# Contents

**Chapter 1 About Oracle Cloud Infrastructure** ................................................. 22

- Prefer Online Help? ................................................................. 24
- Need API Documentation? .......................................................... 24

**Chapter 2 Welcome to Oracle Cloud Infrastructure** .................................... 26

- Getting Started ........................................................................ 26
- About the Services ................................................................. 26
- Accessing Oracle Cloud Infrastructure ........................................ 29
- How Do I Get Started? .............................................................. 29
- Key Concepts and Terminology .................................................. 29
- Request and Manage Free Oracle Cloud Promotions .................. 32
- Buy an Oracle Cloud Subscription ........................................... 36
- Request and Manage the Oracle Startup Program ................... 38
- Understanding the Sign-In Options ........................................... 39
- Signing In to the Console .......................................................... 41
- Using the Console ................................................................. 42
- Using the Mobile App ............................................................ 49
- Changing Your Password .......................................................... 52
- Checking Your Expenses and Usage .......................................... 55
- Adding Users ........................................................................ 57
- Oracle Cloud Infrastructure Tutorials ....................................... 60
- Tutorial - Launching Your First Linux Instance ......................... 61
- Tutorial - Launching Your First Windows Instance .................. 73
- Putting Data into Object Storage .............................................. 82
- Getting Started with the Command Line Interface ................... 83
- Getting Started ....................................................................... 102
- Getting Started with Load Balancing ....................................... 103
- Getting Started with Audit ...................................................... 116
- Getting Started with Oracle Platform Services ......................... 119
- Getting Started with Oracle Applications ................................ 121
- Setting Up Your Tenancy .......................................................... 122
- Getting Help and Contacting Support ....................................... 125
- Task Mapping from My Services .............................................. 132
- Frequently Asked Questions ..................................................... 135

**Chapter 3 Oracle Cloud's Free Tier** ............................................................... 140

- Free Trial ............................................................................ 140
- Always Free Resources .......................................................... 140
- To provision your Always Free using Terraform and Resource Manager ........................................ 141
- Upgrading to a Paid Account .................................................... 141
- Additional Information ............................................................. 142
- Details of the Always Free Resources ........................................ 142
- Compute ............................................................................ 142
- Database .............................................................................. 142
- Load Balancing ..................................................................... 143
- Block Volume ........................................................................ 143
- Object Storage ...................................................................... 144
# Table of contents

- Resource Manager................................................................. 144
- Service Connector Hub........................................................... 145
- Vault..................................................................................... 145
- Frequently Asked Questions: Oracle Cloud Infrastructure Free Tier......................................................... 145
  - How do I change which resources I want to designate as Always Free?......................................................... 145
  - What happens when my Free Trial expires or my credits are used up?......................................................... 145
  - If I upgrade, do I keep my Free Trial credit balance?.................................................................................. 146
  - After I upgrade my account, can I downgrade?.......................................................................................... 146
  - My resources no longer appear. How can I restore them?.......................................................................... 146
  - I get an "out of host capacity" error when I try to create an Always Free Compute instance. What can I do?.......................................................................................................................... 146
  - Is it possible to extend my Free Trial?........................................................................................................ 146
  - Is my Free Tier account eligible for support?........................................................................................... 146

## Chapter 4 Oracle Cloud Infrastructure Government Cloud................. 148

- Oracle Cloud Infrastructure US Government Cloud....................................................................................... 148
- Oracle Cloud Infrastructure US Government Cloud with FedRAMP Authorization........................................ 157
- Oracle Cloud Infrastructure US Government Cloud with DISA Impact Level 5 Authorization.................. 162
- Oracle Cloud Infrastructure United Kingdom Government Cloud........................................................................... 171
- Regions.................................................................................... 171
- Console Sign-in URLs................................................................................................................................. 171
- API Reference and Endpoints...................................................... 171
- Services Not Supported in Oracle Cloud Infrastructure United Kingdom Government Cloud..................... 175
- SMTP Authentication and Connection Endpoints........................................................................................ 175
- SPF Record Syntax.................................................................................. 176

## Chapter 5 Service Essentials.......................................................... 178

- Security Credentials............................................................................................................................... 179
- Console Password................................................................................................................................. 179
- API Signing Key................................................................................................................................. 179
- Instance SSH Key............................................................................................................................... 179
- Auth Token...................................................................................... 180
- Regions and Availability Domains........................................................................................................ 180
- About Regions and Availability Domains............................................................................................ 180
- Fault Domains................................................................................ 182
- Subscribed Region Limits.................................................................................................................. 183
- Service Availability Across Regions.................................................................................................. 183
- Resource Availability.......................................................................................................................... 184
- Dedicated Regions............................................................................................... 186
- IP Address Ranges.......................................................................................... 193
- Public IP Addresses for VCNs and the Oracle Services Network............................................................ 193
- Public IP Addresses for the Oracle YUM Repos......................................................................................... 196
- Resource Identifiers............................................................................................................................ 197
- Oracle Cloud IDs (OCIDs).................................................................................................................. 197
- Where to Find Your Tenancy's OCID.................................................................................................. 198
- Name and Description (IAM Only)..................................................................................................... 198
- Display Name................................................................................................................................. 198
- Resource Monitoring.......................................................................................................................... 199
- Prerequisites.......................................................................................... 199
- Working with Resource Monitoring.................................................................................................. 199
- Using the API.......................................................................................... 211
- Resource Tags.......................................................................................... 211
- Working with Resource Tags........................................................................ 212

## Chapter 6 API Gateway

- API Gateway
  - Ways to Access Oracle Cloud Infrastructure
  - Resource Identifiers
  - Authentication and Authorization
  - API Gateway Capabilities and Limits
  - Required IAM Service Policy
  - API Gateway Concepts
  - Preparing for API Gateway
  - Creating an API Gateway
  - Creating an API Resource with an API Description
  - Creating an API Deployment Specification
  - Deploying an API on an API Gateway by Creating an API Deployment
  - Setting Up Custom Domains and TLS Certificates
  - Adding Path Parameters and Wildcards to Route Paths
  - Adding Context Variables to Policies and HTTP Back End Definitions
  - Calling an API Deployed on an API Gateway
  - Listing API Gateways and API Deployments
  - Updating API Gateways and API Deployments
  - Moving API Gateways and API Deployments Between Compartments
  - Deleting API Gateways and API Deployments
  - Adding Logging to API Deployments
  - Adding an HTTP or HTTPS URL as an API Gateway Back End
  - Adding a Function in Oracle Functions as an API Gateway Back End
  - Adding Stock Responses as an API Gateway Back End
  - Adding Request Policies and Response Policies to API Deployment Specifications
  - Limiting the Number of Requests to API Gateway Back Ends
  - Adding CORS support to API Deployments
  - Adding Authentication and Authorization to API Deployments
  - Transforming Incoming Requests and Outgoing Responses
  - Troubleshooting API Gateway
  - API Gateway Internal Limits
  - API Gateway Metrics

## Chapter 7 Archive Storage

- Archive Storage
  - Using Archive Storage
  - Ways to Access Archive Storage
  - Authentication and Authorization
  - WORM Compliance
  - Limits on Archive Storage Resources

## Chapter 8 Audit

- Audit
  - Version 2 Audit Log Schema
  - Ways to Access Oracle Cloud Infrastructure
  - Authentication and Authorization
  - Contents of an Audit Log Event
  - Viewing Audit Log Events
  - Bulk Export of Audit Log Events
# Table of contents

## Chapter 9 Block Volume........................................................................................................... 500

*Block Volume................................................................. 500*

- Typical Block Volume Scenarios.................................................. 500
- Volume Attachment Types.......................................................... 501
- Volume Access Types............................................................... 502
- Device Paths............................................................................. 502
- Regions and Availability Domains.............................................. 502
- Resource Identifiers................................................................. 503
- Ways to Access Oracle Cloud Infrastructure............................ 503
- Authentication and Authorization.............................................. 503
- Monitoring Resources.............................................................. 503
- Moving Resources................................................................. 503
- Tagging Resources................................................................. 503
- Creating Automation with Events........................................... 504
- Block Volume Encryption.......................................................... 504
- Block Volume Data Eradication................................................ 504
- Block Volume Performance...................................................... 504
- Block Volume Durability........................................................... 505
- Block Volume Capabilities and Limits...................................... 505
- iSCSI Information...................................................................... 505
- Volume Groups......................................................................... 506
- Creating a Volume................................................................. 515
- Attaching a Volume............................................................... 517
- Attaching a Volume to Multiple Instances.............................. 520
- Connecting To a Volume......................................................... 524
- Listing Volumes....................................................................... 529
- Listing Volume Attachments..................................................... 530
- Renaming a Volume............................................................... 530
- Editing a Volume's Settings..................................................... 531
- Resizing a Volume................................................................. 532
- Overview of Block Volume Backups....................................... 540
- Cloning a Volume..................................................................... 560
- Disconnecting From a Volume.................................................. 562
- Detaching a Volume............................................................... 563
- Deleting a Volume.................................................................... 563
- Move Block Volume Resources Between Compartments........ 564
- Block Volume Performance...................................................... 567
- Block Volume Metrics............................................................. 585

## Chapter 10 Compliance Documents...................................................................................... 588

*Compliance Documents........................................................... 588*

- Types of Compliance Documents.............................................. 588
- Types of Environments......................................................... 588
- Regions and Availability Domains............................................ 588
- Ways to Access Oracle Cloud Infrastructure............................ 589
- Viewing and Downloading Compliance Documents.................. 589

## Chapter 11 Compute.............................................................................................................. 590

*Compute................................................................. 590*

- Instance Types........................................................................ 590
- Components for Launching Instances..................................... 591
- Creating Automation with Events........................................... 592

Chapter 12 Container Engine .............................................................................. 832

Container Engine ............................................................................................... 832
Ways to Access Oracle Cloud Infrastructure .................................................. 832
Creating Automation with Events ........................................................................ 832
Resource Identifiers ......................................................................................... 833
Authentication and Authorization ........................................................................ 833
Container Engine for Kubernetes Capabilities and Limits .............................. 833
Required IAM Service Policy .............................................................................. 833
Container Engine and Kubernetes Concepts .................................................... 833
Preparing for Container Engine for Kubernetes .............................................. 835
Creating a Kubernetes Cluster ........................................................................... 871
Setting Up Cluster Access .................................................................................. 876
### Table of contents

Modifying Kubernetes Cluster Properties.......................................................... 881
Modifying Node Pool and Worker Node Properties........................................ 883
Updating Worker Nodes by Creating a New Node Pool................................. 885
Deleting a Kubernetes Cluster........................................................................... 885
Monitoring Clusters.......................................................................................... 886
Viewing Work Requests and Kubernetes API Server Audit Logs.................. 888
Viewing Application Logs on Worker Nodes.................................................. 888
Accessing a Cluster Using Kubectl................................................................. 890
Accessing a Cluster Using the Kubernetes Dashboard..................................... 891
Adding a Service Account Authentication Token to a Kubeconfig File........... 894
Deploying a Sample Nginx App on a Cluster Using Kubectl......................... 896
Pulling Images from Registry during Deployment......................................... 897
Supported Labels for Different Usecases......................................................... 898
Encrypting Kubernetes Secrets at Rest in Etcd.............................................. 900
Connecting to Worker Nodes Using SSH....................................................... 903
Using Pod Security Polices with Container Engine for Kubernetes.............. 905
Autoscaling Kubernetes Clusters..................................................................... 910
About Access Control and Container Engine for Kubernetes......................... 920
Supported Images (Including Custom Images) and Shapes for Worker Nodes... 923
Supported Admission Controllers................................................................. 924
Kubernetes Versions and Container Engine for Kubernetes......................... 926
Supported Versions of Kubernetes................................................................. 926
Upgrading Clusters to Newer Kubernetes Versions....................................... 929
Configuring DNS Servers for Kubernetes Clusters....................................... 932
Creating Load Balancers to Distribute Traffic Between Cluster Nodes.......... 937
Creating a Persistent Volume Claim............................................................... 947
Adding OCI Service Broker for Kubernetes to Clusters............................... 952
Example: Setting Up an Ingress Controller on a Cluster.............................. 953
Example: Installing Calico and Setting Up Network Policies......................... 960
Frequently Asked Questions About Container Engine for Kubernetes........... 962
Container Engine for Kubernetes Metrics................................................... 963

### Chapter 13 Data Transfer............................................................................. 968

Data Transfer.................................................................................................. 968
Supported Regions......................................................................................... 968
Limits on Data Transfer Service Resources.................................................. 969
Tagging Resources......................................................................................... 969
Automation for Objects Using the Events Service........................................ 969
Notifications................................................................................................. 969
Inputting Text into Data Transfer................................................................... 969
What's Next..................................................................................................... 969
Data Import - Disk......................................................................................... 970
Data Import - Appliance................................................................................. 1015
Data Export................................................................................................... 1082
Troubleshooting............................................................................................ 1122
Help Sheets.................................................................................................... 1127

### Chapter 14 Database.................................................................................. 1140

Database......................................................................................................... 1140
License Types and Bring Your Own License (BYOL) Availability................ 1140
Always Free Database Resources................................................................. 1141
Moving Database Resources to a Different Compartment........................... 1141
Monitoring Resources................................................................................... 1142
Creating Automation with Events............................................................... 1142

Chapter 1

About Oracle Cloud Infrastructure

Oracle Cloud Infrastructure provides bare metal cloud infrastructure that lets you create networking, compute, and storage resources for your enterprise workloads.

If you're new to Oracle Cloud Infrastructure and would like to learn some key concepts and take a quick tutorial, see the Oracle Cloud Infrastructure Getting Started Guide.

If you're ready to create cloud resources such as users, access controls, cloud networks, instances, and storage volumes, this guide is right for you. It provides the following information about using Oracle Cloud Infrastructure:

</table>

For a description of the terminology used throughout this guide, see the PrintGlossary.

**Prefer Online Help?**

The information in this guide and the Getting Started Guide is also available in the online help at https://docs.cloud.oracle.com/iaas/Content/home.htm.

**Need API Documentation?**

For general information, see REST APIs on page 4368. For links to the detailed service API documentation, see the online help at https://docs.cloud.oracle.com/iaas/Content/home.htm.
Welcome to Oracle Cloud Infrastructure

Chapter 2

Welcome to Oracle Cloud Infrastructure

This chapter provides brief descriptions of Oracle Cloud Infrastructure features and resources.

Introduction

Oracle Cloud Infrastructure is a set of complementary cloud services that enable you to build and run a wide range of applications and services in a highly available hosted environment. Oracle Cloud Infrastructure offers high-performance compute capabilities (as physical hardware instances) and storage capacity in a flexible overlay virtual network that is securely accessible from your on-premises network.

About the Services

Analytics Cloud empowers business analysts and consumers with modern, AI-powered, self-service analytics capabilities for data preparation, visualization, enterprise reporting, augmented analysis, and natural language processing.

API Gateway enables you to create governed HTTP/S interfaces for other services, including Oracle Functions, Oracle Cloud Infrastructure Container Engine for Kubernetes, and Oracle Cloud Infrastructure Registry. API Gateway also provides policy enforcement such as authentication and rate-limiting to HTTP/S endpoints.

Application Migration simplifies the migration of applications from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure.

Archive Storage lets you preserve cold data in a cost-efficient manner.

Audit provides visibility into activities related to your Oracle Cloud Infrastructure resources and tenancy. Audit log events can be used for security audits, to track usage of and changes to Oracle Cloud Infrastructure resources, and to help ensure compliance with standards or regulations.

Big Data provides enterprise-grade Hadoop as a service, with end-to-end security, high performance, and ease of management and upgradeability.

Block Volume provides high-performance network storage capacity that supports a broad range of I/O intensive workloads. You can use block volumes to expand the storage capacity of your compute instances, to provide durable and persistent data storage that can be migrated across compute instances, and to host large databases.

Blockchain Platform Cloud enables creation of managed, permissioned-blockchain networks for secure, real-time data sharing and trusted transactions among business partners.

Cloud Advisor finds potential inefficiencies in your tenancy and offers guided solutions that explain how to address them. The recommendations help you maximize cost savings and improve the security of your tenancy.

Cloud Guard is a cloud-native service that helps customers monitor, identify, achieve, and maintain a strong security posture on Oracle Cloud. Use the service to examine your Oracle Cloud Infrastructure resources for security weakness related to configuration, and your Oracle Cloud Infrastructure operators and users for risky activities. Upon detection, Cloud Guard can suggest, assist, or take corrective actions, based on your configuration.

Use Compute to provision and manage compute instances. You can launch an Oracle bare metal compute resource in minutes. Provision instances as needed to deploy and run your applications, just as you would in your on-premises
Welcome to Oracle Cloud Infrastructure

data center. Managed virtual machine (VM) instances are also available for workloads that don't require dedicated physical servers or the high-performance of bare metal instances.

**Container Engine for Kubernetes** helps you define and create Kubernetes clusters to enable the deployment, scaling, and management of containerized applications.

**Content and Experience** is a cloud-based content hub to drive omni-channel content management and accelerate experience delivery. It offers powerful collaboration and workflow management capabilities to streamline the creation and delivery of content and improve customer and employee engagement.

**Data Catalog** is a collaborative metadata management solution that lets you be more insightful about the data you have in Oracle Cloud and beyond. With Data Catalog, data consumers can easily find, understand, govern, and track Oracle Cloud data assets.

**Data Flow** is a fully managed service with a rich user interface to allow developers and data scientists to create, edit, and run Apache Spark applications at any scale without the need for clusters, an operations team, or highly specialized Spark knowledge. As a fully managed service, there is no infrastructure to deploy or manage. It is entirely driven by REST APIs, giving easy integration with applications or workflows.

**Data Integration** is a fully managed service that helps data engineers and ETL developers with common extract, load, and transform (ETL) tasks such as ingesting data from a variety of data assets, cleansing, transforming, and reshaping that data, and then efficiently loading it to target data assets.

**Data Safe** is a fully-integrated Cloud service focused on the security of your data. It provides a complete and integrated set of features for protecting sensitive and regulated data in Oracle Cloud databases. Features include Security Assessment, User Assessment, Data Discovery, Data Masking, and Activity Auditing.

**Data Science** is a platform for data scientists to build, train, and manage machine learning models on Oracle Cloud Infrastructure, using Python and open source machine learning libraries. Teams of data scientists can organize their work and access data and computing resources in this collaborative environment.

**Data Transfer** lets you migrate large volumes of data to Oracle Cloud Infrastructure.

**Database** lets you easily build, scale, and secure Oracle databases with license-included pricing in your Oracle Cloud Infrastructure cloud. You create databases on DB Systems, which are bare metal servers with local NVMe flash storage. You launch a DB System the same way you do a bare metal instance, you just add some additional configuration parameters. You can then use your existing tools, Recovery Manager (RMAN), and the database CLI to manage your databases in the cloud the same way you manage them on-premises. To get started with the Database, see "Overview of the Database Service," in the Oracle Cloud Infrastructure User Guide.

**Database Management** provides comprehensive database performance diagnostics and management capabilities to monitor and manage Oracle databases.

**Digital Assistant** is a platform that allows you to create and deploy digital assistants, which are AI-driven interfaces that help users accomplish a variety of tasks in natural language conversations.

**Edge Services** encompasses several services that allow you to manage, secure, and maintain your domains and endpoints.

**Email Delivery** is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients. Email Delivery provides the tools necessary to send application-generated email for mission-critical communications such as receipts, fraud detection alerts, multi-factor identity verification, and password resets.

The **Events** service helps to create automation in your tenancy.

**File Storage** allows you to create a scalable, distributed, enterprise-grade network file system. File Storage supports NFSv3 with NLM for full POSIX semantics, snapshots capabilities, and data at-rest encryption.

The **Functions** service helps you build and deploy applications and functions.

**Fusion Analytics Warehouse** empowers you with industry-leading, AI-powered, self-service analytics capabilities for data preparation, visualization, enterprise reporting, augmented analysis, and natural language processing.
You can control access to Oracle Cloud Infrastructure using IAM Service. Create and manage compartments, users, groups, and the policies that define permissions on resources.

Oracle Integration is a fully managed, preconfigured environment where you can integrate your applications, automate processes, gain insight into your business processes, create visual applications, and support B2B integrations. Use integrations to design, monitor, and manage connections between your applications, selecting from our portfolio of over 60 adapters to connect with Oracle and third-party applications.

Load Balancing allows you to create a highly available load balancer within your virtual cloud network (VCN) so that you can distribute internet traffic to your compute instances within the VCN.

Logging Analytics is a unified, integrated cloud solution that enables users to monitor, aggregate, index, analyze, search, explore, and correlate all log data from their applications and system infrastructure.

Management Agent is a service that provides low latency interactive communication and data collection between Oracle Cloud Infrastructure and any other targets.

Use Monitoring to query metrics and manage alarms. Metrics and alarms help monitor the health, capacity, and performance of your cloud resources.

MySQL Database is a fully managed database service that enables organizations to deploy cloud-native applications using the world’s most popular open source database. It is 100% compatible with On-Premises MySQL for a seamless transition to public or hybrid cloud. Leverage your existing Oracle investments and easily integrate MySQL Database Service with Oracle technologies.

Use Networking to create and manage the network components for your cloud resources. You can configure your virtual cloud network (VCN) with access rules and gateways to support routing of public and private internet traffic.

NoSQL Database Cloud is a high performance data store which is distributed, sharded for horizontal scalability, and highly available. It is optimized for applications requiring predictable low latency (such as fraud detection, gaming, and personalized user experience), very high throughput, or extreme ingestion rates (such as event processing, IoT, and sensor data).

Use Notifications to set up topics and subscriptions for broadcasting messages. Topics are used with alarms.

Operations Insights provides 360-degree insight into the resource utilization and capacity of Oracle Autonomous Databases. You can easily analyze CPU and storage resources, forecast capacity issues, and proactively identify SQL performance issues across a fleet of Autonomous Databases.

OS Management helps you keep operating platforms in your Compute instances secure and up to date with the latest patches and updates from the respective vendor.

Registry helps you store, share, and manage development artifacts like Docker images in an Oracle-managed registry.

Resource Manager helps you install, configure, and manage resources using the "infrastructure-as-code" model.

Search lets you find resources in your tenancy without requiring you to navigate through different services and compartments.

Security Zones let you be confident that your resources comply with Oracle security principles. If any resource operation violates a security zone policy, then the operation is denied.

Service Connector Hub is a cloud message bus platform that offers a single pane of glass for describing, executing, and monitoring interactions when moving data between Oracle Cloud Infrastructure services.

Storage Gateway is a cloud storage gateway that lets you connect your on-premises applications with Oracle Cloud Infrastructure. Applications that can write data to an NFS target can also write data to the Oracle Cloud Infrastructure Object Storage, without requiring application modification to uptake the REST APIs.

Use Streaming to ingest, consume, and process high-volume data streams in real-time.

The Support Management service allows you to create, view, and manage support tickets.

The Tagging service lets you use metadata tags to organize and manage the resources in your tenancy.
Welcome to Oracle Cloud Infrastructure

The **Vault** service helps you centrally manage the encryption keys that protect your data and the secret credentials that you use for access to resources.

Use **Oracle Cloud VMware Solution** to create and manage VMware enabled software-defined data centers (SDDCs) in Oracle Cloud Infrastructure. To get started with the VMware solution, see "Oracle Cloud VMware Solution," in the Oracle Cloud Infrastructure User Guide.

**WAF** helps you make your endpoints more secure by monitoring and filtering out potentially malicious traffic.

### Accessing Oracle Cloud Infrastructure

You can create and manage resources in the following ways:

- **Oracle Cloud Infrastructure Console** The Console is an intuitive, graphical interface that lets you create and manage your instances, cloud networks, and storage volumes, as well as your users and permissions. See Using the Console on page 42.

- **Oracle Cloud Infrastructure APIs** The Oracle Cloud Infrastructure APIs are typical REST APIs that use HTTPS requests and responses. See "Using the API" in the Oracle Cloud Infrastructure User Guide.

- **SDKs** Several Software Development Kits are available for easy integration with the Oracle Cloud Infrastructure APIs, including SDKs for Java, Ruby, and Python. For more information, see "Developer Tools" in the Oracle Cloud Infrastructure User Guide.

- **Command Line Interface (CLI)** You can use a command line interface with some services. For more information, see "Developer Tools" in the Oracle Cloud Infrastructure User Guide.

- **Terraform** Oracle supports Terraform. Terraform is "infrastructure-as-code" software that allows you to define your infrastructure resources in files that you can persist, version, and share. For more information, see Getting Started on page 102.

- **Ansible** Oracle supports the use of Ansible for cloud infrastructure provisioning, orchestration, and configuration management. Ansible allows you to automate configuring and provisioning your cloud infrastructure, deploying and updating software assets, and orchestrating your complex operational processes. For more information, see Getting Started on page 4331.

- **Resource Manager** Resource Manager is an Oracle Cloud Infrastructure service that allows you to automate the process of provisioning your Oracle Cloud Infrastructure resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model. For more information, see Overview of Resource Manager on page 3534.

For new capabilities, Oracle targets the release of relevant APIs, as well as CLI, SDKs, and Console updates, at the time of general availability (GA). We also target the release of an updated Terraform provider within 30 days of GA.

### How Do I Get Started?

- Sign up for Oracle Cloud Infrastructure
- Understand Oracle Cloud Infrastructure concepts and terminology
- Follow guided tutorials to:
  - Launch your first instance (**Linux** or **Windows**)
  - Add users
  - Put data into object storage
  - Create a load balancer

- FAQs

### Key Concepts and Terminology

Understand the following concepts and terminology to help you get started with Oracle Cloud Infrastructure.

**BARE METAL HOST**

Oracle Cloud Infrastructure provides you control of the physical host ("bare metal") machine. Bare metal compute instances run directly on bare metal servers without a hypervisor. When you provision a bare metal
compute instance, you maintain sole control of the physical CPU, memory, and network interface card (NIC). You can configure and utilize the full capabilities of each physical machine as if it were hardware running in your own data center. You do not share the physical machine with any other tenants.

REGIONS AND AVAILABILITY DOMAINS

Oracle Cloud Infrastructure is physically hosted in regions and availability domains. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of one or more availability domains. Oracle Cloud Infrastructure resources are either region-specific, such as a virtual cloud network, or availability domain-specific, such as a compute instance.

Availability domains are isolated from each other, fault tolerant, and very unlikely to fail simultaneously or be impacted by the failure of another availability domain. When you configure your cloud services, use multiple availability domains to ensure high availability and to protect against resource failure. Be aware that some resources must be created within the same availability domain, such as an instance and the storage volume attached to it.

For more details see "Regions and Availability domains" in the Oracle Cloud Infrastructure User Guide.

REALM

A realm is a logical collection of regions. Realms are isolated from each other and do not share any data. Your tenancy exists in a single realm and has access to the regions that belong to that realm. Oracle Cloud Infrastructure currently offers a realm for commercial regions and two realms for government cloud regions: FedRAMP authorized and IL5 authorized.

CONSOLE

The simple and intuitive web-based user interface you can use to access and manage Oracle Cloud Infrastructure.

tenancy

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for your company, which is a secure and isolated partition within Oracle Cloud Infrastructure where you can create, organize, and administer your cloud resources.

compartments

Compartments allow you to organize and control access to your cloud resources. A compartment is a collection of related resources (such as instances, virtual cloud networks, block volumes) that can be accessed only by certain groups that have been given permission by an administrator. A compartment should be thought of as a logical group and not a physical container. When you begin working with resources in the Console, the compartment acts as a filter for what you are viewing.

When you sign up for Oracle Cloud Infrastructure, Oracle creates your tenancy, which is the root compartment that holds all your cloud resources. You then create additional compartments within the tenancy (root compartment) and corresponding policies to control access to the resources in each compartment. When you create a cloud resource such as an instance, block volume, or cloud network, you must specify to which compartment you want the resource to belong.

Ultimately, the goal is to ensure that each person has access to only the resources they need.

SECURITY ZONES

A security zone is associated with a compartment. When you create and update cloud resources in a security zone, Oracle Cloud Infrastructure validates these operations against security zone policies. If any policy is violated, then the operation is denied. Security zones let you be confident that your resources comply with Oracle security principles.

VIRTUAL CLOUD NETWORK (VCN)

A virtual cloud network is a virtual version of a traditional network—including subnets, route tables, and gateways—on which your instances run. A cloud network resides within a single region but includes all the region's availability domains. Each subnet you define in the cloud network can either be in a single availability domain or span all the availability domains in the region (recommended). You need to set up
Welcome to Oracle Cloud Infrastructure

at least one cloud network before you can launch instances. You can configure the cloud network with an optional internet gateway to handle public traffic, and an optional IPSec VPN connection or FastConnect to securely extend your on-premises network.

INSTANCE

An instance is a compute host running in the cloud. An Oracle Cloud Infrastructure compute instance allows you to utilize hosted physical hardware, as opposed to the traditional software-based virtual machines, ensuring a high level of security and performance.

IMAGE

The image is a template of a virtual hard drive that defines the operating system and other software for an instance, for example, Oracle Linux. When you launch an instance, you can define its characteristics by choosing its image. Oracle provides a set of images you can use. You can also save an image from an instance that you have already configured to use as a template to launch more instances with the same software and customizations.

SHAPE

In Compute, the shape specifies the number of CPUs and amount of memory allocated to the instance. Oracle Cloud Infrastructure offers shapes to fit various computing requirements. See “Compute Shapes” in the Oracle Cloud Infrastructure User Guide.

In Load Balancing, the shape determines the load balancer's total pre-provisioned maximum capacity (bandwidth) for ingress plus egress traffic. Available shapes include 100 Mbps, 400 Mbps, and 8000 Mbps.

KEY PAIR

A key pair is an authentication mechanism used by Oracle Cloud Infrastructure. A key pair consists of a private key file and a public key file. You upload your public key to Oracle Cloud Infrastructure. You keep the private key securely on your computer. The private key is private to you, like a password.

Key pairs can be generated according to different specifications. Oracle Cloud Infrastructure uses two types of key pairs for specific purposes:

- Instance SSH Key pair: This key pair is used to establish secure shell (SSH) connection to an instance. When you provision an instance, you provide the public key, which is saved to the instance's authorized key file. To log on to the instance, you provide your private key, which is verified with the public key.
- API signing key pair: This key pair is in PEM format and is used to authenticate you when submitting API requests. Only users who will be accessing Oracle Cloud Infrastructure via the API need this key pair.

For details about the syntax of an OCID, see "Security Credentials" in the Oracle Cloud Infrastructure User Guide.

BLOCK VOLUME

A block volume is a virtual disk that provides persistent block storage space for Oracle Cloud Infrastructure instances. Use a block volume just as you would a physical hard drive on your computer, for example, to store data and applications. You can detach a volume from one instance and attach it to another instance without loss of data.

OBJECT STORAGE

Object Storage is a storage architecture that allow you to store and manage data as objects. Data files can be of any type and up to 50 GB in size. Once you upload data to Object Storage it can be accessed from anywhere. Use Object Storage when you want to store a very large amount of data that does not change very frequently. Some typical use cases for Object Storage include data backup, file sharing, and storing unstructured data like logs and sensor-generated data.

BUCKET

A bucket is a logical container used by Object Storage for storing your data and files. A bucket can contain an unlimited number of objects.
ORACLE CLOUD IDENTIFIER (OCID)

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). This ID is included as part of the resource's information in both the Console and API.

For details about the syntax of an OCID, see "Resource Identifiers" in the Oracle Cloud Infrastructure User Guide.

Request and Manage Free Oracle Cloud Promotions

You can sign up for a 30-day Oracle Cloud promotion and receive free credits. This promotion applies to eligible Oracle Cloud Infrastructure services.

Estimate Your Monthly Cost on page 32
Sign Up for the Free Oracle Cloud Promotion on page 34
Monitor the Credit Balance for Your Free Oracle Cloud Promotion on page 35
What Happens When the Promotion Expires on page 35
Upgrade Your Free Oracle Cloud Promotion on page 35

Estimate Your Monthly Cost

Oracle provides you with a cost estimator to help you figure out your monthly usage and costs for Oracle’s Infrastructure and Platform Cloud (Oracle IaaS/PaaS) services before you commit to an amount.

The cost estimate is automatically calculated based on your choice of the Oracle Cloud service category, its service configurations, and the usage of each resource in the configuration.

You can start using Oracle Cloud with no up-front cost. Oracle will bill you for the services and resources you use. For the purpose of planning, use the results from the Cost Estimator to estimate how much you are likely to be charged for usage each month.

To use the Cost Estimator:

1. Go to the Cost Estimator page on the Oracle Cloud website.
2. Select a category of cloud services, such as Infrastructure or Data Management, from the list on the left side of the page.
   The cost estimator displays a set of packages, which represent the services and resources that are typically required to support the selected service category. To see all the packages of the selected service category, scroll to the right.
3. Select one of the packages, as a starting point for your estimate. The estimator begins calculating the cost for the selected service and package.
4. In the Configuration Options section, expand each service, use the sliders, or select from the drop-down lists to adjust the values to match your project’s or organization’s needs.
   As soon as you adjust the amount of resources, the cost estimate changes.
   If you have existing software licences for services such as Oracle Database or Oracle Middleware, you can use them to estimate your cost for cloud services. Simply select the BYOL (Bring Your Own License) option from the service packages or under the Configuration Options section. For example, if you have an existing license for Autonomous Data Warehouse, then select the Autonomous Data Warehouse Cloud - BYOL package from the service packages set. If you’ve an Oracle Database Enterprise Edition license, then select the Enterprise Edition Extreme Performance BYOL option from the Edition list under Configuration Options. The cost immediately reflects the BYOL pricing, which is typically lower than the normal cloud service costs.
   You can experiment with different configuration options until you balance the cost with your organization’s needs.
5. Review your estimates, and then click Start for Free to sign up for the Oracle Cloud Free Tier and get free credits. You can upgrade your free promotion to a paid account at any time during the promotion period.
Example: Estimating Your Monthly Cost for Oracle Database Cloud Service

In this example, see how you can estimate your monthly cost for Oracle Database Cloud Service based on your requirements.

To estimate your costs:

1. In the Cost Estimator page, select the Data Management category from the list on the left side of the screen.
2. From the list of configurations displayed, select Oracle Database Cloud Service and click Add.

   The cost estimator displays a set of packages, which represent the services and resources that are typically required to support the selected service category. To see all the packages of the selected service category, scroll to the right.
3. In the Configuration Options section of the page, expand Database.
4. Expand each of the resources under Database, such as Number of Instances, Average Days Usage per Month, or Average Hours Usage per Day. You’ll see some default values as you expand each item.
5. Increase the number of instances to 2: One for development and one for testing.
6. Use the slider to adjust values for Average Days Usage per Month or Average Hours Usage per Day, as needed. By default, they are set to 31 days (in a month) and 24 hours (per day) of usage. If you intend to use the Database service for a lesser period, then adjust the values accordingly.
7. Select Enterprise Edition High Performance - General Purpose from the Edition drop-down menu to see how this affects the monthly estimate.
8. You can also remove certain sections by clicking the trash icon next to them. For example, if you don’t need Database Backup service, you can remove it by clicking the trash icon.
9. When you have estimated all your requirements, select the payment plan, and click Buy Now.

You can also add other configurations in the Data Management category such as Oracle Database Exadata Cloud Service or Oracle Big Data Cloud Service to estimate your total cost. Or, you can add other service categories, such as Infrastructure or Integration and their configurations, as needed, to get your total usage cost estimate.

Save and Share Your Cost Estimator Results

When you are satisfied with your monthly usage estimates, you can save them either by downloading them as a PDF file or exporting them to an .oce file. The .oce file is only used to export and import your saved estimates in the Cost Estimator. This is useful when you want to share and review the quotes with your management, finance, or other departments to get their approval.

Save Your Cost Estimates

To save your cost estimate:

- In the Cost Estimator page, select from the following options:
  - Load/Save: Click this button to save your service configurations in your browser. Provide a name for your configuration and click Save. Note that this action is browser specific. You can’t use a configuration that you saved on Google Chrome in Firefox, or vice versa.
  - Save as PDF: Click this button to save the estimates as a PDF file. This is useful for presenting the estimates to others. The PDF is read-only.
  - Export: Click this button to export the estimates to an .oce file. This is useful if you need to share the estimates with reviewers or might need to make changes to them later. The reviewers can then import the .oce file to their own Cost Estimator pages and make changes as needed.

Import or Load Your Saved Estimates

If you want to make changes to your saved estimates, or if you’re reviewing them, you can import them to the Cost Estimator. You can also load previously saved service configurations on your browser to continue with your estimate.

To import or load your saved cost estimate, use any of the following options:
Welcome to Oracle Cloud Infrastructure

- **Load/Save**: Click this button to load your saved service configurations. Note that this action is browser specific.
  1. Click **Select Saved Configuration**.
  2. Select a saved configuration and then click **Load**.
- **Import**: Click this button to import any previously exported estimates. Ensure that you have exported the estimates to an `.oce` file.
  - Browse for the `.oce` file and click **Open**.

The saved estimates appear in the Cost Estimator page. You can then make changes as required.

### Sign Up for the Free Oracle Cloud Promotion

Signing up for Oracle Cloud Free Tier is easy.

2. Provide information for your Oracle Cloud account.
   - Select your country. For some countries, such as Russia, you must manually accept the Terms of Use by selecting the check boxes when prompted.
   - Enter your name and optionally enter the name of your company.
   - Provide a valid email address. You'll use this email ID later to sign in to your Oracle Cloud account. Instructions about signing in to your new cloud account are sent to this address. Your email ID is also used to check if you are eligible for any special offers. If you are, then you'll be prompted to select a special offer from a list of applicable offers.
   - Oracle permits one cloud account to be created per email address. If your email address is already associated with a cloud account, then you can click the link to get all your accounts associated with your email address.
   - Enter a password based on the password policy specified on the web page. You will use this password later to sign in to your Oracle Cloud account. Password must contain a minimum of 8 characters, 1 lowercase, 1 uppercase, 1 numeric, and 1 special character. Password can't exceed 40-characters, contain the users first name, last name, email address, spaces, or `~ < > \` characters.
   - Re-enter the password to confirm it.
   - Create a cloud account name, which is used to identify your cloud account.
   - Select a **Home Region**, where your services will be hosted.

