and out of resources in that subnet. Make sure to allow only the desired types of internet traffic.
- The internet gateway can be used only by resources in the gateway's VCN. Hosts in the connected on-premises network or in a peered VCN cannot use that internet gateway.
- You can't add or move an internet gateway to a VCN within a security zone. Security zones do not permit public subnets.

**Overview of Internet Gateways**
Before continuing, make sure you've read **Access to the Internet** on page 2752 and also understand how to set up security rules for the resources in a subnet.

An internet gateway as an optional virtual router that connects the edge of the VCN with the internet. To use the gateway, the hosts on both ends of the connection must have public IP addresses for routing. Connections that originate in your VCN and are destined for a public IP address (either inside or outside the VCN) go through the
internet gateway. Connections that originate outside the VCN and are destined for a public IP address inside the VCN go through the internet gateway.

A given VCN can have only one internet gateway. You control which public subnets in the VCN can use the gateway by configuring the subnet’s associated route table. You use security rules to control the types of traffic allowed in and out of resources in those public subnets.

The following diagram illustrates a simple VCN setup with two public subnets. The VCN has an internet gateway, and the two public subnets are both configured to use the VCN’s default route table. The table has a route rule that sends all egress traffic from the subnets to the internet gateway. The gateway allows any ingress connections from the internet with a destination IP address equal to the public IP address of a resource in the VCN. However, the public subnet’s security list rules ultimately determine the specific types of traffic that are allowed in and out of the resources in the subnet. Those specific security rules are not shown in the diagram.

Tip:
Traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure (such as Object Storage) is routed without being sent over the internet.

Working with Internet Gateways
You create an internet gateway in the context of a specific VCN. In other words, the internet gateway is automatically attached to a VCN. However, you can disable and re-enable the internet gateway at any time. Compare this with a dynamic routing gateway (DRG), which you create as a standalone object that you then attach to a particular VCN. DRGs use a different model because they’re intended to be modular building blocks for privately connecting VCNs to your on-premises network.
For traffic to flow between a subnet and an internet gateway, you must create a route rule accordingly in the subnet's route table (for example, destination CIDR = 0.0.0.0/0 and target = internet gateway). If the internet gateway is disabled, that means no traffic will flow to or from the internet even if there's a route rule that enables that traffic. For more information, see Route Tables on page 2921.

For the purposes of access control, you must specify the compartment where you want the internet gateway to reside. If you're not sure which compartment to use, put the internet gateway in the same compartment as the cloud network. For more information, see Access Control on page 2831.

You may optionally assign a friendly name to the internet gateway. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the internet gateway a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

To delete an internet gateway, it does not have to be disabled, but there must not be a route table that lists it as a target.

Using the Console

To set up an internet gateway

Prerequisites:

• You've determined which subnets in the VCN need access to the internet, and you've created those public subnets.
• You've determined the types of ingress and egress internet traffic that you want to enable for the resources in each public subnet (examples: ingress HTTPS connections, ingress ICMP ping connections).
• The required IAM policy is in place to allow you to work with Networking service resources. For administrators: see IAM Policies for Networking on page 2832.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you've configured the public subnet to use the default security list, remember that the list includes several helpful default rules that enable basic required access (examples: ingress SSH, egress access to all destinations). Oracle recommends that you become familiar with the basic access that these default rules provide. If you choose not to use the default security list, make sure to provide this basic access by implementing these security rules either in network security groups (NSGs) or custom security lists.</td>
</tr>
<tr>
<td>The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.</td>
</tr>
</tbody>
</table>
1. For each public subnet that needs to use the internet gateway, set up the subnet's security list rules to allow the desired internet traffic.
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in (a security list associated with the public subnet).
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a new rule, click Add Ingress Rule (or Add Egress Rule).
      
      Example
      
      Imagine you have web servers in the public subnet. This example shows how to add an ingress rule for HTTPS connections (TCP port 443) coming from the internet to the web server. Without this rule, inbound HTTPS connections are not allowed.
      
      1. Leave the Stateless check box unselected.
      2. Source Type: CIDR
      3. Source CIDR: 0.0.0.0/0
      4. IP Protocol: Leave as TCP.
      5. Source Port Range: Leave as All.
      6. Destination Port Range: Enter 443.
      7. Description: An optional description of the rule.
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

2. Create the VCN's internet gateway:
   a. In the Console, while viewing the VCN you're interested in, click Internet Gateways.
   b. Click Create Internet Gateway.
   c. Enter the following:
      
      • Name: A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      • Create in Compartment: The compartment where you want to create the internet gateway, if different from the compartment you're currently working in.
      • Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
   d. Click Create Internet Gateway.
      
      Your internet gateway is created and displayed on the Internet Gateways page of the compartment you chose. It's already enabled, but you still need to add a route rule that allows traffic to flow to the gateway.

3. For each public subnet that needs to use the internet gateway, update the subnet's route table:
   a. While viewing the VCN's details, click Route Tables.
   b. Click the public subnet's route table to view its details.
   c. Click Add Route Rule.
   d. Enter the following:
      
      • Target Type: Internet Gateway
      • Destination CIDR block: 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule)
      • Compartment: The compartment where the internet gateway is located.
      • Target: The internet gateway you just created.
      • Description: An optional description of the rule.
   e. Click Save.
      
      An internet gateway is now enabled and working for your cloud network.
To disable/enable an internet gateway

This is available only through the API. If you don't have access to the API and need to disable or enable an internet gateway, contact Oracle Support. You can also easily delete and recreate the internet gateway if needed. Just make sure to update any route tables that refer to the internet gateway.

To delete an internet gateway

Prerequisite: The internet gateway does not have to be disabled, but there must not be a route table that lists it as a target.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Internet Gateways.
4. Click the Actions icon (three dots) for the internet gateway, and then click Terminate.
5. Confirm when prompted.

To manage tags for an internet gateway

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Internet Gateways.
4. Click the Actions icon (three dots) for the internet gateway, and then click View Tags. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 211.

To move an internet gateway to a different compartment

You can move an internet gateway from one compartment to another. When you move an internet gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Under Resources, click Internet Gateways.
4. Click the the Actions icon (three dots) for the internet gateway, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your internet gateways, use these operations:

- ListInternetGateways
- CreateInternetGateway
- GetInternetGateway
- UpdateInternetGateway
- DeleteInternetGateway
- ChangeInternetGatewayCompartment

NAT Gateway

This topic describes how to set up and manage a Network Address Translation (NAT) gateway. A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.
Networking

Highlights

- You can add a NAT gateway to your VCN to give instances in a private subnet access to the internet.
- Instances in a private subnet don't have public IP addresses. With the NAT gateway, they can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.
- NAT gateways are highly available and support TCP, UDP, and ICMP ping traffic.

Overview of NAT

NAT is a networking technique commonly used to give an entire private network access to the internet without assigning each host a public IPv4 address. The hosts can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.

When a host in the private network initiates an internet-bound connection, the NAT device's public IP address becomes the source IP address for the outbound traffic. The response traffic from the internet therefore uses that public IP address as the destination IP address. The NAT device then routes the response to the host in the private network that initiated the connection.

Overview of NAT Gateways

The Networking service offers a reliable and highly available NAT solution for your VCN in the form of a NAT gateway.

Example scenario: Imagine you have resources that need to receive inbound traffic from the internet (for example, web servers). You also have private resources that need to be protected from inbound traffic from the internet. All of these resources need to initiate connections to the internet to request software updates from sites on the internet.

You set up a VCN and add a public subnet to hold the web servers. When launching the instances, you assign public IP addresses to them so they can receive inbound internet traffic. You also add a private subnet to hold the private instances. They cannot have public IP addresses because they are in a private subnet.

You add an internet gateway to the VCN. You also add a route rule in the public subnet's route table that directs internet-bound traffic to the internet gateway. The public subnet's instances can now initiate connections to the internet and also receive inbound connections initiated from the internet. Remember that you can use security rules to control the types of traffic that are allowed in and out of the instances at the packet level.

You add a NAT gateway to the VCN. You also add a route rule in the private subnet's route table that directs internet-bound traffic to the NAT gateway. The private subnet's instances can now initiate connections to the internet. The NAT gateway allows responses, but it does not allow connections that are initiated from the internet. Without that NAT gateway, the private instances would instead need to be in the public subnet and have public IP addresses to get their software updates.

The following diagram illustrates the basic network layout for the example. The arrows indicate whether connections can be initiated in only one direction or both.
A NAT gateway can be used only by resources in the gateway's own VCN. If the VCN is **peered with another**, resources in the other VCN cannot access the NAT gateway.

Also, resources in an on-premises network connected to the NAT gateway's VCN with **FastConnect** or an **IPSec VPN** cannot use the NAT gateway.

**Here are a few basics about NAT gateways:**

- The NAT gateway supports TCP, UDP, and ICMP ping traffic.
- The gateway supports a maximum of approximately 20,000 concurrent connections to a single destination address and port.
- The Networking service automatically assigns a public IP address to the NAT gateway. You can't choose the public IP address or use one of your **reserved public IP addresses**.
- There's a limit on the number of NAT gateways per VCN. You can request an increase to that limit. See **Service Limits** on page 215.

**Routing for a NAT Gateway**

You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use a NAT gateway. You can have more than one NAT gateway on a VCN (although you must **request an increase in your limits**). For example, if you want an external application to distinguish traffic from the VCN's different subnets, you could set up a different NAT gateway (and thus a different public IP address) for each subnet. A given subnet can route traffic to only a single NAT gateway.

**Blocking Traffic Through a NAT Gateway**

You create a NAT gateway in the context of a specific VCN. In other words, the NAT gateway is automatically always attached to only one VCN of your choice. However, you can block or allow traffic through the NAT gateway at any time. By default, the gateway allows traffic upon creation. Blocking the NAT gateway prevents all traffic from flowing, regardless of any existing route rules or security rules in your VCN. For instructions on how to block traffic, see **To block/allow traffic for a NAT gateway** on page 3251.
**Transitioning to a NAT Gateway**

If you're switching from using a **NAT instance in your VCN** to a NAT gateway, consider that the public IP address for your NAT device will change.

If you're switching from using an internet gateway to a NAT gateway, the instances with access to the NAT gateway no longer need public IP addresses to reach the internet. Also, the instances no longer need to be in a public subnet. You can't switch a subnet from **public to private**. However, you can delete the **ephemeral public IPs** from your instances if you like.

**Deleting a NAT Gateway**

To delete a NAT gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. For instructions, see **To delete a NAT gateway** on page 3251.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: see **IAM Policies for Networking** on page 2832.

**Setting Up a NAT Gateway**

**Task 1: Create the NAT gateway**

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the NAT gateway to. For information about compartments and access control, see **Access Control** on page 2831.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
3. Click the VCN you're interested in.
4. Under **Resources**, click **NAT Gateways**.
5. Click **Create NAT Gateway**.
6. Enter the following values:
   - **Name**: A friendly name for the NAT gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the NAT gateway, if different from the compartment you're currently working in.
   - **Choose IP Address Type**: Specify whether the public IP address is reserved or ephemeral.
     - **Ephemeral IP Address**: Choose this option to let Oracle specify an **ephemeral IP address** for you from the Oracle IP pool. This is the default.
     - **Reserved IP Address**: Choose this option to specify an existing **reserved IP address** by name, or to create a new reserved IP address by assigning a name and selecting a source **IP pool** for the address. If you don't select a pool you've created, the default Oracle IP pool is used.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click **Create NAT Gateway**.

The NAT gateway is then created and displayed on the **NAT Gateways** page in the compartment you chose. The gateway allows traffic by default. At any time, you can **block or allow traffic** through it.

**Task 2: Update routing for the subnet**

When you create a NAT gateway, you must also create a route rule that directs the desired traffic from the subnet to the NAT gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the NAT gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following values:
      • Target Type: NAT Gateway.
      • Destination CIDR Block: 0.0.0.0/0
      • Compartment: The compartment where the NAT gateway is located.
      • Target NAT Gateway: The NAT gateway.
      • Description: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to the NAT gateway. For more information about setting up route rules, see Route Tables on page 2921.

Later, if you no longer need the NAT gateway and want to delete it, you must first delete all the route rules in your VCN that specify the NAT gateway as the target.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without the required routing, traffic doesn't flow over the NAT gateway. If a situation occurs where you need to temporarily stop the traffic flow over the gateway, you can simply remove the route rule that enables traffic. Or you can block traffic through the gateway entirely. You do not need to delete it.</td>
</tr>
</tbody>
</table>

Using the Console

**To create a NAT gateway**

See the instructions in To create a NAT gateway on page 3251.