   **Note:**
   Your home region is the geographic location where your account and identity resources will be created. You can't change this after signing up. If you are not sure which region to select as your home region, contact your sales representative before you create your account.

   - Click **Continue**.
3. Enter your address, and then click **Continue**.
   Provide additional information, such as a PO box number, if you're asked for it. For Brazil, enter your CPF number for tax purposes in the format `xxxxxxxx-xx`. For example, `655156112-18`.
   If you have selected a special offer, then you'll be prompted to enter a phone number. You don't have to provide verification code for certain offers, so in these cases skip to step 8.
4. Enter a valid mobile number, along with country code, and then click **Text me a code**. A verification code will be sent as a text message to your mobile phone. VOIP or internet-only mobile numbers are not accepted as we may need to speak to you if there are questions about your account.
5. Enter the verification code that you received on your phone as a text message, and then click Verify my code. If you already have a verification code, then follow the on-screen instructions to verify your phone number.

You can also click Request another code if you don't receive a verification code soon or if your verification code expires.

6. Click Add payment verification method, and then click Credit Card.

7. Enter your credit card information, and then click Finish. You may see a small, temporary charge on your payment method. This is a verification hold that will be removed automatically. Note that your credit card won't be charged unless you elect to upgrade your cloud account.

8. Accept the terms and conditions, and then click Start my free trial to submit your request for a new Oracle Cloud account.

After the services are provisioned in your tenancy, you'll be redirected to the Oracle Cloud Infrastructure Console. Use the Oracle Cloud Infrastructure Console to create instances of your services.

You'll also receive a welcome (Get Started) email with more information about your account.

For some countries, you may not be able to request a free promotion from the Oracle Cloud website. In these cases, contact Oracle Sales to request a free promotion.

Monitor the Credit Balance for Your Free Oracle Cloud Promotion

After you get free credits, you can monitor and manage your service usage and your credit balance.

In the Console, you can monitor your usage costs from the Account Management page. See Checking Your Expenses and Usage on page 55 for more information.

Oracle sends you a notice when you get close to your credit limit.

What Happens When the Promotion Expires

If you don’t upgrade your free credit promotion to a paid subscription, then it’s important to understand what happens to your cloud account.

All Oracle Cloud Infrastructure accounts (whether free or paid) have a set of resources that are available free of charge for the life of the account. These resources are called Always Free resources. If you have subscribed to a free credit promotion, your account continues to be available to you after the trial period ends (or after you use all of your credits). You can continue to use the Always Free resources in your account for as long as your account remains active. Free accounts remain active and available to you as long as the account has been used within the past 60 days. If you have a paid account, you will not be billed for any Always Free resources you are using. See Oracle Cloud Infrastructure Free Tier on page 140 for more information.

Your Free Credit Promotion expires:

• Thirty (30) days from the day you signed up.

OR

• When you use up the free credits available in your promotion offer.

In both cases, Oracle Cloud sends you warning messages that you are nearing the end of your promotion period or getting close to your free credit limit. Another email will let you know when the promotion actually expires. You will have a grace period of 30 days. You can continue to use paid resources during the grace period. However, you can't create new paid resources during the grace period unless you upgrade your account. If you don't upgrade your account during this period, then your paid resources will be reclaimed. Your Always Free resources will continue to be available.

Upgrade Your Free Oracle Cloud Promotion

You can choose to upgrade your free promotion to a paid account at any time during the promotion period or within 30 days of the promotion expiration.
If you are using the Oracle Cloud Infrastructure Console, then you can upgrade your promotion to a paid account from the Account Management page. For more information, see Changing Your Payment Method on page 56.

Buy an Oracle Cloud Subscription

Use the Oracle Cloud website to estimate your cloud usage and costs for Oracle Cloud Infrastructure services and to sign up for an Oracle Cloud account. You can also contact an Oracle Sales representative to order Oracle Cloud services on your behalf.

To purchase a subscription to Oracle Cloud Applications (SaaS), see Order Oracle Cloud Applications.

About Bring Your Own License Subscriptions

If you already have Oracle software licenses for services such as Oracle Database, Oracle Middleware, or Oracle Analytics, you can reuse them when subscribing to Oracle Platform Cloud Services (Oracle PaaS). This is called Bring Your Own License (BYOL).

With BYOL, you can leverage existing software licenses for Oracle PaaS at a lower cost. For example, if you have purchased a perpetual license for Oracle Database Standard Edition earlier, then you can use the same when you buy Database Standard Package with BYOL pricing. This enables you to get a discounted price for your services. Oracle BYOL to PaaS includes Compute and Compute support along with automation.

You continue to get the same license support (that you had for your existing licenses) and contract when you buy Oracle PaaS with BYOL pricing. This flexible licensing allows you to move between your on-premises and cloud services with ease.

How do You Use Your BYOL for Oracle PaaS?

When you have an existing Oracle software license and you want to use it on Oracle Cloud, you can do so in the following ways:

- Select specific Oracle BYOL options in the Cost Estimator to get your BYOL pricing.
- Apply your BYOL pricing to individual cloud service instances when creating a new instance of your PaaS service. BYOL is the default licensing option during instance creation for all services that support it. For example, when creating a new instance of Oracle Database Cloud Service using the QuickStarts wizard, BYOL option is automatically applied.

For a list of cloud services that support BYOL, search for BYOL in the Universal Credits Service Descriptions Document.

For more information, see BYOL Overview video and Frequently Asked Questions.

About Universal Credits

Oracle Cloud provides a flexible buying and usage model for Oracle Cloud Services, called Universal Credits.

When you sign up for an Oracle Cloud Account, you have unlimited access to all eligible IaaS and PaaS services. You can sign up for a Pay-As-You-Go subscription to pay in arrears based on your actual usage at the end of your monthly billing cycle.

After you sign up, you can start using any of the IaaS or PaaS services at any time. Not all services are available in all the data regions. You can only use services in the data regions that your subscription is enabled in. However, you can always extend your subscription to other data regions to access services available there. See Extending Your Subscription to Another Data Region.

When new eligible services become available as part of the Universal Credits program, you'll receive an email with the details of the newly added services if they are available in one of your enabled data regions.

For new services added to data regions where your subscription is not enabled, see the Service Availability Matrix.
Upgrade Your Free Oracle Cloud Promotion

You can choose to upgrade your free promotion to a paid account at any time during the promotion period or within 30 days of the promotion expiration.

If you are using the Oracle Cloud Infrastructure Console, then you can upgrade your promotion to a paid account from the Account Management page. For more information, see Changing Your Payment Method on page 56.

Activate Your Order from Your Welcome Email

If you ordered Oracle Infrastructure as a Service (Oracle IaaS) and Oracle Platform as a Service (Oracle PaaS) cloud services with Universal Credits through Oracle Sales, then you must activate your services before you start using them.

When an Oracle Sales representative orders Oracle Cloud services on your behalf, you’ll receive a welcome email and you’ll be designated as an activator of the services. To activate your services, you must provide your details and set up your account with Oracle. Review the instructions in the email to create an account and start using your services.

1. Open the email you received from Oracle Cloud.
2. Review the information about your service in the email.
3. Click Activate My Services.
4. Complete the form to sign up for your new Oracle Cloud account.

You will be asked to:

• Provide a new account name, which will be used to identify your Cloud account.
• Provide your email address. You must provide the same email address at which you received your welcome email. Instructions for signing in to your new Oracle Cloud account will be sent to this address. You’ll be prompted for the email ID only if you don’t already have an Oracle Cloud account.
• If prompted, select a Home Region. If you need more information, click the Regions link below the field.

Note:

Your home region contains your account information and identity resources. It is not changeable after your tenancy is provisioned. If you are unsure which region to select as your home region, contact your sales representative before you create your account.

• Provide Oracle Cloud account administrator details. The person you specify here will be a Cloud Account Administrator and a Service Administrator and can create other users in your account. This person will manage and monitor services in the specified Oracle Cloud account.
• After you enter all the required information, click Create Account to submit your request for an Oracle Cloud account.

After successful activation, you’ll receive another email with your sign in credentials. Use this information to sign in to your account and change your password after initial sign in.

Verify That Your Services Are Ready

When you sign up for a Free Oracle Promotion or a paid account, your Oracle Cloud account is created soon after sign up, but the service provisioning takes some time. You’ll receive a Welcome email soon after you sign up.

The email contains information required to access your account and sign in to Infrastructure Classic Console:

• Your user name and temporary password (sign-in credentials)
• The name of your Cloud Account

Sign in to Infrastructure Classic Console to see how many services are provisioned. A message at the top of the Infrastructure Classic Console indicates how many services are active.

1. Click Get Started with Oracle Cloud from your welcome email.
2. Change your password when prompted.
3. Scan the dashboard to check the current status of your service. When the services are provisioned, they might not immediately be displayed on the Infrastructure Classic Console. Services with instances are automatically displayed.
4. Click the gear icon next to Dashboard and set the services to Show. By default, all service tiles are hidden, unless a service has at least one instance. The Customize Dashboard dialog box appears.

When all the services in your order are provisioned, you’ll get a message on the Infrastructure Classic Console. You can then add users, view service details, monitor account usage, and access the service consoles.

Some services in your order may require additional sign-in credentials, which you can find in the Manage Account, My Admin Accounts page. For more information about these services, see Access Traditional Cloud Account Services.

Request and Manage the Oracle Startup Program

You can sign up for the Oracle Startup Program and receive free credits. This promotion applies to eligible Oracle Infrastructure as a Service (Oracle IaaS) and Platform as a Service (Oracle PaaS) services.

After you consume your free credits, you’ll be charged for the services and resources you use. For information about monitoring the usage of your free credits, see Monitor the Credit Balance for Your Free Oracle Cloud Promotion on page 35.

Sign Up for the Oracle Startup Program

Signing up for the Oracle Startup Program is easy. You create an Oracle Cloud account, and then you get a welcome email with the details that you need to sign in.

1. Go to the Oracle for Startups website, and then click Join Oracle for Startups.
2. Fill out the Oracle for Startups form. You are asked to:

   Create Account:
   • Select your country. For some countries such as Russia, you must manually accept the Terms of Use by selecting the check boxes when prompted.
   • Provide a valid email address, and then click Next. Instructions for signing in to your new cloud account are sent to this address. You can sign up for only one Oracle Startup Program even if you have an existing Oracle Cloud account. If your email address is already associated with the Oracle Startup Program, then you’ll be provided information to access your existing account.

   Enter Account Details:
   • Create a cloud account name, which is used to identify your cloud account.
   • Select a Home Region, where your services will be hosted. See Data Regions for Platform and Infrastructure Services for service availability in each region.

   Note: Your home region contains your account information and identity resources. It is not changeable after your tenancy is provisioned. If you
Welcome to Oracle Cloud Infrastructure

If you are unsure which region to select as your home region, contact your sales representative before you create your account.

- Provide your name, company name, and address.
- Provide additional information, such as a PO box number, if you're asked for it. For Brazil, enter your CNPJ number for tax purposes in the format xxxxxxx/xxxx-xx. For example, 12345678/0001-18.
- Enter a valid mobile number, so that Oracle can text you a verification code, and then click Next: Verify Mobile Number. VOIP or internet-only mobile numbers are not accepted.
- Your address is validated and displayed with corrections, if any. Confirm your address if prompted.

Verify Your Mobile Number:

- Enter the SMS code you received on your phone and click Verify Code. If you already have a verification code, then follow the on-screen instructions to verify your phone number.
- You can also request another code if you don't receive a verification code soon.

Payment Information:

- Click Add Credit Card Details. Enter your credit card information. During sign up, you may see an authorization of $100 USD (or local currency equivalent) on your payment card account. Authorizations do not represent charges nor money owed to Oracle. This is a temporary hold on available credit that will be removed automatically.
- Click Finish.

3. Accept the terms and conditions, and then click Complete Sign-Up to submit your request for a new Oracle Cloud account.

Your account is created. After the services in your tenancy are provisioned, you'll be redirected to the sign-in page. You'll also receive a welcome (Get Started) email with your sign-in credentials.

Understanding the Sign-In Options

This topic describes sign in options available to you when you sign up for an Oracle Cloud account.

About the Sign In Options

When you sign up for Oracle Cloud, Oracle creates a user for you in two different identity systems, giving you two options to sign in to Oracle Cloud Infrastructure.
Welcome to Oracle Cloud Infrastructure

When you want to use Oracle Cloud Infrastructure, you can choose which identity provider to sign in through:

**Oracle Identity Cloud Service**

Many Oracle Cloud services, including Oracle Cloud Infrastructure, are integrated with Oracle Identity Cloud Service. When you sign up for an Oracle Cloud account, a user is created for you in Oracle Identity Cloud Service with the username and password you selected at sign up. You can use this single sign-on option to sign in to Oracle Cloud Infrastructure and then navigate to other Oracle Cloud services without reauthenticating. This user has administrator privileges for all the Oracle Cloud services included with your account.

**Oracle Cloud Infrastructure**

Oracle Cloud Infrastructure includes its own identity service, called the Identity and Access Management service, or IAM, for short. When you sign up for an Oracle Cloud account, this service is included. A second, separate user is created for you in the IAM service with the username and password you selected at sign up. You are granted administrator privileges in Oracle Cloud Infrastructure so you can get started right away with all Oracle Cloud Infrastructure services.
Welcome to Oracle Cloud Infrastructure

Important:

Although the credentials are identical in both systems when your account is created, the users are in separate identity management systems, and you manage them separately. If you change your password in the Oracle Cloud Infrastructure IAM, your password in Oracle Identity Cloud Service is not changed, and conversely.

When to Use Each Sign-In Option

If you plan to use Oracle Cloud Infrastructure services exclusively, it makes sense for you to use your direct sign-in credentials to the IAM service.

If you want to use other Oracle Cloud services that are managed through Oracle Identity Cloud Service, then sign in with your single sign-on credentials.

More Information About Managing Users in Oracle Cloud Identity Providers

Managing Users in the IAM Service

Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372

Adding Users on page 57

Signing In to the Console

This topic describes how to sign in to the Oracle Cloud Infrastructure Console.

Supported Browsers

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Signing In for the First Time

To sign in to Oracle Cloud at https://cloud.oracle.com, you need:

- Your cloud account name (also sometimes referred to as your tenancy name)
- User name and password
Welcome to Oracle Cloud Infrastructure

When your tenancy is provisioned, Oracle sends an email to the default administrator at your company with the sign-in credentials and URL. This administrator can then create a user for each person who needs access to Oracle Cloud Infrastructure. Check your email or contact your administrator for your credentials and account name.

1. Open a supported browser and go to https://cloud.oracle.com.
2. Enter your Cloud Account Name and click Next.
3. On the Single Sign-On (SSO) panel, click Continue.
4. Enter your user name and temporary password from your welcome email. You will be prompted to change your temporary password.

After you sign in, the Console Home page is displayed.

Note:
When you're logged in to the Console for one of the commercial realm regions, the browser times out after 60 minutes of inactivity, and you need to sign in again to use the Console.

Next Steps

Get to know the Console. See Using the Console on page 42.

Follow guided tutorials to launch your first instance, add users, or put data into object storage.

Begin setting up your tenancy for other users. See Setting Up Your Tenancy on page 122.

Using the Console

This topic provides basic information about the Oracle Cloud Console. To access the Console, you must use a supported browser.

About the Console Home Page

When you sign in to the Console, you see the home page.

### The Get Started tab
- Provides features helpful for new users.

### The Dashboard tab
- Supports widgets that provide an overview of your resources and billing usage.

### The Help menu
- Provides links to support and documentation.
The home page offers features for both new and experienced users. For new users, the Get Started tab provides features to help you start learning about and working with Oracle Cloud Infrastructure. The Dashboard tab supports widgets to help you quickly access and monitor your resources and billing usage.

Features of the Get Started Tab

The Get Started tab includes features that are particularly helpful for new users or users who want to jump in and quickly create common resources.

Quick Actions

Use the Quick Actions tiles to navigate directly to common tasks, like creating a VM instance, setting up a network with a wizard, and setting up a load balancer. Use these links to set up your environment.

Start Exploring

The Start Exploring section provides links to tutorials, developer tools, and blogs that demonstrate how to use Oracle Cloud Infrastructure to build solutions.

- In the Get Started category, find introductory materials that you can use to learn more about basics, such as information about virtual training classes, key concepts, and introductory demos.
- In the Deploy Websites & Apps category, find tutorials that leverage both basic and more advanced features available to build solutions.
- In the Explore Developer Tools category, explore the developer kits, tools, and plug-ins that you can use to facilitate the development of apps and to simplify the management of infrastructure.
- In the Manage Bills category, learn about the billing and payment tools that to help you manage your service costs.

Features of the Dashboard Tab

The Dashboard tab includes widgets you can use to explore your resources and billing usage.

Get an Overview of All Your Resources with the Resource Explorer

Use the resource explorer to get an overview of the number and types of resources that exist in a selected compartment and region.
To use the resource explorer to find resources:

1. On the Console home page, click the **Dashboard** tab.
2. The resource explorer displays the list of services and count of resources in the selected **compartment** and **region**. By default, the root compartment is selected. To view another compartment, select it from the compartment picker.
3. Expand the entry for a service to see the count for each resource-type within the service.
4. To see more information about a resource-type in the list, click the resource-type to open the detailed list. To navigate directly to a specific resource in the list, click the **Display Name**.

**Monitor Your Usage with the Billing Widget**

Administrators and users with appropriate permissions can view the billing widget. The billing widget lets you quickly view your current charges or usage and the days elapsed in your billing cycle. Your view depends on your account type.

- Pay-as-you-go customers see the current charges and the numbers of days elapsed in the current billing cycle.
- Universal credit customers see the total credits used and number of days elapsed in the credit period.
- Trial customers see the total credits used and number of days elapsed in the trial period.

To get a more detailed view of your spending, click the **Analyze Costs** link to go to the **Cost Analysis tool** where you can generate charts and reports of aggregated cost data for your Oracle Cloud Infrastructure consumption. If your account is a free tier or promotional trial account, you’ll see an option to **Upgrade your account**. If you have a paid account, you’ll see the option to **Manage payment method** to view or change your payment method.

**Navigating to Oracle Cloud Infrastructure Services**

Open the navigation menu in the upper left to work with services and resources. Services and resources are organized by functional group. For example, to work with Compute service instances: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

**Navigating to More Oracle Cloud Services from the Console**

For more details about accessing other Oracle Cloud offerings, see **Navigate to Your Cloud Services**.

The Oracle Cloud Console provides navigation to other Oracle Cloud services in addition to Oracle Cloud Infrastructure services.

If your account also has Oracle Cloud Platform services, Oracle Cloud Infrastructure Classic services, or Oracle Cloud Applications, then you can navigate to these services from the Oracle Cloud Console:
Navigating to Platform Services
Open the navigation menu. Under More Oracle Cloud Services, go to Platform Services, and then click the service you want to access.

Navigating to Classic Data Management Services
Open the navigation menu. Under More Oracle Cloud Services, go to Classic Data Management Services, and then click the service you want to access.

Navigating to Classic Infrastructure Services
Open the navigation menu. Under More Oracle Cloud Services, go to Classic Infrastructure Services, and then click the service you want to access.

Navigating to the Applications Console
If your Cloud account also has Cloud Applications services provisioned, then you have access to the Applications Console.
In the Console header, click Applications to switch to the Applications Console.
For more information about the consoles for these Oracle Cloud services, see About the Consoles.

Switching Regions
Your current region is displayed at the top of the Console. If your tenancy is subscribed to multiple regions, you can switch regions by selecting a different region from the Region menu.
Welcome to Oracle Cloud Infrastructure

Working Across Regions

When working within a service, the Console displays resources that are in the currently selected region. So if your tenancy has instances in CompartmentA in US West (Phoenix), and instances in CompartmentA in US East (Ashburn), you can only view the instances in one region at a time, even though the instances are in the same compartment.

Using the following figure as an example, if you select US West (Phoenix) and then select CompartmentA, you see instances 1 and 2 listed. To see instances 3 and 4 in the Console, you must switch to US East (Ashburn) (and then you no longer see instances 1 and 2).

To view resources across regions that are in a specific compartment, you can use the tenancy explorer.

IAM resources (compartments, users, groups, policies, tags, and federation providers) are global, so you can see those resources no matter which region you have selected in the Console.
Switching Languages

The Console automatically detects the language setting in your browser. However, if you want to view the Console in a different language, you can change it by using the language selector in the Console.

The language selector supports the following languages:

Supported Languages

- Chinese (Simplified)
- Chinese (Traditional)
- Croatian
- Czech
- Danish
- Dutch
- English
- Finnish
- French (Canada)
- French (Europe)
- German
- Greek
- Hungarian
- Italian
- Japanese
- Korean
- Norwegian
- Polish
- Portuguese (Brazil)
- Portuguese (Portugal)
- Romanian
- Russian
- Serbian
- Slovak
- Slovenian
- Spanish
- Swedish
- Thai
- Turkish
The language you choose persists between sessions. However, the language setting is specific to the browser. If you change to a different browser, the Console displays text in the language last selected in the language selector. If it’s the first time you’re viewing the Console in a particular browser, the Console displays content according to the browser’s language setting.

**Contact Support**

In the Console, you can create a support request or start a live online chat with an Oracle Support or Sales representative. For more information, see *Getting Help and Contacting Support* on page 125.

**Understanding Compartments**

After you select a service from the navigation menu, the menu on the left includes the compartments list.

Compartments help you organize resources to make it easier to control access to them. Your root compartment is created for you by Oracle when your tenancy is provisioned. An administrator can create more compartments in the root compartment and then add the access rules to control which users can see and take action in them. To manage compartments, see *Managing Compartments* on page 2431.

The list of compartments is filtered to show you only the compartments that you have permission to access. Compartments can be nested, and you might have access to a compartment but not its parent. The names of parent compartments that you don’t have permission to access are dimmed, but you can traverse the hierarchy down to the compartment that you do have access to.

After you select a compartment, the Console displays only the resources that you have permission to view in the compartment for the region that you are in. The compartment selection filters the view of your resources. To see resources in another compartment, you must switch to that compartment. To see resources in another region, you must switch to that region, or use the tenancy explorer.

For more details about compartments, see *Setting Up Your Tenancy* on page 122 and *Managing Compartments* on page 2431.

**Filtering the Displayed List of Resources**

To help you locate a resource, some resources let you filter the list that is displayed.
Filters include:

**State:** You can display only the resources that are in the state you select. Valid values for state can vary by resource. Examples are:

- Any state - includes all lifecycle states for the resource
- Available
- Provisioning
- Terminating
- Terminated

**Availability Domain:** For resources that reside in a single availability domain, you can limit the list to the resources that reside in the availability domains you select. For a list of availability domain-specific resources, see Resource Availability on page 184.

**Tags:** Resources that support tagging let you filter the list by tags.

### To filter a list of resources by a defined tag

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
   a. **Namespace:** Select the tag namespace.
   b. **Key:** Select a specific key.
   c. **Value:** Select from the following:
      - **Match Any Value** - returns all resources tagged with the selected namespace and key, regardless of the tag value.
      - **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same namespace and key, click + to display another text box. Enter one value per text box.
   d. Click **Apply Filter**.

### To filter a list of resources by a free-form tag

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
   a. **Key:** Enter the tag key.
   b. **Value:** Select from the following:
      - **Match Any Value** - returns all resources tagged with the selected free-form tag key, regardless of the tag value.
      - **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same key, click + to display another text box. Enter one value per text box.
   c. Click **Apply Filter**.

### Signing Out

To sign out of the Console, open the **Profile menu (👤)** and then click **Sign Out**.

### Using the Mobile App

The Oracle Cloud Infrastructure Mobile app let you review alerts, notifications, and limits on the go. Quickly access information about infrastructure resources, billing, and usage data from your mobile device. Read more to learn about installing and using the app.
Welcome to Oracle Cloud Infrastructure

Download Now

To download and install the app, click the Google Play Store or Apple App Store badge below and follow the instructions at the link.

Alternately, in the Google Play Store or Apple App Store, search for Oracle Cloud Infrastructure, select the app, and follow the installation steps.

This app is supported on the following operating systems:

- Android 8 and later versions
- iOS 11 and later versions

Signing In

To sign in to the Oracle Cloud Infrastructure Mobile app, use the same credentials and steps that you use to sign in to the Console. For more information, see Understanding the Sign-In Options.

The first time you sign in, you must read and accept the End User License Agreement to access the app.

Enabling Automatic Sign-in

For faster sign-in to the mobile app, you can enable automatic sign-in. Automatic sign-in uses an API key to authenticate you when you access the app, keeping you signed in until you sign out. The private key and the generated fingerprint are encrypted and stored in either the Android Keystore or the iCloud Keychain, depending on your device operating system. This encryption and storage ensures that your information is only accessible through the Oracle Cloud Infrastructure Mobile app. For more information about API keys, see Working with Console Passwords and API Keys on page 2456.

To enable automatic sign-in:

1. In the app, open the Profile menu ( ) and then tap Settings.
2. Under Login Security, for Enable automatic sign-in, toggle the Enabled or Disabled switch. When enabled, automatic sign-in will be used next time you open the app.

Generating the API signing key can take a few minutes. Automatic sign-in is available after the key is generated.

After you enable automatic sign-in, if you want to find the API key used by the app:

1. In the app, open the Profile menu ( ) and then tap Settings.
2. Under Login Security, the API key fingerprint value is the API signing key that the mobile app is using.

Each user has a limit of three API keys. If your account has reached this limit, you can't use this feature in the mobile app until you delete one of the existing API keys. You can use the Console to delete API signing keys.

To delete an API signing key

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.
Welcome to Oracle Cloud Infrastructure

1. View the user's details:
   • If you're deleting an API key for yourself:
     Open the Profile menu (👤) and click User Settings.
   • If you're an administrator deleting an API key for another user: Open the navigation menu. Under Governance and Administration, go to Identity and click Users. Locate the user in the list, and then click the user's name to view the details.

2. For the API key you want to delete, click Delete.

3. Confirm when prompted.

The API key is no longer valid for sending API requests.

Securing Your Account if Your Device is Compromised

If you have automatic sign-in enabled in the Oracle Cloud Infrastructure Mobile app and your device is stolen, you need to secure your account. To secure your account, in the Console, delete your API signing keys.

Switching Regions

Your current region is displayed at the top of the mobile app. If your tenancy is subscribed to multiple regions, you can switch regions by selecting a different region from the Region picker.

Switching Time Zones

You can set the mobile app to use UTC time or local time. To switch the time zone:

1. In the app, open the Profile menu (👤) and then tap Settings.
2. In the Time zone menu, for Set time zone, select Local or UTC.

Navigating in the Mobile App

When you sign in to the app, you see the Home tab.

Home

• The Alarms section displays information about alarms fired within the last 24 hours. For more details, tap an alarm in the list, or navigate to the Alarms tab.
• Tap the tiles in the Resources menu to see details about that type of resource.
• For trial users, the Billing section displays current information about costs associated with resource usage.

In addition to the Home tab, the app has Alarms, Resources, and Limits tabs.

Alarms

The Alarms tab displays details about alarms fired within the last 24 hours. At the top of the tab, use the Compartment picker to select your compartment. To see details about a specific alarm, tap that alarm in the list. For more information about alarms, see Monitoring Overview.

Resources

The Resources tab displays details about a selection of resources. At the top of the tab, use the Compartment picker to select your compartment.

Currently, you can view details about the following types of resources in the mobile app:

• Compute instances
• Block volumes
• Object Storage
• Load balancers
• Autonomous Transaction Processing
Welcome to Oracle Cloud Infrastructure

- Autonomous Data Warehouse

Tap a section to see a list of resources of that type. At the top of the tab, use the Compartments picker to select your compartment. Use the Filter resources text box to search for resources using a free text search based on keywords. For more information, see Search Overview. The indicator next to the resource name tells you the status of the resource.

To see resource details, tap the resource name in the list. This action takes you to a view that displays information about that resource, including:

- Resource status
- Visualizations with metrics that let you monitor the health, capacity, and performance of your resources
- Metadata for the resource

Limits

The Limits tab displays details about your current service limits and usage. The service limit is the quota or allowance set on a resource. For example, your tenancy is allowed a maximum number of compute instances per availability domain. These limits are usually established with your Oracle sales representative when you purchase Oracle Cloud Infrastructure. For more information about service limits, see Service Limits.

To view limits, at the top of the Limits tab:

1. Filter the list to the limits you want to see:
   - Use the Compartments picker to select your compartment.
   - Use the Resource picker to select a service.
2. After making your selections, tap Search limits to see the list of limits and current usage.

Each item in the resulting list shows a description of the service limit, the current usage for that service, and the total limit available.

Signing Out

To sign out of the Oracle Cloud Infrastructure Mobile app, open the Profile menu (👤) and then tap Sign Out.

Contacting Support

To open a support request for the Oracle Cloud Infrastructure Mobile app, sign in to the Console on a computer and follow the steps to create a support request. When you create the request, in the issue summary, include the prefix OCI_Mobile to specify that the support request is for the mobile app. For more information, see Getting Help and Contacting Support on page 125.

To create a support ticket

1. Open the Help menu (",
   go to Support, and click Create support request.
2. Enter the following:
   - Issue Summary: Enter a title that summarizes your issue. Avoid entering confidential information.
   - Describe Your Issue: Provide a brief overview of your issue.
     - Include all the information that support needs to route and respond to your request. For example, "I am unable to connect to my Compute instance."
     - Include troubleshooting steps taken and any available test results.
   - Select the severity level for this request.
3. Click Create Request.

Changing Your Password

This topic describes how users can change their own passwords.
To Change Your Password
Procedure for Oracle Identity Cloud Service users

1. Open the Profile menu and click User Settings.

Your Oracle Cloud Infrastructure IAM service User Details page is displayed. Notice that your username is prefixed with the name of your IDCS federation, for example: oracleidentitycloudservice/User

2. The information banner at the top of the page tells you that your account is managed in Oracle Identity Cloud Service. Click the here link.
3. Your Identity Cloud Service User Details page is displayed. Notice that on this page, your username is displayed without the prefix.

![User Details Page](image)

4. Click Change Password.
5. Follow the instructions in the dialog to create a new password.

**Procedure for local Oracle Cloud Infrastructure users**

Use this procedure if your sign-in page looks like the following image and you sign in through Oracle Cloud Infrastructure.

![Sign In Page](image)

1. Sign in to the Console using the Oracle Cloud Infrastructure Username and Password.
2. After you sign in, go to the top-right corner of the Console, open the Profile menu and then click Change Password.

3. Enter the current password.

4. Follow the prompts to enter the new password, and then click Save New Password.

Checking Your Expenses and Usage

This topic describes how to analyze the Oracle Cloud Infrastructure costs associated with your account.

You can use the following cost-related tools in the Console, which can help you gain insight into your costs and attribution of Oracle Cloud Infrastructure resources:

- Budgets
- Cost Analysis
- Cost and Usage Reports

See Working with Costs Analysis Tools on page 55, and Billing and Payment Tools Overview on page 273 for more information.

Required IAM Policy

To enable users to monitor the costs associated with this account, you will have to grant them access by writing a policy. If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

See Required IAM Policy on page 281 for more information on the required policy statements. Also see Cost and Usage Reports Overview on page 278 for more information on cost and usage reports.

Working with Costs Analysis Tools

Cost Analysis is a visualization tool that helps you track and optimize your Oracle Cloud Infrastructure spending, allows you to generate charts, and download accurate, reliable tabular reports of aggregated cost data on your Oracle Cloud Infrastructure consumption. Use the tool for spot checks of spending trends and for generating reports.

To filter costs by dates
Welcome to Oracle Cloud Infrastructure

1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Cost Analysis.
2. In Start Date, select a date.
3. In End Date, select a date (within six months of the start date).
4. Click Apply Filters.

To filter costs by tags
1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Cost Analysis.
2. From Tag Key, select a tag.
3. Click Apply Filters.

To filter costs by compartments
1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Cost Analysis.
2. From Compartment, select a compartment.
3. Click Apply Filters.

To remove a compartment or tag filter
• When you filter costs, a label appears with the name of the tag or compartment filter. To clear that filter, click the x.

For more information on Cost Analysis, see Cost Analysis Overview on page 282.

Changing Your Payment Method

This topic describes how to upgrade to a paid account, or change your payment method. This topic also describes how to terminate your paid subscription.

Required IAM Policy

To upgrade to a paid account or change your credit card, you must be a member of the Administrators group. See The Administrators Group and Policy on page 2125.

Upgrade Your Free Account

Most new customers in the United States who create new accounts after January 28, 2019 can use these tools.

Note:

If you created your account prior to January 28, 2019 or from outside the United States, use the following links:
• To upgrade to a paid account, see Upgrade Your Free Oracle Cloud Promotion on page 35.
• To change your credit card, see Updating Your Billing Details.

To upgrade to Pay-as-You-Go
1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Payment Method.
2. Under Account Type, select Pay-as-You-Go.
3. Take one of the following actions:
   • Click Edit to review the current credit card
   • Click Add a Credit Card
4. Type or review your information and click Finish.
5. Read the terms and conditions and select the check box to indicate your agreement.
6. Click Start Paid Account.
To request a sales call
1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Payment Method.
2. Under Account Type, select Request a Sales Call.
3. Type a phone number, an email address, or both.
4. Click Submit.

To change your payment method
You cannot change the payment method for promotional accounts.
1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Payment Method.
2. Click Edit Card.
3. Type your information and click Finish.

Terminating Your Account
You can terminate your account at any time through a support request. From the time that your request has been duly processed, billing is stopped (even if you have running instances), and any running resources are terminated.

Adding Users
This chapter provides a quick hands-on tutorial for adding users and groups and creating simple policies to grant them permissions to work with Oracle Cloud Infrastructure resources.

Use these instructions to quickly add some users to try out features. To fully understand the features of IAM and how to manage access to your cloud resources, see "Overview of IAM" in the Oracle Cloud Infrastructure User Guide.

For an overview of user management for all Oracle Cloud services, see Managing Users, User Accounts, and Roles.

About Users, Groups, and Policies
A user’s permissions to access Oracle Cloud Infrastructure services comes from the groups to which they belong. The permissions for a group are defined by policies. Policies define what actions members of a group can perform, and in which compartments. Users can then access services and perform operations based on the policies set for the groups they are members of.

About Oracle Identity Cloud Service Federated Users
When you sign up for Oracle Cloud Infrastructure, your tenancy is federated with Oracle Identity Cloud Service (IDCS) as the identity provider. You can create users and groups in IDCS that you can use with your Oracle Cloud products. To give these users permissions in Oracle Cloud Infrastructure, you need to perform some steps in IDCS and some steps in Oracle Cloud Infrastructure.

You can create your IDCS users and groups directly in the Console. The examples in the following sections include examples of creating IDCS users who can use Oracle Cloud Infrastructure services.

For more details on managing federated users, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 2372.

You can also choose to use Oracle Cloud Infrastructure’s IAM service as your identity provider to manage users and groups exclusively in the IAM service. These users can have permissions to use Oracle Cloud Infrastructure services only. If you want to manage users in the IAM service, see Managing Users on page 2414.

Sample Users and Groups
To help you understand how to set up users with the access permissions they need, perform the following tasks to set up these two basic types of users:
• An IDCS federated user with full administrator permissions (Cloud Administrator)
• An IDCS federated user with permissions to use one compartment only
Add a User with Oracle Cloud Administrator Permissions

The user you create in this task will have full administrator permissions of the default administrator. This means that the user has full access to all compartments and can create and manage all resources in Oracle Cloud Infrastructure as well as other services managed through Oracle Identity Cloud Service. You must have Cloud Administrator permissions to complete this task.

Create a Cloud Administrator user

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Click Create IDCS User.
4. In the Create IDCS User dialog enter the following:
   - **Username**: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Email**: Enter an email address for this user. The initial sign-in credentials will be sent to this email address.
   - **First Name**: Enter the user's first name.
   - **Last Name**: Enter the user's last name.
   - **Phone Number**: Optionally, enter a phone number.
   - **Groups**: You can skip this step. You will be granting this user full administrator privileges.
5. Click Create.
6. Click Email Password Instructions to send the password link and instructions to the user. If your email app does not launch, copy the reset instructions and manually email them to the user.
7. Click close to close the dialog. You are returned to the Users list on the Identity Provider Details page.
8. Click the name of the user you just created. The User Details page is displayed.
9. Click Manage Roles.
10. Select the check box next to Add Cloud Account Administrator Role.
11. Click Apply Role Settings.
12. A dialog confirms the entitlements granted to the user. To notify the user of these updates, click Send Email to User. Click Close to close the dialog.

Create a Compartment and Add a User with Access to It

In this example, create a compartment called "Sandbox" and then create a user with access to only that compartment.

Procedure Overview: To provide access to the Sandbox compartment and all the resources in it, you create a group (SandboxGroup), and then create a policy (SandboxPolicy) to define the access rule.

To enable access for users created in Identity Cloud Service, create a group in IDCS (IDCSSandboxGroup), and map it to the SandboxGroup.

Finally, create an IDCS user and add them to the IDCSSandboxGroup.

Create a sandbox compartment

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
2. Click Create Compartment.
3. Enter the following:
   - **Name**: Enter Sandbox.
   - **Description**: Enter a description (required), for example: Sandbox compartment for users to try out OCI.
4. Click **Create Compartment**.
   