**To block/allow traffic for a NAT gateway**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the NAT gateway you're interested in, click the Actions icon (three dots) and then click Block Traffic (or Allow Traffic if you're enabling traffic for the NAT gateway).
5. Confirm when prompted.

When the traffic is blocked, the NAT gateway’s icon turns gray, and the label changes to BLOCKED. When the traffic is allowed, the NAT gateway’s icon turns green, and the label changes to AVAILABLE.

**To update a NAT gateway**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the NAT gateway you're interested in, click the Actions icon (three dots), and then click Edit.
5. Make your changes and click Save Changes.

**To delete a NAT gateway**

Prerequisite: There must not be a route table that lists the NAT gateway as a target.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the NAT gateway you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

**To manage tags for a NAT gateway**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. Click the Actions icon (three dots) for the NAT gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 211.

**To move a NAT gateway to a different compartment**

You can move a NAT gateway from one compartment to another. When you move a NAT gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. In **Resources**, click **NAT Gateways**.
4. Find the NAT gateway in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

The NAT gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the NAT gateway.

For more information about using compartments and policies to control access to your cloud network, see **Access Control** on page 2831. For general information about compartments, see **Managing Compartments** on page 2431.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your NAT gateways, use these operations:

- **ListNatGateways**
- **CreateNatGateway**
- **GetNatGateway**
- **UpdateNatGateway**
- **DeleteNatGateway**
- **ChangeNatGatewayCompartment**

To manage route tables, see Route Tables on page 2921.

**Access to Your On-Premises Network**

The following topics have information about ways to privately connect your cloud network to your existing on-premises network. Regardless of which method you use, you need a dynamic routing gateway (DRG) attached to your cloud network.

Private Access

This topic gives an overview of the options for enabling private access to services within Oracle Cloud Infrastructure. Private access means that traffic does not go over the internet. Access can be from hosts within your virtual cloud network (VCN) or your on-premises network.

**Tip:**

This topic does not discuss access to services through an internet gateway. However, remember that traffic through an internet gateway between a VCN and a public IP address that is part of Oracle Cloud Infrastructure is routed without being sent over the internet.

**Highlights**

- You can enable private access to certain services within Oracle Cloud Infrastructure from your VCN or on-premises network by using either a private endpoint or a service gateway. See the sections that follow.
• For each private access option, these services or resource types are available:
  
  • **With a private endpoint:**
    
    • Autonomous Database (shared Exadata infrastructure)
    • Streaming
    • Data Safe
    • Data Catalog
    • Oracle Analytics Cloud
    • Data Flow
  
  • **With a service gateway:** Available services
  
  • With either private access option, the traffic stays within the Oracle Cloud Infrastructure network and does not traverse the internet. However, if you use a service gateway, requests to the service use a public endpoint for the service.
  
  • If you do not want to access a given Oracle service through a public endpoint, Oracle recommends using a private endpoint in your VCN (assuming the service supports private endpoints). A private endpoint is represented as a private IP address within a subnet in your VCN.

**About Private Endpoints**

A private endpoint is a private IP address within your VCN that you can use to access a given service within Oracle Cloud Infrastructure. The service sets up the private endpoint in a subnet of your choice within the VCN. You can think of the private endpoint as just another *VNIC* in your VCN. You can control access to it like you would for any other VNIC: by using *security rules*. However, the service sets up this VNIC and maintains its availability on your behalf. You only need to maintain the subnet and the security rules.

The following diagram illustrates the concept.

The private endpoint gives hosts within your VCN and your on-premises network access to a *single resource* within the Oracle service of interest (for example, one Autonomous Database with shared Exadata infrastructure). Compare that private access model with a service gateway (see the next section): If you created five Autonomous Databases for a given VCN, all five would be accessible through a single service gateway by sending requests to a public endpoint for the service. However, with the private endpoint model, there would be five separate private endpoints: one for each Autonomous Database, and each with its own private IP address.
The service that sets up the private endpoint in your VCN might provide you a DNS name (fully qualified domain name, or FQDN) for the private endpoint, and not the private IP address itself. If you've configured your network setup for DNS, your hosts can access the private endpoint by using the FQDN. If the service supports the use of network security groups (NSGs) with its resources, you can request that the service set up the private endpoint in an NSG of your choice within your VCN. NSGs let you write security rules to control access to the private endpoint without knowing the private IP address assigned to the private endpoint.

If you have a private endpoint for a resource, hosts within the VCN can use the private endpoint's FQDN or private IP address to access the resource. You set up security rules to control access between hosts in the VCN and the private endpoint. For an example of how to do this with Autonomous Data Warehouse, see Autonomous Database with Private Endpoint on page 1163.

You can also set up transit routing with your VCN so that hosts in the on-premises network can use the private endpoint. To enable on-premises hosts to use the private endpoint's FQDN instead of its private IP address, you have two options:

- Set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see Hybrid DNS Configuration.
- Manage hostname resolution yourself manually.

You might have multiple VCNs with hosts that need access to the specific resource of interest. You can peer the VCNs so that hosts in the other VCNs can also use the private endpoint (the preceding diagram does not show any peered VCNs).

### About Service Gateways

A service gateway gives resources in your VCN and on-premises network private access to multiple services within Oracle Cloud Infrastructure, without the traffic going over the internet.

The following diagram illustrates the concept. The diagram refers to the Oracle Services Network, which is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services.

To use a service gateway from a particular subnet within your VCN, you set up a route rule in the subnet's route table, and specify the service gateway as the target of the rule. You also set up security rules to control access between hosts in the VCN and the services available through the service gateway.

If you have more than one VCN in your tenancy, you can configure each with its own service gateway.
You can also set up transit routing for the Oracle Services Network so that hosts in your on-premises network can use a VCN's service gateway.

Access to Oracle Services: Service Gateway

This topic describes how to set up and manage a service gateway. A service gateway enables cloud resources without public IP addresses to privately access Oracle services.

Access to Oracle Services

The Oracle Services Network is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the internet. However, you can access the Oracle Services Network without the traffic going over the internet. There are different ways, depending on which of your hosts need the access:

- **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or VPN Connect: The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the VCN's service gateway.
  - Public access with FastConnect public peering: The on-premises hosts use public IP addresses.

- **Hosts in your VCN:**
  - Private access through a service gateway: This is the scenario covered in this topic. The VCN's hosts use private IP addresses.

Highlights

- A service gateway lets your virtual cloud network (VCN) privately access specific Oracle services without exposing the data to the public internet. No internet gateway or NAT is required to reach those specific services. The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the internet.
- The service gateway is regional and enables access only to supported Oracle services in the same region as the VCN.
- The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your workloads may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.
- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.
- The service gateway uses the concept of a service CIDR label, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, OCI PHX Object Storage is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service's public IP addresses change in the future, you don't have to adjust those rules.
- You can set up a VCN so that your on-premises network has private access to Oracle services by way of the VCN and the VCN's service gateway. The hosts in your on-premises network communicate with their private IP addresses and the traffic does not go over the internet. For more information, see Transit Routing: Private Access to Oracle Services on page 2803

Overview of Service Gateways

A service gateway lets resources in your VCN privately access specific Oracle services, without exposing the data to an internet gateway or NAT. The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the service of interest travels over the Oracle network fabric and never traverses the internet.

The following simple diagram illustrates a VCN that has both a public subnet and a private subnet. Resources in the private subnet have only private IP addresses.

The VCN has three gateways:
Networking

- **Internet gateway**: To provide the public subnet direct access to public endpoints on the internet. Connections can be initiated from the subnet or from the internet. The resources in the public subnet must have public IP addresses. For more information, see *Internet Gateway* on page 3243.
- **Service gateway**: To provide the private subnet with private access to supported Oracle services within the region. Connections can be initiated only from the subnet.
- **NAT gateway**: To provide the private subnet with private access to public endpoints on the internet. Connections can be initiated only from the subnet. For more information, see *NAT Gateway* on page 3247.

You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use each gateway. In the diagram, the route table for the public subnet sends non-local traffic through the internet gateway. The route table for the private subnet sends traffic destined for the Oracle services through the service gateway. It sends all remaining traffic to the NAT gateway.

**Important:**

See this known issue for information about configuring route rules with service gateway as the target on route tables associated with public subnets.

A service gateway can be used by resources in the gateway's own VCN. However, if the VCN is peered with another, resources in the other VCN cannot access the service gateway unless a service gateway is configured in both VCNs. You could configure traffic destined for Oracle Services Network that originates on a spoke to travel through a network virtual appliance (NVA) in the hub and then through the hub's service gateway. See Using a Private IP as a Route Target on page 2924 and Transit Routing: Private Access to Oracle Services on page 2803 for more information.

Resources in your on-premises network that is connected to the service gateway's VCN with FastConnect or VPN Connect can also use the service gateway. For more information, see Transit Routing: Private Access to Oracle Services on page 2803.

Notice that your on-premises network can also use FastConnect public peering for private access to public Oracle services. That means that your on-premises network could have multiple paths to access Oracle services public IP address ranges. If that is the case, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network on page 2942.

A VCN can have only one service gateway. For more information about limits, see Service Limits on page 215.
For instructions on setting up a service gateway, see Setting Up a Service Gateway in the Console on page 3260.

About Service CIDR Labels

Each Oracle service has a regional public endpoint that uses public IP addresses for access. When you set up a service gateway with access to an Oracle service, you also set up Networking service route rules and optionally security rules that control traffic with the service. That means you need to know the service's public IP addresses to set up those rules. To make it easier for you, the Networking service uses service CIDR labels to represent all the public CIDRs for a given Oracle service or a group of Oracle services. If a service's CIDRs change in the future, you don't have to adjust your route rules or security rules.

Examples:

- **OCI PHX Object Storage** is a service CIDR label that represents all the Object Storage CIDRs in the US West (Phoenix) region.
- **All PHX Services in Oracle Services Network** is a service CIDR label that represents all the CIDRs for the supported services in the Oracle Services Network in the US West (Phoenix) region. For a list of the services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

As you can see, a service CIDR label can be associated with either a single Oracle service (example: Object Storage), or multiple Oracle services.

The term service is often used in this topic in place of the more accurate term service CIDR label. The important thing to remember is that when you set up a service gateway (and related route rules), you specify the service CIDR label you're interested in. In the Console, you're presented with the available service CIDR labels. If you use the REST API, the ListServices operation returns the available Service objects. The Service object's cidrBlock attribute contains the service CIDR label (example: all-phx-services-in-oracle-services-network).

Available Service CIDR Labels

Here are the available service CIDR labels:

- **OCI <region> Object Storage**: For information about the service, see Overview of Object Storage on page 3392
- **All <region> Services in Oracle Services Network**: For a list of supported services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>See this known issue for information about accessing Oracle YUM services through the service gateway.</td>
</tr>
</tbody>
</table>

Enabling a Service CIDR Label for a Service Gateway

To give your VCN access to a given service CIDR label, you must **enable** that service CIDR label for the VCN's service gateway. You can do that when you create the service gateway, or later after it's created. You can also disable a service CIDR label for the service gateway at any time.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Because Object Storage is covered by both OCI &lt;region&gt; Object Storage and All &lt;region&gt; Services in Oracle Services Network, a service gateway can use only one of those service CIDR labels. Likewise, a route table can have a single rule for one of the service CIDR labels. It cannot have two separate rules, one for each label.</td>
</tr>
<tr>
<td>If the service gateway is configured to use All &lt;region&gt; Services in Oracle Services Network, the route rule can use either CIDR label. However, if the service gateway is configured to use OCI &lt;region&gt; Object Storage and the route rule uses All &lt;region&gt; Services in Oracle Services Network, traffic to services in the Oracle Services Network except Object Storage will be</td>
</tr>
</tbody>
</table>
Networking

blackholed. The Console prohibits you from configuring the service gateway and corresponding route table in that manner.

If you want to switch the service gateway to use a different service CIDR label, see To switch to a different service CIDR label on page 3263.

Blocking Traffic Through a Service Gateway

You create a service gateway in the context of a specific VCN. In other words, the service gateway is always attached to that one VCN. However, you can block or allow traffic through the service gateway at any time. By default, the gateway allows traffic flow upon creation. Blocking the service gateway traffic prevents all traffic from flowing, regardless of what service CIDR labels are enabled, or any existing route rules or security rules in your VCN. For instructions on how to block traffic, see To block or allow traffic for a service gateway on page 3263.

Route Rules and Security Rules for a Service Gateway

For traffic to be routed from a subnet in your VCN to a service gateway, you must add a rule accordingly to the subnet's route table. The rule must use the service gateway as the target. For the destination, you must use the service CIDR label that is enabled for the service gateway. This means that you don't have to know the specific public CIDRs, which could change over time.

Any traffic leaving the subnet and destined for the service's public CIDRs is then routed to the service gateway. If the service gateway traffic is blocked, no traffic flows through it even if there's a route rule that matches the traffic. For instructions on setting up route rules for a service gateway, see Task 2: Update routing for the subnet on page 3260.

The VCN's security rules must also allow the desired traffic. If you like, you can use a service CIDR label instead of a CIDR for the source or destination of the desired traffic. Again, this means that you don't have to know the specific public CIDRs for the service. For convenience, you can use a service CIDR label in security rules even if your VCN doesn't have a service gateway, and the traffic to the services uses an internet gateway.

You can use stateful or stateless security rules that use a service CIDR label:

- **For stateful rules**: Create an egress rule with the destination service = the service CIDR label of interest. As with any security rule, you can specify other items such as the IP protocol and source and destination ports.
- **For stateless rules**: You must have both egress and ingress rules. Create an egress rule with the destination service = the service CIDR label of interest. Also create an ingress rule with the source service = the service CIDR label of interest. As with any security rule, you can specify other items such as the IP protocol and source and destination ports.

For instructions on setting up security rules that use a service CIDR label, see Task 3: (Optional) Update security rules on page 3261.

Object Storage: Allowing Bucket Access from Only a Particular VCN or CIDR Range

If you use a service gateway to access Object Storage, you can write an IAM policy that allows access to a particular Object Storage bucket only if these requirements are met:

- The request goes through a service gateway.
- The request originates from the particular VCN that is specified in the policy.

For examples of this particular type of IAM policy, and important caveats about its use, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access on page 3262.

Alternatively, you can use IAM IP-based filtering to restrict access to an IP address or ranges of addresses. For more information, see Managing Network Sources on page 2427.

Deleting a Service Gateway

To delete a service gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. See To delete a service gateway on page 3264.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: see IAM Policies for Networking on page 2832.

Setting Up a Service Gateway in the Console

Following is the process for setting up a service gateway. It assumes that you already have a VCN with a subnet (either private or public).

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your applications may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.</td>
</tr>
</tbody>
</table>

Task 1: Create the service gateway

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the service gateway to. For information about compartments and access control, see Access Control on page 2831.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
3. Click the VCN you're interested in.
4. On the left side of the page, click Service Gateways.
5. Click Create Service Gateway.
6. Enter the following values:
   - **Name**: A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - **Services**: Optionally select the service CIDR label you're interested in. If you don't select one now, you can later update the service gateway and add a service CIDR label then. Without at least one service CIDR label enabled for the gateway, no traffic flows through it.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click Create Service Gateway.

The service gateway is then created and displayed on the Service Gateways page in the compartment you chose. The gateway allows traffic through it by default. At any time, you can block or allow the traffic through it.

Task 2: Update routing for the subnet

When you configure a service gateway for a particular service CIDR label, you must also create a route rule that specifies that label as the destination and the target as the service gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the service gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Edit Route Rules.
   f. Click Add Route Rule and enter the following values:
      • Target Type: Service Gateway.
      • Destination Service: The service CIDR label that is enabled for the gateway.
      • Compartment: The compartment where the service gateway is located.
      • Target: The service gateway.
      • Description: An optional description of the rule.
   g. Click Save.

Any subnet traffic with a destination that matches the rule is routed to the service gateway. For more information about setting up route rules, see Route Tables on page 2921.

Later, if you no longer need the service gateway and want to delete it, you must first delete all the route rules in your VCN that specify the service gateway as the target.

**Tip:**
Without the required routing, traffic doesn't flow over the service gateway.
If a situation occurs where you want to temporarily stop the traffic flow over the gateway to a particular service, you can simply remove the route rule that enables traffic. You can also disable that particular service CIDR label for the gateway. Or you can block all traffic through the service gateway entirely.
You do not have to delete the gateway.

**Task 3: (Optional) Update security rules**

When you configure a service gateway to access a service CIDR label, you must also ensure that the security rules are configured to allow the desired traffic. Your security rules might already allow this traffic, which is why this task is optional. The following procedure assumes you are using security lists to implement your security rules. The procedure describes how to set up a rule that uses the service CIDR label. You do this for each subnet that needs to access the gateway.

**Tip:**
Security lists are one way to control traffic in and out of the VCN's resources.
You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

1. Determine which subnets in your VCN need to connect to the services you're interested in.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic with the particular service:
   
a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   
b. Click the security list you're interested in.
   
c. Click Edit All Rules and create one or more rules, each for the specific type of traffic you want to allow. See the following example for more details.
   
   Example
   
   Let's say you want to add a stateful rule that enables egress HTTPS (TCP port 443) traffic from the subnet to both Object Storage and Oracle YUM repos. Here are the basic steps you take when adding a rule:
   
   1. In the Allow Rules for Egress section, click +Add Rule.
   
   2. Leave the Stateless check box unselected.
   
   3. Destination Type: Service.
   
   4. Destination Service: The service CIDR label that you're interested in. To access both Object Storage and Oracle YUM repos, it's All <region> Services in Oracle Services Network.
   
   5. IP Protocol: Leave as TCP.
   
   6. Source Port Range: Leave as All.
   
   7. Destination Port Range: Enter 443.
   
   8. Description: An optional description of the rule.
   
   d. Click Save Security List Rules at the bottom of the dialog box.
   
   For more information about setting up security rules, see Security Rules on page 2833.

   Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access
   
   This task is applicable only if you're using a service gateway to access Object Storage. You can optionally create a network source and write an IAM policy to allow only the resources in a specific VCN to write objects to a particular bucket.
   
   Important:
   
   If you use one of the following IAM policies to restrict access to a bucket, the bucket is not accessible from the Console. It's accessible only from within the specific VCN.
   
   Also, the IAM policies allow requests to Object Storage only if they go from the specified VCN through the service gateway. If they go through the internet gateway, the requests are denied.
   
   • Create a network source to specify the allowed VCN. For information on creating network sources, see Managing Network Sources on page 2427.
   
   • Create the policy. The following example lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a compartment called ABC.
   
   Allow group ObjectBackup to read buckets in compartment ABC
   
   Allow group ObjectBackup to manage objects in compartment ABC where all [target.bucket.name='db-backup', request.networkSource.name='<VCN_NETWORK_SOURCE>', any [request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT']]}

   You can specify multiple VCNs by creating and specifying multiple network sources in the policy. The next example has network sources for two VCNs. You might do this if you've set up your on-premises network with private access to Oracle services through a VCN, and you've also set up one or more other VCNs with their own service gateways. For more information, see Overview of On-Premises Network Private Access to Oracle Services on page 2804.
   
   Allow group ObjectBackup to read buckets in compartment ABC
Allow group ObjectBackup to manage objects in compartment ABC where
all {target.bucket.name='db-backup',
    any {request.networkSource.name='<NETWORK_SOURCE_FOR_VCN_1>',
        request.networkSource.name='<NETWORK_SOURCE_FOR_VCN_2>',
        any {request.permission='OBJECT_CREATE',
        request.permission='OBJECT_INSPECT'})

Managing a Service Gateway in the Console

To create a service gateway

See the instructions in Task 1: Create the service gateway on page 3260.

To switch to a different service CIDR label

To avoid disrupting your Object Storage connections while switching between the OCI <region> Object Storage
service CIDR label and All <region> Services in Oracle Services Network, use the following process:

1. **Update the service gateway:** Remove the existing service CIDR label, and then add the one you want to switch to.
   You can't enable both labels for the service gateway.
2. **Update relevant route rules:** For each rule that uses the service gateway as the target, switch the rule's destination
   service from the existing service CIDR label to the one you want to switch to.
3. **Update relevant security rules:** Change any security rules that specify the existing service CIDR label to instead
   use the one you want to switch to. The rules can be in network security groups or security lists.

If you instead delete your existing service gateway and create a new one, your Object Storage connections will be
interrupted. Remember that before you can delete a service gateway, you must delete any route rules that specify that
gateway as a target.

To update a service gateway

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Service Gateways.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click Edit.
5. Make your changes and click Save.

To block or allow traffic for a service gateway

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
3. Click Service Gateways.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click Block Traffic (or
   Allow Traffic if you're enabling traffic for the service gateway).
   When the traffic is blocked, the service gateway's icon turns gray, and the label changes to BLOCKED. When the
   traffic is allowed, the service gateway's icon turns green, and the label changes to AVAILABLE.

To associate a route table with an existing service gateway

You perform this task only if you're implementing an advanced transit routing scenario.

A service gateway can exist without a route table associated with it. However, after you associate a route table with a
service gateway, there must always be a route table associated with it. But, you can associate a different route table.
You can also edit the table's rules, or delete some or all of the rules.

**Prerequisite:** The route table must exist and belong to the VCN that the service gateway belongs to.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click either:
   - **Associate With Route Table:** If the service gateway has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the service gateway.
5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

**To delete a service gateway**

Prerequisite: The service gateway does not have to block traffic, but there must not be a route table that lists it as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Delete**.
5. Confirm when prompted.

**To manage tags for a service gateway**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. For the service gateway you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see **Resource Tags** on page 211.

**To move a service gateway to a different compartment**

You can move a service gateway from one compartment to another. When you move a service gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. In **Resources**, click **Service Gateways**.
4. Find the service gateway in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

The service gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the service gateway.

For more information about using compartments and policies to control access to your cloud network, see **Access Control** on page 2831. For general information about compartments, see **Managing Compartments** on page 2431.

**Managing a Service Gateway with the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

**Caution:**

If anyone in your organization implements a service gateway, be aware that you **may need to update any client code that works with Networking service route rules and security lists**. There are possible breaking API changes. For more information, see the **service gateway release notes**.

To manage your service gateways, use these operations:

- **ListServiceGateways**
- **CreateServiceGateway**
- **GetServiceGateway**
- **UpdateServiceGateway**
Networking

- DeleteServiceGateway
- ChangeServiceGatewayCompartment
- ListServices: Use this to determine the available service CIDR labels.
- GetService: Gets the details for a particular service CIDR label.
- AttachServiceld: Enables a service CIDR label for a service gateway.
- DetachServiceld: Disables a service CIDR label for a service gateway.

To manage route tables, see Route Tables on page 2921. To manage security lists, see Security Lists on page 2850. To manage network security groups, see Network Security Groups on page 2841. To manage IAM policies, see Managing Policies on page 2450.

Access to Other VCNs: Peering

VCN peering is the process of connecting multiple virtual cloud networks (VCNs). There are two types of VCN peering:

- Local VCN peering (within region)
- Remote VCN peering (across regions)

You can use VCN peering to divide your network into multiple VCNs (for example, based on departments or lines of business), with each VCN having direct, private access to the others. There's no need for traffic to flow over the internet or through your on-premises network by way of an IPSec VPN or FastConnect. You can also place shared resources into a single VCN that all the other VCNs can access privately.

Because remote VCN peering crosses regions, you can use it (for example) to mirror or back up your databases in one region to another.

Important Implications of Peering

This section summarizes some access control, security, and performance implications for peered VCNs. In general, you can control access and traffic between two peered VCNs by using IAM policies, route tables in each VCN, and security lists in each VCN.

Controlling the Establishment of Peerings

With IAM policies, you can control:

- Who can subscribe your tenancy to another region (required for remote VCN peering).
- Who in your organization has the authority to establish VCN peerings (for example, see the IAM policies in Setting Up a Local Peering on page 3271 and Setting Up a Remote Peering on page 3284). Be aware that deletion of these IAM policies does not affect any existing peerings, only the ability for future peerings to be created.
- Who can manage route tables and security lists.

Controlling Traffic Flow Over the Connection

Even if a peering connection has been established between your VCN and another, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the other VCN.

Without terminating the peering, you can stop traffic flow to the other VCN by simply removing route rules that direct traffic from your VCN to the other VCN. You can also effectively stop the traffic by removing any security list rules that enable ingress or egress traffic with the other VCN. This doesn't stop traffic flowing over the peering connection, but stops it at the VNIC level.

For more information about the routing and security lists, see the discussions in these sections:

Local VCN peering:

- Important Local Peering Concepts on page 3268
- Task E: Configure the route tables on page 3277
Controlling the Specific Types of Traffic Allowed

It’s important that each VCN administrator ensure that all outbound and inbound traffic with the other VCN is intended/expected and well defined. In practice, this means implementing security list rules that explicitly state the types of traffic your VCN can send to the other and accept from the other.