   Your compartment is displayed in the list.

**Create an Oracle Cloud Infrastructure group**

Next, create the "SandboxGroup" that you will create the policy for.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
2. Click **Create Group**.
3. In the **Create Group** dialog:
   
   • **Name:** Enter a unique name for your group, for example, SandboxGroup.
     
     Note that the name cannot contain spaces.
   
   • **Description:** Enter a description (required).
4. Click **Create**.

**Create a policy**

Create the policy to give the SandboxGroup permissions in the Sandbox compartment.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
2. Under **List Scope**, ensure that you are in your root compartment.
3. Click **Create Policy**.
4. Enter a unique **Name** for your policy, for example, SandboxPolicy.
   
   Note that the name cannot contain spaces.
5. Enter a **Description** (required), for example, Grants users full permissions on the Sandbox compartment.
6. Enter the following **Statement**:

   ```plaintext
   Allow group SandboxGroup to manage all-resources in compartment Sandbox
   ```

   This statement grants members of the SandboxGroup group full access to the Sandbox compartment.
7. Click **Create**.

**Create an Oracle Identity Cloud Service group**

Next, create the "IDCS_SandboxGroup" in Oracle Identity Cloud Service.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
4. Click create **IDCS Group**.
5. In the **Create IDCS Group** dialog enter the following:
   
   • **Name:** Enter a unique name for your group, for example, IDCS_SandboxGroup.
     
     Note that the name cannot contain spaces.
   
   • **Description:** Enter a description (required).
6. Click **Create**.

   The group is created and it is displayed in the identity provider details page. Next, map the group.

**Map the Oracle Identity Cloud Service Group to the Oracle Cloud Infrastructure group**

Next, you need to map the Oracle Identity Cloud Service group to the Oracle Cloud Infrastructure group you created. The mapping gives the members of the IDCS group the permissions you granted to the OCI group.

1. On the identity provider details page, click **Group Mapping**. The group mappings are displayed.
2. Click **Edit Mapping**.
3. Click + Add Mapping.
4. From the **Identity Provider Group** menu list, choose the IDCS_SandboxGroup.

5. From the **OCI Group** menu list, select the SandboxGroup.

6. Click **Submit**.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See **Managing User Capabilities for Federated Users** on page 2408 for more information on assigning these users additional credentials.

**Create a user**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.

3. Click **Create IDCS User**.

4. In the **Create IDCS User** dialog enter the following:

   - **Username**: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Email**: Enter an email address for this user. The initial sign-in credentials will be sent to this email address.
   - **First Name**: Enter the user's first name.
   - **Last Name**: Enter the user’s last name.
   - **Phone Number**: Optionally, enter a phone number.
   - **Groups**: Select the group you created in the previous step, for example, IDCS_SandboxGroup.

5. Click **Create**.

   The user is created in Oracle Identity Cloud Service. This user can't access their account until they complete the password reset steps.

6. Click **Email Password Instructions** to send the password link and instructions to the user.

   The password link is good for 24 hours. If the user does not reset their password in time, you can generate a new password link by clicking **Reset Password** for the user.

   When this user signs in they can see the compartments they have access to and they can only view, create, and manage resources in the Sandbox compartment. This user cannot create other users or groups.

**Oracle Cloud Infrastructure Tutorials**

---

After you create your **Free Trial account**, use these tutorials to get started.

- **Autonomous Database Quickstart**

  Create an instance in just a few clicks. Then load data into your database from Object Storage and query it.

- **Oracle APEX**

  Use APEX and Autonomous Database

  Oracle Application Express (APEX) is a low-code development framework that enables you to rapidly build modern, data-driven apps right from your browser - no additional tools required.
<table>
<thead>
<tr>
<th>Migrating To Oracle Cloud Infrastructure</th>

**Tutorial - Launching Your First Linux Instance**

In this tutorial, you'll learn the basic features of Oracle Cloud Infrastructure by performing some guided steps to launch and connect to an instance. After your instance is up and running, you can optionally create and attach a block volume to your instance.

In this tutorial, you will:

- Create a cloud network and subnet that enables internet access
- Launch an instance
- Connect to the instance
- Add and attach a block volume
The following figure depicts the components you create in the tutorial.

### Task Flow to Launch an Instance

Linux instances use an SSH key pair instead of a password to authenticate a remote user. If you do not already have a key pair, your first task is to create one using common third-party tools (if you have OpenSSH, you can instead use a key pair that is generated by Oracle Cloud Infrastructure). Next, prepare for your instance by launching a cloud network with subnets. You will then launch your instance into one of the subnets and connect to it. If you want to attach some storage, continue with the tutorial to add a cloud block storage volume. When finished with the tutorial, be sure to terminate the resources that you created.

Prepare:
- Create a key pair.
- Choose a compartment for your resources.
- Create a cloud network.

Launch and connect:
- Launch an instance.
- Connect to your instance.

Add storage and clean up:
- Add a block volume (optional).
- Clean up your resources.
Creating a Key Pair

Linux instances use an SSH key pair instead of a password to authenticate a remote user. A key pair file contains a private key and public key. You keep the private key on your computer and provide the public key when you create an instance. When you connect to the instance using SSH, you provide the path to the private key in the SSH command.

**Caution:**
Anyone who has access to the private key can connect to the instance. Store the private key in a secure location.

If you're connecting to your instance from a computer that has OpenSSH installed, you can use a key pair that is generated by Oracle Cloud Infrastructure instead of creating your own key pair.

**Before You Begin**

- If you will connect to your instance from a Windows system using OpenSSH or from a UNIX-based system, you can use a key pair that is generated by Oracle Cloud Infrastructure and skip this step. OpenSSH should be installed on Windows 10 and Windows Server 2019. Proceed to Choosing a Compartment on page 63.
- If you already have an SSH-2 RSA key pair, you can use your existing key pair and skip this step. Proceed to Choosing a Compartment on page 63.
- If you will connect to your instance from a Windows system that does not have OpenSSH, download and install the PuTTY Key Generator from http://www.putty.org.

**Creating an SSH Key Pair on Windows Using PuTTY Key Generator**

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, C:\Program Files (x86)\PuTTY. Double-click `puttygen.exe` to open it.
2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the Key menu, confirm that the default value of SSH-2 RSA key is selected.
   - For the Type of key to generate, accept the default key type of RSA.
   - Set the Number of bits in a generated key to 2048 if it is not already set.
3. Click Generate.
4. Move your mouse around the blank area in the PuTTY window to generate random data in the key.
   When the key is generated, it appears under Public key for pasting into OpenSSH authorized_keys file.
5. A Key comment is generated for you, including the date and time stamp. You can keep the default comment or replace it with your own more descriptive comment.
6. Leave the Key passphrase field blank.
7. Click Save private key, and then click Yes in the prompt about saving the key without a passphrase.
   The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.
   You can name the key anything you want, but use the .ppk file extension. For example, mykey.ppk.
8. Select all of the generated key that appears under Public key for pasting into OpenSSH authorized_keys file, copy it using Ctrl + C, paste it into a text file, and then save the file in the same location as the private key.
   (Do not use Save public key because it does not save the key in the OpenSSH format.)
   You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of pub. For example, mykey.pub.
9. Write down the names and location of your public and private key files. You will need the public key when launching an instance. You will need the private key to access the instance via SSH.

**Choosing a Compartment**

Compartments help you organize and control access to your resources. A compartment is a collection of related resources (such as cloud networks, compute instances, or block volumes) that can be accessed only by those groups
that have been given permission by an administrator in your organization. For example, one compartment could contain all the servers and storage volumes that make up the production version of your company's Human Resources system. Only users with permission to that compartment can manage those servers and volumes.

In this tutorial you use one compartment for all your resources. When you are ready to create a production environment you will most likely separate these resources in different compartments.

**Before You Begin**

Sign in to the Console.

**Choosing a Compartment**

To begin working with a service, you must first select a service, and then select a compartment that you have permissions in.

1. In this tutorial, the first resource you create is the cloud network. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.

2. Select the Sandbox compartment (or the compartment designated by your administrator) from the list on the left, as shown in the image. If the Sandbox compartment does not exist, you can create it as described in Creating a Compartment.

**Creating a Compartment**

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.

2. Click **Create Compartment**.

3. Enter the following:
   - **Name**: Enter "Sandbox".
   - **Description**: Enter a description (required), for example: "Sandbox compartment for the getting started tutorial".
   - **Parent Compartment**: Select the compartment you want this compartment to reside in. Defaults to the root compartment (or tenancy).

4. Click **Create Compartment**.

Your compartment is displayed in the list.

5. Return to Choosing a Compartment.

When you select the Sandbox compartment, you will only see resources that are in the Sandbox. When you create new resources you will be prompted to choose the compartment to create them in, but your current compartment will be the default. If you change compartments, you must come back to the Sandbox compartment to see the resources that were created there.
Creating a Virtual Cloud Network

Before you can launch an instance, you need to have a virtual cloud network (VCN) and subnet to launch it into. A subnet is a subdivision of your VCN. The subnet directs traffic according to a route table. For this tutorial, you'll access the instance over the internet using its public IP address, so your route table will direct traffic to an internet gateway. The subnet also uses a security list to control traffic in and out of the instance.

For information about VCN features, see “Overview of Networking” in the Oracle Cloud Infrastructure User Guide.

Before You Begin

• You or an administrator has created a compartment for your network. See Choosing a Compartment on page 63.

Create a Cloud Network Plus Related Resources

Tip:
The Console offers two choices when you create a VCN: to create only the VCN, or to create the VCN with several related resources that are necessary if you want to immediately launch an instance. To help you get started quickly, the following procedure creates the VCN plus the related resources.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.

   Ensure that the Sandbox compartment (or the compartment designated for you) is selected in the Compartment list on the left.

2. Click Networking Quickstart.

3. Select VCN with Internet Connectivity, and then click Start Workflow.

4. Enter the following:

   • **VCN Name**: Enter a name for your cloud network. The name is incorporated into the names of all the related resources that are automatically created. Avoid entering confidential information.
   • **Compartment**: This field defaults to your current compartment. Select the compartment you want to create the VCN and related resources in, if not already selected.
   • **VCN CIDR Block**: Enter a valid CIDR block for the VCN. For example 10.0.0.0/16.
   • **Public Subnet CIDR Block**: Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block. For example: 10.0.0.0/24.
   • **Private Subnet CIDR Block**: Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block and not overlap with the public subnet's CIDR block. For example: 10.0.1.0/24.
   • Accept the defaults for any other fields.

5. Click Next.

6. Review the list of resources that the workflow will create for you. Notice that the workflow will set up security list rules and route table rules to enable basic access for the VCN.

7. Click Create to start the short workflow.

8. After the workflow completes, click View Virtual Cloud Network.

The cloud network has the following resources and characteristics:

• Internet gateway.
• NAT gateway.
• Service gateway with access to the Oracle Services Network.
• A regional public subnet with access to the internet gateway. This subnet uses the VCN's default security list and default route table. Instances in this subnet may optionally have public IP addresses.
• A regional private subnet with access to the NAT gateway and service gateway. This subnet uses a custom security list and custom route table that the workflow created. Instances in this subnet cannot have public IP addresses.
• Use of the Internet and VCN Resolver for DNS.
Welcome to Oracle Cloud Infrastructure

Important:
This simple cloud network is designed to make it easy to launch an instance when trying out Oracle Cloud Infrastructure. When you create your production instances, ensure that you create appropriate security lists and route table rules to restrict network traffic to your instances.

What’s Next
Now you can launch an instance. See Launching a Linux Instance on page 66.

Launching a Linux Instance
Now you will launch an instance with the Oracle Linux image and basic shape. More advanced options are available; see "Managing Instances" in the Oracle Cloud Infrastructure User Guide for more information.

Before You Begin
• You have created a virtual cloud network (VCN) and public subnet. See Creating a Virtual Cloud Network on page 65.
• If you will connect to your instance from a Windows system that does not have OpenSSH, you have a created an SSH key pair. See Creating a Key Pair on page 63.

Launching an Instance
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click Create Instance.
3. Enter a name for the instance, for example: <your initials> _Instance. Avoid entering confidential information.
4. In the Placement and hardware section, make the following selections:
   a. Accept the default Availability domain.
   b. In the Image section, accept the default, Oracle Linux 7.x.
   c. In the Shape section, click Change Shape. Then, do the following:
      1. For Instance type, accept the default, Virtual Machine.
      2. For Shape series, select Intel Skylake, and then choose the VM.Standard2.1 shape (1 OCPU, 15 GB RAM).

Tip:
To create an instance using the Always Free-eligible VM.Standard.E2.1.Micro shape, select Specialty and Legacy, and then choose the VM.Standard.E2.1.Micro shape. If the Micro shape
Welcome to Oracle Cloud Infrastructure

is disabled, cancel out of the shape selection page, select a different availability domain, and then try again.

The shape defines the number of CPUs and amount of memory allocated to the instance.

3. Click Select Shape.

5. In the Networking section, configure the network details for the instance:

   • For Network, leave Select existing virtual cloud network selected.
   • Virtual cloud network in <compartment_name>: Select the cloud network that you created. If necessary, click Change compartment to switch to the compartment containing the cloud network that you created.
   • For Subnet, leave Select existing subnet selected.
   • Subnet in <compartment_name>: Select the public subnet that was created with your cloud network. If necessary, click Change compartment to switch to the compartment containing the correct subnet.
   • Leave the Use network security groups to control traffic check box cleared.
   • Select the Assign a public IPv4 address option. This creates a public IP address for the instance, which you need to access the instance. If you have trouble selecting this option, confirm that you selected the public subnet that was created with your VCN, not a private subnet.

6. In the Add SSH keys section, select one of the following options:

   • Generate SSH keys: If you will connect to the instance using OpenSSH, select this option. Click Save Private Key and then save the private key on your computer. Optionally, click Save Public Key and then save the public key.

      Caution:
      Anyone who has access to the private key can connect to the instance.
      Store the private key in a secure location.

   • Choose SSH key files: If you will connect to the instance using PuTTY, select this option. To upload the public key portion of the key pair that you want to use for SSH access to the instance, browse to the key file that you want to upload, or drag and drop the file into the box.

7. In the Boot volume section, leave all the options cleared.

8. Click Create.

The instance is displayed in the Console in a provisioning state. Expect provisioning to take several minutes before the state updates to running. Do not refresh the page. After the instance is running, allow another few minutes for the operating system to boot before you attempt to connect.

Getting the Instance Public IP Address

To connect to the instance in the next step, you'll need its public IP address.

To get the instance public IP address:

1. Click the instance name to see its details.
2. The **Public IP Address** and **Username** are displayed on the details page under **Instance Access**, as shown in the following image:

![Instance Access Image]

3. Make a note of the **Public IP Address** before you continue.

### Connecting to Your Instance

You connect to a running Linux instance using a Secure Shell (SSH) connection. Most Linux distributions include an SSH client by default. Windows 10 and Windows Server 2019 systems should include the **OpenSSH client**, which you’ll need if you created your instance using the SSH keys generated by Oracle Cloud Infrastructure. For other Windows versions, you can download a free SSH client called PuTTY from [http://www.putty.org](http://www.putty.org).

**Before You Begin**

- You know the public IP address of your instance. See Launching a Linux Instance on page 66.
- You know the path to the private key file.

**Connecting to Your Linux Instance Using SSH**

Log in to the instance using SSH.

**To connect to a Linux instance from a Unix-style system**
1. Use the following command to set the file permissions so that only you can read the file:

```
chmod 400 <private_key_file>
```

\(<private_key_file>\) is the full path and name of the file that contains the private key associated with the instance you want to access.

2. Use the following SSH command to access the instance.

```
ssh -i <private_key_file> <username>@<public-ip-address>
```

\(<private_key_file>\) is the full path and name of the file that contains the private key associated with the instance you want to access.

\(<username>\) is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

\(<public-ip-address>\) is your instance IP address that you retrieved from the Console.

**To connect to a Linux instance from a Windows system using OpenSSH**

If the instance uses a key pair that was generated by Oracle Cloud Infrastructure, use the following procedure.

1. If this is the first time you are using this key pair, you must set the file permissions so that only you can read the file. Do the following:
   a. In Windows Explorer, navigate to the private key file, right-click the file, and then click Properties.
   c. Ensure that the Owner is your user account.
   d. Click Disable Inheritance, and then select Convert inherited permissions into explicit permissions on this object.
   e. Select each permission entry that is not your user account and click Remove.
   f. Ensure that the access permission for your user account is Full control.
   g. Save your changes.

2. To connect to the instance, open Windows PowerShell and run the following command:

```
ssh -i <private_key_file> <username>@<public-ip-address>
```

\(<private_key_file>\) is the full path and name of the file that contains the private key associated with the instance you want to access.

\(<username>\) is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

\(<public-ip-address>\) is your instance IP address that you retrieved from the Console.

**To connect to a Linux instance from a Windows system using PuTTY**

SSH private key files generated by Oracle Cloud Infrastructure are not compatible with PuTTY. If you are using a private key file generated during the instance creation process you need to convert the file to a .ppk file before you can use it with PuTTY to connect to the instance.

**Convert a generated .key private key file:**

1. Open PuTTYgen.
2. Click Load, and select the private key generated when you created the instance. The extension for the key file is .key.
3. Click Save private key.
4. Specify a name for the key. The extension for new private key is .ppk.
5. Click Save.

**Connect to the Linux instance using a .ppk private key file:**
If the instance uses a key pair that you created using PuTTY Key Generator, use the following procedure.

1. Open PuTTY.
2. In the Category pane, select Session and enter the following:
   • Host Name (or IP address):
     
     <username>@<public-ip-address>

     <username> is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

     <public-ip-address> is your instance public IP address that you retrieved from the Console
   • Port: 22
   • Connection type: SSH
3. In the Category pane, expand Window, and then select Translation.
4. In the Remote character set drop-down list, select UTF-8. The default locale setting on Linux-based instances is UTF-8, and this configures PuTTY to use the same locale.
5. In the Category pane, expand Connection, expand SSH, and then click Auth.
6. Click Browse, and then select your .ppk private key file.
7. Click Open to start the session.

If this is your first time connecting to the instance, you might see a message that the server’s host key is not cached in the registry. Click Yes to continue the connection.

**Tip:**

If the connection fails, you may need to update your PuTTY proxy configuration.

### Running Administrative Tasks on the Instance

When you’re logged in as the default user, opc, you can use the `sudo` command to run administrative tasks.

### What’s Next

Now that you’ve got an instance and have successfully connected to it, consider the following next steps:

- Install software on the instance.
- Add a block volume. See Adding a Block Volume on page 70.
- Add more users to work with Oracle Cloud Infrastructure. See Adding Users on page 57.
- Allow additional users to connect to your instance. See Adding Users on an Instance on page 737.
- Or, if you are finished with your instance, delete the resources that you created in the tutorial. See Cleaning Up Resources from the Tutorial on page 72.

If you’re having trouble connecting, see Troubleshooting the SSH Connection on page 737.

### Adding a Block Volume

Block Volume provides network storage to use with your Oracle Cloud Infrastructure instances. After you create, attach, and mount a volume to your instance, you can use it just as you would a physical hard drive on your computer. A volume can be attached to a single instance at a time, but you can detach it from one instance and attach to another instance, keeping your data intact.

This task shows you how to create a volume, attach it to an instance, and then connect the volume to the instance.

For complete details on Block Volume, see "Overview of Block Volume" in the Oracle Cloud Infrastructure User Guide.

#### Creating a Volume

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. Click Create Block Volume.
3. In the **Create Block Volume** dialog, enter the following:

   - **Create in Compartment:** This field defaults to your current compartment. Select the compartment you want to create the volume in, if not already selected.
   - **Name:** Enter a user-friendly name. Avoid entering confidential information.
   - **availability domain:** Select the same **availability domain** that you selected for your instance. If you followed the tutorial instructions when launching your instance, this is the first AD in the list. The volume and the instance must be in the same availability domain.
   - **Size:** Enter 50 to create a 50 GB block volume.
   - **Backup Policy:** Do not select a backup policy.
   - **Tags:** Leave the tagging fields blank.

4. Click **Create Block Volume**.

   A 50 GB block volume is displayed in the provisioning state. When the volume is no longer in the provisioning state, you can attach it to your instance.

**Attaching the Volume to an Instance**

Next you attach the volume via an **iSCSI** network connection to your instance:

1. Find your instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click your instance name to view its details.
3. In the **Resources** section, click **Attached Block Volumes**.
4. Click **Attach Block Volume**.
5. Enter the following:
   - **Select ISCSI**.
   - **Block Volume Compartment:** Select the compartment where you created the block volume.
   - **Select Volume:** Select this option.
   - **Block Volume:** Select the block volume from the list.
   - **Device Path:** If the instance supports consistent device paths, you will see a list of device paths. Select one from the list.
   - **Require CHAP Credentials:** Leave cleared.

   **Tip:**

   **CHAP** is a security protocol. You can leave this box cleared for the purposes of the tutorial. When you set up your production environment, Oracle recommends requiring CHAP credentials.

6. Click **Attach**.

**Connecting to the Volume**

After your volume is attached, you can configure the iSCSI connection. You connect to the volume using the `iscsiadm` command-line tool. The commands you need to configure, authenticate, and log on are provided by the Console so you can easily copy and paste them into your instance session window. After the connection is configured, you can mount the volume on your instance and use it just as you would a physical hard drive.

To connect to your volume:

1. Log on to your instance as described in **Connecting to Your Instance** on page 68.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click your instance name to view its details.
4. In the **Resources** section, click **Attached Block Volumes**.
5. Click the Actions icon (three dots) next to the volume you just attached and then click **iSCSI Commands and Information**.

   The **iSCSI Commands and Information** dialog is displayed. Notice that the dialog displays specific identifying information about your volume (such as IP address and port) as well as the iSCSI commands you'll need to use. The commands are ready to use with the appropriate information already included in each command.

6. The **Attach Commands** configure the iSCSI connection and log on to iSCSI. Copy and paste each command from the **Attach Commands** list into the instance session window.

   Be sure to paste and run each command individually. There are three attach commands. Each command begins with `sudo iscsiadm`.

7. After entering the final command to log on to iSCSI, you are ready to format (if needed) and mount the volume. To get a list of mountable iSCSI devices on the instance, run the following command:

   ```
   sudo fdisk -l
   ```

   If your disk attached successfully, you'll see it in the returned list as follows:

   ```
   Disk /dev/sdb: 50.0 GB, 50010783744 bytes, 97677312 sectors
   Units = sectors of 1 * 512 = 512 bytes
   Sector size (logical/physical): 512 bytes / 512 bytes
   I/O size (minimum/optimal): 4096 bytes / 1048576 bytes
   ```

   **Important:**

   Connecting to Volumes on Linux Instances

   When connecting to volumes on Linux instances, if you want to automatically mount these volumes on instance boot, you need to use some specific options in the `/etc/fstab` file, or the instance may fail to launch. See Traditional fstab Options on page 528 and fstab Options for Block Volumes Using Consistent Device Paths on page 527 for more information.

**What's Next**

Now that you've got an instance running and attached some storage, consider the following next steps:

- Install your own software on the instance.
- Add more users to work with Oracle Cloud Infrastructure. See Adding Users on page 57.
- Or, if you are finished with your instance, delete the resources that you created in the tutorial. See Cleaning Up Resources from the Tutorial on page 72.

**Cleaning Up Resources from the Tutorial**

After you've finished with the resources you created for this tutorial, clean up by terminating the instance and deleting the resources you don't intend to continue working with.

**Detach and Delete the Block Volume**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Find your instance in the Instances list and click its name to display its details.
3. In the Resources section on the Instance Details page, click Attached Block Volumes.
4. Find your volume, click the Actions icon (three dots), and then click Detach.
5. Click Continue Detachment and then click OK.
6. When the Console shows the volume status as Detached, you can delete the volume. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
7. Find your volume, click the Actions icon (three dots), and then click Terminate. Confirm when prompted.
Terminate the Instance
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the list of instances, find the instance you created in the tutorial.
3. Click the Actions icon (three dots), and then click Terminate.
4. Select the Permanently delete the attached boot volume check box, and then click Terminate Instance.

Delete the Virtual Cloud Network
1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. In the list of VCNs, find the one you created in the tutorial.
3. Click the Actions icon (three dots), and then click Terminate.
4. Click Terminate All to delete all the underlying resources of your VCN.
   When all the resources are successfully deleted you can close the dialog.

Tutorial - Launching Your First Windows Instance

In this tutorial you'll learn the basic features of Oracle Cloud Infrastructure by performing some guided steps to launch and connect to a Windows instance. After your instance is up and running, you can optionally create and attach a block volume to your instance.

In this tutorial you will:
• Create a cloud network and subnet that enables internet access
• Launch an instance
• Connect to the instance
• Add and attach a block volume

The following figure depicts the components you create in the tutorial.
Welcome to Oracle Cloud Infrastructure

Task Flow to Launch a Windows Instance

You will connect to your instance using Remote Desktop Connection and a one-time password that is created when you launch the instance. Before you can launch the instance, you must create a virtual cloud network (VCN) with subnets. You will then launch your instance into one of the subnets of your VCN and connect to it. If you want to attach some storage, continue with the tutorial to add a cloud block storage volume. When finished with the tutorial, be sure to terminate the resources that you created.

Prepare:
- Choose a compartment for your resources.
- Create a cloud network.

Launch and connect:
- Launch a Windows instance.
- Connect to your Windows instance.

Add storage and clean up:
- Add a block volume (optional).
- Clean up your resources.

Choosing a Compartment

Compartments help you organize and control access to your resources. A compartment is a collection of related resources (such as cloud networks, compute instances, or block volumes) that can be accessed only by those groups that have been given permission by an administrator in your organization. For example, one compartment could contain all the servers and storage volumes that make up the production version of your company's Human Resources system. Only users with permission to that compartment can manage those servers and volumes.
In this tutorial you use one compartment for all your resources. When you are ready to create a production environment you will most likely separate these resources in different compartments.

**Before You Begin**

Sign in to the Console.

**Choosing a Compartment**

To begin working with a service, you must first select a service, and then select a compartment that you have permissions in.

1. In this tutorial, the first resource you create is the cloud network. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
2. Select the Sandbox compartment (or the compartment designated by your administrator) from the list on the left, as shown in the image. If the Sandbox compartment does not exist, you can create it as described in Creating a Compartment.

![Virtual Cloud Networks in Sandbox Compartment](image)

**Creating a Compartment**

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
2. Click Create Compartment.
3. Enter the following:
   - **Name:** Enter "Sandbox".
   - **Description:** Enter a description (required), for example: "Sandbox compartment for the getting started tutorial".
   - **Parent Compartment:** Select the compartment you want this compartment to reside in. Defaults to the root compartment (or tenancy).
4. Click Create Compartment.
   - Your compartment is displayed in the list.
5. Return to Choosing a Compartment.

When you select the Sandbox compartment, you will only see resources that are in the Sandbox. When you create new resources you will be prompted to choose the compartment to create them in, but your current compartment will be the default. If you change compartments, you must come back to the Sandbox compartment to see the resources that were created there.

**Creating a Virtual Cloud Network**

Before you can launch an instance, you need to have a virtual cloud network (VCN) and subnet to launch it into. A subnet is a subdivision of your VCN. The subnet directs traffic according to a route table. For this tutorial, you'll access the instance over the internet using its public IP address, so your route table will direct traffic to an internet gateway. The subnet also uses a security list to control traffic in and out of the instance.
For information about VCN features, see “Overview of Networking” in the *Oracle Cloud Infrastructure User Guide*.

**Before You Begin**

- You or an administrator has created a compartment for your network. See Choosing a Compartment on page 74.

**Create a Cloud Network Plus Related Resources**

**Tip:**

The Console offers two choices when you create a VCN: to create only the VCN, or to create the VCN with several related resources that are necessary if you want to immediately launch an instance. To help you get started quickly, the following procedure creates the VCN plus the related resources.

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.

   Ensure that the Sandbox compartment (or the compartment designated for you) is selected in the Compartment list on the left.

2. Click Networking Quickstart.

3. Select VCN with Internet Connectivity, and then click Start Workflow.

4. Enter the following:

   - **VCN Name:** Enter a name for your cloud network. The name is incorporated into the names of all the related resources that are automatically created. Avoid entering confidential information.
   - **Compartment:** This field defaults to your current compartment. Select the compartment you want to create the VCN and related resources in, if not already selected.
   - **VCN CIDR Block:** Enter a valid CIDR block for the VCN. For example 10.0.0.0/16.
   - **Public Subnet CIDR Block:** Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block. For example: 10.0.0.0/24.
   - **Private Subnet CIDR Block:** Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block and not overlap with the public subnet's CIDR block. For example: 10.0.1.0/24.
   - Accept the defaults for any other fields.

5. Click Next.

6. Review the list of resources that the workflow will create for you. Notice that the workflow will set up security list rules and route table rules to enable basic access for the VCN.

7. Click Create to start the short workflow.

8. After the workflow completes, click View Virtual Cloud Network.

The cloud network has the following resources and characteristics:

- Internet gateway.
- NAT gateway.
- Service gateway with access to the Oracle Services Network.
- A regional public subnet with access to the internet gateway. This subnet uses the VCN's default security list and default route table. Instances in this subnet may optionally have public IP addresses.
- A regional private subnet with access to the NAT gateway and service gateway. This subnet uses a custom security list and custom route table that the workflow created. Instances in this subnet cannot have public IP addresses.
- Use of the Internet and VCN Resolver for DNS.

**Important:**

This simple cloud network is designed to make it easy to launch an instance when trying out Oracle Cloud Infrastructure. When you create your production instances, ensure that you create appropriate security lists and route table rules to restrict network traffic to your instances.
Edit the Default Security List to Allow Traffic to Your Windows Instance

To enable network traffic to reach your Windows instance, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, for the default security list (which is used by the public subnet), you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port.

To edit the VCN’s security list:

1. Click the name of the VCN that you just created. Its details are displayed.
3. Click the default security list for your VCN.
   Its details are displayed.
4. Click Add Ingress Rules.
5. Enter the following for your new rule:
   a. Source Type: CIDR
   b. Source CIDR: 0.0.0.0/0
   c. IP Protocol: RDP (TCP/3389)
   d. Source Port Range: All
   e. Destination Port Range: 3389
6. When done, click Add Ingress Rules.

What’s Next

Now you can launch an instance. See Launching a Windows Instance on page 77.

Launching a Windows Instance

Now you will launch an instance with the Oracle Windows image and basic shape. More advanced options are available, see "Managing Instances" in the Oracle Cloud Infrastructure User Guide for more information.

Before You Begin

• You have created a virtual cloud network (VCN) and public subnet. See Creating a Virtual Cloud Network on page 75.

Launching an Instance

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click Create Instance.
3. Enter a name for the instance, for example: <your initials>_Instance. Avoid entering confidential information.

Important:
Use only these ASCII characters in the instance name: uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), and hyphens (-). See this known issue for more information.

4. In the Placement and hardware section, make the following selections:
   a. Accept the default Availability domain.
   b. In the Image section, click Change Image. Then, do the following:
      1. In the Image source list, select Platform Images.
      3. Review and accept the terms of use, and then click Select Image.
   c. In the Shape section, click Change Shape. Then, do the following:
      1. For Instance type, accept the default, Virtual Machine.
      2. For Shape series, select Intel Skylake, and then choose the VM.Standard2.1 shape (1 OCPU, 15 GB RAM).

      The shape defines the number of CPUs and amount of memory allocated to the instance.
   3. Click Select Shape.

5. In the Networking section, configure the network details for the instance. Do not accept the defaults.
   • For Network, leave Select existing virtual cloud network selected.
   • Virtual cloud network in <compartment_name>: Select the cloud network that you created. If necessary, click Change compartment to switch to the compartment containing the cloud network that you created.
   • For Subnet, leave Select existing subnet selected.
   • Subnet in <compartment_name>: Select the public subnet that was created with your cloud network. If necessary, click Change compartment to switch to the compartment containing the correct subnet.
   • Leave the Use network security groups to control traffic check box cleared.
   • Select the Assign a public IPv4 address option. This creates a public IP address for the instance, which you need to access the instance. If you have trouble selecting this option, confirm that you selected the public subnet that was created with your VCN, not a private subnet.

6. In the Boot volume section, leave all the options cleared.
7. Click Create.

The instance is displayed in the Console in a provisioning state. Expect provisioning to take several minutes before the state updates to Running. Do not refresh the page. After the instance is running, allow another few minutes for the operating system to boot before you attempt to connect.

Getting the Instance Public IP Address and Initial Windows Password

To connect to the instance in the next step, you'll need its public IP address and initial password.

To get the instance public IP address and initial password:
1. Click the instance name to see its details.
2. The **Public IP Address**, **Username**, and **Initial Password** are displayed on the details page, as shown in the following image:

3. To view the **Initial Password**, click **Show**. Although the Console offers a copy option, the paste option is typically not available when you are prompted to enter the password, so be prepared to enter it manually.

4. When you are ready to connect to the instance, make a note of both the public IP address and the initial password.

### Connecting to Your Windows Instance

You connect to a running Windows instance using Remote Desktop.

#### Before You Begin

- You know the public IP address and initial password of your instance, see [Launching a Windows Instance](#) on page 77.
- You have Remote Desktop installed.

#### Connecting to Your Windows Instance from a Remote Desktop Client

1. Open the Remote Desktop client.
2. In the **Computer** field, enter the public IP address that you retrieved from the Console.
3. The **User name** is opc. Depending on the Remote Desktop client you are using, you might have to connect to the instance before you can enter this credential.
4. Click **Connect** to start the session.
5. Accept the certificate if you are prompted to do so.
6. Enter the initial password that you retrieved from the Console. You will be prompted to change the password as soon as you log in.
   
   Your new password must be at least 12 characters long and must comply with Microsoft's password policy.
7. Press **Enter**.

### Running Administrative Tasks on the Instance

The default user, opc, has administrative privileges.

### What's Next

Now that you've got an instance and have successfully connected to it, consider the following next steps:
Welcome to Oracle Cloud Infrastructure

- Install software on the instance.
- Add a block volume. See Adding a Block Volume to a Windows Instance on page 80.
- Add more users to work with Oracle Cloud Infrastructure. See Adding Users on page 57.
- Allow additional users to connect to your instance. See Adding Users on an Instance on page 737.
- Or, if you are finished with your instance, delete the resources that you created in the tutorial. See Cleaning Up Resources from the Tutorial on page 81.

If you're having trouble connecting, see Troubleshooting the SSH Connection on page 737.

Adding a Block Volume to a Windows Instance

Block Volume provides network storage to use with your Oracle Cloud Infrastructure instances. After you create, attach, and mount a volume to your instance, you can use it just as you would a physical hard drive on your computer. A volume can be attached to a single instance at a time, but you can detach it from one instance and attach to another instance, keeping your data intact.

This task shows you how to create a volume, attach it to an instance, and then connect the volume to the instance.

For complete details on Block Volume, see "Managing Volumes" in the Oracle Cloud Infrastructure User Guide.

Creating a Volume

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. Click Create Block Volume.
3. In the Create Block Volume dialog box, enter the following:
   a. Create in Compartment: This field defaults to your current compartment. Select the compartment you want to create the volume in, if not already selected.
   b. Name: Enter a user-friendly name. Avoid entering confidential information.
   c. availability domain: Select the same availability domain that you selected for your instance. If you followed the tutorial instructions when launching your instance, this will be the first availability domain in the list. The volume and the instance must be in the same availability domain.
   d. Size: Enter 256 to create a 256 GB block volume.
4. Click Create Block Volume.

A 256 GB block volume is displayed in the list in the provisioning state. When the volume is no longer in the provisioning state, you can attach it to your instance.

Attaching the Volume to an Instance

Next you attach the volume via an iSCSI network connection to your instance:

1. Find your instance: Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click your instance name to view its details.
3. In the Resources section, click Attached Block Volumes.
4. Click Attach Block Volume.
5. Enter the following:
   a. Block Volume Compartment: Select the compartment where you created the block volume.
   b. Block Volume: Select the block volume from the list.
   c. Require CHAP Credentials: Leave cleared.

Tip:

CHAP is a security protocol. You can leave this box cleared for the purposes of the tutorial. When you set up your production environment, Oracle recommends requiring CHAP credentials.

6. Click Attach.
Connecting to the Volume

After your volume is attached, you can configure the iSCSI connection. After the connection is configured, you can mount the volume on your instance and use it just as you would a physical hard drive.

To connect to your volume:

1. Log on to your instance as described in Connecting to Your Windows Instance on page 79.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Click your instance name to view the instance details.
4. In the Resources section, click Attached Block Volumes.
5. Click the Actions icon (three dots) next to the volume you just attached and then click iSCSI Commands and Information.

The iSCSI Commands and Information dialog box opens. Notice that the dialog box displays specific identifying information about your volume (such as IP address and port) as well as the iSCSI commands that you can use.

6. On your Windows instance, open the iSCSI Initiator.
   For example: Open Server Manager, click Tools, and select iSCSI Initiator.
7. In the iSCSI Initiator Properties dialog box, click the Discovery tab.
8. Click Discover Portal.
9. Enter the block volume IP address and port. Click OK.
10. Click the Targets tab.
11. In the Discovered Targets region, select the volume IQN.
12. Click Connect and then click OK to close the dialog.
13. You are now ready to format (if needed) and mount the volume. To get a list of mountable iSCSI devices on the instance, in Server Manager, click File and Storage Services and then click Disks.

   The 256 GB disk is displayed in the list.

What's Next

Now that you've got an instance running and attached some storage, consider the following next steps:

- Install your own software on the instance.
- Add more users to work with Oracle Cloud Infrastructure. See Adding Users on page 57.
- Or, if you are finished with your instance, delete the resources that you created in the tutorial. See Cleaning Up Resources from the Tutorial on page 81.

Cleaning Up Resources from the Tutorial

After you've finished with the resources you created for this tutorial, clean up by terminating the instance and deleting the resources you don't intend to continue working with.

Detach and Delete the Block Volume

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Find your instance in the Instances list and click its name to display its details.
3. In the Resources section on the Instance Details page, click Attached Block Volumes.
4. Find your volume, click the Actions icon (three dots), and then click Detach.
5. Click Continue Detachment and then click OK.
6. When the Console shows the volume status as Detached, you can delete the volume. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
7. Find your volume, click the Actions icon (three dots), and then click Terminate. Confirm when prompted.

Terminate the Instance

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the list of instances, find the instance you created in the tutorial.
3. Click the Actions icon (three dots), and then click **Terminate**.
4. Select the **Permanently delete the attached boot volume** check box, and then click **Terminate Instance**.

**Delete the Virtual Cloud Network**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. In the list of VCNs, find the one you created in the tutorial.
3. Click the Actions icon (three dots), and then click **Terminate**.
4. Click **Terminate All** to delete all the underlying resources of your VCN.

When all the resources are successfully deleted you can close the dialog.

**Putting Data into Object Storage**

Object Storage provides reliable, secure, and scalable object storage. Object storage is a storage architecture that stores and manages data as objects. Some typical use cases include data backup, file sharing, and storing unstructured data like logs and sensor-generated data.

Object Storage uses buckets to organize your files. To use Object Storage, first create a bucket and then begin adding data files.

Use this procedure to quickly get started. For more details, see "Overview of Object Storage" in the *Oracle Cloud Infrastructure User Guide*.

**Creating a Bucket**

To create a bucket to store objects:

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   
   A list of the buckets in the compartment you're viewing is displayed.

2. Select a compartment from the **Compartment** list on the left side of the page.

   A list of existing buckets is displayed.

3. Click **Create Bucket**.

4. In the **Create Bucket** dialog box, specify the attributes of the bucket:
   
   - **Bucket Name**: The system generates a default bucket name that reflects the current year, month, day, and time, for example **bucket-20190306-1359**. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   
   - **Default Storage Tier**: Select the default tier in which you want to store your data. Once set, you cannot change the default storage tier of a bucket. When you upload objects, this tier will be selected by default. You can, however, select a different tier. Available default tiers include:
     
     - **Standard** is the primary, default storage tier used for Object Storage service data. Use the **Standard** tier for storing frequently accessed data that requires fast and immediate access.
     
     - **Archive** is the default storage tier used for Archive Storage service data. Use the **Archive** tier for storing rarely accessed data that requires long retention periods. Access to data in the **Archive** tier is not immediate. Archived data must be restored before the data is accessible.
   
   - **Object Events**: Select **Emit Object Events** if you want to enable the bucket to emit events for object state changes. For more information about events, see **Overview of Events** on page 1784.
   
   - **Encryption**: Buckets are encrypted with keys managed by Oracle by default, but you can optionally encrypt the data in this bucket using your own Vault encryption key. To use Vault for your encryption needs, select **Encrypt Using Customer-Managed Keys**. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master
Welcome to Oracle Cloud Infrastructure

Encryption Key. For more information about encryption, see Overview of Vault on page 3952. For details on how to create a vault, see Managing Vaults on page 3957.

- Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create Bucket.

The bucket is created immediately and you can add objects to it. Objects added to archive buckets are immediately archived and must be restored before they are available for download.

Uploading Files to a Bucket

Object Storage supports uploading individual files up to 10 TiB. Because memory capacity and browser capability can impact uploading objects using the Console, use the CLI, SDK, or API for larger files. See "Developer Tools" in the Oracle Cloud Infrastructure User Guide.

To upload files to your bucket using the Console:

1. From the Object Storage Buckets screen, click the bucket name to view its details.
2. Click Upload.
3. In the Object Name Prefix field, optionally specify a file name prefix for the files that you plan to upload.
4. If the Storage Tier field displays Standard, you can optionally change the storage tier to upload objects to.
5. Select the object or objects to upload in one of two ways:
   - Drag files from your computer into the Drop files here ... section.
   - Click the select files link to display a file selection dialog box.

As you select files to upload, they are displayed in a scrolling list. If you decide that you do not want to upload a file that you have selected, click the X icon to the right of the file name.

If selected files to upload and files already stored in the bucket have the same name, messages warning you of an overwrite are displayed.

6. Click Upload.

The selected objects are uploaded. Click Close to return to the bucket.

What's Next

For information on managing and accessing your object files, see "Overview of Object Storage" in the Oracle Cloud Infrastructure User Guide.

Getting Started with the Command Line Interface

This topic provides a walk-through of the commands required to launch a Linux instance and a Windows instance. This tutorial includes working with a compartment, creating a virtual cloud network, and launching instances.

About the Command Line Interface (CLI)

The CLI is a tool that lets you work with most of the available services in Oracle Cloud Infrastructure. The CLI provides the same core functionality as the Console, plus additional commands. The CLI's functionality and command help are based on the service's API.
Getting Help with Commands
You can get inline help using the --help, -h, or -? keywords. For example:

oci --help
oci bv volume -h
oci os bucket create -?

You can also view all the CLI help in your browser.

About the CLI Examples
The examples in this document are grouped as a command and a response, where:
• You are told what the command does, and given the command to use
• The result of the command is returned in a drop-down text box

The next example shows a command and response group.

To get the namespace for your tenancy, run the following command.

oci os ns get

Response

Note:

Understanding Response Output
This response to the oci os ns get command shows the standard output, which is returned in JSON format. JSON objects are written as key/value pairs, with the key and value separated by a colon. For example:

```
{
  "data": "docs"
  "id":
  "ocid1.compartment.oc1..aaaaaaaal3gzijdhqol2pqglie6astxxeyqdqeyg35nz5zx1l2u63i35os1aal2j5j24",
  "is-stateless": null
}
```

A key like "id" isn't very informative. To understand the JSON object reference you have to read the key's value.

```
{
  "data": "docs"
}
```

Most of the command and response groups in this guide aren't as simple as the preceding example. However, as you work through the tasks, they are easier to read and work with.

Before You Begin
Before you start using the command line interface, verify that you meet all the requirements described in "Command Line Interface (CLI)" in the Oracle Cloud Infrastructure User Guide.

As a best practice, complete the tasks in this tutorial in a test environment. This approach ensures that your configurations do not affect other environments in the tenancy. At the end of the tutorial, you can safely delete the test resources.
Welcome to Oracle Cloud Infrastructure

Working in a Compartment

In this tutorial, you use one compartment for all your resources. When you are ready to create a production environment, you will most likely separate these resources in different compartments.

You can either use an existing compartment (recommended), or create a new compartment.

Choose a Compartment

Help: oci iam compartment list -h

To list the compartments in your tenancy, run the following command.

oci iam compartment list -c <tenancy_id>

Command Example and Response

```
oci iam compartment list -c
ocid1.tenancy.oc1..aaaaaaaal1fvgn0h9njji5u6ldrwb416aay2x87qatw2wte30f7141al9oom

{
  "data": [
    {
      "compartment-id": "ocid1.tenancy.oc1..aaaaaaaal1fvgn0h9njji5u6ldrwb416aay2x87qatw2wte30f7141al9oom",
      "description": "For testing CLI features",
      "id": "ocid1.tenancy.oc1..aaaaaaaal1fvgn0h9njji5u6ldrwb416aay2x87qatw2wte30f7141al9oom",
      "inactive-status": null,
      "lifecycle-state": "ACTIVE",
      "name": "CLIsandbox",
      "time-created": "2017-06-27T18:52:52.214000+00:00"
    },
    {
      "compartment-id": "ocid1.compartment.oc1..aaaaaaaasqn3hj6e6tq6s1j4rdqqja7qsyuqipmu4sv5ucmyp3rkmrhuv2q",
      "description": "for testing",
      "id": "ocid1.compartment.oc1..aaaaaaaasqn3hj6e6tq6s1j4rdqqja7qsyuqipmu4sv5ucmyp3rkmrhuv2q",
      "inactive-status": null,
      "lifecycle-state": "ACTIVE",
      "name": "CLISandbox",
      "time-created": "2017-05-12T21:31:27.709000+00:00"
    }
  ],
  "opc-next-page": "AAAAAAALGB28zJTjpUeNvgmLxg9QuJdAAAzr110FfKymIMh4y1XItQkO_Xk6RXbGxChkgkYm_pRpf1v6hVoXPTB53F2T231dRelsbxza31jbjwqGwzQsUPYROLXA4OEIjFdr2oYp67AozxSW8jt8MWFC8y19PsHEEEBH1jw8TT7VgP3ZFu6Y-Rab-gPnjs4plh91bkDkwzybHr0OmH4W1rhTJ5HFZ8YGpa0Ntm7_rOyNbd06qeBU496A9Hk24-U_19p4NvAvHuJ_fR-Z6ahgVWP1Qc1icCTR1j6elM7Ed3JnehIV0onOVQvGquJpF2WeEWFPCioQaqF4iScqHEchv--3Mn2klyP_-b4AsVtSPRFYGB8UiRACPzg6ENVFjyeGOk3rrHjLR3j7s61pdgqtMKZ1WtbOv8AcNON8ac1xJPN70Ymj03D0H4JjIt"
}
```

Create a Compartment

Help: oci iam compartment create -h

Before you create a compartment, review "Working with Compartments" in the Oracle Cloud Infrastructure User Guide to understand compartment design, resource management, and compartment constraints.
To create a compartment, run the following command.

```bash
oci iam compartment create --name <compartment_name> -c <root_compartment_id> --description "<friendly_description>"
```

**Command Example and Response**

```bash
oci iam compartment create --name CLIsandbox -c ocid1.tenancy.oc1..aaaaaaaal1fvgn0h9njjj5u61drwb416aay2x87qatw2wte30f7141a19oom --description "For testing CLI features"
```

```json
{
  "data": {
    "compartment-id": "ocid1.tenancy.oc1..aaaaaaaawuu4tdkysd2ups5fsc1gm5ksfjwmx6mwem5sbjyw5ob5ojq2vxxa",
    "description": "For testing CLI features",
    "id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpgel6vfxyrc11",
    "inactive-status": null,
    "lifecycle-state": "ACTIVE",
    "name": "CLIsandbox",
    "time-created": "2017-06-27T18:52:52.214000+00:00"
  },
  "etag": "24a4737ede9d34eae934c93e9549ee684a15efc8"
}
```

**Tip:**
Keep track of the information that's returned when you run commands. In several cases, you need this information as you work through this document. For example, the preceding command returns the OCID for the tenancy, which is also the root compartment.

```
"compartment-id": "ocid1.tenancy.oc1..aaaaaaaawuu4tdkysd2ups5fsc1gm5ksfjwmx6mwem5sbjyw5ob5ojq2vxxa"
```

## Creating a Virtual Cloud Network

Before you can launch any instances, you have to create a virtual cloud network (VCN) and related resources. The following tasks are used to prepare the network environment:

1. **Create the Virtual Cloud Network**

   **Help:** `oci network vcn create -h`

   Create the VCN, specifying a DNS name and a CIDR block range.

   To create the VCN, run the following command.

   ```bash
   oci network vcn create --compartment-id <compartment_id> --display-name "<friendly_name>" --dns-label <dns_name> --cidr-block "<0.0.0.0/0>"
   ```

   **Command Example and Response**

   ```bash
   oci network vcn create --compartment-id ocid1.compartment.oc1..aaaaaaaal1kqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpgel6vfxyrc11 --display-name "cli_vcn" --dns-label sandboxvcn1 --cidr-block "10.0.0.0/16"
   ```

   ```json
   {
   }
   ```
Welcome to Oracle Cloud Infrastructure

You can get information about any of your configurations by sending queries to your tenancy.

For example, to get network information, run the following command.

```bash
oci network vcn list -c <compartment_id>
```

### Command Example and Response

```json
{
    "data": [
        {
            "cidr-block": "10.0.0.0/16",
            "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pf92rdrwo5fm6fcouf0ih1vd4ls4j9jjjopee16vfyxc11",
            "default-dhcp-options-id": "ocid1.dhcpoptions.oc1.phx.aaaaaaaaexnsdswjmxmmt4tpzkcyengrnfpgnznklkzz77f6faeqfbd",
            "default-route-table-id": "ocid1.routeable.oc1.phx.aaaaaaaaexnsdswjmxmmt4tpzkcyengrnfpgnznklkzz77f6faeqfbd",
            "default-security-list-id": "ocid1.securitylist.oc1.phx.aaaaaaaaexnsdswjmxmmt4tpzkcyengrnfpgnznklkzz77f6faeqfbd",
            "display-name": "cli_vcn",
            "dns-label": "sandboxvcn1",
            "id": "ocid1.vcn.oc1.phx.aaaaaaaaexnsdswjmxmmt4tpzkcyengrnfpgnznklkzz77f6faeqfbd",
            "lifecycle-state": "AVAILABLE",
            "time-created": "2017-06-27T22:14:15.683000+00:00",
            "vcn-domain-name": "sandboxvcn1.oraclevcn.com"
        }
    ]
}
```

2. Configure a Security List Ingress Rule

   Help: `oci network security-list create -h`

   When you create a VCN, a default security list is created for you. However, the Windows instance also requires inbound traffic enabled for port 3389. The preferred approach is creating a second list that addresses the Windows
Welcome to Oracle Cloud Infrastructure

port requirement. You use the `--security-list-ids` option to associate both security lists with the subnet when you create it.

**Note:**

**Passing JSON Strings in the CLI**

The next command passes complex input as a JSON text string. For help with formatting JSON input, especially when working in a Windows environment, see "Passing Complex Input" in the Oracle Cloud Infrastructure User Guide.

To create a new security list and configure the ingress rule for port 3389, run the following command.

```
oci network security-list create -c <compartment_id> --egress-security-rules 
"{"destination": "<0.0.0.0/0>" , "protocol": "<6>",
"isStateless": <true> , "tcpOptions": {"destinationPortRange": 
"<null>"}}"
--ingress-security-rules 
"{"source": 
"<0.0.0.0/0>" , "protocol": "<6>",
"isStateless": <false> ,
"tcpOptions": {"destinationPortRange": 
"<null>"}}"
--vcn-id <vcn_id> --display-name <rule_name>
```

**Command Example and Response**

```json
{
"data": {
"compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pf92rdrwo5f6mfcouf0ih1vd4ls4j9jjpge16vfylxc1",
"egress-security-rules": 
"{"destination": "<0.0.0.0/0>" , "protocol": 
"6" ,
"isStateless": true , "tcpOptions": {"destinationPortRange": 
null , "sourcePortRange": null}}",
"ingress-security-rules": 
"{"source": "<0.0.0.0/0>" , "protocol": "6" ,
"isStateless": false ,
"tcpOptions": {"destinationPortRange": 
{"max": 3389 , "min": 3389} ,
"sourcePortRange": null}}"
"vcn-id":
"ocid1.vcn.oc1.phx.aaaaaaaa6va8fkr1m4hvzj3k3nzo8x290qymdrwiblxw5qppz1m64rdd7vcr",
"display-name": "port3389rule"
}
```

Oracle Cloud Infrastructure User Guide 88
3. Create a Subnet

Help: oci iam availability-domain list -h, oci network subnet create -h

In this next step, you have to provide the OCIDs for the default security list and the new security list. If you didn't record these OCIDs, use the oci network security-list list command to get a list of the security lists in the virtual cloud network.

Before you create a subnet, you have to find out which availability domains are available to create the subnet in.

To get the availability domain list for your compartment, run the following command.

oci iam availability-domain list -c <compartment_id>

**Command Example and Response**

```bash
oci iam availability-domain list -c
oci iam compartment ocl..aaaaaaaalkqnr7pf92d9rwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l
```

```json
{
   "data": [
      {
         "compartment-id": "oci1.compartment.o1..aaaaaaaalkqnr7pf92d9rwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l",
         "name": "EMIR:PHX-AD-1"
      },
      {
         "compartment-id": "oci1.compartment.o1..aaaaaaaalkqnr7pf92d9rwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l",
         "name": "EMIR:PHX-AD-2"
      },
      {
         "compartment-id": "oci1.compartment.o1..aaaaaaaalkqnr7pf92d9rwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l",
         "name": "EMIR:PHX-AD-3"
      }
   ]
}
```
To create a subnet in AD-1, run the following command.

```bash
oci network subnet create --vcn-id <vcn_id> -c <compartment_id>
--availability-domain "<availability_domain_name>" --display-name "<display_name>" --dns-label "<dns_label>" --cidr-block "<10.0.0.0/16>" --security-list-ids ["<default_security_list_id>", "<new_security_list_id>"]
```

**Command Example and Response**

```bash
oci network subnet create --vcn-id ocid1.vcn.oc1.phx.aaaaaaaaah2ast7desae6ok3amu64wozj3kskox75awyr5j2nd7tkocplaajq -c ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jppge16vfyxrcll --availability-domain "EMIr:PHX-AD-1" --display-name CLISUB --dns-label "vminstances" --cidr-block "10.0.0.0/16" --security-list-ids ["ocid1.securitylist.oc1.phx.aaaaaaaaw7c62ybv4f5drwv2mup3f75aiquhbkbh4s676muq5t7j5t"]
```

```json
{
  "data": {
    "availability-domain": "EMIr:PHX-AD-1",
    "cidr-block": "10.0.0.0/16",
    "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jppge16vfyxrcll",
    "dhcp-options-id": "ocid1.dhcpoptions.oc1.phx.aaaaaaaaexnsdjmnnmnt4tpzkengrnfwspgnqz1drw7qfx6cbfaeqfbd",

    "etag": "92d20c35"
  }
}
```
4. Create an Internet Gateway

Help: `oci network internet-gateway create -h`

To create an Internet Gateway, run the following command.

```
oci network internet-gateway create -c <compartment_id> --is-enabled <true> --vcn-id <vcn_id> --display-name <gateway_display_name>
```

**Command Example and Response**

```
oci network internet-gateway create -c ocid1.compartment.oc1..aaaaaaaalkqnr7pfdrwo5f6m6fcooufoih1vd4ls49jgjgei6vfxycFormsModule --is-enabled true --vcn-id ocid1.vcn.oc1.phx.aaaaaaa6va8fxr1m4hvjzjk3nzo8x290qymdrwbilw5qplm64rdd74vchr --display-name sbgateway
```

```
{
    "data": {
        "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfdrwo5f6m6fcooufoih1vd4ls49jgjgei6vfxycFormsModule",
        "display-name": "sbgateway",
        "id": "ocid1.internetgateway.oc1.phx.aaaaaaa3vcd7gmgqah4p06wsmjhc4dxdldfieqnmhbanzz2wsh5gdr",
        "is-enabled": true,
        "lifecycle-state": "AVAILABLE",
        "time-created": "2017-08-25T20:03:48.482000+00:00",
        "vcn-id": "ocid1.vcn.oc1.phx.aaaaaaa6va8fxr1m4hvjzjk3nzo8x290qymdrwbilw5qplm64rdd74vchr"
    },
    "etag": "d13fb7e3"
}
```

5. Add a Rule to the Route Table

Help: `oci network route-table list -h, oci network route-table update -h`

When you create a VCN, a route table is created automatically. Before you add a rule to the route table, you need the OCID for the table.

To get the route table OCID, run the following command.

```
oci network route-table list -c <compartment_id> --vcn-id <vcn_id>
```

**Command Example and Response**

```
oci network route-table list -c ocid1.compartment.oc1..aaaaaaaalkqnr7pfdrwo5f6m6fcooufoih1vd4ls49jgjgei6vfxycFormsModule --vcn-id ocid1.vcn.oc1.phx.aaaaaaa6va8fxr1m4hvjzjk3nzo8x290qymdrwbilw5qplm64rdd74vchr
```

```
{
    "data": [
        {
            "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfdrwo5f6m6fcooufoih1vd4ls49jgjgei6vfxycFormsModule",
            "display-name": "Default Route Table for cli_vcn",
            "id": "ocid1.routetable.oc1.phx.aaaaaaaagdjqga3i6qrxvf3stedpre4rmkdrw6qeqkftjtzyn7vctmujo",
            "lifecycle-state": "AVAILABLE",
            "route-rules": [],
            "time-created": "2017-08-25T21:46:04.324000+00:00",
        }
    ],
    "etag": "d13fb7e3"
}
```
Welcome to Oracle Cloud Infrastructure

The information in the previous response shows that there is a route table without any rules: "route rules": 
[]. Because the table exists, you create a rule by updating the table. When you run the next command, you get a warning about updates to route rules. Any update to the route rules replaces all the existing rules. If you want to continue and process the update, Enter "y".

To update the route rules, run the following command.

```bash
oci network route-table update --rt-id <route_table_id> --route-rules 
"[{"cidrBlock":"<0.0.0.0/0","networkEntityId":"<internet_gateway_id>"}]
```

WARNING: Updates to route-rules will replace any existing values. Are you sure you want to continue? [y/N]: y

Command Example and Response

```bash
oci network route-table update --rt-id ocid1.routetable.oc1.phx.aaaaaaaagdjqga3i6qrxvf23stedpre4rmkdwr6geqkftjtzy7vctmujo2 --route-rules "[{"cidrBlock":"0.0.0.0/0","networkEntityId":"ocid1.internetgateway.oc1.phx.aaaaaaaa3vcd7gmqqh4po6wnsjhcdxddeqinmnbanzz2wsh5gdr"}]
```

WARNING: Updates to route-rules will replace any existing values. Are you sure you want to continue? [y/N]: y

```json
{
"data": {
"compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jppge16vfyxrc1ll",
"display-name": "Default Route Table for cli_vcn",
"id": "ocid1.routetable.oc1.phx.aaaaaaaa4kujevzdsnd7bh6aetvrhwzdrwcxmblspmyj3pqwckchajvz6",
"lifecycle-state": "AVAILABLE",
"route-rules": [
{"cidr-block": "0.0.0.0/0",
 "network-entity-id": "ocid1.internetgateway.oc1.phx.aaaaaaaa3vcd7gmqqh4po6wnsjhcdxddeqinmnbanzz2wsh5gdr"},
],
"time-created": "2017-08-25T23:46:04.324000+00:00","vcn-id": "ocid1.vcn.oc1.phx.aaaaaaaa6va8fzr1m4hvzjk3nzo8x290qymdrwiblxw5qpzl64rdd74vchr" },
"etag": "3fc998d8"
}
```

Preparing to Launch an Instance

When you launch an instance you have to provide the following information, some of which you've already obtained:

- compartment-id
- availability-domain
- subnet-id
- image-id
- shape
1. Get Information About the Available Images

   Help: oci compute image list -h

   The image-id identifies the operating system that you want to install. For more information, see "Oracle-
   Provided Images" in the Oracle Cloud Infrastructure User Guide.

   To get a list of images, run the following command.

   ```
   oci compute image list -c <compartment_id>
   ```

   **Command Example and Response**

   Images are available for: Oracle Linux, CentOS, Ubuntu, and Windows Server. This response example only
   shows the information for Oracle Linux 7.3.

   ```
   oci compute image list -c
   ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vfyxrc11
   ```

   ```
   {"base-image-id": null,
    "compartment-id": null,
    "create-image-allowed": true,
    "display-name": "Oracle-Linux-7.3-2017.03.03-0",
    "id": "ocid1.image.oc1.phx.aaaaaaaaevkccomzepja4yahz6rguhbuomuto7gdrw5hjimqsig6syeqda",
    "lifecycle-state": "AVAILABLE",
    "operating-system": "Oracle Linux",
    "operating-system-version": "7.3",
    "time-created": "2017-03-03T19:04:30.824000+00:00"
   }
   ```

2. Get Information About the Available Shapes

   Help: oci compute shape list -h

   The shape identifies the configuration of the virtual machine or bare metal host that you want to use. "Overview of
   the Compute Service" in the Oracle Cloud Infrastructure User Guide contains up-to-date information about the
   available shapes.

   For the purposes of this walk-through, use this virtual machine shape for testing: --shape
   "VM.Standard1.1". This shape is configured with 1 CPU and 7 GB of memory.

   **Note:**

   Shape and Block Volume Sizing
   Sizing for compute instance shapes and block volumes are not part of this
   walk-through. The examples use the minimum sizes that are available.

   To get a list of all the available bare metal and virtual machine shapes, run the following command.

   ```
   oci compute shape list -c <compartment_id> --availability-domain
   "<availability_domain_name>"
   ```

   **Command Example and Response**

   ```
   oci compute shape list -c
   ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vfyxrc11
   --availability-domain "EMIr:PHX-AD-1"
   ```

   ```
   { "data": [ ...
   ```
Welcome to Oracle Cloud Infrastructure

Launching a Linux Instance

Now you're ready to launch a Linux instance based on the configurations you prepared.

1. Use a Public/Private Key Pair to Connect to the Instance
   When you launch an instance using the CLI, you need an existing key pair to access the instance. (This key pair is not the same as an API signing key.)

2. Launch the Instance
   Help: oci compute instance launch -h

   **Caution:**
   In this example, the --ssh-authorized-keys-file parameter references a file that contains the public key required to access the compute instance. If you don't provide this key when you launch the instance you can't connect to the instance after it's launched.

To launch the Linux instance, run the following command.

```
oci compute instance launch --availability-domain "<availability_domain_name>" -c <compartment_id> --shape "<shape_name>"
--display-name "<instance_display_name>" --image-id <image_id> --ssh-authorized-keys-file "<path_toAuthorized_keys_file>" --subnet-id <subnet_id>
```

**Command Example and Response**

```
oci compute instance launch --availability-domain "EMIr:PHX-AD-1" -c ocid1.compartment.oc1..aaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l --shape "VM.Standard1.1" --display-name "Linux Instance" --image-id ocid1.image.oc1.phx.aaaaaaaa5yu6pw3riqtuhxzov7fndqi4tsteganmao54nq3pyxu3hxcuzmoa --ssh-authorized-keys-file "C:\Users\testuser\.oci\linux_key.pem" --subnet-id ocid1.subnet.oc1.phx.aaaaaaaaahvx05fhw7p320cxdwro5wlf50egig9cmdzs1plb1xl6c5wvb5s2
```

{
3. Get VNIC Information for the Instance

Help: oci compute instance list-vnics -h

You need the public IP address of the instance in order to connect to the instance. The VNIC for the instance has this information.

To get a list of VNICs for the instance, run the following command.

```
oci compute instance list-vnics --instance-id <instance_id>
```

**Command Example and Response**

```
oci compute instance list-vnics --instance-id ocid1.instance.oc1.phx.abcdefgh6kykdowc8ozzvr4421kwp7apdrwk6wrj17su82d60c6sp4nap88d
```
4. Create a Block Volume for the Instance

Help: `oci bv volume create -h`

Create a block volume, using the minimum available size.

**Caution:**

Block volume sizes are expressed as increments of 1024 MB. The next command example uses the minimum size, `--size-in-mbs 51200`, or 50 GB.

To create a block volume, run the following command.

```
oci bv volume create --availability-domain "<availability_domain_name>"
-c <compartment_id> --size-in-mbs <51200> --display-name <volume_display_name>
```

**Command Example and Response**

```
oci bv volume create --availability-domain "EMIr:PHX-AD-1" -c
ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpgel16vfyrcl
--size-in-mbs 51200 --display-name LinuxVol
```

```
{
  "data": {
    "availability-domain": "EMIr:PHX-AD-1",
    "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpgel16vfyrcl",
    "display-name": "LinuxVol",
    "id": "ocid1.volume.oc1.phx.abyhqlsktp2ec7pdazl1y324drw51xruh5nxjrgbgqq7zn5s5004t25nvcta",
    "lifecycle-state": "PROVISIONING",
    "size-in-mbs": 51200,
    "time-created": "2017-08-26T00:51:30.462000+00:00"
  },
  "etag": "720652578"
}
```

After the lifecycle state changes from "PROVISIONING" to "AVAILABLE" you can attach the volume to the Linux instance.

**Tip:**

Finding out the Lifecycle State

You can find out the lifecycle state for the block volume using the `oci bv volume get` command for the volume you created. You can also query other resources such as compute instances and VNICs, to find out their lifecycle state.

5. Attach the Block Volume to the Instance

Help: `oci compute volume-attachment attach -h`

To attach the block volume to the Linux instance, run the following command.

```
oci compute volume-attachment attach --instance-id <instance_id> --type <iscsi> --volume-id <volume_id>
```

**Command Example and Response**

```
oci compute volume-attachment attach --instance-id
ocid1.instance.oc1.phx.abcdefgh6kykdcw58ozzvr4421kwp7apdrkw6wrj17su82d60c6sp4nap88d
```
Launching a Windows Instance

Launching a Windows instance follows the same pattern and requires the same information as launching a Linux instance. The only significant differences are the operating system and shape, as shown in the following commands.

1. Launch the Instance

   Help: oci compute instance launch -h

   To launch the Windows instance, run the following command.

   ```bash
   oci compute instance launch --availability-domain "EMIr:PHX-AD-1" -c ocid1.compartment.oc1..aaaaaaaalkqnr7pfdf92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vfyxrc1ll
   --shape "VM.Standard1.2" --display-name "Windows Instance" --image-id ocid1.image.oc1.phx.aaaaaaaa53cliasgvmueus5byytfdwafbro2y4ywjebc15szc42e2b7ua
   --subnet-id ocid1.subnet.oc1.phx.aaaaaaaaypsr25bzjmx3drwiha61odzus3yn6xwgcrgxgafscirb5hj0bpa
   ```

   ```json
   {   "data": {   "availability-domain": "EMIr:PHX-AD-1",   "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfdf92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vfyxrc1ll",   "display-name": "Windows Instance",   "extended-metadata": {},   "id": "ocid1.instance.oc1.phx.zsutzirph7cbrbx6ruz91stavdrw58puq3iskn1r07zfc6dq6p9",  }
   }
   ```
2. Get VNIC Information for the Instance
   To get the VNIC information, run the following command.
   
   ```bash
   oci compute instance list-vnics --instance-id <instance_id>
   ```

3. Create a Block Volume for the Instance
   To create a block volume, run the following command.
   
   ```bash
   oci bv volume create --availability-domain "<availability_domain_name>" -c <compartment_id> --size-in-mbs <51200> --display-name <display_name>
   ```

4. Attach the Block Volume to the Instance
   To attach the Block Volume to the Windows instance, run the following command.
   
   ```bash
   oci compute volume-attachment attach --instance-id <instance_id> --type <iscsi> --volume-id <volume_id>
   ```

### Connecting to Your Instances

Although the Public IP address is required for connecting to Linux and Windows instances, that is the only thing 
the two have in common. Some of these differences include: authentication, port configuration, and desktop client 
programs.

1. Connect to Your Linux Instance
   
   **Connecting to Your Instance** describes how to connect to a Linux instance from a Unix-style or Windows-style 
system.

2. Connect to Your Windows Instance
   
   **Help:** `oci compute instance list-vnics -h` and `oci compute instance get-windows-initial-creds -h`
   
   To connect to the instance using Remote Desktop Client (RDC), you need:
   
   - The public IP address for the instance
   - The initial Windows credentials
   
   To get the public IP address of the Windows instance, run the following command.
   
   ```bash
   oci compute instance list-vnics --instance-id <instance_id>
   ```

### Command Example and Response

```bash
oci compute instance list-vnics --instance-id
ocid1.instance.oc1.phx.zsutzirph7cbrbx6ruz91stavdrw58puq3iskn1r07zfd6rq6p9

{
```
To get the initial Windows credentials, run the following command.

```
oci compute instance get-windows-initial-creds --instance-id <instance_id>
```

### Command Example and Response

```
oci compute instance get-windows-initial-creds --instance-id ocid1.instance.oc1.phx.zsutzirph7cbrbx6ru91stavdrw58puq3iskn1r07zfcx6rq6p9
```

```json
{
   "data": {
      "password": "Cz{73~~vf@dnK7A",
      "username": "opc"
   }
}
```

Connecting to Your Windows Instance describes how to connect to your instance using RDC.

### Cleaning Up the Test Environment

When you've finished setting up the test environments described in this tutorial, clean up the test environment by removing resources you aren't using.

#### Detach and Delete the Block Volumes

Help: `oci compute volume-attachment list -h`, `oci compute volume-attachment detach -h` and `oci bv volume delete -h`

Removing a block volume from an instance is a 3-step process. Use the following steps to detach and delete the block volume for the Linux instance.
1. Get the volume-attachment-id

   The volume attachment ID is created when you create a block volume.

   To get the volume attachment ID, run the following command.

   `oci compute volume-attachment list -c <compartment_id>`

   **Command Example and Response**

   ```
   oci compute volume-attachment list -c
   ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l
   {
     "data": [
     {
       "attachment-type": "iscsi",
       "availability-domain": "EMIr:PHX-AD-1",
       "chap-secret": null,
       "chap-username": null,
       "compartment-id": "ocid1.compartment.oc1..aaaaaaaalkqnr7pfd92rdrwo5fm6fcoufoih1vd4ls4j9jjpge16vyxrc1l",
       "display-name": null,
       "id": "ocid1.volumeattachment.oc1.phx.abyhqlyto1vg6eaybdwb7mqqms6utjrefofrplyip7f1lf3vtpk",
       "instance-id": "ocid1.instance.oc1.phx.abcdefgh6kykdowc8ozzvr4421kwp7apdrwk6wrjl7su82d60c6sp4nap88d",
       "ipv4": "169.254.2.2",
       "iqn": "iqn.2015-12.com.oracleiaas:e3fd73db-b164-4d76-bc3f-f58b093989d0",
       "lifecycle-state": "ATTACHED",
       "port": 3260,

       "volume-id": "ocid1.volume.oc1.phx.abyhqpa3ati7ggfjvba7y6dcg7imdrwskgq4bd1jroo2cbwchrebuprxddvca"
     }
     ]
   }
   ```

2. Detach the volume-attachment-id

   To detach the volume attachment-id, run the following command.

   `oci compute volume-attachment detach --volume-attachment-id <volume_attachment_id>`

   **Command Example and Response**

   ```
   oci compute volume-attachment detach --volume-attachment-id
   ocid1.volumeattachment.oc1.phx.abyhqlyto1vg6eaybdwb7mqqms6utjrefofrplyip7f1lf3vtpk5
   Are you sure you want to delete this resource? [y/N]:
   ```

   All destructive actions, such as detaching and deleting resources allow you to use the `--force` parameter, and the resource is removed without requiring confirmation. As a best practice, use the y/N option instead of --force.

   Confirm the deletion. No response is returned after the resource is deleted.
3. **Delete the Block Volume**

To delete the block volume, run the following command.

```bash
oci bv volume delete --volume-id <volume_id> --force
```

**Command Example and Response**

```bash
oci bv volume delete --volume-id
ocid1.volume.oc1.phx.abyhqljroo2cbwchrpa3ati7ggfjvba7y6dcg7imnleskq4bdebuprxddvca
--force
```

There is no response to this action. To verify that the block volume was deleted, run the following command.

```bash
oci bv volume list -c <compartment_id>
```

The response to this query returns "lifecycle-state": "TERMINATED", showing that the volume doesn't exist.

To delete the block volume attached to the Windows instance, use the preceding steps (1-3) as a guide.

**Terminate the Instances**

**Help:** `oci compute instance terminate -h`

To delete the Linux instance, run the following command.

```bash
oci compute instance terminate --instance-id <instance_id>
```

**Command Example and Response**

```bash
oci compute instance terminate --instance-id
ocid1.instance.oc1.phx.abcdefgh6kykdowc8ozzvr4421kwp7apdrwk6wrj17su82d60c6sp4nap88d
```

Are you sure you want to delete this resource? [y/N]:

Confirm the deletion. No response is returned after the instance is deleted.

To delete the Windows instance, run the following command.

```bash
oci compute instance terminate --instance-id <instance_id>
```

**Command Example and Response**

```bash
oci compute instance terminate --instance-id
ocid1.instance.oc1.phx.zsutzirph7cbrbx6ru91stavdrw58puq3iskn1r07zfcd6rg6p9
```

Are you sure you want to delete this resource? [y/N]:

Confirm the deletion. No response is returned after the instance is deleted.

**Delete the Virtual Cloud Network**

**Help:** `oci network subnet delete -h, oci network vcn delete -h`

It takes the following 2 steps to delete the VCN.
1. Delete the subnet

To delete the subnet, run the following command.

```
oci network subnet delete --subnet-id <subnet_id> --force
```

**Command Example and Response**

```
oci network subnet delete --subnet-id
ocid1.subnet.oc1.phx.aaaaaaaaahvx05fhw7p320cxmdrwo5wlf50egig9cmdzs1plblx16c5wvb5s2
--force
```

None

2. Delete the virtual cloud network

To delete the VCN, run the following command.

```
oci network vcn delete --vcn-id <vcn_id> --force
```

**Command Example and Response**

```
oci network vcn delete --vcn-id
ocid1.vcn.oc1.phx.aaaaaaaa6va8fxr1m4hvzjk3nzo8x290qymdrwiblxw5qz1m64rdd74vchr
--force
```

None

**Getting Started**

Terraform is "infrastructure-as-code" software that allows you to define your Oracle Cloud Infrastructure (OCI) resources in files that you can persist, version, and share. These files describe the steps required to provision your infrastructure and maintain its desired state:

*Resources* can create OCI infrastructure objects such as virtual cloud networks or compute instances. Your first application of the configuration creates the objects, and subsequent applications can update or delete them.

*Data sources* represent read-only views of your existing OCI infrastructure.

*Variables* represent parameters for Terraform.

Terraform then executes these steps and builds out the described infrastructure. Using the OCI Terraform provider requires you to:

- Install or access a distribution of Terraform.
- Download and install the OCI Terraform provider.
- Configure the OCI Terraform provider.
- Describe your infrastructure as code.