Important:

Your instances running Oracle-provided Linux images or Windows images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance’s subnet
- The instance’s OS firewall rules

For more information, see Oracle-Provided Images on page 629.

If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, or Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp
sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding --reload command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

In addition to security lists and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don’t apply to your own VCN’s CIDR, but inadvertently apply to the other VCN’s CIDR.

Using Default Security List Rules

If your VCN’s subnets use the default security list with the default rules it comes with, be aware that there are two rules that allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the other VCN):

- Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
- Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Make sure to evaluate these rules and whether you want to keep or update them. As stated earlier, you should ensure that all inbound or outbound traffic that you permit is intended/expected and well defined.

Preparing for Performance Impact and Security Risks

In general, you should prepare your VCN for the ways it could be affected by the other VCN. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the other VCN.
Regarding performance: If your VCN is providing a service to another, be prepared to scale up your service to accommodate the demands of the other VCN. This might mean being prepared to launch additional instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security list rules to limit the level of connection tracking your VCN must perform. Stateless security list rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: You can't necessarily control whether the other VCN is connected to the internet. If it is, be aware that your VCN can be exposed to bounce attacks in which a malicious host on the internet can send traffic to your VCN but make it look like it's coming from the VCN you're peered with. To guard against this, as mentioned earlier, use your security lists to carefully limit the inbound traffic from the other VCN to expected and well-defined traffic.

**Local VCN Peering (Within Region)**

This topic is about *local VCN peering*. In this case, *local* means that the VCNs reside *in the same region*. If the VCNs are in different regions, see Remote VCN Peering (Across Regions) on page 3280.

**Overview of Local VCN Peering**

*Local VCN peering* is the process of connecting two VCNs in the same region so that their resources can communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. The VCNs can be in the same Oracle Cloud Infrastructure *tenancy* or different ones. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN.

For more information, see Access to Other VCNs: Peering on page 3265.

**Summary of Networking Components for Peering**

At a high level, the Networking service components required for a local peering include:

- Two VCNs with non-overlapping CIDRs, in the same region
- A *local peering gateway (LPG)* on each VCN in the peering relationship.
- A *connection* between those two LPGs.
- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if desired).
- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.

![Diagram of local VCN peering](image_url)

**Note:**

A given VCN can use the peered LPGs to reach these resources:

- VNICs in the other VCN
Networking

• An on-premises network attached to the other VCN, if an advanced routing scenario called **transit routing** has been set up for the VCNs

A VCN can't use its peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could not use it to send traffic to endpoints on the internet. However, be aware that VCN-2 could receive traffic from the internet by way of VCN-1. For more information, see **Important Implications of VCN Peering** on page 3271.

**Explicit Agreement Required from Both Sides**

Peering involves two VCNs that might be owned by the same party or two different ones. The two parties might both be in your company but in different departments. Or the two parties might be in entirely different companies (for example, in a service-provider model).

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's **compartment** or tenancy. If the VCNs are in different tenancies, each administrator must provide their tenancy **OCID** and put in place special policy statements to enable the peering.

**Advanced Scenario: Transit Routing**

There's an advanced routing scenario called **transit routing** that enables communication between an on-premises network and multiple VCNs over a single Oracle Cloud Infrastructure FastConnect or IPSec VPN. The VCNs must be in the same region and locally peered in a hub-and-spoke layout. As part of the scenario, the VCN that is acting as the hub has a route table associated with each LPG (typically route tables are associated with a VCN's subnets).

When you create an LPG, you can optionally associate a route table with it. Or if you already have an existing LPG without a route table, you can associate a route table with it. The route table must belong to the LPG's VCN. A route table associated with an LPG can contain only rules that use the VCN's attached DRG as the target.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

**Important Local Peering Concepts**

The following concepts help you understand the basics of VCN peering and how to establish a local peering.

**PEERING**

A **peering** is a single peering relationship between two VCNs. Example: If VCN-1 peers with three other VCNs, then there are three peerings. The **local** part of **local peering** indicates that the VCNs are in the same region. A given VCN can have a maximum of ten local peerings at a time.

**Caution:**

The two VCNs in the peering relationship must not have overlapping CIDRs. However, if VCN-1 is peered with three other VCNs, those three VCNs can have overlapping CIDRs with each other. You would set up the subnets in VCN-1 to have route rules that direct traffic to the targeted peered VCN.

**VCN ADMINISTRATORS**

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

• Share some basic information with each other.
• Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
• Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies.

For more information about the required policies and VCN configuration, see Setting Up a Local Peering on page 3271.

**ACCEPTOR AND REQUESTOR**

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the requestor and the other as the acceptor. The requestor must be the one to initiate the request to connect the two LPGs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to LPGs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

**LOCAL PEERING GATEWAY (LPG)**

A local peering gateway (LPG) is a component on a VCN for routing traffic to a locally peered VCN. As part of configuring the VCNs, each administrator must create an LPG for their VCN. A given VCN must have a separate LPG for each local peering it establishes (maximum ten LPGs per VCN). To continue with the previous example: VCN-1 would have three LPGs to peer with three other VCNs. In the API, a LocalPeeringGateway is an object that contains information about the peering. You can't reuse an LPG to later establish another peering.

**PEERING CONNECTION**

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to connect the two LPGs. The requestor must have information to identify each LPG (such as the LPG’s compartment and name, or the LPG’s OCID). Each administrator must put the required IAM policies in place for their compartment or tenancy.

Either VCN administrator can terminate a peering by deleting their LPG. In that case, the other LPG's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules or security rules that enable traffic to flow across the connection (see the next sections).

**ROUTING TO THE LPG**

As part of configuring the VCNs, each administrator must update the VCN’s routing to enable traffic to flow between the VCNs. In practice, this looks just like routing you set up for any gateway (such as an internet gateway or dynamic routing gateway). For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your LPG as the target. Your LPG routes traffic that matches that rule to the other LPG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to LPG-1 based on the rule in Subnet A's route table. From there the traffic is routed to LPG-2, and then from there, on to its destination in Subnet X.
As mentioned earlier, a given VCN can use the peered LPGs to reach VNICs in the other VCN, or the on-premises network if transit routing is set up for the VCNs. But a VCN can’t use the peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.
Important Implications of VCN Peering

If you haven't yet, read Important Implications of Peering on page 3265 to understand important access control, security, and performance implications for peered VCNs.

Setting Up a Local Peering

Here's the general process for setting up a peering between two VCNs in the same region:

1. **Create the LPGs:** Each VCN administrator creates an LPG for their own VCN.
2. **Share information:** The administrators share the basic required information.
3. **Set up the required IAM policies for the connection:** The administrators set up IAM policies to enable the connection to be established.
4. **Establish the connection:** The requestor connects the two LPGs.
5. **Update route tables:** Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as desired.
6. **Update security rules:** Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as desired.

If desired, the administrators can perform tasks E and F before establishing the connection. In that case, each administrator must know the CIDR block or specific subnets from the other's VCN and share that in task B. After the connection is established, you can also get the CIDR block of the other VCN by viewing your own LPG's details in the Console. Look for Peer Advertised CIDR. Or if you're using the API, see the peerAdvertisedCidr parameter.

**Task A: Create the LPGs**

Each administrator creates an LPG for their own VCN. “You” in the following procedure means an administrator (either the acceptor or requestor).

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required IAM Policy to Create LPGs</strong></td>
</tr>
<tr>
<td>If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network on page 2143), then they have permission to create, update, and delete LPGs. Otherwise, here's an example policy giving the necessary permissions to a group called LPGAdmins. The second statement is required because creating an LPG affects the VCN it belongs to, so the administrator must have permission to manage VCNs.</td>
</tr>
<tr>
<td>Allow group LPGAdmins to manage local-peering-gateways in tenancy</td>
</tr>
<tr>
<td>Allow group LPGAdmins to manage vcns in tenancy</td>
</tr>
</tbody>
</table>

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the LPG to. For information about compartments and access control, see Access Control on page 2831.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
3. Click the VCN you're interested in.
4. Under Resources, click Local Peering Gateways.
5. Click Create Local Peering Gateway.
6. Enter the following:
   - **Name**: A friendly name for the LPG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the LPG, if different from the compartment you're currently working in.
   - **Associate with Route Table (optional)**: Only if you're setting up the advanced routing scenario called transit routing. Select the compartment that contains the route table you want to associate with the LPG, and the route table itself. You can skip this part and associate the LPG with a route table later if you like.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

7. Click **Create Local Peering Gateway**.

   The LPG is then created and displayed on the **Local Peering Gateways** page in the compartment you chose.

**Task B: Share information**

If you're the **requestor**, give this information to the acceptor (for example, by email or other out-of-band method):

   - If the VCNs are in the **same tenancy**: Name of the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, the group is RequestorGrp.
   - If the VCNs are in **different tenancies**: OCID for your tenancy, and OCID for the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, it's the OCID for the RequestorGrp.
   - Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

If you're the **acceptor**, give this information to the requestor:

   - If the VCNs are in the **same tenancy**: OCID for your LPG. Optionally, also the names of your VCN, LPG, and the compartment each is in.
   - If the VCNs are in **different tenancies**: OCID for your LPG, and OCID for your tenancy.
   - Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

**Task C: Set up the IAM policies (VCNs in same tenancy)**

In this version of task C, both VCNs are in the same tenancy. If they're in different tenancies, instead see Task C: Set up the IAM policies (VCNs in different tenancies) on page 3274.

Both the requestor and acceptor must ensure that the right policies are in place:

   - **Policy R (implemented by the requestor)**:
     
     ```
     Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
     ```

     The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any LPG in the requestor’s compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or to RequestorComp. For information about why you would attach it to one versus the other, see Policy Basics on page 2137.

   - **Policy A (implemented by the acceptor)**:
     
     ```
     Allow group RequestorGrp to manage local-peering-to in compartment AcceptorComp
     Allow group RequestorGrp to inspect vcns in compartment AcceptorComp
     ```
Networking

**Allow group RequestorGrp to inspect local-peering-gateways in compartment AcceptorComp**

The first statement in the policy lets the requestor connect to any LPG in the acceptor's compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.

**Tip:**

The second and third statements in Policy A let the requestor list the VCNs and LPGs in AcceptorComp. The statements are required for the requestor to use the Console UI to select from a list of VCNs and LPGs in AcceptorComp and establish the connection. The following diagram focuses only on the first statement, which is the critical one that permits the connection.

Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called local-peering-from, and Policy A has a resource-type called local-peering-to. Together, these policies let someone in RequestorGrp establish the connection from an LPG in the requestor's compartment to an LPG in the acceptor's compartment. The API call to create the connection specifies which two LPGs.

**Tip:**

The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all of the Networking components in RequesterComp. For example, there might be a general Network Admin policy like this:

**Allow group NetworkAdmin to manage virtual-network-family in compartment RequestorComp**
Networking

If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes LPGs). And further, if the policy is instead written to cover the entire tenancy instead of only compartment RequestorComp, then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

Task C: Set up the IAM policies (VCNs in different tenancies)

In this version of task C, the VCNs are in different tenancies (in other words, it's a cross-tenancy peering). If the VCNs are in the same tenancy, instead see Task C: Set up the IAM policies (VCNs in same tenancy) on page 3272.

Both the requestor and acceptor must ensure that the right policies are in place:

- **Policy R (implemented by the requestor):**

  Define tenancy Acceptor as <acceptor_tenancy_OCID>

  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp

  Endorse group RequestorGrp to manage local-peering-to in tenancy Acceptor

  Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp
  with local-peering-gateways in tenancy Acceptor

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in that group initiate a connection from any LPG in the requestor's compartment (RequestorComp).

  The first statement is a "define" statement that assigns a friendly label to the acceptor's tenancy OCID. The statement happens to use "Acceptor" as the label, but it could be a value of the requestor's choice. All "define" statements in a policy must be the first ones (at the top).

  The second statement lets the RequestorGrp establish a connection from an LPG in the requestor's compartment.

  The third and fourth statements are special ones required because the LPGs are in different tenancies. They let the RequestorGrp connect an LPG in the requestor's tenancy to an LPG in the acceptor's tenancy.

  If the desire is to give the RequestorGrp permission to connect to an LPG in any tenancy, the policy would instead look like this:

  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp

  Endorse group RequestorGrp to manage local-peering-to in any-tenancy

  Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp
  with local-peering-gateways in any-tenancy

  Regardless, Policy R must be attached to the requestor's tenancy (root compartment), and not the requestor's compartment. Policies that enable cross-tenancy access must be attached to the tenancy. For more information about attachment of policies, see Policy Basics on page 2137.
• **Policy A (implemented by the acceptor):**

```
Define tenancy Requestor as <requestor_tenancy_OCID>
Define group RequestorGrp as <RequestorGrp_OCID>
Admit group RequestorGrp of tenancy Requestor to manage local-peering-to
  in compartment AcceptorComp
Admit group RequestorGrp of tenancy Requestor to associate local-peering-
  gateways in tenancy Requestor
  with local-peering-gateways in compartment AcceptorComp
```

Similar to the requestor's policy, this policy first uses "define" statements to assign friendly labels to the requestor's tenancy OCID and the RequestorGrp OCID. As mentioned earlier, the acceptor could use other values for those labels if desired.

The third and fourth statements let the RequestorGrp connect to an LPG in the acceptor's compartment (AcceptorComp). **These statements reflect the critical agreement required for the peering to be established.** The word Admit indicates that the access applies to a group **outside the tenancy** where the policy resides.

Policy A must be attached to the acceptor's tenancy (root compartment), and not the acceptor's compartment.
Task D: Establish the connection

The requestor must perform this task.

Prerequisite: The requestor must have the OCID of the acceptor's LPG.

Tip:

If you're using the Console and the peering is between two VCNs in the same tenancy: Instead of specifying the acceptor's LPG OCID, you can instead pick the acceptor's VCN and LPG from lists of resources in the tenancy. However, you need to know both the name and compartment for the acceptor's VCN and LPG instead of the LPG's OCID. For reference, see Task B: Share information on page 3272.

1. In the Console, view the details for the requestor LPG that you want to connect to the acceptor LPG.
2. For the requestor LPG, click the Actions icon (three dots), and then click Establish Peering Connection.
3. Specify which LPG you want to peer with:
   - If the VCNs are in different tenancies: Select Enter Local Peering Gateway OCID, and enter the acceptor LPG's OCID.
   - If the VCNs are in the same tenancy: Do one of the following:
     - Select Enter Local Peering Gateway OCID, and enter the acceptor LPG's OCID.
     - Select Browse Below, and then select the acceptor's VCN and LPG from the lists provided. Remember that the VCN and LPG each might be in a different compartment than the one you're currently working in.

4. Click Establish Peering Connection.

The connection is established and the LPG's state changes to PEERED.

At this point, the details of each LPG update to show the Peer VCN CIDR Block for the other VCN. This is the CIDR of the other VCN across the peering from the LPG. Each administrator can use this information to update the route tables and security rules for their own VCN.

Task E: Configure the route tables

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. If the connection is already established, look at the Peer VCN CIDR Block for your LPG in the Console. Otherwise, get the information from the other administrator by email or other method.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN's CIDR to your LPG:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following:
      - Target Type: Local Peering Gateway.
      - Destination CIDR Block: The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
      - Target Compartment: The compartment where the LPG is located, if not the current compartment.
      - Target: The LPG.
      - Description: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to your LPG. For more information about setting up route rules, see Route Tables on page 2921.

Later, if you no longer need the peering and want to delete your LPG, you must first delete all the route rules in your VCN that specify the LPG as the target.

Tip:

Without the required routing, traffic doesn't flow between the peered LPGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the LPGs.

Task F: Configure the security rules

As mentioned earlier, each administrator can do this task before or after the connection is established.
Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in Task E: Configure the route tables on page 3277.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

**Note:**

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
   c. Under Resources, click either Ingress Rules or Egress Rules depending on the type of rule you want to work with.
   d. If you want to add a new rule, click Add Ingress Rule (or Add Egress Rule).
      
      **Example**
      
      Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

      1. Leave the Stateless check box unselected.
      2. Source Type: Leave as CIDR.
      3. Source CIDR: Enter the same CIDR block that the route rules use (see Task E: Configure the route tables on page 3277).
      4. IP Protocol: Leave as TCP.
      5. Source Port Range: Leave as All.
      6. Destination Port Range: Enter 443.
      7. Description: An optional description of the rule.
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click Remove.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click Edit.

For more information about security rules, see Security Rules on page 2833.

**Using the Console**

*To create a local peering gateway*

See the instructions in Task A: Create the LPGs on page 3271.

*To associate a route table with an existing local peering gateway*

This task is related to an advanced routing scenario called transit routing.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.

**Prerequisite:** The route table must exist and belong to the VCN that the LPG belongs to.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Click the VCN you're interested in.
4. For the LPG you're interested in, click the Actions icon (three dots), and then click either:
   - **Associate With Route Table:** If the LPG has no route table associated with it yet.
   - **Replace Route Table Association:** If you're changing which route table is associated with the LPG.
5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

### To delete a local peering gateway

**Prerequisite:** First delete all the route rules in your VCN that specify the LPG as the target. Deleting those rules stops the routing in your VCN to the LPG. However, the LPG's state may still be PEERED if the other LPG still exists. Whenever an LPG is deleted, the LPG at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click Local Peering Gateways.
4. For the LPG you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

#### Note:

After deleting an LPG (and thus terminating a peering), it's recommended you review your security rules to remove any rules that enabled traffic with the other VCN.

### To manage tags for a local peering gateway

1. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click the Actions icon (three dots) for the local peering gateway, and then click View Tags. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags on page 211.

### To move a local peering gateway to a different compartment

You can move a local peering gateway from one compartment to another. When you move a local peering gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
4. Click the Actions icon (three dots) for the local peering gateway, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control on page 2831. For general information about compartments, see Managing Compartments on page 2431.

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your LPGs and create connections, use these operations:

- ListLocalPeeringGateways
- CreateLocalPeeringGateway
- GetLocalPeeringGateway
• UpdateLocalPeeringGateway
• DeleteLocalPeeringGateway
• ConnectLocalPeeringGateways
• ChangeLocalPeeringGatewayCompartment

Remote VCN Peering (Across Regions)

This topic is about remote VCN peering. In this case, remote means that the VCNs reside in different regions. If the VCNs you want to connect are in the same region, see Local VCN Peering (Within Region) on page 3267.

Overview of Remote VCN Peering

Remote VCN peering is the process of connecting two VCNs in different regions (but the same tenancy). The peering allows the VCNs' resources to communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN in a different region.

Summary of Networking Components for Remote Peering

At a high level, the Networking service components required for a remote peering include:

• Two VCNs with non-overlapping CIDRs, in different regions that support remote peering. The VCNs must be in the same tenancy.

Note:

All VCN CIDRs Must Not Overlap
The two VCNs in the peering relationship must not have overlapping CIDRs. Also, if a particular VCN has multiple peering relationships, those other VCNs must not have overlapping CIDRs with each other. For example, if VCN-1 is peered with VCN-2 and also VCN-3, then VCN-2 and VCN-3 must not have overlapping CIDRs.

• A dynamic routing gateway (DRG) attached to each VCN in the peering relationship. Your VCN already has a DRG if you're using an IPSec VPN or an Oracle Cloud Infrastructure FastConnect private virtual circuit.

• A remote peering connection (RPC) on each DRG in the peering relationship.

• A connection between those two RPCs.

• Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if desired).

• Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.
**Spoke-to-Spoke: Remote Peering with Transit Routing**

Imagine that in each region you have multiple VCNs in a hub-and-spoke layout, as shown in the following diagram. This type of layout within a region is discussed in detail in [Transit Routing: Access to Multiple VCNs in the Same Region](#) on page 2780. The spoke VCNs in a given region are locally peered with the hub VCN in the same region, using local peering gateways.

You can set up remote peering between the two hub VCNs. You can then also set up transit routing for the hub VCN's DRG and LPGs, as discussed in [Transit Routing: Access to Multiple VCNs in the Same Region](#) on page 2780. This setup allows a spoke VCN in one region to communicate with one or more spoke VCNs in the other region without needing a remote peering connection directly between those VCNs.

For example, you could configure routing so that resources in VCN-1-A could communicate with resources in VCN-2-A and VCN-2-B by way of the hub VCNs. That way, VCN 1-A is not required to have a separate remote peering with each of the spoke VCNs in the other region. You could also set up routing so that VCN-1-B could communicate with the spoke VCNs in region 2, without needing its own remote peerings to them.

---

**Explicit Agreement Required from Both Sides**

Peering involves two VCNs in the same tenancy that might be administered by the same party or two different ones. The two parties might both be in your company but in different departments.

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's compartment.
Important Remote Peering Concepts

The following concepts help you understand the basics of VCN peering and how to establish a remote peering.

**PEERING**

A peering is a single peering relationship between two VCNs. Example: If VCN-1 peers with two other VCNs, then there are two peerings. The remote part of remote peering indicates that the VCNs are in different regions. For remote peering, the VCNs must be in the same tenancy.

**VCN ADMINISTRATORS**

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

- Share some basic information with each other.
- Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
- Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies. The VCNs must be in the same tenancy.

For more information about the required policies and VCN configuration, see Setting Up a Remote Peering on page 3284.

**ACCEPTOR AND REQUESTOR**

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the requestor and the other as the acceptor. The requestor must be the one to initiate the request to connect the two RPCs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to RPCs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

**REGION SUBSCRIPTION**

To peer with a VCN in another region, your tenancy must first be subscribed to that region. For information about subscribing, see Managing Regions on page 2445.

**REMOTE PEERING CONNECTION (RPC)**

A remote peering connection (RPC) is a component you create on the DRG attached to your VCN. The RPC's job is to act as a connection point for a remotely peered VCN. As part of configuring the VCNs, each administrator must create an RPC for the DRG on their VCN. A given DRG must have a separate RPC for each remote peering it establishes for the VCN (maximum 10 RPCs per tenancy). To continue with the previous example: the DRG on VCN-1 would have two RPCs to peer with two other VCNs. In the API, a RemotePeeringConnection is an object that contains information about the peering. You can't reuse an RPC to later establish another peering with it.

**CONNECTION BETWEEN TWO RPCS**

When the requestor initiates the request to peer (in the Console or API), they're effectively asking to connect the two RPCs. This means the requestor must have information to identify each RPC (such as the RPC's region and OCID).

Either VCN administrator can terminate a peering by deleting their RPC. In that case, the other RPC's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules that enable traffic to flow across the connection (see the next section).

**ROUTING TO THE DRG**

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your DRG as the target. Your DRG routes traffic that matches that rule to the other DRG, which in turn routes the traffic to the next hop in the other VCN.
In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in Subnet A's route table. From there the traffic is routed through the RPCs to DRG-2, and then from there, on to the destination in Subnet X.

Note:
As mentioned earlier, a given VCN can use the connected RPCs to reach only VNICs in the other VCN, and not destinations outside of the VCNs (such as the internet or your on-premises network). For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

SECURITY RULES
Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify another NSG as the source or destination of traffic. However, the two NSGs must belong to the same VCN.
Important Implications of Peering

If you haven't yet, read Important Implications of Peering on page 3265 to understand important access control, security, and performance implications for peered VCNs.

Setting Up a Remote Peering

This section covers the general process for setting up a peering between two VCNs in different regions.

Important:

The following procedure assumes that:

- Your tenancy is subscribed to the other VCN's region. If it's not, see Managing Regions on page 2445.
- You already have a DRG attached to your VCN. If you don't, see Dynamic Routing Gateways (DRGs) on page 2927.

1. Create the RPCs: Each VCN administrator creates an RPC for their own VCN's DRG.
2. Share information: The administrators share the basic required information.
3. Set up the required IAM policies for the connection: The administrators set up IAM policies to enable the connection to be established.
4. Establish the connection: The requestor connects the two RPCs (see Important Remote Peering Concepts on page 3282 for the definition of the requestor and acceptor).
5. Update route tables: Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as desired.
6. Update security rules: Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as desired.

If desired, the administrators can perform tasks E and F before establishing the connection. Each administrator needs to know the CIDR block or specific subnets from the other's VCN and share that in task B.

Task A: Create the RPCs

Each administrator creates an RPC for their own VCN's DRG. "You" in the following procedure means an administrator (either the acceptor or requestor).

Note:

Required IAM Policy to Create RPCs

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network on page 2143), then they have permission to create, update, and delete RPCs. Otherwise, here's an example policy giving the necessary permissions to a group called RPCAdmins. The second statement is required because creating an RPC affects the DRG it belongs to, so the administrator must have permission to manage DRGs.

Allow group RPCAdmins to manage remote-peering-connections in tenancy
Allow group RPCAdmins to manage drgs in tenancy

1. In the Console, confirm you're viewing the compartment that contains the DRG that you want to add the RPC to. For information about compartments and access control, see Access Control on page 2831.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Dynamic Routing Gateways.
3. Click the DRG you're interested in.
5. Click Create Remote Peering Connection.
6. Enter the following:
   - **Name**: A friendly name for the RPC. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the RPC, if different from the compartment you're currently working in.