**Installing the Provider**

To use the Oracle Cloud Infrastructure (OCI) Terraform provider, you must install both Terraform and the OCI Terraform provider. You can install both Terraform and the OCI Terraform provider with *yum*, or directly download them from HashiCorp.

Government Cloud customers should follow the installation and configuration steps in Enabling FIPS Compatibility on page 4284.

**Tip:**

You can use Resource Manager to reinstall the Oracle Cloud Development Kit on a Compute instance in your compartment. The Oracle Cloud
After downloading and installing, you must configure the Terraform provider so that Terraform can interact with OCI resources.

**Prerequisites for Installing and Using the Provider**

- An Oracle Cloud Infrastructure (OCI) account that has user credentials sufficient to execute a Terraform plan.
- A user in that account.
- Required keys and OCI IDs (OCIDs). For guidance, see "Required Keys and OCIDs" in the Oracle Cloud Infrastructure User Guide.
- The correct Terraform binary file for your operating system. We recommend using Terraform version 0.12.20 or greater.

**Installing with Yum**

If you're running Oracle Linux 7, you can use yum to install Terraform and the OCI Terraform provider.

To use yum to install Terraform:

```bash
sudo yum install terraform
```

To use yum to install the Terraform provider:

```bash
sudo yum install terraform-provider-oci
```

**Download and Install Terraform**

Terraform is available for direct download from the HashiCorp download page. Ensure that you download the correct binary file for your system.

**Download and Install the Provider**

To use the latest version of the OCI Terraform provider, run `terraform init` from the directory that contains a configuration file with the provider `"oci" { ... configuration block. The provider is automatically downloaded. Terraform configurations also allow you to specify a particular version of the OCI Terraform provider.

You can also download the Terraform provider directly to a location of your choice.

**Test the Terraform Installation**

Open a terminal window and run the following command to test your installation:

```bash
terraform -v
```

**Getting Started with Load Balancing**

This chapter provides a hands-on tutorial to introduce you to the components of Load Balancing.

The Load Balancing service allows you to create highly available load balancers within your VCN. All load balancers come with provisioned bandwidth. You can choose to create a load balancer with either a public or a private IP address. Load balancers support SSL handling for both incoming traffic and traffic with your application servers.

When you create a load balancer with a public IP address you specify two subnets, each in a different availability domain, on which the load balancer can run. The two subnets ensure the high availability of the load balancer. A private load balancer requires only one subnet.
Welcome to Oracle Cloud Infrastructure

This tutorial is an introduction to Load Balancing. You can follow the steps here to create a public load balancer and verify it with a basic web server application. For complete details about the service and its components, see Overview of Load Balancing in the Oracle Cloud Infrastructure User Guide.

Before You Begin

To try out the Load Balancing service for this tutorial, you must have these things set up first:

- A virtual cloud network (VCN) with two subnets (each in a different availability domain) and an internet gateway
- Two instances running (in different subnets)
- A web application (such as Apache HTTP Server) running on each instance

If you don't have these items set up yet, you can follow the steps shown here.

Tip:

If you need an introduction to VCNs and instances, try the Tutorial - Launching Your First Linux Instance on page 61 first.

VCN and Instance Setup

The following diagram shows the prerequisite VCN and instances:
Create a VCN

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks. Ensure that the Sandbox compartment (or the compartment designated for you) is selected in the Compartment list on the left.

2. Click Networking Quickstart.

3. Select VCN with Internet Connectivity, and then click Start Workflow.

4. Enter the following:
   - VCN Name: Enter a name for your cloud network. The name is incorporated into the names of all the related resources that are automatically created. Avoid entering confidential information.
   - Compartment: This field defaults to your current compartment. Select the compartment you want to create the VCN and related resources in, if not already selected.
   - VCN CIDR Block: Enter a valid CIDR block for the VCN. For example 10.0.0.0/16.
   - Public Subnet CIDR Block: Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block. For example: 10.0.0.0/24.
   - Private Subnet CIDR Block: Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block and not overlap with the public subnet's CIDR block. For example: 10.0.1.0/24.
   - Accept the defaults for any other fields.

5. Click Next.

6. Review the list of resources that the workflow will create for you. Notice that the workflow will set up security list rules and route table rules to enable basic access for the VCN.

7. Click Create to start the short workflow.

8. After the workflow completes, click View Virtual Cloud Network.

The cloud network has the following resources and characteristics:
- Internet gateway.
- NAT gateway.
- Service gateway with access to the Oracle Services Network.
- A regional public subnet with access to the internet gateway. This subnet uses the VCN's default security list and default route table. Instances in this subnet may optionally have public IP addresses.
- A regional private subnet with access to the NAT gateway and service gateway. This subnet uses a custom security list and custom route table that the workflow created. Instances in this subnet cannot have public IP addresses.
- Use of the Internet and VCN Resolver for DNS.

Launch two instances

This example uses the VM.Standard2.1 shape. If you prefer, you can choose a larger shape.

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.

2. Click Create Instance.

3. On the Create Compute Instance page, for Name, enter a name, for example: Webserver1. Avoid entering confidential information.

4. In the Placement and hardware section, enter the following:
   - Availability domain: Select the first availability domain in the list (AD-1).
   - Image: Select the Oracle Linux 7.x image.
   - Shape: Click Change Shape, and then make the following selections:
     1. For Instance type, select Virtual Machine.
     2. For Shape series, select Intel Skylake, and then select the VM Standard2.1 shape (1 OCPU, 15 GB RAM).
     3. Click Select Shape.
5. In the **Configure networking** section, configure the network details for the instance. Do not accept the defaults.
   
   a. For **Network**, leave **Select existing virtual cloud network** selected.
   
   b. **Virtual cloud network in `<compartment_name>`**: Select the cloud network that you created. If necessary, click **Change compartment** to switch to the compartment containing the cloud network that you created.
   
   c. For **Subnet**, leave **Select existing subnet** selected.
   
   d. **Subnet in `<compartment_name>`**: Select the public subnet in availability domain 1. If necessary, click **Change compartment** to switch to the compartment that contains the correct subnet.
   
   e. Leave the **Use network security groups to control traffic** check box cleared.
   
   f. Select the **Assign a public IPv4 address** option. This creates a public IP address for the instance, which you need to access the instance. If you have trouble selecting this option, confirm that you selected the public subnet that was created with your VCN, not a private subnet.

6. In the **Add SSH keys** section, upload the public key portion of the key pair that you want to use for SSH access to the instance. Browse to the key file that you want to upload, or drag and drop the file into the box.

   If you do not have an SSH key pair, see Creating a Key Pair on page 63.

7. In the **Boot volume** section, leave all the options cleared.

8. Click **Show Advanced Options**. On the **Networking** tab, ensure that the **Hostname** field is blank.

9. Click **Create**.

10. Repeat the previous steps. This time, enter the name **Webserver2** and select the subnet in availability domain 2.

**Start a web application on each instance**

This example uses Apache HTTP Server.

1. Connect to your instance. If you need help, see Connecting to Your Instance on page 68.

2. Run yum update:

   ```bash
   sudo yum -y update
   ```

3. Install the Apache HTTP Server:

   ```bash
   sudo yum -y install httpd
   ```

4. Allow Apache (HTTP and HTTPS) through the firewall:

   ```bash
   sudo firewall-cmd --permanent --add-port=80/tcp
   
sudo firewall-cmd --permanent --add-port=443/tcp
   ```

   **Note:**

   Open the Firewall

   If you choose to run a different application than Apache, ensure that you run the preceding command to open the firewall for your application's port.

5. Reload the firewall:

   ```bash
   sudo firewall-cmd --reload
   ```

6. Start the web server:

   ```bash
   sudo systemctl start httpd
   ```
7. Add an index.htm file on each server that indicates which server it is, for example:
   a. On Webserver 1:
      ```
sudo su

    echo 'WebServer1' >/var/www/html/index.html
      ```
   b. On Webserver 2:
      ```
sudo su

    echo 'WebServer2' >/var/www/html/index.html
      ```

**Tutorial Overview**

In this tutorial, you create a public load balancer and verify it. A load balancer requires configuration of several components to be functional, and this tutorial walks you through each step to help you understand these components.

To create and test the load balancer, complete the following steps:

1. Add two subnets to your VCN to host your load balancer.
2. Create a load balancer.
3. Create a backend set with health check.
4. Add backend servers to your backend set.
5. Create a listener.
6. Update the load balancer subnet security list and allow internet traffic to the listener.
7. Verify your load balancer.
8. Update rules to protect your backend servers.
9. Delete your load balancer.

**Add Two Subnets to Your VCN to Host Your Load Balancer**

Your load balancer must reside in different subnets from your application instances. This configuration allows you to keep your application instances secured in subnets with stricter access rules, while allowing public internet traffic to the load balancer in the public subnets.

To add the public subnets to your VCN:

**Add a Security List**

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.

    The list of VCNs in the current compartment is displayed.

2. Click the name of the VCN that includes your application instances.

4. Click Create Security List.

   a. **Create in Compartment**: This field defaults to your current compartment. Select the compartment you want to create the security list in, if not already selected.
   b. Enter a **Name**, for example, "LB Security List". Avoid entering confidential information.
   c. Delete the entry for the ingress rule and the entry for the egress rule. The security list must have no rules. The correct rules are added automatically during the load balancer workflow.
   d. **Tags**: Leave as is (you can add tags later if you like).
   e. Click **Create Security List**.
   f. Return to your Virtual Cloud Network Details page.
Add a Route Table

1. Under Resources, click Route Tables.
2. Click Create Route Table. Enter the following:
   a. Create in Compartment: This field defaults to your current compartment. Select the compartment you want to create the route table in, if not already selected.
   b. Name: Enter a name, for example, "LB Route Table". Avoid entering confidential information.
   c. Target Type: Select Internet Gateway.
   d. Destination CIDR Block: Enter 0.0.0.0/0.
   e. Compartment: Select the compartment that contains your VCN's internet gateway.
   f. Target: Select your VCN's internet gateway.
   g. Tags: Leave as is (you can add tags later if you like).
   h. Click Create Route Table.

Create the first subnet

1. Under Resources, click Subnets.
2. Click Create Subnet.
3. Enter or select the following:
   a. Name: Enter a name, for example, "LB Subnet 1". Avoid entering confidential information.
   b. availability domain: Choose the first availability domain (AD-1).
   c. CIDR Block: Enter 10.0.4.0/24.
   d. Route Table: Select the LB Route Table you created.
   e. Subnet Access: Select Public Subnet.
   f. DNS Resolution: Select Use DNS Hostnames in this Subnet.
   g. DHCP Options: Select Default DHCP Options for LB_Network.
   h. Security Lists: Select the LB Security List you created.
   i. Tags: Leave as is (you can add tags later if you like).
4. Click Create.

Create the second subnet

Create a second load balancer subnet in a different availability domain.

1. In the details page of your VCN, click Create Subnet.
2. Enter the following:
   a. Name: Enter a name, for example, "LB Subnet 2". Avoid entering confidential information.
   b. availability domain: Choose the second availability domain (AD-2).
   c. CIDR Block: Enter 10.0.5.0/24.
   d. Route Table: Select the LB Route Table you created.
   e. Subnet Access: Select Public Subnet.
   f. DNS Resolution: Select Use DNS Hostnames in this Subnet.
   g. DHCP Options: Select Default DHCP Options for LB_Network.
   h. Security Lists: Select the LB Security List you created.
   i. Tags: Leave as is (you can add tags later if you like).
3. Click Create.

The following figure shows the new components added to the VCN:
Create the Load Balancer

When you create a public load balancer, you choose its shape (size) and you select two subnets, each in a different availability domain. This configuration ensures that the load balancer is highly available. It is active in only one subnet at a time. This load balancer comes with a public IP address and provisioned bandwidth corresponding to the shape you chose.

**Tip:**

Although the load balancer resides in a subnet, it can direct traffic to backend sets that reside in any of the subnets within the VCN.

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

   Ensure that the Sandbox compartment (or the compartment designated for you) is selected on the left.

2. Click **Create Load Balancer**.

3. Enter the following:

   - **Name**: Enter a name for your load balancer. Avoid entering confidential information.
   - **Shape**: Select 100 Mbps. The shape specifies the bandwidth of the load balancer. For the tutorial, use the smallest shape. The shape cannot be changed later.
   - **Virtual Cloud Network**: Select the virtual cloud network for your load balancer.
   - **Visibility**: Choose **Create Public Load Balancer**.
   - **Subnet (1 of 2)**: Select LB Subnet 1.
   - **Subnet (2 of 2)**: Select LB Subnet 2. The second subnet must be in a different availability domain than the first subnet you chose.

4. Click **Create**.
Welcome to Oracle Cloud Infrastructure

When the load balancer is created, you get a public IP address. You route all your incoming traffic to this IP address. The IP address is available from both subnets that you specified, but it is active in only one subnet at a time.

Create a Backend Set

A backend set is a collection of backend servers to which your load balancer directs traffic. A list of backend servers, a load balancing policy, and a health check script define each backend set. A load balancer can have multiple backend sets, but for this tutorial, you create only one backend set that includes both of your web servers.

In this step, you define the backend set policy and health check. You add your servers in a separate step.

To create the backend set:

1. Click the name of your load balancer and view its details.
2. Click Create Backend Set.
3. In the dialog box, enter:
   a. Name: Give your load balancer backend set a name. The name cannot contain spaces. Avoid entering confidential information.
   b. Policy: Choose Weighted Round Robin.
4. Enter the Health Check details.

   Load Balancing automatically checks the health of the instances for your load balancer. If it detects an unhealthy instance, it stops sending traffic to the instance and reroutes traffic to healthy instances. In this step, you provide the information required to check the health of servers in the backend set and ensure that they can receive data traffic.

   • Protocol: Select HTTP.
   • Port: Enter 80
   • URL Path (URI): Enter /

   The rest of the fields are optional and can be left blank for this tutorial.
5. Click Create.

When the Backend Set is created, the Work Request shows a status of Succeeded. Close the Work Request dialog box.

What is a policy?
The policy determines how traffic is distributed to your backend servers.

- Round Robin - This policy distributes incoming traffic sequentially to each server in a backend set list. When each server has received a connection, the load balancer repeats the list in the same order.
- IP Hash - This policy uses an incoming request's source IP address as a hashing key to route non-sticky traffic to the same backend server. The load balancer routes requests from the same client to the same backend server as long as that server is available.
- Least Connections - This policy routes incoming non-sticky request traffic to the backend server with the fewest active connections.

Add Backends (Servers) to Your Backend Set
After the backend set is created, you can add compute instances (backend servers) to it. To add a backend server, you can enter the OCID for each instance and your application port. The OCID enables the Console to create the security list rules required to enable traffic between the load balancer subnets and the instance subnets.

Tip:

Security lists are virtual firewall rules for your VCN that provide ingress and egress rules to specify the types of traffic allowed in and out of a subnet. Update your VCN's security list rules to allow traffic flow between the load balancer subnets and the backend server subnets. In this step, you can have the security lists automatically updated by providing the instance OCIDs.

To add a server to your backend set:
1. On the details page of your load balancer, click Backend Sets. The backend set you just created is displayed.
2. Click the name of the backend set and view its details.
3. Click Edit Backends.

In the dialog:

1. Ensure that Help me create proper security list rules is checked.
2. OCID: Paste the OCID of the first instance (Webserver1).
3. Port: Enter 80.
4. Weight: Leave blank to weight the servers evenly.
5. Repeat Steps 2 through 4, pasting in the OCID for the second instance (Webserver2).
6. Click Create Rules.

The following figure shows the components created in this task:
What rules are added to my security lists?

The system updates the security list used by your load balancer subnets to allow egress traffic from the load balancer to each backend server's subnet:

- Updates to the security list for your load balancer subnets:
  - Allow egress traffic to the backend server 1 subnet (for example, Public-Subnet-AD1)
  - Allow egress traffic to the backend server 2 subnet (for example, Public-Subnet-AD2)

![Egress Rules for LB Security List](image)

The system updates the security list used by your backend server subnets to allow ingress traffic from the load balancer subnets:
Welcome to Oracle Cloud Infrastructure

- Updates to the security list for your backend server subnets:
  - Allow ingress traffic from load balancer subnet 1
  - Allow ingress traffic from load balancer subnet 2

![Ingress Rules for Default Security List](image1)

**How do I get the OCID of an instance?**

The OCID (Oracle Cloud Identifier) is displayed when you view the instance, on the instance details page.

1. In the dialog, right-click **View Instances** and select a browser option to open the link in a new tab.

![Edit Backends](image2)

A new Console browser tab launches, displaying the instances in the current compartment.

2. In the tab that just opened, if your instances are not in the current compartment, select the compartment to which the instance belongs. (Select from the list on the left side of the page.)

A shortened version of the OCID is displayed next to each instance.

3. Click the instance that you're interested in.

A shortened version of the OCID is displayed on the instance details page.

4. Click **Copy** to copy the OCID. You can then paste it into the Instance ID field.
Create the Listener for Your Load Balancer

A listener is an entity that checks for connection requests. The load balancer listener listens for ingress client traffic using the port you specify within the listener and the load balancer's public IP.

In this tutorial, you define a listener that accepts HTTP requests on port 80.

Note:

Listening on Multiple Ports
A listener can listen on one port. To listen on more ports (such as 443 for SSL), create another listener. For information on enabling SSL for your load balancer, see "Managing SSL Certificates" in the Oracle Cloud Infrastructure User Guide.

To create a listener:

1. On your Load Balancer Details page, click Listeners.
2. Click Create Listener.
3. Enter the following:
   - Name: Enter a friendly name. Avoid entering confidential information.
   - Protocol: Select HTTP.
   - Port: Enter 80 as the port on which to listen for incoming traffic.
   - Backend Set: Select the backend set you created.
4. Click Create.

Update Load Balancer Security Lists and Allow Internet Traffic to the Listener

When you create a listener, you must also update your VCN's security list to allow traffic to that listener.

Allow the Listener to Accept Traffic

The subnets where the load balancer resides must allow the listener to accept traffic. To enable the traffic to get to the listener, update the load balancer subnet's security list.

To update the security list to allow the listener to accept traffic:

1. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
   - The list of VCNs in the current compartment is displayed.
2. Click Security Lists. A list of the security lists in the cloud network is displayed.
3. Click the LB Security List. The details are displayed.
4. Click Edit All Rules.
5. Under Allow Rules for Ingress, click Add Rule.
6. Enter the following ingress rule:
   - Source Type: Select CIDR
   - Source CIDR: Enter 0.0.0.0/0
   - IP Protocol: Select TCP
   - Destination Port Range: Enter 80 (the listener port).

If you created other listeners, add an ingress rule for each listener port to allow traffic to the listener. For example, if you created a listener on port 443, repeat the previous steps using Destination Port Range: 443.

The following figure shows the component created in this task:
Verify Your Load Balancer

To test your load balancer's functionality, you can open a web browser and navigate to its public IP address (listed on the load balancer's detail page). If the load balancer is properly configured, you can see the name of one of the web server instances:

1. Open a web browser.
2. Enter the load balancer public IP address.
   
The index.htm page of one of your web servers appears.

3. Refresh the web page.
   
The index.htm page of the other web server now appears.
Because you configured the load balancer backend set policy as Round Robin, refreshing the page alternates between the two web servers.

**Update Rules to Limit Traffic to Backend Servers**

Update the default security list and the default route table to limit traffic to your backend servers. If you used the *Create Virtual Cloud Network Plus Related Resources* option to create your VCN and you are not going to terminate this load balancer immediately, these actions are important.

**To delete the default route table rule:**

1. Open the navigation menu. Under *Core Infrastructure*, go to *Networking* and click *Virtual Cloud Networks*.
2. Click the name of your VCN and review its details.
3. Under *Resources*, click *Route Tables*.
4. Click the Default Route Table for the VCN.
5. Click *Edit Route Rules*.
6. Click the X next to the route rule, and then click *Save*.

There are now no Route Rules for the default route table.

**To edit the default security list rules:**

1. Go to your *Virtual Cloud Network Details* page.
3. Click the Default Security List for the VCN.
4. Click *Edit All Rules*.
5. Under *Allow Rules for Ingress*, delete the following rules:

<table>
<thead>
<tr>
<th>Action</th>
<th>Source CIDR</th>
<th>IP Protocol</th>
<th>Destination Port Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>22</td>
</tr>
<tr>
<td>Delete</td>
<td>0.0.0.0/0</td>
<td>ICMP</td>
<td>3,4</td>
</tr>
<tr>
<td>Delete</td>
<td>10.0.0.0/16</td>
<td>ICMP</td>
<td>3</td>
</tr>
</tbody>
</table>

6. Under *Allow Rules for Egress*, delete the rule. There can be no Egress Rules.

Now your instances can receive data traffic from, and direct traffic to, only the load balancer subnets. You no longer can connect directly to your instance's public IP address.

**Delete Your Load Balancer**

When your load balancer becomes available, you are billed for each hour that you keep it running. Once you no longer need a load balancer, you can delete it. When the load balancer is deleted, you stop incurring charges for it. Deleting a load balancer does not affect the backend servers or subnets used by the load balancer.

To delete your load balancer:

1. Open the navigation menu. Under the *Core Infrastructure* group, go to *Networking* and click *Load Balancers*.
2. Choose the *Compartment* that contains your load balancer.
3. Next to your load balancer, click the Actions icon (three dots), and then click *Terminate*.
4. Confirm when prompted.

If you want to delete the instances and VCN you created for this tutorial, follow the instructions in *Cleaning Up Resources from the Tutorial* on page 72.

**Getting Started with Audit**

This chapter provides a hands-on tutorial to introduce you to the components of the Oracle Cloud Infrastructure Audit service.
Welcome to Oracle Cloud Infrastructure

The Oracle Cloud Infrastructure Audit service is included with your Oracle Cloud Infrastructure tenancy. The Audit service automatically records calls to the public application programming interface (API) endpoints for your Oracle Cloud Infrastructure tenancy. The service records events relating to the actions taken on the Oracle Cloud Infrastructure resources. Events recorded in the log can be viewed, retrieved, stored, and analyzed. These log events include information such as:

- ID of the caller
- target resource
- time of the recorded event
- request parameters
- response parameters

This task helps you get started with the Audit service by showing you how to find and view a specific event.

For complete details on Audit, see "Overview of the Audit in the Oracle Cloud Infrastructure User Guide."

**Prerequisite**

To create an event to view, create and delete a VCN in the Networking service.

**Create and Delete a VCN**

1. Select the *compartment* (from the list on the left) in which you want to create the VCN.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
3. Click Create Virtual Cloud Network.
4. Enter the following:
   a. Name: Enter "Audit_Test".
   b. CIDR Block: Enter "10.0.0.0/16".
   c. Leave all other fields with their default settings. Click Create Virtual Cloud Network.

The VCN is displayed in the list.

5. Next to your VCN name, click the **OCID: Copy** link. You will use the **OCID** to help you find the event.
6. Terminate the VCN: Click the Actions icon (three dots), and then click **Terminate**. Confirm when prompted.

**Using Audit to View Events**

In this task, you will use Audit to find the delete VCN event.

**Tip:**

Audit time stamps events according to Greenwich Mean Time (GMT). Before you get started, be aware of your local time zone offset.

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Audit.

The list of events that occurred in the current compartment is displayed. Audit logs are organized by compartment, so if you are looking for a particular event, you must know which compartment the event occurred in.

2. From the **Compartments** list, select the compartment in which you created the VCN.

The list of events for the compartment is displayed.
3. To find the delete VCN event, you can try the following filters:

**Filter by time**

- **a.** Click in the **Start Date** box to display the date and time editor.
- **b.** Select the current date from the calendar. Type or select values for hour and minute to approximate the preceding hour. Enter the time as Greenwich Mean Time (GMT) using 24-hour clock notation.
- **c.** Repeat the above steps to enter an end date for the current date and time, so that you filter results for the preceding hour.

**Example**

If you are in located in the America/Los Angeles time zone and you are looking for an event that occurred between 1:15 PM and 2:15 PM local time on October 25, enter 21:15 and 22:15 to account for the GMT offset.

d. Click **Search**.

**Filter events by keywords**

You can further filter the results list to display only log entries that include a specific text string. Try the following entries to help you find the delete VCN event:

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you filter by keywords, use quotes to avoid results that have a similar string embedded in a longer string. For example, the quotes around ...</td>
</tr>
</tbody>
</table>
Welcome to Oracle Cloud Infrastructure

the responseStatus "204" prevent matches of 204 embedded in a longer string somewhere else in the audit event.

- Filter by the responseStatus value
  In the Keywords box, type "204" and click Search to display only events that returned the 204 (i.e., deleting resource) response status.
- Filter by requestResource value
  In the Keywords box, paste the VCN OCID that you copied to your clipboard in the prerequisite step and click Search.

Review the events to find the DELETE event.

Filter events by request action types

- Filter by the request action types
  In Request Actions Types, select "DELETE" and click Search.

The list filters to show only DELETE events. Scan the list to find your VCN termination event.

4. View the details of your event:
   - To see only the top-level details, click the down arrow to the right of an event.
   - To see lower-level details, click { . . . } to the right of the collapsed parameter.

Getting Started with Oracle Platform Services

This chapter helps you get started with Oracle Platform Services on Oracle Cloud Infrastructure.

Note:
Oracle Platform Services are not available in Oracle Cloud Infrastructure Government Cloud tenancies.

Supported Platform Services

The following platform services are supported on Oracle Cloud Infrastructure:

- Analytics Cloud
- API Platform Cloud Service
- Autonomous Data Warehouse
- Integration
- Autonomous Mobile Cloud Enterprise
- NoSQL Database Cloud Service
- Oracle Visual Builder
- Content and Experience Cloud
- Data Hub Cloud Service
- Data Integration Platform Cloud
- Database Cloud Service
- Developer Cloud Service
- Event Hub Cloud Service
- Java Cloud Service
- Oracle SOA Cloud Service

For services that are supported on both Oracle Cloud Infrastructure and Oracle Cloud Infrastructure Classic, you can choose Oracle Cloud Infrastructure during instance creation by selecting an appropriate region.
Welcome to Oracle Cloud Infrastructure

Understand the Infrastructure Prerequisites

Before creating instances of your service on Oracle Cloud Infrastructure, you must create certain resources in Oracle Cloud Infrastructure for use by your platform service instances.

See "Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure" in the Oracle Cloud Infrastructure User Guide.

Learn About Service-Specific Differences and Workflows

Broadly, the service features are the same regardless of the infrastructure you choose (Oracle Cloud Infrastructure or Oracle Cloud Infrastructure Classic), but differences may exist in some services. And the workflows for creating instances on Oracle Cloud Infrastructure may vary across services.

See the following documentation:

<table>
<thead>
<tr>
<th>Service</th>
<th>More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Hub Cloud Service</td>
<td>About Oracle Data Hub Cloud Service Clusters in Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Database Cloud Service</td>
<td>About Database Deployments in Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Event Hub Cloud Service</td>
<td>About Instances in Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Java Cloud Service</td>
<td>About Java Cloud Service Instances in Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Oracle SOA Cloud Service</td>
<td>About SOA Cloud Service Instances in Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure</td>
</tr>
</tbody>
</table>

REST API Endpoints for Platform Services

You can use the following URL structure to access the REST API endpoints for a Platform Service:

https://<rest_server>/<endpoint_path>

where:

- `<endpoint_path>` is the relative path that defines the REST resource. For a list of available paths, refer to the REST API documentation for the specific service.
- `<rest_server>` is the REST server. Choose the REST server based on the region in which your platform service was created. Refer to the following table.

<table>
<thead>
<tr>
<th>REST Server</th>
<th>Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>psm.us.oraclecloud.com</td>
<td>• US East (Ashburn)</td>
</tr>
<tr>
<td></td>
<td>• US West (Phoenix)</td>
</tr>
<tr>
<td></td>
<td>• US West (San Jose)</td>
</tr>
<tr>
<td></td>
<td>• Canada Southeast (Montreal)</td>
</tr>
<tr>
<td></td>
<td>• Canada Southeast (Toronto)</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 120
Welcome to Oracle Cloud Infrastructure

<table>

</tr>
<tr>
<td></td>
<td>&lt;account_id&gt; is the alphanumeric ID of your tenant name or cloud account</td>
</tr>
</tbody>
</table>

You can find `<account_name>` or `<account_id>` in either:
- The welcome email sent to your cloud account administrator
- The URL used to access the console for the Platform Service

### Getting Started with Oracle Applications

This chapter helps you get started with Oracle Applications on Oracle Cloud Infrastructure.

### Support for Oracle Applications

Oracle Cloud Infrastructure is an ideal place to host your Oracle Applications. You can deploy and manage Oracle applications on Oracle Cloud Infrastructure using the standard procedures found in the application product documentation, or using Oracle-provided automation solutions (available for some applications).

Oracle applications that meet the following criteria are supported:

- The application version is under Premier, Extended, or Sustained support.
- You plan to run the application on an operating system and database version that is supported on Oracle Cloud Infrastructure and certified for the application.

Oracle offers solutions and documentation to make deploying applications on Oracle Cloud Infrastructure easier. Solutions are available for the following applications:

- [Oracle E-Business Suite](#)
Welcome to Oracle Cloud Infrastructure

• Oracle JD Edwards EnterpriseOne
• Oracle PeopleSoft

Setting Up Your Tenancy

After Oracle creates your tenancy in Oracle Cloud Infrastructure, an administrator at your company will need to perform some set up tasks and establish an organization plan for your cloud resources and users. Use the information in this topic to help you get started.

Tip:
To quickly get some users up and running while you are still in the planning phase, see Adding Users on page 57.

Create a Plan

Before adding users and resources you should create a plan for your tenancy. Fundamental to creating your plan is understanding the components of the Oracle Cloud Infrastructure Identity and Access Management (IAM). Ensure that you read and understand the features of IAM. See "Overview of the IAM" in the Oracle Cloud Infrastructure User Guide.

Your plan should include the compartment hierarchy for organizing your resources and the definitions of the user groups that will need access to the resources. These two things will impact how you write policies to manage access and so should be considered together.

Use the following primer topics to help you get started with your plan:

• Understanding Compartments on page 122
• Consider Who Should Have Access to Which Resources on page 123

Understanding Compartments

Compartments are the primary building blocks you use to organize your cloud resources. You use compartments to organize and isolate your resources to make it easier to manage and secure access to them.

When your tenancy is provisioned, a root compartment is created for you. Your root compartment holds all of your cloud resources. You can think of the root compartment like a root folder in a file system.

The first time you sign in to the Console and select a service, you will see your one, root compartment.
Welcome to Oracle Cloud Infrastructure

You can create compartments under your root compartment to organize your cloud resources in a way that aligns with your resource management goals. As you create compartments, you control access to them by creating policies that specify what actions groups of users can take on the resources in those compartments.

Keep in mind the following when you start working with compartments:

• At the time you create a resource (for example, instance, block storage volume, VCN, subnet), you must decide in which compartment to put it.
• Compartments are logical, not physical, so related resource components can be placed in different compartments. For example, your cloud network subnets with access to an internet gateway can be secured in a separate compartment from other subnets in the same cloud network.
• You can create a hierarchy of compartments up to six compartments deep under the tenancy (root compartment).
• When you write a policy rule to grant a group of users access to a resource, you always specify the compartment to apply the access rule to. So if you choose to distribute resources across compartments, remember that you will need to provide the appropriate permissions for each compartment for users that will need access to those resources.
• In the Console, compartments behave like a filter for viewing resources. When you select a compartment, you only see resources that are in the compartment selected. To view resources in another compartment, you must first select that compartment. You can use the Search feature to get a list of resources across multiple compartments. See Overview of Search on page 3626.
• You can use the tenancy explorer to get a complete view of all the resources (across regions) that reside in a specific compartment. See Viewing All Resources in a Compartment on page 235.
• If you want to delete a compartment, you must delete all resources in the compartment first.
• Finally, when planning for compartments you should consider how you want usage and auditing data aggregated.

Consider Who Should Have Access to Which Resources

Another primary consideration when planning the setup of your tenancy is who should have access to which resources. Defining how different groups of users will need to access the resources will help you plan how to organize your resources most efficiently, making it easier to write and maintain your access policies.

For example, you might have users who need to:
• View the Console, but not be allowed to edit or create resources
Welcome to Oracle Cloud Infrastructure

- Create and update specific resources across several compartments (for example, network administrators who need to manage your cloud networks and subnets)
- Launch and manage instances and block volumes, but not have access to your cloud network
- Have full permissions on all resources, but only in a specific compartment
- Manage other users' permissions and credentials

To see some sample policies, see "Common Policies" in the Oracle Cloud Infrastructure User Guide.

Sample Approaches to Setting Up Compartments

Put all your resources in the tenancy (root compartment)

If your organization is small, or if you are still in the proof-of-concept stage of evaluating Oracle Cloud Infrastructure, you might consider placing all of your resources in the root compartment (tenancy). This approach makes it easy for you to quickly view and manage all your resources. You can still write policies and create groups to restrict permissions on specific resources to only the users who need access.

High-level tasks to set up the single compartment approach:

1. (Best practice) Create a sandbox compartment. Even though your plan is to maintain your resources in the root compartment, Oracle recommends setting up a sandbox compartment so that you can give users a dedicated space to try out features. In the sandbox compartment you can grant users permissions to create and manage resources, while maintaining stricter permissions on the resources in your tenancy (root) compartment. See Create a Sandbox Compartment.

Create compartments to align with your company projects

Consider this approach if your company has multiple departments that you want to manage separately or if your company has several distinct projects that would be easier to manage separately.

In this approach, you can add a dedicated administrators group for each compartment (project) who can set the access policies for just that project. (Users and groups still must be added at the tenancy level.) You can give one group control over all their resources, while not allowing them administrator rights to the root compartment or any other projects. In this way, you can enable different groups at your company to set up their own "sub-clouds" for their own resources and administer them independently.

High-level tasks to set up the multiple project approach:

1. Create a sandbox compartment. Oracle recommends setting up a sandbox compartment so you can give users a dedicated space to try out features. In the sandbox compartment you can grant users permissions to create and manage resources, while maintaining stricter permissions on the resources in your tenancy (root) compartment.

2. Create a compartment for each project, for example, ProjectA, ProjectB.

3. Create an administrators group for each project, for example, ProjectA_Admins.

4. Create a policy for each administrators group.

   Example:
   
   Allow group ProjectA_Admins to manage all-resources in compartment ProjectA

6. Let the administrators for ProjectA and ProjectB create subcompartments within their designated compartment to manage resources.

7. Let the administrators for ProjectA and ProjectB create the policies to manage the access to their compartments.

Create compartments to align with your security requirements

Consider this approach if your company has projects or applications that require different levels of security.
A security zone is associated with a compartment and a security zone recipe. When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the policies in the security zone recipe. If any security zone policy is violated, then the operation is denied.

In this approach, you create security zone compartments for projects that must comply with our maximum security architecture and best practices. You create standard compartments for projects that don't require this level of security compliance.

Security zone policies align with Oracle security principles, including:

- Data in a security zone can't be copied to a standard compartment because it might be less secure.
- Resources in a security zone must not be accessible from the public internet.
- Resources in a security zone must use only configurations and templates approved by Oracle.

**Caution:**

To ensure the integrity of your data, you can't move certain resources from a security zone compartment to a standard compartment.

Similar to the previous approach, you can add a dedicated administrator group for each compartment who can then set the access policies for that single project.

- Access (IAM) policies grant users the ability to manage certain resources in a compartment.
- Security zone policies ensure that management operations in a security zone compartment comply with Oracle security best practices.

To learn more, see [Security Zones](#).

**Getting Help and Contacting Support**

When using Oracle Cloud Infrastructure, sometimes you need to get help from the community or to talk to someone in Oracle support. This topic provides more information about accessing these tools.

**Tip:**

Console announcements appear at the top of the Console to communicate timely, important information about service status. For more information, see [Console Announcements](#).

1. **Use a search engine**

   For common issues, someone else has likely asked this question in the past. You can use scoped search to look for answers in our documentation and our forum platforms – Cloud Customer Connect and Stack Overflow. To perform a scoped search, go to your favorite search engine and specify the site URLs along with your specific search terms, as follows:

   ```
   <Your Search Terms> (site:docs.cloud.oracle.com/iaas OR site:cloudcustomerconnect.oracle.com OR site:stackoverflow.com)
   ```

2. **Use Live Chat in the Console**

   Use Live Chat in the Console to get immediate help with common issues. To start a live online chat with an Oracle Support or Sales representative, at the top of the Console, click the **Live Chat** button ( ). A chat window opens that connects you to Oracle Support.

3. **Post a question to our forums**

   If you can't find an answer to your question through search, submit a new question to one of the forums we support. This option is available to all customers.
Cloud Customer Connect

For any issue related to Oracle Cloud Infrastructure, including provisioning of new resources, Console issues, identity, networking, documentation, storage, database, Edge services, or other solutions, you can post a question to Cloud Customer Connect at:

https://cloudcustomerconnect.oracle.com/resources/9c8fa8f96f/summary

If you are using only Always Free resources or using a Free Tier account, use Cloud Customer Connect for support queries.

Stack Overflow

If you are creating an application that integrates with Oracle Cloud Infrastructure APIs, endpoints, or services, you can also use Stack Overflow forums for development-related questions. Tag your questions with oracle-cloud-infrastructure, as follows:

https://stackoverflow.com/questions/tagged/oracle-cloud-infrastructure

4. Open a support service request

This option is only available to paid accounts.

The first time you open a support request, you're automatically taken through a series of steps to provision your support account. If you want to make changes or if you run into problems, see Configuring Your Oracle Support Account on page 130.

Note:

Customers using only Always Free resources and customers using Free Tier accounts are not eligible for Oracle Support. You must upgrade to a paid account to access Oracle Support. If you need support, post a question to Cloud Customer Connect.