7. Click **Create Remote Peering Connection**.

   The RPC is then created and displayed on the **Remote Peering Connections** page in the compartment you chose.

8. If you're the acceptor, record the RPC's region and OCID to later give to the requestor.

**Task B: Share information**

- If you're the acceptor, give this information to the requestor (for example, by email or other out-of-band method):
  - The region your VCN is in (the requestor's tenancy must be subscribed to this region).
  - Your RPC's OCID.
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The requestor needs this information when setting up routing for the requestor VCN.

- If you're the requestor, give this information to the acceptor:
  - The region your VCN is in (the acceptor's tenancy must be subscribed to this region).
  - The name of the IAM group that should be granted permission to create a connection in the acceptor's compartment (in the example in the next task, the group is RequestorGrp).
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The acceptor needs this information when setting up routing for the acceptor VCN.

**Task C: Set up the IAM policies (VCNs in same tenancy)**

Both the requestor and acceptor must ensure the right policies are in place. These consist of:

- **Policy R (implemented by the requestor):**
  
  Allow group RequestorGrp to manage remote-peering-from in compartment RequestorComp

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any RPC in the requestor's compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or to RequestorComp. For information about why you would attach it to one versus the other, see **Policy Basics** on page 2137.

- **Policy A (implemented by the acceptor):**
  
  Allow group RequestorGrp to manage remote-peering-to in compartment AcceptorComp

  This policy lets the requestor connect to any RPC in the acceptor's compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.
Networking

Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called remote-peering-from, and Policy A has a resource-type called remote-peering-to. Together, these policies let someone in RequestorGrp establish the connection from an RPC in the requestor's compartment to an RPC in the acceptor's compartment. The API call to actually create the connection specifies which two RPCs.

Tip:
The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all of the Networking components in RequesterComp. For example, there might be a general Network Admin policy like this: Allow group NetworkAdmin to manage virtual-network-family in compartment RequestorComp. If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes RPCs). And further, if the policy is instead written to cover the entire tenancy (Allow group NetworkAdmin to manage virtual-network-family in tenancy), then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

Task D: Establish the connection
The requestor must perform this task.

Prerequisite: The requestor must have:
• The region the acceptor's VCN is in (the requestor's tenancy must be subscribed to the region).
• The OCID of the acceptor's RPC.

1. In the Console, view the details for the requestor RPC that you want to connect to the acceptor RPC.
2. Click Establish Connection.
3. Enter the following:
   • Region: The region that contains the acceptor's VCN. The drop-down list includes only those regions that both support remote VCN peering and your tenancy is subscribed to.
   • Remote Peering Connection OCID: The OCID of the acceptor's RPC.
4. Click **Establish Connection**.

The connection is established and the RPC's state changes to PEERED.

**Task E: Configure the route tables**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN to your DRG:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
      - **Description**: An optional description of the rule.
   f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see **Route Tables** on page 2921.

**Tip:**

Without the required routing, traffic doesn't flow between the peered DRGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the RPCs.

**Task F: Configure the security rules**

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in **Task E: Configure the route tables** on page 3287.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

**Note:**

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
   a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
   b. Click the security list you're interested in.
   c. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
   d. If you want to add a new rule, click **Add Ingress Rule** (or **Add Egress Rule**).
   e. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
   f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

For more information about security rules, see **Security Rules** on page 2833.

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

1. In the **Allow Rules for Ingress** section, click **+Add Rule**.
2. Leave the **Stateless** checkbox unchecked.
3. **Source Type:** Leave as CIDR.
4. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task E: Configure the route tables on page 3287).
5. **IP Protocol:** Leave as TCP.
6. **Source Port Range:** Leave as All.
7. **Destination Port Range:** Enter 443.
8. **Description:** An optional description of the rule.

**Using the Console**

*To create a remote peering connection*

See the instructions in Task A: Create the RPCs on page 3284.

*To delete a remote peering connection*

Deleting an RPC terminates the peering. The RPC at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
4. Click the RPC you're interested in.
5. Click **Terminate**.
6. Confirm when prompted.

**Note:**

After deleting an RPC (and thus terminating a peering), it's recommended you review your route tables and security rules to remove any rules that enabled traffic with the other VCN.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage your RPCs and create connections, use these operations:

- **ListAllowedPeerRegionsForRemotePeering**
- **ListRemotePeeringConnections**
- **CreateRemotePeeringConnection**
Access to Oracle Cloud Infrastructure Classic

There are two ways to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN):

- **Option 1: Connection over the Oracle network**
  - You file a ticket with My Oracle Support and Oracle provisions a connection between the IP network's private gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over Oracle's network and not the internet.
  - The two environments must be in the same geographical area, and the connection is available only between the specific regions listed in Overview on page 3289.
  - The two environments must belong to the same company. Oracle validates ownership when setting up the connection.

- **Option 2: Connection over an IPSec VPN**
  - You set up an IPSec VPN between the IP network's VPN as a Service (VPNaaS) gateway and the VCN's attached DRG. The connection runs over the internet.
  - The two environments do not have to be in the same geographical area or regions.
  - The two environments do not have to belong to the same company.

Connection Over Oracle Network

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over Oracle's network.

Another option is to connect the two clouds with an IPSec VPN. For more information, see Connection Over IPSec VPN on page 3294.

Highlights

- You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
- Oracle connects the IP network's private gateway to the VCN's attached dynamic routing gateway (DRG). The connection runs over the Oracle network. You configure routing and security rules in the environments to enable traffic.
- The two environments must belong to the same company and not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
- The two environments must both be in the Ashburn area, the London area, or the Sydney area, and in specific regions listed in the next section. Connectivity to other regions is not supported.
- The connection is free of charge.

Overview

You can request Oracle to provision a connection between your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to an IPSec VPN: the resources in the two environments have a more reliable and consistent network connection, with better throughput, because the traffic uses Oracle's internal links. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.
Here are other important details to know:

- The connection is supported only between these regions:
  - Oracle Cloud Infrastructure Australia East (Sydney) region and the Sydney Classic region
  - Oracle Cloud Infrastructure US East (Ashburn) region and the Ashburn Classic region
  - Oracle Cloud Infrastructure UK South (London) region and the Slough Classic region
- The connection enables communication that uses private IP addresses only.
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- The IP network and VCN must belong to the same company. Oracle validates this when setting up the connection.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

<table>
<thead>
<tr>
<th>Component</th>
<th>Oracle Cloud Infrastructure Classic</th>
<th>Oracle Cloud Infrastructure VCN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud network</td>
<td>IP network</td>
<td>VCN</td>
</tr>
</tbody>
</table>
### Component | Oracle Cloud Infrastructure Classic | Oracle Cloud Infrastructure
--- | --- | ---
Gateway | private gateway | dynamic routing gateway (DRG)
Routing | routes | route tables with route rules
Security rules | security rules | network security groups, security lists

## Connecting Your IP Network and VCN

The following flow chart shows the overall process of connecting your IP network and VCN.

### Prerequisites:

You must already have:

- An Oracle Cloud Infrastructure Classic IP network.
- An Oracle Cloud Infrastructure VCN with subnets.

**Task 1: Set up a private gateway for your IP network**

If you do not already have a private gateway for your IP network, create one.
Task 2: Set up a dynamic routing gateway (DRG) for your VCN

If you do not already have a DRG attached to your VCN, create a DRG and attach it:

- To create a DRG on page 2929
- To attach a DRG to a VCN on page 2930

Task 3: Configure route tables

For the IP network

When you create the private gateway and attach an IP network to it, traffic from cloud resources in the IP network uses the private gateway as the next hop. You do not need to update any routes for the IP network.

For the VCN

You must add a route rule that directs traffic from the VCN's subnets to the DRG:

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   b. Click the VCN you're interested in.
   c. Under Resources, click Route Tables.
   d. Click the route table you're interested in.
   e. Click Add Route Rule and enter the following:
      - Destination CIDR Block: The IP network's CIDR block.
      - Target Type: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - Description: An optional description of the rule.
   f. Click Add Route Rule.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see Route Tables on page 2921.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

Task 4: Configure the security rules

To ensure traffic flows between the IP network and VCN, the IP network security rules and the VCN's security rules must be set to allow traffic.

Here are the types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow traffic.

For the VCN

Note:

The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.
1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow egress or ingress traffic specifically with the CIDR block of the IP network:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.

   Under Resources, you can click Ingress Rules or Egress Rules to switch between the different types of rules.
   c. Add one or more rules, each for the specific type of traffic you want to allow.

For more information about setting up security rules, see Security Rules on page 2833.

### Important:

The VCN's default security list does not allow ICMP echo reply and echo request (ping). You must add rules to enable that traffic. See Rules to Enable Ping on page 2841

Example:

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

1. On the **Ingress Rules** page, click **Add Ingress Rule**.
2. Leave the **Stateless** check box unselected.
3. **Source CIDR**: Enter the same CIDR block that the route rules use (see Task 3: Configure route tables on page 3292).
4. **IP Protocol**: Leave as TCP.
5. **Source Port Range**: Leave as All.
6. **Destination Port Range**: Enter 443.
7. **Description**: Optionally enter a description of the rule.
8. Click **Add Ingress Rule**.

### Task 5: Create a My Oracle Support ticket

To have Oracle set up the connection, create a ticket at My Oracle Support and provide the following information:

- Ticket name: Create IP Network - VCN Connection - `<your_company_name>` - Ashburn
- OCI-C identity domain
- OCI-C private gateway name
- Region
- OCI tenancy OCID
- OCI DRG OCID

For example:

- Ticket name: Create IP Network - VCN Connection - ACME - Ashburn
- OCI-C identity domain: 123456789, uscom-east-1
- OCI-C private gateway name: Compute-acme/jack.jones@example.com/privategateway1
- Region: uscom-east-1 (OCI-C) / us-ashburn-1 (OCI)
- OCI tenancy OCID: ocid1.tenancy.oc1..examplefbpnk5cmdl7gkr6kcakfqmvhvbpcv
- OCI DRG OCID: ocid1.drg.oc1.iad.exampleutg6cmd3fqwqbea7ctadcatm

It can take three to four business days before your My Oracle Support ticket is complete and the connection is ready to test.

### Task 6: Test the connection

After you receive confirmation from your support person that the connection is ready, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to launch an
instance in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.

**Terminating the Connection**

If you want to terminate the connection, file a ticket at My Oracle Support.

**Connection Over IPSec VPN**

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over an IPSec VPN.

Another option is to have Oracle set up a connection over the Oracle network. For more information, see Connection Over Oracle Network on page 3289.

**Highlights**

- You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
- You set up an IPSec VPN between the IP network's VPN as a Service (VPNaas) gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over the internet. You configure routing and security rules in the environments to enable traffic.
- The two environments must not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
- The two environments do not have to be in the same geographical area or region.
- The connection is free of charge.

**Overview**

You can connect your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment with an IPSec VPN. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to using the Oracle network for the connection: you can set up the IPSec VPN yourself in a matter of minutes. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.
Here are other important details to know:

- The connection is supported in any of the Oracle Cloud Infrastructure and Oracle Cloud Infrastructure Classic regions. The two environments do not need to be in the same geographical area.
- The connection enables communication that uses private IP addresses only.
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

<table>

Setting Up the IPSec VPN Between Your IP Network and VCN

The following flow chart shows the overall process of connecting your IP network and VCN with an IPSec VPN.

Prerequisites:

You must already have:

• An Oracle Cloud Infrastructure Classic IP network.
• An Oracle Cloud Infrastructure VCN with subnets.
**Task 1: Set up a VPNaaS gateway for your IP network**

1. Use these values when setting up the VPNaaS gateway:
   - **IP Network**: The Oracle Cloud Infrastructure Classic IP network you want to connect to your VCN. You can only specify a single IP network.
   - **Customer Gateway**: A placeholder value such as 129.213.240.51. Using this placeholder value lets you move forward in the process. You update the value later with the Oracle Cloud Infrastructure VPN router’s IP address.
   - **Customer Reachable Routes**: The CIDR block for the VCN. You can specify only a single VCN.
   - **Specify Phase 2 ESP Proposal**: Check box selected.
   - **ESP Encryption**: AES 256
   - **ESP Hash**: SHA1
   - **IPSec Lifetime**: 1800
   - **Require Perfect Forward Secrecy**: Check box selected.