If the preceding options did not resolve your issue and you need to talk to someone, you can create a support request. In addition to support for technical issues, you can open support requests if you need to:

• Reset the password or unlock the account for the tenancy administrator
• Add or change a tenancy administrator
• Ask a question about billing and payments
• Request a service limit increase
• Request a root cause analysis (RCA)

Creating a Service Request Using the Console

To create a support ticket

1. Open the Help menu ( ), go to Support, and click Create support request.
2. Enter the following:
   • Issue Summary: Enter a title that summarizes your issue. Avoid entering confidential information.
   • Describe Your Issue: Provide a brief overview of your issue.
     • Include all the information that support needs to route and respond to your request. For example, "I am unable to connect to my Compute instance."
     • Include troubleshooting steps taken and any available test results.
   • Select the severity level for this request.
3. Click Create Request.

To request a root cause analysis (RCA)

To request a root cause analysis for an outage, create a support request and include Root Cause Analysis (RCA) Request in the Issue Summary field.
To request a service limit increase

1. Open the Help menu, go to Support and click Request service limit increase.
2. Enter the following:
   - **Primary Contact Details:** Enter the name and email address of the person making the request. Enter one email address only. A confirmation will be sent to this address.
   - **Service Category:** Select the appropriate category for your request.
   - **Resource:** Select the appropriate resource.
     Depending on your selection for resource, additional fields might display for more specific information.
   - **Reason for Request:** Enter a reason for your request. If your request is urgent or unusual, please provide details here.
3. Click Create Request.

After you submit the request, it is processed. A response can take anywhere from a few minutes to a few days. If your request is granted, a confirmation email is sent to the address provided in the primary contact details.

If we need additional information about your request, a follow-up email is sent to the address provided in the primary contact details.

To view support tickets

- Open the Help menu, go to Support and click View support requests.

To add a comment to a support ticket

1. Open the Help menu, go to Support and click View support requests.
   A list of technical support requests appears.
2. Click the name of the support request on which you want to comment.
3. Under Comments, click Add Comment.
   The Add Comment dialog appears.
4. Type your comment, and then click Add Comment.

To close a support ticket

1. Open the Help menu, go to Support and click View support requests.
   A list of technical support requests appears.
2. Click the name of the support request you want to close.
3. Click Close Request.
   The Request to close dialog appears.
4. Enter the reason for closing the ticket, and then click Close Request.

Creating a Service Request Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage support requests with the API, use the Support Management API.
Locating Oracle Cloud Infrastructure IDs

Use the following tips to help you locate identifiers you might be asked to provide.

Finding Your Customer Support Identifier (CSI)

The Customer Support Identifier (CSI) number is generated after you purchase Oracle Cloud services. This number can be found in several places, including in your contract document and also on your tenancy details page. You’ll need the CSI number to register and log support requests in My Oracle Support (MOS).

To find your CSI number:

1. Open the Profile menu and click Tenancy: <your_tenancy_name>.
2. The CSI number is shown under Tenancy Information.

Finding Your Tenancy OCID (Oracle Cloud Identifier)

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

Finding the OCID of a Compartment

The OCID (Oracle Cloud Identifier) of a resource is displayed when you view the resource in the Console, on the resource details page.
For example, to get the OCID for a Compute instance:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments in your tenancy is displayed.
   A shortened version of the OCID is displayed next to each compartment.

   ![Compartments](image)

2. Click the shortened OCID string to view the entire value in a pop-up. Click **Copy** to copy the OCID to your clipboard. You can then paste it into the service request form field.

**Finding the OCID of a Resource**

The OCID (Oracle Cloud Identifier) of a resource is displayed when you view the resource in the Console, both in the list view and on the details page.

For example, to get the OCID for a compute instance:

1. Open the Console.
2. Select the **Compartment** to which the instance belongs from the list on the left side of the page.
   
   Note that you must have appropriate permissions in a compartment to view resources.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of instances in the selected compartment is displayed.
4. Click the instance that you're interested in.
   A shortened version of the OCID is displayed on the instance details page.
5. Click **Copy** to copy the OCID to your clipboard. You can then paste it into the service request form field.

**Finding Your opc-request-id in the Console**

To locate the opc-request-id value when you are using the Oracle Cloud Infrastructure Console, you must first access the developer tools in the browser in which you are running the Console. Depending on your browser, this is called either Developer Tools or Web Console and can be opened by clicking **F12**. In Safari on a Mac, it's called the Web Inspector.

1. Open your browser's developer tools by clicking **F12** (in Safari on Mac, click **Option + Cmd + i**).
2. Select the **Network** tab, then filter on XHR.

   ![Network Tab](image)

   **Note:**

   Different browsers present filtering options in different ways. Firefox present an XHR filtering button on the Network tab UI. Internet Explorer and Edge provide a filter icon with the label **Content type**, which you click to expose an XHR filter.

3. Select results that return a 500 error to view the request details.
4. In the request details pane, click the **Headers** tab.
5. Locate and copy both the opc-request-id and date values and include them in your support ticket.
Configuring Your Oracle Support Account

The first time you use Oracle Support in the Console, you're automatically taken through a series of steps to provision your support account. If you want to make changes or if you run into problems, this topic explains how to manually update your support account settings. If you're a tenancy administrator, the first time you use Oracle Support in the Console, you might need to approve yourself as a user in MOS.

The following steps are automatically completed for you during the provisioning process. These sections explain how to manually change your account settings.

- Approve pending users (administrators)
- Add an email to your IAM user account
- Create an Oracle Single Sign On (SSO) account
- Change your linked account

To use an identity provider other than IAM, IDCS, or Okta, follow the steps to link the identity provider account to your MOS account.

Approving Pending Users (Administrators)

If you're an administrator, you need to accept the MOS terms of service and approve pending users. Follow these steps to approve users in MOS:

1. Go to https://support.oracle.com and sign in.
2. Accept the terms and conditions, and then click Next.
3. Navigate to the My Account page: Go to your user name at the top of the page, open the menu, and then click My Account.
4. In the menu bar at the top of the page, click the Message Center icon, and then click Approve Pending User Request.
5. Approve the user.

Adding an Email to Your IAM User Account

To create support requests in the Console, your user account must have an associated email address. The first time you create a support request in the Console, the provisioning process adds this email for you. If you want to add the email manually, you can follow these steps.

If your user account already has an email address or you aren't an IAM user, this section does not apply.

1. Open the Profile menu ( altında) and click User Settings. Your Oracle Cloud Infrastructure IAM service User Details page is displayed.
2. Click Edit User.
3. In the Email field, enter your email, and then click Save Changes.

Creating an Oracle Single Sign On (SSO) Account

To create service requests with My Oracle Support, you need to have an Oracle Single Sign On account and register your Customer Support Identifier with My Oracle Support. The first time you create a support request in the Console, the provisioning process creates an Oracle Single Sign On account for you if needed. If you want to create the account manually, you can follow these steps.

- If you already have an Oracle SSO account with a registered CSI, use your existing account.
- If you have an Oracle SSO account but it doesn't have an associated CSI, see Registering Your CSI for Oracle Cloud Infrastructure on page 131.

Tip:

Before you begin this procedure, have your CSI number available. Not sure what that number is or how to locate it? See Finding Your Customer Support Identifier (CSI) on page 132.

To request an SSO account and register with My Oracle Support:
1. To create your Oracle Single Sign On account, go to the My Oracle Support Create Your Oracle Account page.
2. Enter your company email address in the Email address field, complete the rest of the form, and then click Create Account. A verification email is generated.

   **Important:**
   
   If you use an identity provider other than IAM, IDCS, or Okta, this email address must match the user name that you use with your identity provider.

3. Check your email account for an email from Oracle asking you to verify your email address.
4. Open the email and click Verify Email Address.
5. Sign in with the credentials you just set up.
6. At sign-in, you are prompted to enter a Note to the Approver and the Support Identifier (your CSI).
7. Click Request Access.
8. Enter the first five characters of the name of the organization that owns the Customer Support Identifier (listed in the Welcome letter), and then click Validate. The support identifier appears in the table.
9. Click Next.
10. Enter your contact information and click Next.
11. Accept the terms and click Next.

If you are the first person requesting this support identifier, the status of the request is pending until you receive approval from the Customer User Administrator (CUA) or from Oracle Support.

**Changing Your Linked Account**

If you want to change the Console user account linked to your MOS account, follow these steps. You might want to change your account if you have an Oracle support account that doesn't use your Oracle Cloud Infrastructure profile email. For information about IAM user accounts, see Signing In to the Console on page 41.

1. Open the Profile menu (👤) and click User Settings. Your Oracle Cloud Infrastructure IAM service User Details page is displayed.
2. Click More Actions > Link Support Account. The Oracle account sign-in page prompts you to enter your Oracle credentials.
3. Enter the User name and Password of the Oracle support account that you want to link to this user, and then click Sign in. The IAM user account is linked to the Oracle support account. The email address associated with the support account is displayed in the user details in the field My Oracle Support account.

**Using an Identity Provider Other than IAM, IDCS, or Okta**

If you use an identity provider other than IAM, IDCS, or Okta, to access support in the Console, your MOS email address must match the user name that you use with your identity provider.

If your identity provider user name and MOS email address do not match and you would like to access support in the Console, change your MOS email address to a value that matches your identity provider user name.

**Registering Your CSI for Oracle Cloud Infrastructure**

To submit support requests, your MOS account must be associated with your tenancy CSI number. If you already added the CSI for Oracle Cloud Infrastructure, these steps don't apply to you. If you previously registered for My Oracle Support but need to add the CSI for Oracle Cloud Infrastructure, the provisioning process registers your CSI for you, but if you want to register your CSI manually, you can follow these steps.

1. Go to https://support.oracle.com and sign in.
2. Navigate to the My Account page: Go to your user name at the top of the page, open the menu, and then click My Account.
3. The Support Identifiers region displays the accounts that your user name is associated with.
4. Click Request Access.
5. Enter a Note to the Approver and then enter the Support Identifier (your CSI).
6. Enter the first five characters of the name of the organization that owns the Customer Support Identifier (listed in the Welcome letter), and then click Validate. The support identifier appears in the table.
7. Click Next.
8. Enter your contact information and accept the terms. Click Next.

The status of the request is pending until you receive approval from the Customer User Administrator (CUA).

For more information about signing in and using My Oracle Support, see Registration, Sign In, and Accessibility Options in My Oracle Support Help.

Finding Your Customer Support Identifier (CSI)

The following steps explain how to locate your CSI number.

The Customer Support Identifier (CSI) number is generated after you purchase Oracle Cloud services. This number can be found in several places, including in your contract document and also on your tenancy details page. You’ll need the CSI number to register and log support requests in My Oracle Support (MOS).

To find your CSI number:

1. Open the Profile menu and click Tenancy: <your_tenancy_name>.
2. The CSI number is shown under Tenancy Information.

Task Mapping from My Services

This topic summarizes how to perform tasks that you previously performed in My Services prior to the Oracle Cloud Console updates.

Navigation and Task Flow Changes

The updates recently introduced to unify the Console experience enhance and simplify managing your cloud. To achieve the overall reduction in interfaces, some navigation paths and workflows have changed. The following tables summarize the changes to expect:

- Navigation and General Feature Changes on page 133
- Account Management Changes on page 133
- User Management and Identity Changes on page 134
- Platform Service Region Management Changes on page 134
# Navigation and General Feature Changes

<table>
<thead>
<tr>
<th>Task or Feature</th>
<th>Workflow in the Unified Console</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Landing page</strong></td>
<td>After signing in, you now land on the Oracle Cloud Console home page and access all services from this page. The navigation menu includes services that you previously navigated to through My Services. For general information about the Console home page, see Using the Console on page 42.</td>
</tr>
</tbody>
</table>
| **Navigate to Services**                | **Navigating to Platform Services**  
Open the navigation menu. Under More Oracle Cloud Services, go to Platform Services, and then click the service you want to access.  
**Navigating to Classic Data Management Services**  
Open the navigation menu. Under More Oracle Cloud Services, go to Classic Data Management Services, and then click the service you want to access.  
**Navigating to Classic Infrastructure Services**  
Open the navigation menu. Under More Oracle Cloud Services, go to Classic Infrastructure Services, and then click the service you want to access.  
**Navigating to the Applications Console**  
If your Cloud account also has Cloud Applications services provisioned, then you'll have access to the Applications Console.  
In the Console header, click Applications to switch to the Applications Console. |
| **View Platform or Classic Announcements** | Announcements for Platform and Classic services display in a banner above the header bar in the Console.                                                                                                                                 |
| **Navigate to My Home**                 | From the Oracle Cloud Console: Open the Profile menu (👤), and then click Service User Console.                                                                                                                                  |
| **Chat Support**                        | See Use Live Chat in the Console.                                                                                                                                                                                                 |

## Account Management Changes

<table>
<thead>
<tr>
<th>Task or Feature</th>
<th>Workflow in the Unified Console</th>
</tr>
</thead>
</table>
| **View Invoices**    | Open the navigation menu. Under Governance and Administration, go to Account Management and click Invoices.  
Your list of invoices is displayed. You can access your invoices in PDF format. |

<table>
<thead>

<td>Open the Identity Cloud Service (IDCS) console</td>
<td>Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. A list of the identity providers in your tenancy is displayed. Click the Oracle Identity Cloud Service Console link to open the Identity Cloud Service console.</td>
</tr>
</tbody>
</table>

**Platform Service Region Management Changes**

To view and subscribe to Platform Services regions

1. Open the Console, open the Region menu, and then click Manage Regions.
2. On the Manage Regions page, click Platform Services Regions.

The list of geographical regions is displayed. Regions that you have not subscribed to provide a button to create a subscription. A sample of the Platform Services Regions page is shown in the following screenshot:

3. To subscribe to a region, locate the region in the list and click Subscribe.

It might take several minutes to activate your tenancy in the new region.

Frequently Asked Questions

I’m not seeing Platform Services or Classic Services on my navigation menu. What happened?

Make sure that you are signing in with your Oracle Identity Cloud Service login credentials. To ensure that you sign in through IDCS:

2. Enter your tenancy name and click Next. The IDCS sign in page is displayed.
3. Enter your username and password and click Sign In.
4. On the Console, open the navigation menu. If your account has access to Platform or Classic services, you'll see them displayed on the menu under More Oracle Cloud Services. See also Navigating to More Oracle Cloud Services from the Console on page 44.

How do I get to my IDCS console?

To access the IDCS console:

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Federation. The list of identity providers is displayed. OracleIdentityCloudService is displayed in the list of identity providers, with details about the federation.
2. Click the link for **Oracle Identity Cloud Service Console**. An example is shown in the following screenshot.

![Oracle Identity Cloud Service Console](image)

The Oracle Identity Cloud service console opens in a new window.

**My team needs reports that were only available from My Services. How can I get back to the old dashboard?**

You can access the My Services dashboard by using this URL:

```plaintext
http://myservices-<tenancyname>.console.oraclecloud.com/mycloud/cloudportal/dashboard
```

where you replace `<tenancyname>` with your company's tenancy name.

**Where can I find more information about the changes to other task workflows and navigation?**

See [Task Mapping from My Services](#) on page 132.

**Where do I sign in to the Oracle Cloud Infrastructure Console?**

Go to [https://cloud.oracle.com](https://cloud.oracle.com).

You are prompted to enter your cloud tenant, your user name, and your password. Once authenticated, you are directed to a region your tenancy is subscribed to. You can **switch to other regions** you are subscribed to by using the region selector at the top of the Console.

If you need more help signing in, see [Signing In to the Console](#) on page 41.

**How do I find my tenancy home region?**

To find out what your home region is:

Open the **Profile** menu (🔗) and click **Tenancy: <your_tenancy_name>**.

The Tenancy details page shows your Home Region.

**What are my Oracle Cloud Infrastructure account service limits (or resource quotas) and can I request more?**

You can view your tenancy's service limits in the Console and request an increase. For more information and the default tenancy limits, see [Service Limits](#) on page 215.

**Where do I find information about what APIs are available?**

Oracle Cloud Infrastructure provides a set of APIs for the core services (network, compute, block volumes) as well as for the IAM and the Object Storage services.

See "API Requests" in the **Oracle Cloud Infrastructure User Guide.**
What browsers can I use with the Console?

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Why can't I sign in using Firefox?

If you are having trouble signing in to the Console using the Firefox browser, it might be due to one of the following conditions:

- You are in Private Browsing mode. The Console does not support Private Browsing mode. Open a new session of Firefox with Private Browsing turned off.
- You are not on the latest version of Firefox. Upgrade to the latest version. To check to see if you are on the latest version, follow these instructions: https://support.mozilla.org/en-US/kb/find-what-version-firefox-you-are-using
  When checking the version, note whether you are using Firefox or Firefox ESR.
- Your Firefox user profile is corrupted. To fix this issue:
  1. Upgrade to the latest version of Firefox.
  2. Create a new user profile and open Firefox with the new profile. See Mozilla Support for instructions on how to create a new user profile: https://support.mozilla.org/en-US/kb/profile-manager-create-and-remove-firefox-profiles

If none of the above resolves your issue, contact Oracle Support. In your problem description, make sure you specify whether you are using Firefox or Firefox ESR.

How do I know if I am in Private Browsing mode?

When you are in Private Browsing mode, a mask icon is displayed in the upper right corner of your Firefox window.

How do I change my password?

For Federated Users

If your company uses an identity provider (other than Oracle Identity Cloud Service) to manage user logins and passwords, you can't use the Console to update your password. You do that with your identity provider.

1. Sign in to the Console using the Oracle Cloud Infrastructure Username and Password.
2. After you sign in, go to the top-right corner of the Console, open the Profile menu (👤) and then click Change Password.

3. Enter the current password.
4. Follow the prompts to enter the new password, and then click Save New Password.

How do I reset my password if I forget it?

If you added an email address to your user settings, you can use the Forgot Password link on the sign-in page to have a temporary password sent to you. If you don’t have an email address included with your user details, then an administrator must reset your password. Contact your administrator to reset your password for you. Your administrator will give you a temporary password that is good for 7 days. If you do not use it in 7 days, the password will expire and you’ll need to get your administrator to create a new one-time password for you.

If you are the default or tenant administrator for your site and you forgot your password, contact Oracle Support. For tips on filing a service request, see Getting Help and Contacting Support on page 125.

How do I get support?

See Getting Help and Contacting Support on page 125.

Where do I find my Tenancy OCID?

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu (👤) and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under **Tenancy Information**. Click **Copy** to copy it to your clipboard.
Oracle Cloud Infrastructure Free Tier

Oracle Cloud Infrastructure's Free Tier includes a free time-limited promotional trial that allows you to explore a wide range of Oracle Cloud Infrastructure products, and a set of Always Free offers that never expire.

Free Trial

The Free Trial provides you with $300 of cloud credits that are valid for up to 30 days. You may spend these credits on any eligible Oracle Cloud Infrastructure service.

Getting Started

Start for Free

For more information, and to see a complete list of services available to you during the trial, visit the Free Trial website.

Note:

During sign up, choose your home region carefully. You can provision Always Free Autonomous Databases only in your home region.

For security purposes, most users will need a mobile phone number and a credit card to create an account. Your credit card will not be charged unless you upgrade your account.

When Your Trial Period Ends

After your trial ends, your account remains active. There is no interruption to the availability of the Always Free Resources you have provisioned. You can terminate and re-provision Always Free resources as needed.

Paid resources that were provisioned with your credits during your free trial are reclaimed by Oracle unless you upgrade your account.

Pay as You Go accounts are available with no commitment, or contact an Oracle sales representative in your location to learn about monthly and annual flex accounts that offers discounted pricing. For more information, see Oracle Cloud Infrastructure Pricing.

Always Free Resources

All Oracle Cloud Infrastructure accounts (whether free or paid) have a set of resources that are free of charge for the life of the account. These resources display the Always Free label in the Console.

Using the Always Free resources, you can provision a virtual machine (VM) instance, an Oracle Autonomous Database, and the networking, load balancing, and storage resources needed to support the applications that you want to build. With these resources, you can do things like run small-scale applications or perform proof-of-concept testing.

The following list summarizes the Oracle Cloud Always Free-eligible resources that you can provision in your tenancy:
Oracle Cloud Infrastructure Free Tier

- **Compute** (up to two instances)
- **Autonomous Database** (up to two database instances)
- **Load Balancing** (one load balancer)
- **Block Volume** (up to 100 GB total storage)
- **Object Storage** (up to 20 GiB)
- **Vault** (up to 20 keys and up to 150 secrets)

For detailed information about the Always Free resources, see Details of the Always Free Resources on page 142.

You can find your tenancy’s limits for Always Free resources in the Console. To check these limits: Open the navigation menu. Under Governance and Administration, go to Limits, Quotas and Usage.

**Quickly Launch Your Always Free Resources Using Resource Manager**

Oracle offers you the ability to automatically create a full set of Always Free resources in a few minutes using the Resource Manager service’s templates feature. Templates are pre-built Terraform configurations that help you easily create sets of resources used in common scenarios using a single, simple workflow. When you provision your Always Free resources using the provided template, your resources are created with the settings and configuration you need to start creating applications in the cloud. You don't need to have experience with Terraform to use the template. See To provision your Always Free using Terraform and Resource Manager for step-by-step instructions.

**To provision your Always Free using Terraform and Resource Manager**

**Tip:**
Note that Terraform refers to the set of resources being provisioned as a "stack". For a general introduction to Terraform and the "infrastructure-as-code" model, see Terraform: Write, Plan, and Create Infrastructure as Code.

1. Log into your Oracle Cloud Infrastructure account.
2. Open the navigation menu. Under Solutions and Platform, go to Resource Manager and click Stacks.
3. Click the Create Stack button to open the Create Stack dialog.
4. In the Create Stack dialog, click Sample Solution.
5. Click Select Solution to browse available solutions.
6. Select the check box for Sample E-Commerce Application.
7. Click Select Solution.
8. Optionally, provide a name for the new stack. If you don't provide a name, a default name is provided on the server. Avoid entering confidential information.
9. Optionally, provide a description for the stack.
10. Optionally, select a different compartment from your current compartment in which to create the stack. To do so, select a compartment from the Create In Compartment drop-down.
11. Click Next to proceed to the Configure Variables panel.
12. The variables displayed in the Configure Variables panel are auto-populated from the Terraform file that you uploaded. You don't need to change these variables if you are provisioning your Always Free resources using the Terraform file provided by Oracle.
13. Click Next to proceed to the Review panel.
14. Verify your stack configuration, then click Create to create your stack.

Your set of Always Free resources should take no more than a few minutes to provision.

**Upgrading to a Paid Account**

You can upgrade to a paid account at any time through the Oracle Cloud Infrastructure Console. To do so, click the Upgrade link in the banner at the top of the Console web page. If you don't see an Upgrade link on the page you are viewing, you can click the Oracle Cloud logo at the top of the Console and then look for the Upgrade link in the
sidebar on the right side of the Console home page. You will continue to have access to all of your cloud resources after upgrading your account.

Additional Information

See Frequenty Asked Questions: Oracle Cloud Infrastructure Free Tier on page 145 for answers to your questions about Free Tier accounts and resources.

Details of the Always Free Resources

This topic provides reference information about Oracle Cloud Infrastructure's Always Free resources.

Compute

All tenancies get two Always Free Compute virtual machine (VM) instances.

You must create the Always Free Compute instances in your home region.

Details of the Always Free Compute instance

- **Shape:** VM.Standard.E2.1.Micro
- **Processor:** 1/8th of an OCPU with the ability to use additional CPU resources
- **Memory:** 1 GB
- **Networking:** Includes one VNIC with one public IP address and up to 50 Mbps network bandwidth via the internet. Traffic to private IPs, on-premise endpoints via a Dynamic Routing Gateway, or to endpoints within the same Oracle Cloud region is up to 480 Mbps.
- **Operating System:** Your choice of one of the following Always Free-eligible operating systems:
  - Oracle Linux (including Oracle Autonomous Linux)
  - Canonical Ubuntu Linux
  - CentOS Linux

Tip:
The Linux operating systems labeled "Always Free Eligible" in the Console are compatible with Always Free Compute instances and incur no licensing fees. These operating systems are also compatible with paid resources and are available to users of paid accounts. To provision a Compute instance with an operating system that is not Always Free-eligible, you must have a paid account or a Free Trial account with available credits.

See Oracle-Provided Images on page 629 for more information about the available operating systems. For steps to create an Always Free-eligible Compute instance, see "Tutorial - Launching Your First Linux Instance" in the Oracle Cloud Infrastructure Getting Started Guide.

Database

All tenancies get two Always Free Oracle Autonomous Databases. The Autonomous Databases use shared Exadata infrastructure (meaning Oracle handles the database infrastructure provisioning and maintenance). For current regional availability, see the "Always Free Cloud Services" section of Data Regions for Platform and Infrastructure Services.

Details of the Always Free Oracle Autonomous Database instance

- **Processor:** 1 Oracle CPU processor (cannot be scaled)
- **Memory:** 8 GB RAM
• **Database Storage:** 20 GB storage (cannot be scaled)
• **Workload Type:** Your choice of either the transaction processing or data warehouse workload type
• **Maximum Simultaneous Database Sessions:** 20

**Tip:**
Always Free Autonomous Databases can be upgraded to paid instances after provisioning if you need features like more storage or CPU scaling.

**Note:**
• Before creating an Always Free Autonomous Database, check your home region for Always Free Autonomous Database support. See [Data Regions for Platform and Infrastructure Services](#).
• You cannot create an Always Free Autonomous Database in a Home Region where Always Free Autonomous Databases are not supported.
• Not all regions support the same database version. The supported version may be 19c-only or 21c-only, depending on the region.

See [Overview of the Always Free Autonomous Database](#) on page 1220 for additional product details. See [To create an Always Free Autonomous Database](#) on page 1159 for steps to create an Always Free Autonomous Database.

**Load Balancing**
All tenancies get one Always Free 10 Mbps load balancer.

**Details of the Always Free load balancer**
• **Shape:** Micro (10 Mbps)
• **Listeners:** 10
• **Virtual Hostnames:** 10
• **Backend Sets:** 10
• **Backend Servers:** 128

For information about provisioning an Always Free load balancer, see [Getting Started with Load Balancing](#) on page 103.

**Block Volume**
All tenancies receive a total of 100 GB of Always Free Block Volume storage, and five volume backups. These amounts apply to both boot volumes and block volumes combined. When you provision a Compute instance, the instance automatically receives a 50 GB boot volume for storage. You can also create and attach block volumes to expand the storage capacity of a Compute instance. For more information, see [Creating a Volume](#) on page 515 and [Attaching a Volume](#) on page 517.

**Details of the Always Free Block Volume resources**
• 100 GB total of combined boot volume and block volume Always Free Block Volume storage.
• Five total volume backups (boot volume and block volume combined).

When you create a Compute instance, the default boot volume size for the instance is 50 GB, which counts towards your allotment of 100 GB. You can customize the instance's boot volume size up to 100 GB; however, this will use up your full allotment of storage for Always Free Block Volume resources. Also, because the minimum boot volume size allowed for Compute instances is 50 GB, launching two instances will use all your Always Free Block Volume resources. Alternatively, you can launch one instance with the default boot volume size of 50 GB, and then create and attach a 50 GB block volume to expand the storage capacity of the instance. For more information, see [Creating a Volume](#) on page 515 and [Attaching a Volume](#) on page 517. Although it is possible to mix paid and Always Free resources, Oracle does not recommend this. If you have used up your allotment of Always Free Block Volume...
resources, you can free up block storage resources by terminating an Always Free instance and deleting the boot volume, or terminating an Always Free block volume.

You can have a maximum of five Always Free volume backups at any time. This applies to both boot volume and block volume backups. For example, you could have three boot volume backups for your Always Free instance and two block volume backups for your Always Free block volumes. In this example, if you try to create new backups, the operation will fail with an error until you delete existing Always Free volume backups. For more information about volume backups, see Overview of Block Volume Backups on page 540 and Overview of Boot Volume Backups on page 615.

Object Storage

All tenancies get a total of 20 GiB (gibibytes) of Always Free Object Storage.

Details of the Always Free Object Storage resources

If you have a free account (including trial accounts), Always Free includes the following:

- 20 GiB of combined Standard tier, Infrequent Access tier, and Archive tier data
- 50,000 Object Storage API requests per month

If you have a paid account, Always Free includes the following:

- 10 GiB of Standard tier data
- 10 GiB of Infrequent Access tier data
- 10 GiB of Archive tier data
- 50,000 Object Storage API requests per month

Important:

If you are participating in an Oracle Cloud Free Trial, you can store unlimited data and can use 20 GiB for free (your usage of the first 20 GiB incurs no deduction of your initial $300 trial credit balance). Upgrade to a paid account to continue access to unlimited storage. If you do not upgrade before your trial ends, your free account will be limited to 20 GiB of combined Standard tier, Infrequent Access tier, and Archive tier data. If you are using more than the 20-GiB limit when your Free Trial ends, all of your objects will be deleted. You can then upload objects until you reach your Always Free usage limits.

See Putting Data into Object Storage on page 82 for instructions on using your Always Free storage resources.

Resource Manager

All tenancies get the following Always Free resources for Resource Manager.

<table>
<thead>
<tr>
<th>Resource (per tenant)</th>
<th>Always Free resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration source providers</td>
<td>100</td>
</tr>
<tr>
<td>Jobs (concurrent)</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Job duration: 24 hours</td>
</tr>
<tr>
<td>Private templates</td>
<td>10</td>
</tr>
</tbody>
</table>
## Resource (per tenant) | Always Free resources
---|---
Stacks | 10  
Variables per stack: 250  
Size per variable: 8192 bytes  
Zip file per stack: 11 MB

### Service Connector Hub

All tenancies get 2 Always Free service connectors.

**Details of the Always Free Service Connector Hub resources**

If you have a free account (including trial accounts), Always Free Service Connector Hub includes 2 Always Free service connectors.

If you have a paid account, see Service Connector Hub Limits on page 231.

### Vault

All master encryption keys protected by software are free. All tenancies get 20 key versions of master encryption keys protected by a hardware security module (HSM) and 150 Always Free Vault secrets. You can spread these keys or secrets across any number of vaults in the tenancy, although virtual private vaults are not included in the Always Free resources.

**Details of the Always Free Vault resources**

- all key versions of a master encryption key protected by software (across any number of keys or vaults)
- 20 total key versions of a master encryption key protected by an HSM (across any number of keys or vaults)
- 150 total Always Free secrets (across any number of vaults).
- 40 secret versions of any given secret (including up to 20 in some form of active use and 20 pending deletion).

If you have used up your allotment of Always Free secrets, you can release resources by scheduling a secret or secret version for deletion. At minimum, you do have to wait a day before the secret or secret version is deleted.

### Frequently Asked Questions: Oracle Cloud Infrastructure Free Tier

**I just signed up and I cannot access specific services. What can I do?**

Registering your account with all services and regions can take a few minutes. Check again after a few minutes have passed.

**How do I change which resources I want to designate as Always Free?**

In short, you cannot. Eligible resources are designated Always Free when they are created. After you provision an Always Free resource, the Always Free status is not transferable to another existing resource. However, you can delete an existing Always Free resource in order to create a new Always Free resource in its place.

**What happens when my Free Trial expires or my credits are used up?**

When you’ve reached the end of your 30 day trial, or used all of your Free Trial credits ( whichever comes first), you will no longer be able to create new paid resources. However, your account will remain active. Your existing resources will continue to run for a few days, allowing you to upgrade your account and keep your resources before they’re reclaimed by Oracle. (Note that reclaimed resources cannot be recovered—they are permanently deleted.)
Resources identified as Always Free will not be reclaimed. After your Free Trial expires, you'll continue to be able to use and manage your existing Always Free resources, and create new Always Free resources according to tenancy limits.

If I upgrade, do I keep my Free Trial credit balance?

Yes, if you upgrade during the Free Trial period, you will not be billed until you've reached the end of your 30 day trial, or used all of your Free Trial credits (whichever comes first). You will be notified by email when billing begins.

After I upgrade my account, can I downgrade?

There is no option to downgrade your account. However, with a paid account, you'll continue to have access to Always Free resources, and you'll only pay for the standard resources you use. No minimums and no prepayment are required for your paid account.

My resources no longer appear. How can I restore them?

If you have a Free Tier account and your resources no longer appear, it is likely that your Free Trial has expired and your paid resources have been reclaimed (terminated). You can verify this if this is the case by doing the following:

1. Log in to the Console
2. Check for a banner at the top of the Console with the following text: "You are using a Free Tier account. To access all services and resources, upgrade to a paid account."

If you see this message, your resources have been reclaimed and cannot be restored.

I get an "out of host capacity" error when I try to create an Always Free Compute instance. What can I do?

An "out of host capacity" error indicates a temporary lack of Always Free shapes in your home region. Oracle is working to provide more capacity, though it might take several days before additional capacity is available in your home region. Wait a while, and then try to launch the instance again.

Is it possible to extend my Free Trial?

If you need additional credits or time, you can schedule a call with an Oracle sales representative using the Upgrade page in the Console. Sales representatives have the authority to extend trials or issue additional credits if appropriate.

If you don't see an Upgrade link on the Console page you are viewing, you can click the Oracle Cloud logo at the top of the Console and then look for the Upgrade link in the sidebar on the right side of the page.

Is my Free Tier account eligible for support?

Community support through our forums is available to all customers. Customers using only Always Free resources are not eligible for Oracle Support. Limited support is available to Free Tier accounts with Free Trial credits. After you use all of your credits or after your trial period ends (whichever comes first), you must upgrade to a paid account to access Oracle Support. If you choose not to upgrade and continue to use Always Free Services, you will not be eligible to raise a service request in My Oracle Support. See Getting Help and Contacting Support on page 125.
Chapter 4

Oracle Cloud Infrastructure Government Cloud

Oracle Cloud Infrastructure includes the following government cloud services:

- Oracle Cloud Infrastructure US Government Cloud on page 148
- Oracle Cloud Infrastructure United Kingdom Government Cloud on page 171

Oracle Cloud Infrastructure US Government Cloud

Oracle Cloud Infrastructure US Government Cloud provides cloud services for two levels of government operators:

- Oracle Cloud Infrastructure US Government Cloud with FedRAMP Authorization on page 157
- Oracle Cloud Infrastructure US Federal Cloud with DISA Impact Level 5 Authorization on page 162

For All US Government Cloud Customers

This topic contains information common to both the US Government Cloud with FedRAMP High Joint Authorization Board authorization and to the US Federal Cloud with DISA Impact Level 5 authorization.

Shared Responsibilities

Oracle Cloud Infrastructure for government offers best-in-class security technology and operational processes to secure its enterprise cloud services. However, for you to securely run your workloads, you must be aware of your security and compliance responsibilities. By design, Oracle provides security of cloud infrastructure and operations (cloud operator access controls, infrastructure security patching, and so on), and you are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

For more information about shared responsibilities in the Oracle Cloud, see the following white papers:

- Making Sense of the Shared Responsibility Model
- Oracle Cloud Infrastructure Security

Setting Up an Identity Provider for Your Tenancy

As a Government Cloud customer, you must bring your own identity provider that meets your agency’s compliance requirements and supports common access card/personal identity verification card (CAC/PIV) authentication. You can federate Oracle Cloud Infrastructure with SAML 2.0 compliant identity providers that also support CAC/PIV authentication. For instructions on setting up a federation, see Federating with Identity Providers on page 2362.

Remove the Oracle Cloud Infrastructure Default Administrator User and Any Other Non-Federated Users

When your organization signs up for an Oracle account and Identity Domain, Oracle sets up a default administrator for the account. This person will be the first IAM user for your company and will have full administrator access to your tenancy. This user can set up your federation.

After you have successfully set up the federation with your chosen identity provider, you can delete the default administrator user and any other IAM service local users you might have added to assist with setting up your tenancy.
Deleting the local, non-federated users ensures that only users in your chosen identity provider can access Oracle Cloud Infrastructure.

To delete the default administrator:

1. Sign in to the Console through your identity provider.
   
   **More details**
   
   a. Open a supported browser and go to the Government Cloud Console URL.
   b. Enter your Cloud Tenant and click Continue.
   c. On the Single Sign-On pane, select your identity provider and click Continue. You will be redirected to your identity provider to sign in.
   d. Enter your user name and password.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. The list of users is displayed.
3. On the User Type filter, select only Local Users.
4. For each local user, go to the the Actions icon (three dots) and click Delete.

**Using a Common Access Card/Personal Identity Verification Card to Sign in to the Console**

After you set up CAC/PIV authentication with your identity provider and successfully federate with Oracle Cloud Infrastructure, you can use your CAC/PIV credentials to sign in to the Oracle Cloud Infrastructure Console. See your identity provider's documentation for the specific details for your implementation.

In general, the sign in steps are:

1. Insert your CAC/PIV card into your card reader.
2. Navigate to the Oracle Cloud Infrastructure Console sign in page.
3. If prompted, enter your Cloud Tenant name and click Continue.
4. Select the Single Sign-On provider and click Continue.
5. On your identity provider's sign on page, select the appropriate card, for example, PIV Card.
6. If presented with a certificate picker, choose the appropriate certificate or other attributes set up by your organization.
7. When prompted, enter the PIN.

**IPv6 Support for Virtual Cloud Networks**

US Government Cloud customers have the option to enable IPv6 addressing for their VCNs. For more information, see IPv6 Addresses on page 2889.

**Setting Up Secure Access for Compute Hosts**

You can set up CAC/PIV authentication using third-party tools to enable multi-factor authentication for securely connecting to your compute hosts. Example tools include PuTTY-CAC for Windows and Open SC for macOS. For more information see the U.S. Government website, PIV Usage Guidelines.