2. Record the resulting public IP address of the VPNaaS gateway.

**Task 2: Set up the VCN's components and IPSec tunnel**

**Task 2a: Set up a dynamic routing gateway (DRG) for your VCN**

If you do not already have a DRG attached to your VCN, create a DRG and attach it:
   - To create a DRG on page 2929
   - To attach a DRG to a VCN on page 2930

**Task 2b: Configure routing to the DRG**

Add a route rule that directs traffic from the VCN's subnets to the DRG. Use the IP network's CIDR block as the destination for the rule.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following:
      - **Destination CIDR Block**: The IP network's CIDR block.
      - **Target Type**: Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Description**: An optional description of the rule.
   f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see **Route Tables** on page 2921.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

**Task 2c: Configure the security rules**

To ensure traffic flows between the IP network and VCN, set the IP network security rules and the VCN's security rules to allow the wanted traffic.

Here are the types of rules to add:
   - Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
Networking

- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow the wanted traffic.

For the VCN

Note:
The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow the wanted egress or ingress traffic specifically with the CIDR block of the IP network:
   a. In the Console, while viewing the VCN you're interested in, click Security Lists.
   b. Click the security list you're interested in.
      Under Resources, you can click Ingress Rules or Egress Rules to switch between the different types of rules.
   c. Add one or more rules, each for the specific type of traffic you want to allow.

   For more information about setting up security list rules, see Security Lists on page 2850.

Important:
The VCN's default security list does not allow ICMP echo reply and echo request (ping). Add rules to enable that traffic. See Rules to Enable Ping on page 2841

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

2. Leave the Stateless check box unselected.
3. Source CIDR: Enter the same CIDR block that the route rules use (see Task 2b: Configure routing to the DRG on page 3297).
4. IP Protocol: Leave as TCP.
5. Source Port Range: Leave as All.
6. Destination Port Range: Enter 443.
7. Click Add Ingress Rule.
8. Description: Optionally enter a description of the rule.

Task 2d: Create a CPE object

Create a CPE object. An IP address is required. Use the VPNaaS gateway's public IP address.

Task 2e: Create the IPSec connection

From your DRG, create an IPSec connection to the CPE object. You must provide one or more static routes. The values must match the IP network's subnets or aggregate.

The resulting IPSec connection consists of two tunnels. Record the IP address and shared secret for one of those tunnels. In the next task, you will provide those values.

Task 3: Update the VPNaaS connection with the tunnel information

Update the VPNaaS connection. Use these values:
• **Customer Gateway:** The tunnel's IP address from the preceding task.

• **VPNaaS VPN Connection’s Pre-shared Key:** The tunnel's shared secret from the preceding task.

After the VPNaaS connection is updated and provisioned, the state of your VCN's IPSec tunnel should change to Available. Provisioning might take a few minutes.

**Task 4: Test the connection**

After the tunnel state changes to Available, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to **launch an instance** in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.

**Terminating the Connection**

If you want to terminate the connection, delete the IPSec connection:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **VPN Connections**.

   A list of the IPSec connections in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.

3. Click **Terminate**.

4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

**Access to Microsoft Azure**

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. This topic describes how to set up virtual networking infrastructure resources to enable this kind of cross-cloud deployment.

**Highlights**

• You can connect a Microsoft Azure virtual network (VNet) with an Oracle Cloud Infrastructure virtual cloud network (VCN) and run a cross-cloud workload. In the typical use case, you deploy your Oracle Database on Oracle Cloud Infrastructure, and deploy an Oracle, .NET, or custom application in Microsoft Azure.

• The two virtual networks must belong to the same company and not have overlapping CIDRs. The connection requires you to create an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit.

• Currently, the connection is only available in these areas:

  • Between the Oracle Cloud Infrastructure location in the US East (Ashburn) region and the **Azure Washington DC and Washington DC2 locations**.
  
  • Between the Oracle Cloud Infrastructure location in the UK South (London) region and the **Azure London location**.
  
  • Between the Oracle Cloud Infrastructure location in the Canada Southeast (Toronto) region and the **Azure Canada Central location**.
  
  • Between the Oracle Cloud Infrastructure location in the Netherlands Northwest (Amsterdam) region and the **Azure Amsterdam2 location**.
  
  • Between the Oracle Cloud Infrastructure location in the Japan East (Tokyo) region and the **Azure Tokyo location**.
  
  • Between the Oracle Cloud Infrastructure location in the US West (San Jose) region and the **Azure Silicon Valley location**.

**Overview of Supported Traffic**

Here are more details about the supported types of traffic.
**VNet-to-VCN Connection: Extension from One Cloud to Another**

You can connect your VNet and VCN so that traffic that uses private IP addresses goes over the cross-cloud connection.

For example, the following diagram shows a VNet that is connected to a VCN. Resources in the VNet are running a .NET application that access an Oracle database that runs on Database service resources in the VCN. The traffic between the application and database uses a logical circuit that runs on the cross-cloud connection between Azure and Oracle Cloud Infrastructure.

To enable the connection between the VNet and VCN, you set up an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit. The connection has built-in redundancy, which means you need to set up only a single ExpressRoute circuit and single FastConnect virtual circuit. The bandwidth for the connection is the bandwidth value you choose for the ExpressRoute circuit.

For instructions, see [Setting Up a VNet-to-VCN Connection](#) on page 3302.

**Peered VCNs**

The connection enables traffic to flow from the VNet through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.
Types of Traffic Not Supported by the Connection

This cross-cloud connection does not enable traffic between your on-premises network through the VCN to the VNet, or from your on-premises network through the VNet to the VCN.

Important Implications of Connecting Clouds

This section summarizes some access control, security, and performance implications of connecting your VCN to a VNet. In general, you can control access and traffic by using IAM policies, route tables in the VCN, and security rules in the VCN.

The sections that follow discuss implications from the perspective of your VCN. Similar implications affect your VNet. As with your VCN, you can use Azure resources such as route tables and network security groups to secure your VNet.

Controlling the Establishment of a Connection

With Oracle Cloud Infrastructure IAM policies, you can control:

- Who in your organization has the authority to create a FastConnect virtual circuit (see Setting Up a VNet-to-VCN Connection on page 3302). Deletion of the relevant IAM policy does not affect any existing connections to a VNet, only the ability for a future connection to be created.
- Who can manage route tables, network security groups, and security lists.

Controlling Traffic Flow Over the Connection

Even if a connection has been established between your VCN and VNet, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the VNet.

Without terminating the connection, you can stop traffic flow to the VNet by simply removing route rules that direct traffic from your VCN to the VNet. You can also effectively stop the traffic by removing any security rules that enable ingress or egress traffic with the VNet. This doesn't stop traffic flowing over the connection, but stops it at the VNIC level.

Controlling the Specific Types of Traffic Allowed

It's important that you ensure that all outbound and inbound traffic with the VNet is intended or expected and well defined. Implement Azure network security group and Oracle security rules that explicitly state the types of traffic one cloud can send to the other and accept from the other.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your Oracle Cloud Infrastructure instances running Oracle-provided Linux images or Windows images also have firewall rules that control access to the instance. When troubleshooting access to an instance, ensure that the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules. For more information, see Oracle-Provided Images on page 629.</td>
</tr>
<tr>
<td>If your instance is running Oracle Autonomous Linux 7, Oracle Linux 8, or Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):</td>
</tr>
<tr>
<td>sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp</td>
</tr>
<tr>
<td>sudo firewall-cmd --reload</td>
</tr>
</tbody>
</table>
For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

In addition to security rules and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don't apply to your own VCN's CIDR, but inadvertently apply to the VNet's CIDR.

Using Default Security List Rules with Your VCN

If your VCN's subnets use the default security list with the default rules, two rules in that list allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the VNet):

- Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
- Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Evaluate these rules and whether you want to keep or update them. As stated earlier, you should ensure that all permitted inbound or outbound traffic is intended or expected and well defined.

Preparing for Performance Impact and Security Risks

In general, you should prepare your VCN for the ways it could be affected by the VNet. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the VNet.

Regarding performance: If your VCN is providing a service to the VNet, be prepared to scale up your service to accommodate the demands of the VNet. This might mean being prepared to launch more instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security rules to limit the level of connection tracking your VCN must perform. Stateless security rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: If the VNet is connected to the internet, your VCN can be exposed to bounce attacks. A bounce attack involves a malicious host on the internet sending traffic to your VCN that looks like it's coming from the VNet. To guard against this, as mentioned earlier, use your security rules to carefully limit the inbound traffic from the VNet to expected and well-defined traffic.

Setting Up a VNet-to-VCN Connection

This section describes how to set up the logical connection between a VNet and VCN (for background, see Overview of Supported Traffic on page 3299).

Prerequisites: Resources You Need

You must already have:

- An Azure VNet with subnets and virtual network gateway
- An Oracle Cloud Infrastructure VCN with subnets and an attached dynamic routing gateway (DRG). It's easy to forget to attach the DRG to your VCN after you create it. If you already have an IPSec VPN or FastConnect between your on-premises network and VCN, then your VCN already has an attached DRG. You use that same DRG here when setting up the connection to Azure.

As a reminder, here is a table that lists the comparable networking components involved in each side of the connection.

<table>
<thead>
<tr>
<th>Component</th>
<th>Azure</th>
<th>Oracle Cloud Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual network</td>
<td>VNet</td>
<td>VCN</td>
</tr>
<tr>
<td>Virtual circuit</td>
<td>ExpressRoute circuit</td>
<td>FastConnect private virtual circuit</td>
</tr>
<tr>
<td>Gateway</td>
<td>virtual network gateway</td>
<td>dynamic routing gateway (DRG)</td>
</tr>
</tbody>
</table>
**Prerequisites: BGP Information You Need**

The connection between the VNet and VCN uses BGP dynamic routing. When you set up the Oracle virtual circuit, you provide the BGP IP addresses that will be used for the two redundant BGP sessions between Oracle and Azure:

- A primary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)
- A separate, secondary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)

**For each pair, you must provide a separate /30 block of addresses** (each /30 has four IP addresses).

The second and third addresses in each /30 are used for the BGP IP address pair. Specifically:

- The second address in the block is for the Oracle side of the BGP session
- The third address in the block is for the Azure side of the BGP session

The first and last addresses in the block are used for other internal purposes.

For example, if the /30 is 10.0.0.20/30, then the addresses in the block are:

- 10.0.0.20
- 10.0.0.21: Use this for the Oracle side (in the Oracle Console, enter the address as 10.0.0.21/30)
- 10.0.0.22: Use this for the Azure side (in the Oracle Console, enter the address as 10.0.0.22/30, and notice that this address is referred to as the "Customer" side in the Console)
- 10.0.0.23

Remember that you must also provide a /30 block for the secondary BGP addresses. For example: 10.0.0.24/30. In this case, 10.0.0.25 is for the Oracle side, and 10.0.0.26 is for the Azure side. In the Oracle Console, you must enter these as 10.0.0.25/30 and 10.0.0.26/30.

**Prerequisites: Required IAM Policy**

It's assumed that you have the necessary Azure Active Directory access and Oracle Cloud Infrastructure IAM access to create and work with the relevant Azure and Oracle networking resources. Specifically for IAM: If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this one generally covers all the Networking resources:

```yaml
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To only create and manage a virtual circuit, you must have a policy like this:

```yaml
Allow group VirtualCircuitAdmins to manage drgs in tenancy
Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

For more information, see [IAM Policies for Networking](#) on page 232.
Overall Process

The following flow chart shows the overall process of connecting your VNet and VCN.

1. Configure VNet's security groups and VCN's security lists
2. Set up Azure ExpressRoute circuit
3. Confirm both circuits are provisioned
4. Configure routing for VNet and VCN

Task 1: Configure the network security groups and security rules

The first task is to determine what traffic needs to flow between the relevant subnets within the VNet and VCN, and then configure the VNet security groups and VCN security rules accordingly. Here are the general types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's relevant subnets.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the traffic to the VNet. The VCN's default security list includes a broad default egress rule like this.

More specifically, here are recommended types of traffic to allow between the VNet and VCN:

- Ping traffic in both directions for testing the connection from each side
- SSH (TCP port 22)
- Client connections to an Oracle database (SQL*NET on TCP port 1521)

Only allow traffic to and from specific address ranges of interest (for example, the other cloud's relevant subnets).
For the VNet: Determine which subnets in your VNet need to communicate with the VCN. Then configure the network security groups for those subnets to allow traffic.

For the VCN:

**Note:**
The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's relevant resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the security list for each of those subnets to include rules to allow egress or ingress traffic specifically with the VNet's CIDR block or a subnet of the VNet:
   a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
   b. Click the security list you're interested in.
   c. Click **Edit All Rules** and create one or more rules, each for the specific type of traffic you want to allow.
   d. Click **Save Security List Rules** at the bottom of the dialog box.