**Enabling FIPS Mode for Your Operating System**

Government Cloud customers are responsible for enabling FIPS mode for the operating systems on their Compute hosts. To make your operating system compliant with Federal Information Processing Standard (FIPS) Publication 140-2, follow the guidelines for your operating system:

**Oracle Linux**

Follow the guidance provided at Enabling FIPS Mode on Oracle Linux.
**Ubuntu**

Follow the guidance provided at [Ubuntu Security Certifications](#).

**Windows Server 2012**

Follow the guidance provided at [Data Encryption for Web console and Reporting server Connections](#).

**Windows Server 2016 and Windows Server 2019**

First, follow the guidance provided at [How to Use FIPS Compliant Algorithms](#).

Next, go to the Microsoft document, [FIPS 140 Validation](#) and navigate to the topic [Information for System Integrators](#). Follow the instructions under "Step 2 – Setting FIPS Local/Group Security Policy Flag" to complete the FIPS enablement.

**CentOS**

The following guidance is for enabling FIPS on CentOS 7.5. These procedures are valid for both VM and bare metal instances, and only in NATIVE mode. These procedures can be modified for both Emulated and PV modes as needed. Note that this procedure provides an instance that contains the exact FIPS cryptographic modules EXCEPT kernel. However, the kernel module is the same major/minor version but is accelerated in revision, so can be considered compliant under most FIPS compliant models.

After you complete this procedure, Oracle strongly recommends that you do NOT run system-wide yum updates. The system-wide update will remove the FIPS modules contained herein.

**Verify that the version of the kernel, FIPS modules, and FIPS software are at the minimum version:**

1. Validate the current version of the kernel package meets the requirement:
   a. **Current version:** `kernel-3.10.0-693.el7`
   b. Execute `rpm -qa | grep kernel-3`

2. Execute the following and validate the major or minor version is the same as the requirements.
   a. Run
      
      ```
      yum list <package_name>
      ```
   b. Verify that the major/minor version matches the required ones.

      Required packages and versions are:
      - `fipscheck - fipscheck-1.4.1-6.el7`
      - `hmaccalc - hmaccalc-0.9.13-4.el7`
      - `dracut-fips - dracut-fips-033-502.el7`
      - `dracut-fips-aesni - dracut-fips-aesni-033-502.el7`
   c. For each version of package that is not installed, run
      
      ```
      yum install <package_name>
      ```
3. Download and install the following packages:

   a. Packages already installed as part of the image:
      1. Create a directory called `preinstall`.
      2. Download the following packages into this directory:
         openssl, openssl-libs – 1.0.2k-8.el7
         nss, nss-tools, nss-sysinit – 3.28.4-15.el7_4
         nss-util – 3.28.4-3.el7
         nss-softokn, nss-softokn-freebl – 3.28.3-8.el7_4
         openssh, openssh-clients, openssh-server – 7.4p1-11.el7
      3. In the preinstall directory, run
         
         ```
         yum -nogpgcheck downgrade *.rpm
         ```
   
   b. Packages to be added to the image:
      1. Create a directory called `newpackages`.
      2. Download the following packages into this directory:
         libreswan – 3.20-3.el7
         libgcrypt – 1.5.3-14.el7
         gnutls – 3.3.26-9.el7
         gmp – 6.0.0-15.el7
         nettle – 2.7.1-8.el7
      3. In the `newpackages` directory, run
         
         ```
         yum -nogpgcheck localinstall *.rpm
         ```

The URLs for the packages used for this installation are:

**Preinstall:**

- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-3.28.4-15.el7_4.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-util-3.28.4-3.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-tools-3.28.4-15.el7_4.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-sysinit-3.28.4-15.el7_4.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-softokn-freebl-3.28.3-8.el7_4.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-softokn-3.28.3-8.el7_4.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/openssl-1.0.2k-8.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/openssl-libs-1.0.2k-8.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/openssh-7.4p1-11.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/openssh-clients-7.4p1-11.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/openssh-server-7.4p1-11.el7.x86_64.rpm

**Newpackages:**

- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/libreswan-3.20-3.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/libgcrypt-1.5.3-14.el7.x86_64.rpm
- http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/gnutls-3.3.26-9.el7.x86_64.rpm
http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/gmp-6.0.0-15.el7.x86_64.rpm
http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nettle-2.7.1-8.el7.x86_64.rpm

**Kernel FIPS module and initramfs validation installation.**

Perform this procedure as root:

1. Regenerate dracut:
   
   ```
   dracut -f -v
   ```

2. Add the fips argument to the end of the default kernel boot command line:
   
   a. Edit `/etc/default/grub`
   
   b. At the end of the line starting with “GRUB_CMDLINE_LINUX”, add
   
   ```
   fips=1
   ```

   inside the double quotes of the command.
   
   c. Save the result.

3. Generate a new `grub.cfg`:
   
   ```
   grub2-mkconfig -o /etc/grub2-efi.cfg
   ```

**Configure SSH to limit the encryption algorithms.**

1. Sudo to root.
2. Edit `/etc/ssh/sshd_config`.
3. Add the following lines to the bottom of the file:
   
   ```
   Protocol 2
   Ciphers aes128-ctr,aes192-ctr,aes256-ctr,aes128-cbc,3des-cbc,aes192-cbc,aes256-cbc
   Macs hmac-sha1
   ```

4. Reboot the instance.
5. After instance has rebooted, validate that FIPS mode has been enabled in the kernel:
   
   a. Sudo to root.
   
   b. Run the following command:

   ```
   cat /proc/sys/crypto/fips-enabled
   ```

   The result should be '1'.

To further secure CentOS7/RHEL 7.x systems as required by individual agency guidance, follow the checklist contained in the OpenSCAP guide. This guide can be found here: [https://static.open-scap.org/ssg-guides/ssg-centos7-guide-index.html](https://static.open-scap.org/ssg-guides/ssg-centos7-guide-index.html)

The STIG for evaluating compliance under multiple profiles can be found here: [https://iase.disa.mil/stigs/os/unix-linux/Pages/index.aspx](https://iase.disa.mil/stigs/os/unix-linux/Pages/index.aspx). Use the Red Hat Linux 7.x STIG for CentOS 7.5 releases.

**Required VPN Connect Parameters for Government Cloud**

If you use **VPN Connect** with the Government Cloud, you must configure the IPSec connection with the following FIPS-compliant IPSec parameters.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in **bold text**.
Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

### Phase 1 (ISAKMP)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISAKMP protocol</td>
<td>Version 1</td>
</tr>
<tr>
<td>Exchange type</td>
<td>Main mode</td>
</tr>
<tr>
<td>Authentication method</td>
<td>Pre-shared keys *</td>
</tr>
<tr>
<td>Encryption algorithm</td>
<td>AES-256-cbc (recommended)</td>
</tr>
<tr>
<td></td>
<td>AES-192-cbc</td>
</tr>
<tr>
<td></td>
<td>AES-128-cbc</td>
</tr>
<tr>
<td>Authentication algorithm</td>
<td>SHA-2 384 (recommended)</td>
</tr>
<tr>
<td></td>
<td>SHA-2 256</td>
</tr>
<tr>
<td></td>
<td>SHA-1 (also called SHA or SHA1-96)</td>
</tr>
<tr>
<td>Diffie-Hellman group</td>
<td>group 14 (MODP 2048)</td>
</tr>
<tr>
<td></td>
<td>group 19 (ECP 256)</td>
</tr>
<tr>
<td></td>
<td><strong>group 20 (ECP 384)</strong> (recommended)</td>
</tr>
<tr>
<td>IKE session key lifetime</td>
<td>28800 seconds (8 hours)</td>
</tr>
</tbody>
</table>

* Only numbers, letters, and spaces are allowed characters in pre-shared keys.

### Phase 2 (IPSec)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec protocol</td>
<td>ESP, tunnel mode</td>
</tr>
<tr>
<td>Encryption algorithm</td>
<td><strong>AES-256-gcm</strong> (recommended)</td>

<tr>
<td>Authentication algorithm</td>
<td>If using GCM (Galois/Counter Mode), no authentication algorithm is required because authentication is included with GCM encryption.</td>
</tr>
<tr>
<td></td>
<td>If not using GCM, use HMAC-SHA-256-128.</td>
</tr>
<tr>
<td>IPSec session key lifetime</td>
<td>3600 seconds (1 hour)</td>
</tr>
</tbody>
</table>
Parameter | Options
---|---
Perfect Forward Secrecy (PFS) | enabled, group 14

**Oracle’s BGP ASN**

This section is for network engineers who configure an edge device for FastConnect or VPN Connect.

Oracle’s BGP ASN for the Government Cloud depends on the authorization level:

- US Government Cloud: 6142
- US Federal Cloud (Impact Level 5 authorization): 20054

**FIPS Compatible Terraform Provider**

To use Terraform in US Government Cloud regions, refer to Enabling FIPS Compatibility on page 4284 for installation and configuration information.

**Requesting a Service Limit Increase for Government Cloud Tenancies**

If you need to request a service limit increase, use the following instructions to create a service request in My Oracle Support.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Before you can create a service request, you must have an oracle.com account and you must register your Oracle Cloud Infrastructure CSI with My Oracle Support. See Requesting a Service Limit Increase for Government Cloud Tenancies on page 154 for details.</td>
</tr>
<tr>
<td>• Be aware that the support engineer that reviews the information in the service limit request might not be a U.S. citizen.</td>
</tr>
</tbody>
</table>

**Creating a Service Request**

To create a service request for Oracle Government Cloud:

1. Go to My Oracle Support and log in.
   - If you are not signed in to Oracle Cloud Support, click Switch to Cloud Support at the top of the page.
2. At the top of the page, click Service Requests.
3. Click Create Technical SR.
4. Select the following from the displayed menus:
   - **Service Type:** Select Oracle Cloud Infrastructure from the list.
   - **Service Name:** Select the appropriate option for your organization.
   - **Problem Type:** Select Account Provisioning, Billing and Termination, and then select Limit Increase from the submenu.
5. Enter your contact information.
6. Enter a Description, and then enter the required fields specific to your issue. If a field does not apply, you can enter n/a.

For help with any of the general fields in the service request or for information on managing your service requests, click Help at the top of the Oracle Cloud Support page.

**Locating Oracle Cloud Infrastructure IDs**

Use the following tips to help you locate identifiers you might be asked to provide:

**Finding Your tenancy OCID (Oracle Cloud Identifier)**
Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu (≡) and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

Finding the OCID of a Compartment

To find the OCID (Oracle Cloud Identifier) of a compartment:

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
   A list of the compartments in your tenancy is displayed.
   A shortened version of the OCID is displayed next to each compartment.

2. Click Copy to copy the OCID to your clipboard. You can then paste it into the service request form field.

Finding the OCID of a Resource

The OCID (Oracle Cloud Identifier) of a resource is displayed when you view the resource in the Console, both in the list view and on the details page.

For example, to get the OCID for a compute instance:

1. Open the Console.
2. Select the Compartment to which the instance belongs from the list on the left side of the page.
   Note that you must have appropriate permissions in a compartment to view resources.
3. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances. A list of instances in the selected compartment is displayed.
4. A shortened version of the OCID is displayed on the instance details page.
5. Click Copy to copy the OCID to your clipboard. You can then paste it into the service request form field.
Finding Your Customer Service Identifier (CSI)

The Customer Support Identifier (CSI) number is generated after you purchase Oracle Cloud services. This number can be found in several places, including in your contract document and also on your tenancy details page. You’ll need the CSI number to register and log support requests in My Oracle Support (MOS).

To find your CSI number:

1. Open the Profile menu (_profile) and click Tenancy: <your_tenancy_name>.
2. The CSI number is shown under Tenancy Information.

Using My Oracle Support for the First Time

Before you can create service requests with My Oracle Support, you need to have an Oracle Single Sign On (SSO) account and you need to register your Customer Support Identifier (CSI) with My Oracle Support.

**Tip:** Before you begin this procedure, have your CSI handy (see Requesting a Service Limit Increase for Government Cloud Tenancies on page 154).

To request an SSO account and register with My Oracle Support

1. Go to [https://support.oracle.com](https://support.oracle.com).
2. Click New user? Register here to create your Oracle Single Sign On (SSO) account.
3. Enter your company e-mail address in the Email address field, complete the rest of the form, and then click Create Account. A verification email is generated.
4. Check your email account for an email from Oracle asking you to verify your email address.
5. Open the email and click Verify Email Address.
6. Sign in with the credentials you just set up.
7. At sign in, you are prompted to enter a Note to the Approver and the Support Identifier (your CSI).
8. Click Request Access.
9. Enter the first five characters of the name of the organization that owns the Customer Support Identifier (listed in the Welcome letter and on My Services), and then click Validate. The support identifier appears in the table.
10. Click Next.
11. Enter your contact information and click Next.
12. Accept the terms and click Next.

The status of the request is pending until you receive approval from the Customer User Administrator (CUA) or from Oracle Support if you are the first person requesting this support identifier.
If you have previously registered, but need to add the CSI for Oracle Cloud Infrastructure

1. Go to https://support.oracle.com and log in.
2. Navigate to the My Account page: Go to your user name at the of the page, open the menu, and then click My Account.
3. The Support Identifiers region displays the accounts that your user name is currently associated with.
4. Click Request Access.
5. Enter a Note to the Approver and then enter the Support Identifier (your CSI).
6. Click Request Access.
7. Enter the first five characters of the name of the organization that owns the Customer Support Identifier (listed in the Welcome letter and on My Services), and then click Validate. The support identifier appears in the table.
8. Click Validate.
9. The entry is validated. Close the dialog.

The status of the request is pending until you receive approval from the Customer User Administrator (CUA).

For more information about signing in and using My Oracle Support, see Registration, Sign In, and Accessibility Options in My Oracle Support Help.

Oracle Cloud Infrastructure US Government Cloud with FedRAMP Authorization

This topic contains information specific to Oracle Cloud Infrastructure US Government Cloud with FedRAMP High Joint Authorization Board.

Authorizations

Oracle Cloud Infrastructure US Government Cloud has obtained the following authorizations:

- FedRAMP High
- DISA Impact Level 4

For information about the US Government Cloud, see For All US Government Cloud Customers on page 148.

Regions

The region names and identifiers for the US Government Cloud with FedRAMP High Joint Authorization Board are shown in the following table:

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region Identifier</th>
<th>Region Location</th>
<th>Region Key</th>
<th>Realm Key</th>
<th>Availability Domains</th>
</tr>
</thead>
<tbody>
<tr>
<td>US Gov East (Ashburn)</td>
<td>us-langley-1</td>
<td>Ashburn, VA</td>
<td>LFI</td>
<td>OC2</td>
<td>1</td>
</tr>
<tr>
<td>US Gov West (Phoenix)</td>
<td>us-luke-1</td>
<td>Phoenix, AZ</td>
<td>LUF</td>
<td>OC2</td>
<td>1</td>
</tr>
</tbody>
</table>

After your tenancy is created in one of these regions, you can subscribe to the other region. Tenancies in the FedRAMP-authorized regions cannot subscribe to the commercial regions, or to the US Federal Cloud regions. For information about subscribing to a region, see Managing Regions on page 2445.

Console Sign-in URLs

To sign in to the FedRAMP-authorized US Government Cloud, enter one of the following URLs in a supported browser:

- https://console.us-langley-1.oraclegovcloud.com/
- https://console.us-luke-1.oraclegovcloud.com/
US Government Cloud with FedRAMP Authorization API Reference and Endpoints

US Government Cloud with FedRAMP High Joint Authorization Board has these APIs and corresponding regional endpoints:

Announcements API

API reference

- https://announcements.us-langley-1.oraclegovcloud.com
- https://announcements.us-luke-1.oraclegovcloud.com

Autoscaling API

API reference

- https://autoscaling.us-langley-1.oci.oraclegovcloud.com
- https://autoscaling.us-luke-1.oci.oraclegovcloud.com

Core Services (covering Networking, Compute, and Block Volume)

The Networking, Compute, and Block Volume services are accessible with the following API:

Core Services API

API reference

- https://iaas.us-langley-1.oraclegovcloud.com
- https://iaas.us-luke-1.oraclegovcloud.com

Container Engine for Kubernetes API

API reference

- https://containerengine.us-langley-1.oci.oraclegovcloud.com
- https://containerengine.us-luke-1.oci.oraclegovcloud.com

Database API

API reference

- https://database.us-langley-1.oraclegovcloud.com
- https://database.us-luke-1.oraclegovcloud.com

You can track the progress of long-running Database operations with the Work Requests API.

Digital Assistant API

API reference

- https://digitalassistant.us-langley-1.oci.oraclegovcloud.com
- https://digitalassistant.us-luke-1.oci.oraclegovcloud.com

Email Delivery API

API reference

- https://ctrl.email.us-langley-1.oci.oraclegovcloud.com
- https://ctrl.email.us-luke-1.oci.oraclegovcloud.com

Events API

API reference
Note:

Use the Endpoint of Your Home Region for All IAM API Calls

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Key Management API (for the Vault service)

API reference

- https://kms.us-langley-1.oracle.govcloud.com
- https://kms.us-luke-1.oracle.govcloud.com

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

- https://streaming.us-luke-1.oraclegovcloud.com

| Tip: |
| See Understanding Object Storage Namespaces on page 3395 for information regarding how to find your Object Storage namespace. |
**Work Requests API (for Compute and Database work requests)**

API reference

- https://iaas.us-langley-1.oraclegovcloud.com
- https://iaas.us-luke-1.oraclegovcloud.com

**Oracle YUM Repo Endpoints**

The Oracle YUM repo regional endpoints for US Government Cloud with FedRAMP High Joint Authorization Board are shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>YUM Server Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>US Gov East (Ashburn)</td>
<td>• <a href="https://yum.us-langley-1.oci.oraclegovcloud.com">https://yum.us-langley-1.oci.oraclegovcloud.com</a></td>
</tr>
<tr>
<td></td>
<td>• <a href="https://yum-us-langley-1.oracle.com">https://yum-us-langley-1.oracle.com</a></td>
</tr>
<tr>
<td>US Gov West (Phoenix)</td>
<td>• <a href="https://yum-us-luke-1.oci.oraclegovcloud.com">https://yum-us-luke-1.oci.oraclegovcloud.com</a></td>
</tr>
<tr>
<td></td>
<td>• <a href="https://yum-us-luke-1.oracle.com">https://yum-us-luke-1.oracle.com</a></td>
</tr>
</tbody>
</table>

**SMTP Authentication and Connection Endpoints**

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

<table>
<thead>
<tr>
<th>Region</th>
<th>SMTP Connection Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>US Gov East (Ashburn)</td>
<td>smtp.email.us-langley-1.oci.oraclegovcloud.com</td>
</tr>
<tr>
<td>US Gov West (Phoenix)</td>
<td>smtp.email.us-luke-1.oci.oraclegovcloud.com</td>
</tr>
</tbody>
</table>

**SPF Record Syntax**

An SPF record is a TXT record on your sending domain that authorizes Email Delivery IP addresses to send on your behalf. SPF is required for subdomains of oraclegovcloud.com and recommended in other cases. The SPF record syntax for each sending region is shown in the following table:

<table>
<thead>
<tr>
<th>Realm Key</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>OC2</td>
<td>v=spf1 include:rp.email.oci.oraclegovcloud.com ~all</td>
</tr>
</tbody>
</table>

The Realm Key is applicable for any sending regions in that realm.

**Services Not Supported in US Government Cloud with FedRAMP Authorization**

The following services are currently not available or not supported for tenancies in the US Government Cloud with FedRAMP High Joint Authorization Board.

Database services not available:

- Autonomous Data Warehouse
- Autonomous Transaction Processing
- Data Safe

Solutions and Platform services not available:

- Analytics Cloud
- Fusion Analytics Warehouse
• Application Migration
• Compliance Documents
• Content and Experience
• DNS Zone Management
• Functions
• Health Checks
• Integration
• Traffic Management Steering Policies

Governance and Administration features not supported:
• Auto-federation with Oracle Identity Cloud Service
• WAF service

Integration with Oracle SaaS and PaaS services, including those listed here: Getting Started with Oracle Platform Services on page 119

**Additional Information for US Government Cloud with FedRAMP Authorization Customers**

• Shared Responsibilities on page 148
• Setting Up an Identity Provider for Your Tenancy on page 148
• Using a Common Access Card/Personal Identity Verification Card to Sign in to the Console on page 149
• IPv6 Support for Virtual Cloud Networks on page 149
• Setting Up Secure Access for Compute Hosts on page 149
• Enabling FIPS Mode for Your Operating System on page 149
• Required VPN Connect Parameters for Government Cloud on page 152
• Oracle's BGP ASN on page 154
• Requesting a Service Limit Increase for Government Cloud Tenancies on page 154

**Oracle Cloud Infrastructure US Federal Cloud with DISA Impact Level 5 Authorization**

This topic contains information specific to Oracle Cloud Infrastructure US Federal Cloud with DISA Impact Level 5 authorization.

**Note:**

DISA Impact Level 5 authorization is in process for the following services:

• Cloud Shell
• Data Transfer service
• Email Delivery service
• Oracle Cloud VMware Solution

FedRAMP High Joint Authorization Board accreditation for these services is complete.

**Compliance with Defense Cloud Security Requirements**

US Federal Cloud with DISA Impact Level 5 authorization supports applications that require Impact Level 5 (IL5) data, as defined in the Department of Defense Cloud Computing Security Requirements Guide (SRG).

**US Federal Cloud with DISA Impact Level 5 Authorization Regions**

The region names and identifiers for the US Federal Cloud with DISA Impact Level 5 authorization regions are shown in the following table:
After your tenancy is created in one of the US Federal Cloud with DISA Impact Level 5 authorization regions, you can subscribe to the other regions in the US Federal Cloud with DISA Impact Level 5 authorization. These tenancies cannot subscribe to any Oracle Cloud Infrastructure regions not belonging to the OC3 realm. For information about subscribing to a region, see Managing Regions on page 2445.

US Federal Cloud with DISA Impact Level 5 Authorization Console Sign-in URLs

To sign in to the US Federal Cloud with DISA Impact Level 5 authorization, enter one of the following URLs in a supported browser:

- https://console.us-gov-ashburn-1.oraclegovcloud.com/
- https://console.us-gov-chicago-1.oraclegovcloud.com/
- https://console.us-gov-phoenix-1.oraclegovcloud.com/

Note:
When you're logged in to the Console for one of the US Federal Government Cloud regions, the browser times out after 15 minutes of inactivity, and you need to sign in again to use the Console.

US Federal Cloud with DISA Impact Level 5 Authorization API Reference and Endpoints

This section includes the APIs and corresponding regional endpoints with US Federal Cloud DISA Impact Level 5 authorization.

Announcements API

API reference

- https://announcements.us-gov-ashburn-1.oraclegovcloud.com
- https://announcements.us-gov-chicago-1.oraclegovcloud.com
- https://announcements.us-gov-phoenix-1.oraclegovcloud.com

Autoscaling API

API reference

- https://autoscaling.us-gov-ashburn-1.oci.oraclegovcloud.com
- https://autoscaling.us-gov-chicago-1.oci.oraclegovcloud.com
- https://autoscaling.us-gov-phoenix-1.oci.oraclegovcloud.com

Core Services (covering Networking, Compute, and Block Volume)

The Networking, Compute, and Block Volume services are accessible with the following API:

Core Services API

API reference

- https://iaas.us-gov-ashburn-1.oraclegovcloud.com
- https://iaas.us-gov-chicago-1.oraclegovcloud.com
- https://iaas.us-gov-phoenix-1.oraclegovcloud.com

**Container Engine for Kubernetes API**

API reference

- https://containerengine.us-gov-ashburn-1.oci.oraclegovcloud.com
- https://containerengine.us-gov-chicago-1.oci.oraclegovcloud.com
- https://containerengine.us-gov-phoenix-1.oci.oraclegovcloud.com

**Database API**

API reference

- https://database.us-gov-ashburn-1.oraclegovcloud.com
- https://database.us-gov-chicago-1.oraclegovcloud.com
- https://database.us-gov-phoenix-1.oraclegovcloud.com

You can track the progress of long-running Database operations with the [Work Requests API](https://iaas.us-gov-chicago-1.oraclegovcloud.com).

**Digital Assistant API**

API reference

- https://digitalassistant.us-gov-ashburn-1.oci.oraclegovcloud.com
- https://digitalassistant.us-gov-chicago-1.oci.oraclegovcloud.com
- https://digitalassistant.us-gov-phoenix-1.oci.oraclegovcloud.com

**Email Delivery API**

API reference

- https://ctrl.email.us-gov-ashburn-1.oci.oraclegovcloud.com
- https://ctrl.email.us-gov-chicago-1.oci.oraclegovcloud.com
- https://ctrl.email.us-gov-phoenix-1.oci.oraclegovcloud.com

**Events API**

API reference

- https://events.us-gov-ashburn-1.oci.oraclegovcloud.com
- https://events.us-gov-chicago-1.oci.oraclegovcloud.com
- https://events.us-gov-phoenix-1.oci.oraclegovcloud.com

**File Storage API**

API reference

- https://filestorage.us-gov-ashburn-1.oraclegovcloud.com
- https://filestorage.us-gov-chicago-1.oraclegovcloud.com
- https://filestorage.us-gov-phoenix-1.oraclegovcloud.com

**IAM API**

API reference

- https://identity.us-gov-ashburn-1.oraclegovcloud.com
- https://identity.us-gov-chicago-1.oraclegovcloud.com
- https://identity.us-gov-phoenix-1.oraclegovcloud.com

**Note:**

Use the Endpoint of Your Home Region for All IAM API Calls
When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Key Management API (for the Vault service)

API reference
- https://kms.us-gov-ashburn-1.oraclegovcloud.com
- https://kms.us-gov-chicago-1.oraclegovcloud.com
- https://kms.us-gov-phoenix-1.oraclegovcloud.com

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

Marketplace Service API

API reference

Monitoring API

API reference
- https://telemetry-ingestion.us-gov-ashburn-1.oraclegovcloud.com
- https://telemetry-ingestion.us-gov-chicago-1.oraclegovcloud.com
- https://telemetry-ingestion.us-gov-phoenix-1.oraclegovcloud.com
- https://telemetry.us-gov-ashburn-1.oraclegovcloud.com
- https://telemetry.us-gov-chicago-1.oraclegovcloud.com
- https://telemetry.us-gov-phoenix-1.oraclegovcloud.com

Notifications API

API reference
- https://notification.us-gov-ashburn-1.oraclegovcloud.com
- https://notification.us-gov-chicago-1.oraclegovcloud.com
- https://notification.us-gov-phoenix-1.oraclegovcloud.com

The source service must be available in US Government Cloud regions for messages to be successfully sent through the Notifications service. If the source service is not available in these regions, then the message is not sent. For a list of unavailable services, see Services Not Supported in US Federal Cloud with DISA Impact Level 5 Authorization on page 167.

Object Storage and Archive Storage APIs

Both Object Storage and Archive Storage are accessible with the following APIs:

Object Storage API

API reference
- https://objectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://objectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://objectstorage.us-gov-phoenix-1.oraclegovcloud.com
Amazon S3 Compatibility API

API reference
- https://<object_storage_namespace>.compat.objectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://<object_storage_namespace>.compat.objectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://<object_storage_namespace>.compat.objectstorage.us-gov-phoenix-1.oraclegovcloud.com

Tip:
See Understanding Object Storage Namespaces on page 3395 for information regarding how to find your Object Storage namespace.

Swift API (for use with Oracle RMAN)

- https://swiftobjectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://swiftobjectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://swiftobjectstorage.us-gov-phoenix-1.oraclegovcloud.com

Oracle Cloud VMware Solution API

API reference
- https://ocvps.us-ashburn-1.oci.oraclegovcloud.com
- https://ocvps.us-chicago-1.oci.oraclegovcloud.com
- https://ocvps.us-phoenix-1.oci.oraclegovcloud.com

Registry

Registry
- US DoD East (Ashburn)
  - ocir.us-gov-ashburn-1.oci.oraclegovcloud.com
- US DoD North (Chicago)
  - ocir.us-gov-chicago-1.oci.oraclegovcloud.com
- US DoD North (Chicago)
  - ocir.us-gov-phoenix-1.oci.oraclegovcloud.com

Resource Manager API

API reference
- https://resourcemanager.us-ashburn-1.oci.oraclegovcloud.com
- https://resourcemanager.us-chicago-1.oci.oraclegovcloud.com
- https://resourcemanager.us-phoenix-1.oci.oraclegovcloud.com

Streaming API

API reference
- https://streaming.us-gov-ashburn-1.oraclegovcloud.com
- https://streaming.us-gov-chicago-1.oraclegovcloud.com
- https://streaming.us-gov-phoenix-1.oraclegovcloud.com

Work Requests API (for Compute and Database work requests)

API reference
- https://iaas.us-gov-ashburn-1.oraclegovcloud.com
- https://iaas.us-gov-chicago-1.oraclegovcloud.com
- https://iaas.us-gov-phoenix-1.oraclegovcloud.com
Oracle YUM Repo Endpoints

The Oracle YUM repo regional endpoints for US Federal Cloud with DISA Impact Level 5 authorization are shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>YUM Server Endpoint</th>
</tr>
</thead>
</table>
| US DoD East (Ashburn)       | • https://yum.us-gov-ashburn-1.oci.oraclegovcloud.com  
                                • https://yum-us-gov-ashburn-1.oracle.com                                       |
| US DoD North (Chicago)      | • https://yum.us-gov-chicago-1.oci.oraclegovcloud.com  
                                • https://yum-us-gov-chicago-1.oracle.com                                          |
| US DoD West (Phoenix)       | • https://yum.us-gov-phoenix-1.oci.oraclegovcloud.com  
                                • https://yum-us-gov-phoenix-1.oracle.com                                           |

SMTP Authentication and Connection Endpoints

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

<table>
<thead>
<tr>
<th>Region</th>
<th>SMTP Connection Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>US DoD East (Ashburn)</td>
<td>smtp.email.us-gov-ashburn-1.oci.oraclegovcloud.com</td>
</tr>
<tr>
<td>US DoD North (Chicago)</td>
<td>smtp.email.us-gov-chicago-1.oci.oraclegovcloud.com</td>
</tr>
<tr>
<td>US DoD West (Phoenix)</td>
<td>smtp.email.us-gov-phoenix-1.oci.oraclegovcloud.com</td>
</tr>
</tbody>
</table>

SPF Record Syntax

An SPF record is a TXT record on your sending domain that authorizes Email Delivery IP addresses to send on your behalf. SPF is required for subdomains of oraclegovcloud.com and recommended in other cases. The SPF record syntax for each sending region is shown in the following table:

<table>
<thead>
<tr>
<th>Realm Key</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>OC3</td>
<td>v=spf1 include:rp.email.oci.oraclegovcloud.com ~all</td>
</tr>
</tbody>
</table>

The Realm Key is applicable for any sending regions in that realm.

Services Not Supported in US Federal Cloud with DISA Impact Level 5 Authorization

Currently, the following services are not available or not supported for tenancies in the US Federal Cloud with DISA Impact Level 5 authorization.

Core Infrastructure services and features not available:
  • FastConnect with a provider (FastConnect in a colocation model is supported)
  • Data Transfer service

Database services not available:
  • Autonomous Data Warehouse
Oracle Cloud Infrastructure Government Cloud

- Autonomous Transaction Processing
- Data Safe

Solutions and Platform services not available:
- Analytics Cloud
- Fusion Analytics Warehouse
- Application Migration
- Compliance Documents
- Content and Experience
- DNS Zone Management
- Email Delivery
- Functions
- Health Checks
- Integration
- Traffic Management Steering Policies

Governance and Administration features not supported:
- Auto-federation with Oracle Identity Cloud Service
- WAF service

Integration with Oracle SaaS and PaaS services, including those listed here: Getting Started with Oracle Platform Services on page 119.

**Access to Multiple US Federal Cloud with DISA Impact Level 5 Authorization Regions**

This section shows how to give the on-premises resources that are part of NIPRNet access to multiple US Federal Cloud regions over a single FastConnect connection. This is important if one of the regions does not have a direct connection to the NIPRNet's *border cloud access point* (BCAP). The BCAP is also referred to as the *meet me point*.

**Overview**

Some US Federal Cloud regions have a direct connection to a NIPRNet BCAP, but others do not. You can use the Networking service to give on-premises resources that are part of NIPRNet access to a US Federal Cloud region that is not directly connected to the NIPRNet's BCAP. You might do this to extend your on-premises workloads into a particular US Federal Cloud region that you're interested in, or to use that region for disaster recovery (DR).

This scenario is illustrated in the following diagram.
In the diagram, US Federal Government Cloud region 1 has a direct connection to the NIPRNet's BCAP, but US Federal Government Cloud region 2 does not. Imagine that on-premises resources in NIPRNet (in subnet 172.16.1.0/24) need access to your virtual cloud network (VCN) in region 2 (with CIDR 10.0.3.0/24).

Optionally, there could also be a VCN with cloud resources in region 1 (with CIDR 10.0.1.0/24), but a VCN in region 1 is not required for this scenario. The intent of this scenario is for the on-premises resources to get access to resources in region 2.

In general, you set up two types of connections:

- **FastConnect** between the NIPRNet BCAP and region 1.
- **Remote peering connection** between region 1 and region 2.

Here are some details about the connections:

- That FastConnect has at least one physical connection, or cross-connect. You set up a private virtual circuit that runs on the FastConnect. The private virtual circuit enables communication that uses private IP addresses between the on-premises resources and the cloud resources.
- The remote peering connection is between a dynamic routing gateway (DRG) in region 1, and a DRG in region 2. A DRG is a virtual router that you typically attach to a VCN to give that VCN access to resources outside its Oracle region.
- You can control which on-premises subnets are advertised to the VCNs by configuring your BCAP edge router accordingly.
- The subnets in both VCN-1 and VCN-2 are advertised to your BCAP edge router over the FastConnect connection.
- You can optionally configure VCN security rules and other firewalls that you maintain to allow only certain types of traffic (such as SSH or SQL*NET) between the on-premises resources and VCNs.

Here are some basic requirements:

- The VCNs and DRGs in region 1 and region 2 must belong to the same tenancy, but they can be in different compartments within the tenancy.
- For accurate routing, the CIDR blocks of the on-premises subnets of interest and the VCNs must not overlap.
- To enable traffic to flow from a VCN to the on-premises subnets of interest, you must add a route rule to the VCN subnet route tables for each of the on-premises subnets. The preceding diagram shows the route rule for 172.16.1.0/24 in each VCN's route table.

**General Setup Process**
Task 1: Set up FastConnect to region 1

Summary: In this task, you set up the FastConnect between the NIPRNet BCAP and region 1. FastConnect has three connectivity models, and you generally follow the colocate with Oracle model. In this case, colocation occurs in the BCAP (the meet me point). The connection consists of both a physical connection (at least one cross-connect) and logical connection (private virtual circuit).

For instructions, follow the flow chart and tasks listed in Getting Started with FastConnect on page 3211, and notice these specific variations:

- In task 2, the instructions assume that you have a VCN (in region 1), but it is optional.
- In task 8, create a private virtual circuit (not a public one).

Task 2: Set up a VCN and DRG in region 2

Summary: If you don't yet have a VCN in region 2 (VCN-2 in the preceding diagram), you set it up in this task. You also create a DRG in region 2 and attach it to the VCN. Then, for each VCN-2 subnet that needs to communicate with the on-premises network, you update that subnet's route table to include a route rule for the on-premises subnet of interest. If there are multiple on-premises subnets that you want to route to, set up a route rule for each one.

For instructions, see these procedures:
1. To create a VCN on page 2825
2. To create a DRG on page 2929
3. To attach a DRG to a VCN on page 2930
4. To route a subnet's traffic to a DRG on page 2930

Important:

In step 4 in the preceding list, add a route rule with the following settings:
- Destination CIDR = the on-premises subnet of interest
- Target = the VCN's DRG

In the preceding diagram, it's the rule with 172.16.1.0/24 as the destination CIDR, and target as DRG-2. The second rule in the diagram (for 10.0.1.0/24 and DRG-2) is necessary only if resources in VCN-2 need to communicate with resources in VCN-1.

Task 3: Set up remote peering between region 1 and region 2

Summary: In this task, you set up a remote peering to enable private traffic between DRG-1 and DRG-2. The term remote peering typically means that resources in one VCN can communicate privately with resources in a VCN in a different region. In this case, the remote peering also enables private communication between the on-premises network and VCN-2.

For instructions, see Setting Up a Remote Peering on page 3284, and notice these important details:

- Optional region 1 VCN: The instructions assume that each region has a VCN, but in this situation, it is optional for region 1.
- Single VCN administrator: The instructions assume that there are two different VCN administrators: one for the VCN in region 1 and another for the VCN in region 2. In this situation, there might be only a single VCN administrator (you) who handles both regions and configures the remote peering connection.
- Unnecessary IAM policies: The instructions include a task for each VCN administrator to set up particular IAM policies to enable the remote peering connection. One policy is for the VCN administrator who is designated as the requestor, and one is for the VCN administrator who is designated as the acceptor. Those terms are further defined in Important Remote Peering Concepts on page 3282. However, if there's only a single VCN administrator with comprehensive networking permissions across the tenancy, those IAM policies are not necessary. For more information, read the tip that appears at the end of the task.
- RPC anchor points and connection: The remote peering actually consists of multiple components that you must set up. There's an anchor point on each DRG (shown as RPC-1 and RPC-2 in the preceding diagram), plus a
connection between those two RPC anchor points. The instructions include steps for creating those RPCs and the connection between them. Ensure that you create all the components.