For more information about setting up security rules, see Security Rules on page 2833.

**Example: Outgoing ping from VCN to VNet**
The following egress security rule lets an instance initiate a ping request to a host outside the VCN (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate ingress rule for echo reply ICMP type 0 is required.

1. In the **Allow Rules for Egress** section, click **+Add Rule**.
2. Leave the **Stateless** check box unselected.
3. **Destination CIDR**: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. **IP Protocol**: ICMP
5. **Type and Code**: 8
6. **Description**: An optional description of the rule.

**Example: Incoming ping to VCN from VNet**
The following ingress security rule lets an instance receive a ping request from a host in the VNet (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate egress rule for echo reply ICMP type 0 is required.

1. In the **Allow Rules for Ingress** section, click **+Add Rule**.
2. Leave the **Stateless** check box unselected.
3. **Source CIDR**: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. **IP Protocol**: ICMP
5. **Type and Code**: 8
6. **Description**: An optional description of the rule.

**Example: Incoming SSH to VCN**
The following ingress security rule lets an instance receive an SSH connection (TCP port 22) from a host in the VNet.

1. In the **Allow Rules for Ingress** section, click **+Add Rule**.
2. Leave the **Stateless** check box unselected.
3. **Source CIDR**: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. **IP Protocol**: TCP
5. **Source Port Range**: All
6. **Destination Port Range**: 22
7. **Description**: An optional description of the rule.
**Example: SQL*Net connections to database**

The following ingress security rule allows SQL*Net connections (TCP port 1521) from hosts in the VNet.

1. In the **Allow Rules for Ingress** section, click **+Add Rule**.
2. Leave the **Stateless** check box unselected.
3. **Source CIDR**: The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
4. **IP Protocol**: TCP
5. **Source Port Range**: All
6. **Destination Port Range**: 1521
7. **Description**: An optional description of the rule.

**Task 2: Set up Azure ExpressRoute circuit**

Set up an ExpressRoute circuit to Oracle Cloud FastConnect. During the circuit setup, you receive a service key from Microsoft. Record that service key, because you must provide it to Oracle in the next task.

In the next task, you set up a FastConnect private virtual circuit to Microsoft Azure: ExpressRoute. When that virtual circuit finishes being provisioned, your ExpressRoute circuit updates to show that private peering is enabled.

**Task 3: Set up an Oracle Cloud Infrastructure FastConnect virtual circuit**

1. In the Console, confirm you're viewing the **compartment** that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to. This choice of compartment, along with a corresponding IAM policy, controls who can access the virtual circuit you're about to create.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**. The resulting FastConnect page is where you create a new virtual circuit and later return to when you need to manage the virtual circuit.
3. Click **Create Connection**.
4. Select **FastConnect partner** and choose **Microsoft Azure: ExpressRoute** from the list.
5. Enter the following for your virtual circuit:
   • **Name**: A friendly name of your choice. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   • **Create in Compartment**: Leave as is (the compartment you're currently working in).
   • **Virtual Circuit Type**: Select **Private Virtual Circuit**.
   • **Dynamic Routing Gateway Compartment**: Select the compartment where the DRG resides (it should already be selected).
   • **Dynamic Routing Gateway**: Select the DRG.
   • **Provisioned Bandwidth**: Choose the same bandwidth level you chose for the ExpressRoute circuit (or the closest value available).
   • **Provider Service Key**: Enter the key you received from Microsoft when you set up the ExpressRoute circuit.
   • **Customer Primary BGP IP Address**: This field is the Azure primary BGP IP address. Enter the third address in the primary /30 block that you provide, and include /30 at the end. For example: 10.0.0.22/30. For more information about this field and the next ones, see Setting Up a VNet-to-VCN Connection on page 3302.
   • **Oracle Primary BGP IP address (optional)**: You can leave this field blank and Oracle infers the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.21/30.
   • **Customer Secondary BGP IP Address**: This field is the Azure secondary BGP IP address. Enter the third address in the secondary /30 block that you provide, and include /30 at the end. For example: 10.0.0.26/30.
   • **Oracle Primary BGP IP Address (optional)**: You can leave this field blank and Oracle infers the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.25/30.
6. Click **Continue**.
   The virtual circuit is created.
7. Click **Close**.
After you create the Oracle virtual circuit, you do not need to contact Azure to request provisioning of the circuit. It happens automatically.

**Task 4: Confirm that both circuits are provisioned**

Within a few minutes, both circuits should be provisioned. To verify:

- For the ExpressRoute circuit, confirm that private peering is provisioned.
- For the FastConnect virtual circuit, confirm that its status is UP. See *To get the status of your FastConnect virtual circuit* on page 3307.

**Task 5: Configure the route tables**

**For the VNet:** Determine which subnets in your VNet need to communicate with the VCN. Then configure the route tables for those subnets to route traffic to the VNet gateway.

**For the VCN:**

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the VNet's CIDR to your DRG:
   a. In the Console, while viewing the VCN you're interested in, click *Route Tables*.
   b. Click the route table you're interested in.
   c. Click *Edit Route Rules*.
   d. Click *+ Another Route Rule* and enter the following:
      - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram).
      - **Description:** An optional description of the rule.
   e. Click *Save*.

Any subnet traffic with a destination that matches the rule is routed to your DRG. The DRG then knows to route the traffic to the VNet based on the virtual circuit's BGP session information.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

For more information about setting up route rules, see *Route Tables* on page 2921.

**Task 6: Test the connection**

Depending on how you've set up your VNet security groups and VCN security rules, you should be able to create an instance in your VCN and access it from a host in the VNet. Or you should be able to connect from the instance to a host in the VNet. If you can, your connection is ready to use.

**Important:**

If you decide to terminate the connection, you must follow a particular process. See *To terminate the connection to Azure* on page 3309.

**Managing a VNet-to-VCN Connection**

**To get the status of your FastConnect virtual circuit**

1. Open the navigation menu. Under *Core Infrastructure*, go to *Networking* and click *FastConnect*.
2. Select the compartment where the connection resides, and then click the connection you're interested in. If the icon for the virtual circuit is green and says UP, the virtual circuit is provisioned and BGP has been correctly configured. The virtual circuit is ready to use.
To edit a FastConnect virtual circuit

You can change these items for your virtual circuit:

- The name
- Which DRG it uses

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your virtual circuit is in the PROVISIONED state, changing which DRG it uses switches the state to PROVISIONING and may cause the connection to go down. After Oracle reprovisions the virtual circuit, its state returns to PROVISIONED. Confirm that the connection is back up and working.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
2. Select the compartment where the connection resides, and then click the connection.
3. Click the virtual circuit.
4. Click Edit and make your changes. Avoid entering confidential information.
5. Click Save.
To terminate the connection to Azure

The following flow chart shows the overall process of terminating a VNet-to-VCN connection.

1. In the Azure portal, view the ExpressRoute circuit, and then view its Connections. Confirm that there are no Connections still in existence for the ExpressRoute circuit. Delete all Connections before proceeding.

2. In the Oracle portal, delete your FastConnect virtual circuit:
   a. Open the navigation menu. Under Core Infrastructure, go to Networking and click FastConnect.
   b. Select the compartment where the connection resides, and then click the connection.
   c. Click the virtual circuit.
   d. Click Delete.
   e. Confirm when prompted.

   The virtual circuit's Lifecycle State switches to TERMINATING.

3. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not Provisioned".

4. In the Azure portal, delete the ExpressRoute circuit.

The connection between Azure and Oracle Cloud Infrastructure is terminated.
Access to Other Clouds with Libreswan

Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. This topic shows how to connect your Oracle Cloud Infrastructure virtual cloud network (VCN) with another cloud provider by using an IPSec VPN with a Libreswan VM as the customer-premises equipment (CPE).

In the example shown here, the other cloud provider is Amazon Web Services (AWS). The connection is a secure and encrypted site-to-site IPSec VPN between the Oracle and Amazon environments. It enables resources in the two clouds to communicate with each other using their private IP addresses as if they are in the same network segment.

A Libreswan CPE guide is also available for all other use cases.

Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

Architecture

The following diagram shows the general layout of the connection.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters on page 2945.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the US Government Cloud, see Required VPN Connect Parameters for Government Cloud on page 152 and also Oracle's BGP ASN on page 154. For the United Kingdom Government Cloud, see Oracle's BGP ASN on page 171.

Configuration

Important:

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for Libreswan. If you need support or further assistance, consult the Libreswan documentation.
Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

Refer to Supported IPSec Parameters on page 3310 for more details about the specific parameters used in this document.

**Default Libreswan Configuration Files**

The default Libreswan installation creates the following files:

- `/etc/ipsec.conf`: The root of the Libreswan configuration.
- `/etc/ipsec.secrets`: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- `/etc/ipsec.d/`: A directory for storing the `.conf` and `.secrets` files for your Oracle Cloud Infrastructure tunnels (for example: `oci-ipsec.conf` and `oci-ipsec.secrets`). Libreswan encourages you to create these files in this folder.

The default `/etc/ipsec.conf` file includes this line:

```bash
include /etc/ipsec.d/*.conf
```

The default `/etc/ipsec.secrets` file includes this line:

```bash
include /etc/ipsec.d/*.secrets
```

The preceding lines automatically merge all the `.conf` and `.secrets` files in the `/etc/ipsec.d` directory into the main configuration and secrets files that Libreswan uses.

**About Using IKEv2**

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters on page 2945.

You specify the IKE version when setting up the IPSec configuration file in task 4 in the next section. In that example file, there's a comment showing how to configure IKEv1 versus IKEv2.

**Configuration Process**

**Task 1: Prepare the AWS Libreswan instance**

1. Using the AWS Console or APIs, create a Libreswan VM by using its provisioning process. Use Oracle Linux, CentOS, or Red Hat as the main operating system.
2. After the new instance starts, connect to it with SSH and install the Libreswan package:

```bash
sudo yum -y install libreswan
```
3. In the AWS Console, disable the source and destination checks on the Libreswan VM instance by right-clicking the instance, clicking Networking, and then clicking Change Source/Dest. Check. When prompted, click Yes, Disable.

4. On the Libreswan VM, configure IP_forward to allow AWS clients to send and receive traffic through the Libreswan VM. In the /etc/sysctl.conf file, set the following values and apply the updates with `sudo sysctl -p`.

   ```
   net.ipv4.ip_forward=1
   net.ipv4.conf.all.send_redirects = 0
   net.ipv4.conf.all.accept_redirects = 0
   net.ipv4.conf.default.send_redirects = 0
   net.ipv4.conf.default.accept_redirects = 0
   net.ipv4.conf.eth0.send_redirects = 0
   net.ipv4.conf.eth0.accept_redirects = 0
   ```

5. In the AWS Console, edit your AWS route table. Add a rule with the VCN CIDR (172.0.0.0/16) as the destination and the AWS Libreswan instance ID (i-016ab864b43cb368e in this example) as the target.

6. In the AWS Console, enable inbound TCP and UDP traffic on ports 4500 and 500 to allow Oracle Cloud Infrastructure IPSec VPN communication with the AWS Libreswan VM. This task includes editing both the AWS
security groups and network ACLs. You can set the source value can be the Oracle public IP (the Oracle VPN headend IPSec tunnel endpoint) instead of 0.0.0.0/0.

For security groups:

For network ACLs:
Task 2: Configure the Oracle Cloud Infrastructure DRG and CPE object

1. In the Oracle Console, create a customer-premises equipment (CPE) object that points to the Libreswan AWS instance public IP address (34.200.255.174).

2. If you don’t already have a DRG attached to your VCN: in the Oracle Console, create a DRG and then attach it to the VCN (172.0.0.0/16).
3. In the Oracle Console, create an IPSec connection and point it to the AWS VPC CIDR (10.0.0.0/16). In other words, when you create the IPSec connection, set its static route to the AWS VPC CIDR.

For each configured IPSec connection, Oracle creates two tunnels and assigns these items to each one:
- Oracle VPN headend IPSec tunnel endpoint
- Oracle VPN tunnel shared secret

You can view the IPSec tunnel status and Oracle VPN headend IP by clicking the Actions icon (three dots) for the IPSec connection, and then clicking View Details. Initially each tunnel is in the DOWN state (offline) because you still have some additional configuration to do later on the AWS Libreswan VM.

To view the shared secret, click the Actions icon (three dots) for an individual tunnel, and then click View Details. Next to Shared Secret, click Show.