IAM API

API reference
- https://identity.uk-gov-london-1.oraclegovcloud.uk
- https://identity.uk-gov-cardiff-1.oraclegovcloud.uk

**Note:**
Use the Endpoint of Your Home Region for All IAM API Calls

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Key Management API (for the Vault service)

API reference
- https://kms.uk-gov-london-1.oraclegovcloud.uk
- https://kms.uk-gov-cardiff-1.oraclegovcloud.uk

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

Load Balancing API

API reference
- https://iaas.uk-gov-london-1.oraclegovcloud.uk
- https://iaas.uk-gov-cardiff-1.oraclegovcloud.uk

Marketplace Service API

API reference
- https://marketplace.uk-gov-london-1.oraclegovcloud.uk

Monitoring API

API reference
- https://telemetry-ingestion.uk-gov-london-1.oraclegovcloud.uk
- https://telemetry.uk-gov-london-1.oraclegovcloud.uk

Notifications API

API reference
Object Storage and Archive Storage APIs
Both Object Storage and Archive Storage are accessible with the following APIs:

Object Storage API
API reference
• https://objectstorage.uk-gov-london-1.oraclegovcloud.uk
• https://objectstorage.uk-gov-cardiff-1.oraclegovcloud.uk

Amazon S3 Compatibility API
API reference
• https://<object_storage_namespace>.compat.objectstorage.uk-gov-london-1.oraclegovcloud.uk
• https://<object_storage_namespace>.compat.objectstorage.uk-gov-cardiff-1.oraclegovcloud.uk

Tip:
See Understanding Object Storage Namespaces on page 3395 for information regarding how to find your Object Storage namespace.

Swift API (for use with Oracle RMAN)
• https://swiftobjectstorage.uk-gov-london-1.oraclegovcloud.uk
• https://swiftobjectstorage.uk-gov-cardiff-1.oraclegovcloud.uk

OS Management API
API reference
• https://osms.uk-gov-london-1.oci.oraclegovcloud.uk

Registry

<table>
<thead>
<tr>

Services Not Supported in Oracle Cloud Infrastructure United Kingdom Government Cloud

The following services are currently not available for tenancies in the United Kingdom Government Cloud:

Solutions and Platform services not available:

- Announcements
- Application Migration
- Compliance Documents
- Big Data
- Blockchain Platform
- Health Checks

SMTP Authentication and Connection Endpoints

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

<table>
<thead>
<tr>
<th>Region</th>
<th>SMTP Connection Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>UK Gov South (London)</td>
<td>smtp.email.uk-gov-london-1.oci.oraclegovcloud.uk</td>
</tr>
<tr>
<td>UK Gov West (Newport)</td>
<td>smtp.email.uk-gov-cardiff-1.oci.oraclegovcloud.uk</td>
</tr>
</tbody>
</table>
SPF Record Syntax

An SPF record is a TXT record on your sending domain that authorizes Email Delivery IP addresses to send on your behalf. SPF is required for subdomains of oraclegovcloud.com and recommended in other cases. The SPF record syntax for the United Kingdom Government Cloud sending region is shown in the following table:

<table>
<thead>
<tr>
<th>Realm Key</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>OC4</td>
<td>v=spf1 include:rp.oraclegovemaildelivery.uk -all</td>
</tr>
</tbody>
</table>

The Realm Key is applicable for any sending regions in that realm.
Chapter 5

Service Essentials

The following topics provide essential information that applies across Oracle Cloud Infrastructure.

**Security Credentials** on page 179
The types of credentials you'll use when working with Oracle Cloud Infrastructure.

**Regions and Availability Domains** on page 180
An introduction to the concepts of regions and availability domains.

**Resource Identifiers** on page 197
A description of the different ways your Oracle Cloud Infrastructure resources are identified.

**Resource Monitoring** on page 199
Information about how to monitor your resources.

**Resource Tags** on page 211
Information about Oracle Cloud Infrastructure tags and how to apply them to your resources.

**Compartment Quotas** on page 243
Information about how to control resource consumption within compartments using quotas.

**Tenancy Explorer**
View all resources in a selected compartment, across regions.

**Service Limits** on page 215
A list of the default limits applied to your cloud resources and how to request an increase.

**Console Announcements** on page 260
Information about the announcements that occasionally appear in the Oracle Cloud Infrastructure Console

**Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure** on page 265
Instructions for setting up the resources required when running an Oracle Platform Service on Oracle Cloud Infrastructure.

**Renaming a Cloud Account** on page 272
Instructions for renaming an Oracle cloud account.
Billing and Payment Tools Overview on page 273
Information about billing and payment tools that you can use to analyze your service usage and manage your costs.

My Services Use Cases on page 300
Use cases for the Oracle Cloud My Services API, to help you interact programmatically with My Services.

Cloud Shell
A free-to-use browser-based terminal accessible from the Oracle Cloud Console that provides access to a Linux shell with pre-authenticated Oracle Cloud Infrastructure CLI and other useful tools.

Security Credentials
This section describes the types of credentials you'll use when working with Oracle Cloud Infrastructure.

Console Password
- **What it's for:** Using the Console.
- **Format:** Typical password text string.
- **How to get one:** An administrator will provide you with a one-time password.
- **How to use it:** Sign in to the Console the first time with the one-time password, and then change it when prompted. Requirements for the password are displayed there. The one-time password expires in seven days. If you want to change the password later, see To change your Console password on page 2459. Also, you or an administrator can reset the password in the Console or with the API (see To create or reset another user's Console password on page 2460). Resetting the password creates a new one-time password that you'll be prompted to change the next time you sign in to the Console. If you're blocked from signing in to the Console because you've tried 10 times in a row unsuccessfully, contact your administrator.
- **Note for Federated Users:** Federated users do not use a Console password. Instead, they sign in to the Console through their identity provider.

API Signing Key
- **What it's for:** Using the API (see Software Development Kits and Command Line Interface on page 4225 and Request Signatures on page 4383).
- **Format:** RSA key pair in PEM format (minimum 2048 bits required).
- **How to get one:** You can use the Console to generate the private/public key pair for you, or you can generate your own. See Required Keys and OCIDs on page 4179.
- **How to use it:** Use the private key with the SDK or with your own client to sign your API requests. Note that after you've added your first API key in the Console, you can use the API to upload any additional ones you want to use. If you provide the wrong kind of key (for example, your instance SSH key, or a key that isn't at least 2048 bits), you'll get an `InvalidKey` error.
- **Example:** The PEM public key looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY-----
```

Instance SSH Key
- **What it's for:** Accessing a compute instance.
Service Essentials

- **Format**: For Oracle-provided images, these SSH key types are supported: RSA, DSA, DSS, ECDSA, and Ed25519. If you bring your own image, you're responsible for managing the SSH key types that are supported.

  For RSA, DSS, and DSA keys, a minimum of 2048 bits is recommended. For ECDSA keys, a minimum of 256 bits is recommended.

- **How to get one**: See Managing Key Pairs on Linux Instances on page 693. Optionally, you can use a key pair that is generated by Oracle Cloud Infrastructure when you create an instance in the Console.

- **How to use it**: When you launch an instance, provide the public key from the key pair.

- **Example**:

  A public key has the following format:

  

  `<key_type> <public_key> <optional_comment>`

  For example, an RSA public key looks like this:

  

  `ssh-rsa AAAAB3BzaC1yc2EAAAADAQABAAABAQD9BRwrUiLDki6P0+jZhsjS2muM... ...yXDus/5DQ== rsa-key-20201202`

Auth Token

- **What it's for**: Authenticating with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. For example, use an auth token as your password with Swift clients.

- **Format**: Typical password text string.

- **How to get one**: See Working with Console Passwords and API Keys on page 2456.

- **How to use it**: Usage depends on the service you are authenticating with. Typically, you authenticate with third-party APIs by providing your Oracle Cloud Infrastructure Console login, your auth token provided by Oracle, and your organization's Oracle tenant name.

Regions and Availability Domains

This topic describes the physical and logical organization of Oracle Cloud Infrastructure resources.

About Regions and Availability Domains

Oracle Cloud Infrastructure is hosted in regions and availability domains. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of one or more availability domains. Most Oracle Cloud Infrastructure resources are either region-specific, such as a virtual cloud network, or availability domain-specific, such as a compute instance. Traffic between availability domains and between regions is encrypted. Availability domains are isolated from each other, fault tolerant, and very unlikely to fail simultaneously. Because availability domains do not share infrastructure such as power or cooling, or the internal availability domain network, a failure at one availability domain within a region is unlikely to impact the availability of the others within the same region.

The availability domains within the same region are connected to each other by a low latency, high bandwidth network, which makes it possible for you to provide high-availability connectivity to the internet and on-premises, and to build replicated systems in multiple availability domains for both high-availability and disaster recovery.

Oracle is adding multiple cloud regions around the world to provide local access to cloud resources for our customers. To accomplish this quickly, we’ve chosen to launch regions in new geographies with one availability domain.

As regions require expansion, we have the option to add capacity to existing availability domains, to add additional availability domains to an existing region, or to build a new region. The expansion approach in a particular scenario is based on customer requirements as well as considerations of regional demand patterns and resource availability.
For any region with one availability domain, a second availability domain or region in the same country or geopolitical area will be made available within a year to enable further options for disaster recovery that support customer requirements for data residency where they exist.

Regions are independent of other regions and can be separated by vast distances—across countries or even continents. Generally, you would deploy an application in the region where it is most heavily used, because using nearby resources is faster than using distant resources. However, you can also deploy applications in different regions for these reasons:

- To mitigate the risk of region-wide events such as large weather systems or earthquakes.
- To meet varying requirements for legal jurisdictions, tax domains, and other business or social criteria.

Regions are grouped into realms. Your tenancy exists in a single realm and can access all regions that belong to that realm. You cannot access regions that are not in your realm. Currently, Oracle Cloud Infrastructure has multiple realms. There is one commercial realm. There are multiple realms for Government Cloud: US Government Cloud FedRAMP authorized and IL5 authorized, and United Kingdom Government Cloud.

The following table lists the regions in the Oracle Cloud Infrastructure commercial realm:

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region Identifier</th>
<th>Region Location</th>
<th>Region Key</th>
<th>Realm Key</th>
<th>Availability Domains</th>
</tr>

</tbody>
</table>

To subscribe to a region, see Managing Regions on page 2445.

For a list of regions in the Oracle Government Cloud realms, see the following topics:

- Oracle Cloud Infrastructure US Government Cloud with FedRAMP Authorization on page 157
- Oracle Cloud Infrastructure US Federal Cloud with DISA Impact Level 5 Authorization on page 162
- Oracle Cloud Infrastructure United Kingdom Government Cloud on page 171

**Note:**

Your Tenancy's Availability Domain Names

Oracle Cloud Infrastructure randomizes the availability domains by *tenancy* to help balance capacity in the data centers. For example, the availability domain labeled PHX-AD-1 for tenancyA may be a different data center than the one labeled PHX-AD-1 for tenancyB. To keep track of which availability domain corresponds to which data center for each tenancy, Oracle Cloud Infrastructure uses tenancy-specific prefixes for the availability domain names. For example: the availability domains for your tenancy are something like *Uocm:PHX-AD-1*, *Uocm:PHX-AD-2*, and so on.

To get the specific names of your tenancy's availability domains, use the ListAvailabilityDomains operation, which is available in the IAM API. You can also see the names when you use the Console to launch an instance and choose which availability domain to launch the instance in.

**Fault Domains**

A fault domain is a grouping of hardware and infrastructure within an availability domain. Each availability domain contains three fault domains. Fault domains provide anti-affinity: they let you distribute your instances so that the instances are not on the same physical hardware within a single availability domain. A hardware failure or Compute hardware maintenance event that affects one fault domain does not affect instances in other fault domains. In addition, the physical hardware in a fault domain has independent and redundant power supplies, which prevents a failure in the power supply hardware within one fault domain from affecting other fault domains.
To control the placement of your compute instances, bare metal DB system instances, or virtual machine DB system instances, you can optionally specify the fault domain for a new instance or instance pool at launch time. If you don't specify the fault domain, the system selects one for you. Oracle Cloud Infrastructure makes a best-effort anti-affinity placement across different fault domains, while optimizing for available capacity in the availability domain. To change the fault domain for a compute instance, edit the fault domain. To change the fault domain for a bare metal or virtual machine DB system instance, terminate it and launch a new instance in the preferred fault domain.

Use fault domains to do the following things:

- Protect against unexpected hardware failures or power supply failures.
- Protect against planned outages because of Compute hardware maintenance.

For more information:

- For recommendations about how to use fault domains when provisioning application and database servers, see Fault Domains on page 595 in Best Practices for Your Compute Instance on page 594.
- For more information about using fault domains when provisioning Oracle bare metal and virtual machine DB systems, see Virtual Machine DB Systems on page 1355 and Availability Domain and Fault Domain Considerations for Oracle Data Guard on page 1463.

### Subscribed Region Limits

Trial, free tier, and pay-as-you-go tenancies are limited to one subscribed region. You can request an increase to the limit for pay-as-you-go tenancies, see To request a subscribed region limit increase on page 183 for more information.

Universal monthly credit tenancies can subscribe to all publicly released commercial regions.

#### Requesting a Limit Increase to the Subscribed Region Count

You can submit a request to increase the subscribed region count for your tenancies from within the Console. If you try to subscribe to a region beyond the limit for your tenancy, you'll be prompted to submit a limit increase request. Additionally, you can launch the request from the service limits page or at any time by clicking the link under the Help menu (Help).  

#### To request a subscribed region limit increase

1. Open the Help menu (Help), go to Support and click Request service limit increase.
2. Enter the following:
   - **Primary Contact Details:** Enter the name and email address of the person making the request. Enter one email address only. A confirmation will be sent to this address.
   - **Service Category:** Select Regions.
   - **Resource:** Select Subscribed region count.
   - **Tenancy Limit:** Specify the limit number.
   - **Reason for Request:** Enter a reason for your request. If your request is urgent or unusual, please provide details here.
3. Click Submit Request.

After you submit the request, it is processed. A response can take anywhere from a few minutes to a few days. If your request is granted, a confirmation email is sent to the address provided in the primary contact details.

If we need additional information about your request, a follow-up email is sent to the address provided in the primary contact details.

### Service Availability Across Regions

All Oracle Cloud Infrastructure regions offer core infrastructure services, including the following:
• Compute: Compute (Intel-based bare metal & VM, DenseIO & Standard), Container Engine for Kubernetes, Registry
• Storage: Block Volume, File Storage, Object Storage, Archive Storage
• Networking: Virtual Cloud Network, Load Balancing, FastConnect (specific partners as available and requested)
• Database: Database, Exadata Cloud Service, Autonomous Data Warehouse, Autonomous Transaction Processing
• Edge: DNS
• Platform: Audit, Identity and Access Management, Monitoring, Notifications, Tagging, Work Requests
• Security: Vault

Generally available cloud services beyond those in the previous list are made available based on regional customer demand. Any service can be made available within a maximum of three months, with many services deploying more quickly. New cloud services are made available in regions as quickly as possible based on a variety of considerations, including regional customer demand, ability to achieve regulatory compliance where applicable, resource availability, and other factors. Because of Oracle Cloud Infrastructure's low latency interconnect backbone, you can use cloud services in other geographic regions with effective results when those services are not available in your home region, as long as data residency requirements do not prevent you from doing so. We regularly work with customers to help ensure effective access to required services.

Resource Availability

The following sections list the resource types based on their availability: across regions, within a single region, or within a single availability domain.

| Tip: |
| In general: IAM resources are cross-region. DB Systems, instances, and volumes are specific to an availability domain. Everything else is regional. Exception: Subnets were originally designed to be specific to an availability domain. Now, you can create regional subnets, which are what Oracle recommends. |

Cross-Region Resources

• API signing keys
• compartments
• detectors (Cloud Guard; regional to reporting region)
• dynamic groups
• federation resources
• groups
• managed lists (Cloud Guard)
• network sources
• policies
• responders (Cloud Guard; regional to reporting region)
• tag namespaces
• tag keys
• targets (Cloud Guard; regional to reporting region)
• users

Regional Resources

• alarms
• applications (Data Flow service)
• applications (Functions service)
• blockchain platforms (Blockchain Platform service)
• buckets: Although buckets are regional resources, they can be accessed from any location if you use the correct region-specific Object Storage URL for the API calls.
• clusters (Big Data service)
• clusters (Container Engine for Kubernetes service)
• cloudevents-rules
• config work requests (Logging Analytics)
• configuration source providers (Resource Manager)
• content and experience
• customer-premises equipment (CPE)
• dashboards (Management Dashboard)
• data catalogs
• database insights (Operations Insights)
• DB Systems (MySQL Database service)
• DHCP options sets
• dynamic routing gateways (DRGs)
• encryption keys
• entities (Logging Analytics)
• functions
• images
• internet gateways
• jobs (Database Management)
• jobs (Resource Manager)
• load balancers
• local peering gateways (LPGs)
• log groups (Logging Analytics)
• management agent install keys
• management agents
• managed database groups (Database Management)
• managed databases (Database Management)
• metrics
• models
• NAT gateways
• network security groups
• node pools
• notebook sessions
• object collection rules (Logging Analytics)
• private templates (Resource Manager)
• problems (Cloud Guard; regional to reporting region)
• projects
• queryjob work requests (Logging Analytics)
• repositories
• reserved public IPs
• route tables
• runs
• saved searches (Management Dashboard)
• scheduled tasks (Logging Analytics)
• secrets
• security lists
• service connectors
• service gateways
Service Essentials

- stacks (Resource Manager)
- storage work requests (Logging Analytics)
- subnets: When you create a subnet, you choose whether it's regional or specific to an availability domain. Oracle recommends using regional subnets.
- subscriptions
- tables
- tickets (Support Management service)
- topics
- vaults
- virtual cloud networks (VCNs)
- volume backups: They can be restored as new volumes to any availability domain within the same region in which they are stored.
- workspaces

Availability Domain-Specific Resources

- DB systems (Oracle Database service)
- ephemeral public IPs
- instances: They can be attached only to volumes in the same availability domain.
- subnets: When you create a subnet, you choose whether it is regional or specific to an availability domain. Oracle recommends using regional subnets.
- volumes: They can be attached only to an instance in the same availability domain.

Dedicated Regions

Dedicated regions are public regions assigned to a single organization. Region specific details, such as region ID and region key are not available in public documentation, check with your Oracle contact for this information for your dedicated region.

This topic provides general information for dedicated regions. For information about Oracle Cloud Infrastructure services, see Oracle Cloud Infrastructure.

Console URL

The Console URL you use to sign in to your region is constructed as follows:

```
http://console.<region_identifier>.oraclecloud8.com
```

To sign in to your region, enter the Console URL in a supported browser.

Service Endpoint Patterns

This section describes the pattern you use to construct endpoints for each service available in Oracle Cloud Infrastructure. Not all services listed here may be available in your specific region, confirm with your Oracle contact which services are available in your region.

Analytics API

API reference

Endpoint URL pattern:

- https://analytics.<region_identifier>.ocp.oraclecloud8.com

Announcements Service API

API reference

Endpoint URL pattern:
• https://announcements.<region_identifier>.oraclecloud8.com

**API Gateway API**

*API reference*

Endpoint URL pattern:

• https://apigateway.<region_identifier>.oci.oraclecloud8.com

**Application Migration API**

*API reference*

Endpoint URL pattern:

• https://applicationmigration.<region_identifier>.oraclecloud8.com

**Audit API**

*API reference*

Endpoint URL pattern:

• https://audit.<region_identifier>.oraclecloud8.com

**Autoscaling API**

*API reference*

Endpoint URL pattern:

• https://autoscaling.<region_identifier>.oci.oraclecloud8.com

**Big Data Service API**

*API reference*

Endpoint URL pattern:

• https://bigdataservice.<region_identifier>.oci.oraclecloud8.com

**Blockchain Platform Control Plane API**

*API reference*

Endpoint URL pattern:

• https://blockchain.<region_identifier>.oci.oraclecloud8.com

**Budgets API**

*API reference*

Endpoint URL pattern:

• https://usage.<region_identifier>.oci.oraclecloud8.com

**Cloud Advisor API**

*API reference*

Endpoint URL pattern:

• https://advisor.<region_identifier>.oraclecloud8.com

**Cloud Guard API**

*API reference*

Endpoint URL pattern:

• https://cloudguard-cp-api.<region_identifier>.oci.oraclecloud8.com
**Container Engine for Kubernetes API**

**API reference**

Endpoint URL pattern:
- https://containerengine.<region_identifier>.oci.oraclecloud8.com

**Core Services (covering Networking, Compute, and Block Volume)**

The Networking, Compute, and Block Volume services are accessible with the following API:

**API reference**

Endpoint URL pattern:
- https://iaas.<region_identifier>.oraclecloud8.com

**Data Catalog API**

**API reference**

Endpoint URL pattern:
- https://datacatalog.<region_identifier>.oci.oraclecloud8.com

**Data Flow API**

**API reference**

Endpoint URL pattern:
- https://dataflow.<region_identifier>.oci.oraclecloud8.com

**Data Integration API**

**API reference**

Endpoint URL pattern:
- https://dataintegration.<region_identifier>.oci.oraclecloud8.com

**Data Safe API**

**API reference**

Endpoint URL pattern:
- https://datasafe.<region_identifier>.oci.oraclecloud8.com

**Data Science API**

**API reference**

Endpoint URL pattern:
- https://datascience.<region_identifier>.oci.oraclecloud8.com

**Database API**

**API reference**

Endpoint URL pattern:
- https://database.<region_identifier>.oraclecloud8.com

You can track the progress of long-running Database operations with the [Work Requests](#) API.

**Digital Assistant Service Instance API**

**API reference**

Endpoint URL pattern:
- https://digitalassistant.<region_identifier>.oci.oraclecloud8.com
DNS API
API reference
Endpoint URL pattern:
• https://dns.<region_identifier>.oci.oraclecloud8.com

Email Delivery API
API reference
Endpoint URL pattern:
• https://ctrl.email.<region_identifier>.oci.oraclecloud8.com

Events API
API reference
Endpoint URL pattern:
• https://events.<region_identifier>.oci.oraclecloud8.com

File Storage API
API reference
Endpoint URL pattern:
• https://filestorage.<region_identifier>.oraclecloud8.com

Functions Service API
API reference
Endpoint URL pattern:

- https://incidentmanagement.us-phoenix-1.oraclecloud.com

Usage API

API reference

Endpoint URL pattern:

- https://usageapi.<region_identifier>.oci.oraclecloud8.com

Vault Service Key Management API

API reference

Endpoint URL pattern:

- https://kms.<region_identifier>.oraclecloud8.com

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

Vault Service Secret Management API

API reference

Endpoint URL pattern:

- https://vaults.<region_identifier>.oci.oraclecloud8.com

Vault Service Secret Retrieval API

API reference

Endpoint URL pattern:

- https://secrets.vaults.<region_identifier>.oci.oraclecloud8.com

Web Application Acceleration and Security API

API reference

Endpoint URL pattern:

- https://waas.<region_identifier>.oraclecloud8.com

Work Requests API (for Compute and Database work requests)

API reference

Endpoint URL pattern:

- https://iaas.<region_identifier>.oraclecloud8.com

IP Address Ranges

This topic provides information about public IP address ranges for services that are deployed in Oracle Cloud Infrastructure. Allow traffic to these CIDR blocks to ensure access to the services.

Endpoints for Oracle YUM repos are listed on this page. You can use DNS lookup to determine the public IP address for each endpoint.

Public IP Addresses for VCNs and the Oracle Services Network

Public IP address ranges for VCNs and the Oracle Services Network are published to a JSON file which you can download and view manually or consume programmatically.
The Oracle Services Network is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. A service gateway offers private access to the Oracle Services Network from workloads in your VCN and your on-premises network. The published addresses correspond to the service CIDR label called All <region> Services in Oracle Services Network. For a list of the services available with a service gateway, see Service Gateway: Supported Cloud Services in Oracle Services Network.

**Downloading the JSON File**

Use this link to download the current list of public IP ranges.

You can poll the published file to check for new IP address ranges as frequently as every 24 hours. We recommend that you poll the published file at least weekly.

**JSON File Contents and Syntax**

IP addresses are published in the public_ip_ranges.json file with the fields in the following table.

**Example of the public_ip_ranges.json file**

```json
{
    "last_updated_timestamp": "2019-11-18T19:55:47.204985",
    "regions": [
        {
            "region": "us-phoenix-1",
            "cidrs": [
                {
                    "cidr": "129.146.0.0/21",
                    "tags": ["OCI"]
                },
                {
                    "cidr": "134.70.8.0/21",
                    "tags": ["OSN", "OBJECT_STORAGE"]
                }
            ]
        },
        {
            "region": "us-ashburn-1",
            "cidrs": [
                {
                    "cidr": "129.213.8.0/21",
                    "tags": ["OCI"]
                },
                {
                    "cidr": "134.70.24.0/21",
                    "tags": ["OSN", "OBJECT_STORAGE"]
                }
            ]
        }
    ]
}
```
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Definition</th>
<th>Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>last_updated_timestamp</td>
<td>File creation time in ISO 8601 format. Expressed as &lt;date&gt;T&lt;time&gt;</td>
<td>string</td>
<td>&quot;last_updated_timestamp&quot;: &quot;2019-11-18T19:55:47.204985&quot;</td>
</tr>
<tr>
<td>regions</td>
<td>IP CIDR ranges grouped by region.</td>
<td>array</td>
<td>See preceding Example of the public ip ranges.json file</td>
</tr>
<tr>
<td>region</td>
<td>The region of the IP CIDR ranges.</td>
<td>string</td>
<td>&quot;region&quot;: &quot;us-phoenix-1&quot;</td>
</tr>
<tr>
<td></td>
<td>Valid values: Any region in the Oracle Cloud Infrastructure commercial realm.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For a complete list of regions, see Regions and Availability Domains on page 180.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>cidrs</td>
<td>A group of IP address CIDR ranges.</td>
<td>array</td>
<td>See preceding Example of the public ip ranges.json file</td>
</tr>
<tr>
<td>cidr</td>
<td>One or more IPv4 IP addresses expressed in CIDR notation.</td>
<td>string</td>
<td>&quot;cidr&quot;: &quot;147.154.0.0/18&quot;</td>
</tr>
<tr>

<td>---------</td>
</tr>
<tr>
<td>tags</td>
<td>The services associated with the IP address CIDR range. Valid values: • OCI: The VCN CIDR blocks. • OSN: The CIDR block ranges for the Oracle Services Network. • OBJECT_STORAGE: The CIDR block ranges used by the Object Storage service. For more information, see Overview of Object Storage on page 3392.</td>
<td>array of string values</td>
<td>&quot;tags&quot;: [ &quot;OCI&quot; ]</td>
</tr>
</tbody>
</table>

### Filtering the JSON file contents

After you download the JSON file, you can use a command line tool such as `jq` to filter the contents.

**Download jq**

Here are some examples of how you can use the tool to find and filter the information you need:

**Find the creation date of the JSON file:**

```bash
jq .last_updated_timestamp < public_ip_ranges.json
```

**Get all IPv4 addresses for a specific region:**

```bash
jq -r ".regions[] | select (.region=="us-phoenix-1") | .cidrs[] | select (.cidr | contains(".")) | .cidr ' < public_ip_ranges.json
```

### Public IP Addresses for the Oracle YUM Repos

The Oracle YUM repos have the following regional public endpoints.

<table>
<thead>
<tr>
<th>Region</th>
<th>YUM Server Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Netherlands Northwest (Amsterdam)</td>
<td><a href="https://yum-eu-amsterdam-1.oracle.com">https://yum-eu-amsterdam-1.oracle.com</a></td>
</tr>
<tr>
<td>Australia East (Sydney)</td>
<td><a href="https://yum-ap-sydney-1.oracle.com">https://yum-ap-sydney-1.oracle.com</a></td>
</tr>
<tr>
<td>Canada Southeast (Toronto)</td>
<td><a href="https://yum-ca-toronto-1.oracle.com">https://yum-ca-toronto-1.oracle.com</a></td>
</tr>
<tr>
<td>Germany Central (Frankfurt)</td>
<td><a href="https://yum-eu-frankfurt-1.oracle.com">https://yum-eu-frankfurt-1.oracle.com</a></td>
</tr>
<tr>
<td>India West (Mumbai)</td>
<td><a href="https://yum-ap-mumbai-1.oracle.com">https://yum-ap-mumbai-1.oracle.com</a></td>
</tr>
<tr>
<td>Region</td>
<td>YUM Server Endpoint</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>----------------------------------------------</td>
</tr>
<tr>
<td>Japan Central (Osaka)</td>
<td><a href="https://yum-ap-osaka-1.oracle.com">https://yum-ap-osaka-1.oracle.com</a></td>
</tr>
<tr>
<td>Japan East (Tokyo)</td>
<td><a href="https://yum-ap-tokyo-1.oracle.com">https://yum-ap-tokyo-1.oracle.com</a></td>
</tr>
<tr>
<td>Saudi Arabia West (Jeddah)</td>
<td><a href="https://yum-me-jeddah-1.oracle.com">https://yum-me-jeddah-1.oracle.com</a></td>
</tr>
<tr>
<td>Australia Southeast (Melbourne)</td>
<td><a href="https://yum-ap-melbourne-1.oracle.com">https://yum-ap-melbourne-1.oracle.com</a></td>
</tr>
<tr>
<td>South Korea Central (Seoul)</td>
<td><a href="https://yum-ap-seoul-1.oracle.com">https://yum-ap-seoul-1.oracle.com</a></td>
</tr>
<tr>
<td>UK South (London)</td>
<td><a href="https://yum-uk-london-1.oracle.com">https://yum-uk-london-1.oracle.com</a></td>
</tr>
<tr>
<td>US East (Ashburn)</td>
<td><a href="https://yum-us-ashburn-1.oracle.com">https://yum-us-ashburn-1.oracle.com</a></td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td><a href="https://yum-us-phoenix-1.oracle.com">https://yum-us-phoenix-1.oracle.com</a></td>
</tr>
</tbody>
</table>

You can use DNS lookup to determine the public IP address for each endpoint.

**Resource Identifiers**

This chapter describes the different ways your Oracle Cloud Infrastructure resources are identified.

**Oracle Cloud IDs (OCIDs)**

Most types of Oracle Cloud Infrastructure resources have an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). It's included as part of the resource's information in both the Console and API.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To use the API, you need the OCID for your tenancy. For information about where to find it, see the next section.</td>
</tr>
</tbody>
</table>

OCIDs use this syntax:

```
ocid1.<RESOURCE TYPE>.<REALM>.[REGION].<FUTURE USE>.<UNIQUE ID>
```

- **ocid1**: The literal string indicating the version of the OCID.
- **resource type**: The type of resource (for example, instance, volume, vcn, subnet, user, group, and so on).
- **realm**: The realm the resource is in. A realm is a set of regions that share entities. Possible values are oc1 for the commercial realm, oc2 for the Government Cloud realm, or oc3 for the Federal Government Cloud realm. The regions in the commercial realm (OC1) belong to the domain oraclecloud.com. The regions in the Government Cloud (OC2) belong to the domain oraclegovcloud.com.
- **region**: The region the resource is in (for example, phx, iad, eu-frankfurt-1). With the introduction of the Frankfurt region, the format switched from a three-character code to a longer string. This part is present in the OCID only for regional resources or those specific to a single availability domain. If the region is not applicable to the resource, this part might be blank (see the example tenancy ID below).
- **future use**: Reserved for future use. Currently blank.
- **unique ID**: The unique portion of the ID. The format may vary depending on the type of resource or service.

**Example OCIDs**

Tenancy:

```
ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdos
```
Where to Find Your Tenancy's OCID

If you use the Oracle Cloud Infrastructure API, you need your tenancy's OCID in order to sign the API requests. You also use the tenancy ID in some of the IAM API operations.

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the Tenancy Details page:

1. Open the Profile menu and click Tenancy: <your_tenancy_name>.
2. The tenancy OCID is shown under Tenancy Information. Click Copy to copy it to your clipboard.

The tenancy OCID looks something like this (notice the word "tenancy" in it):

`ocid1.tenancy.oc1..<unique_ID>`

Name and Description (IAM Only)

The IAM service requires you to assign a unique, unchangeable name to each of your IAM resources (users, groups, dynamic groups, federations, and policies). The name must be unique within the scope of the type of resource (for example, you can only have one user with the name BobSmith). Notice that this requirement is specific to IAM and not the other services.

The name you assign to a user at creation is their login for the Console.

You can use these names instead of the OCID when writing a policy (for example, Allow group <GROUP NAME> to manage all-resources in compartment <COMPARTMENT NAME>).

In addition to the name, you must also assign a description to each of your IAM resources (although it can be an empty string). It can be a friendly description or other information that helps you easily identify the resource. The description does not have to be unique, and you can change it whenever you like. For example, you might want to use the description to store the user's email address if you're not already using the email address as the user's unique name.

Display Name

For most of the Oracle Cloud Infrastructure resources you create (other than those in IAM), you can optionally assign a display name. It can be a friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. The Console shows the resource's display name along with its OCID.
Caution:
Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Resource Monitoring
You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources when needed using queries or on a passive basis using alarms. Queries and alarms rely on metrics emitted by your resource to the Monitoring service.

Prerequisites
- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.

Working with Resource Monitoring
Not all resources support monitoring. See Supported Services on page 2669 for the list of resources that support the Monitoring service, which is required for queries and alarms used in monitoring.

The Monitoring service works with the Notifications service to notify you when metrics breach. For more information about these services, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

To view default metric charts for a resource
On the page for the resource of interest, under Resources, click Metrics.

For example, to view metric data for a Compute instance:

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance you're interested in.
3. On the instance details page, under Resources, click Metrics.

   A chart is shown for each metric. For a list of metrics related to Compute instances, see Compute Instance Metrics on page 788.

The Console displays the last hour of metric data for the selected resource. A chart is shown for each metric emitted by the selected resource.

For a list of metrics emitted by your resource, see Supported Services on page 2669.

To view default metric charts for a set of resources

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Choose the **Metric Namespace** for the resource types of interest in the selected compartment.

   For example, choose **oci_lbaas** to see metrics for load balancers.

Default charts are displayed for all resources in the selected **Metric Namespace** and **Compartment**. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

**Don't see all expected resources or metrics?**

- Try a different time range.
- Make sure the correct **Compartment** is selected.

Metric namespaces are shown only when associated resources exist in the selected compartment. For example, the **oci_autonomous_database** namespace is shown only when Autonomous Databases exist in the selected compartment.

- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances on page 783.

- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

**To create a query**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.

   The **Metrics Explorer** page displays an empty chart with fields to build a query.

2. Fill in the fields for a new query.

   - **Compartment**: The compartment containing the resources that you want to monitor. By default, the first accessible compartment is selected.
   - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
   - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
   - **Metric Name**: The name of the metric. Only one metric can be specified. Metric selections depend on the selected compartment and metric namespace. Example: **CpuUtilization**
   - **Interval**: The aggregation window.

**Interval values**

Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the **1h** or **1d** interval values are supported.

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour
- **1d** - 1 day

**Note:**

For metric queries, the **interval** you select drives the default **resolution** of the request, which determines the maximum time range of data returned.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

**Maximum time range returned for a query**

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval.
The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console (Basic Mode). To specify an interval value that is not available in Basic Mode in the Console, such as 12 hours, switch to Advanced Mode.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Default resolution (metric queries)</th>
<th>Maximum time range returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>1 day</td>
<td>90 days</td>
</tr>
<tr>
<td>1h</td>
<td>1 hour</td>
<td>90 days</td>
</tr>
<tr>
<td>5m</td>
<td>5 minutes</td>
<td>30 days</td>
</tr>
<tr>
<td>1m</td>
<td>1 minute</td>
<td>7 days</td>
</tr>
</tbody>
</table>

To specify a non-default resolution that differs from the interval, use the `SummarizeMetricsData` operation.

**See examples of returned data**

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of 1m, and the end time defaults to the current time (2019-01-08T10:00:00.789Z). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (2019-01-01T10:00:00.789Z).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (2019-01-06T10:00:00.789Z), the earliest data point possible within this seven-day period would be 10:00 on January 1st.
• Statistic: The aggregation function.

**Statistic values**

- **COUNT**: The number of observations received in the specified time period.
- **MAX**: The highest value observed during the specified time period.
- **MEAN**: The value of Sum divided by Count during the specified time period.
- **MIN**: The lowest value observed during the specified time period.
- **P50**: The value of the 50th percentile.
- **P90**: The value of the 90th percentile.
- **P95**: The value of the 95th percentile.
- **P99**: The value of the 99th percentile.
- **P99.5**: The value of the 99.5th percentile.
- **RATE**: The per-interval average rate of change.
- **SUM**: All values added together.

• **Metric dimensions**: Optional filters to narrow the metric data evaluated.

**Dimension fields**

- **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

**Note:**

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
- To retrieve all dimensions for a given metric, use the following API operation: `ListMetrics`.

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **Additional dimension**: Adds another name-value pair for a dimension.

• **Aggregate Metric Streams**: Aggregates all results to plot a single aggregated average for all metric streams. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

3. **Click Update Chart**.

The chart shows the results of your new query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

**Troubleshooting Errors and Query Limits**

If you see an error that the query has exceeded the maximum number of `metric streams`, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams
by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

4. To customize the y-axis label or range, type the label you want into **Y-Axis Label** or type the minimum and maximum values you want into **Y-Axis Min Value** and **Y-Axis Max Value**.

   Only numeric characters are allowed for custom ranges. Custom labels and ranges are not persisted in shared queries (MQL).

5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.

   **Advanced Mode** is located on the right, under the chart.

   Use Advanced Mode to edit your query using MQL syntax to aggregate results by group. The MQL syntax also supports additional parameter values. For more information about query parameters in Basic Mode and Advanced Mode, see Monitoring Query Language (MQL) Reference on page 2741.

6. To create another query, click **Add Query** below the chart.

### To create an alarm

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.

2. Click **Create alarm**.

   **Note:**
   
   You can also create an alarm from a predefined query on the **Service Metrics** page. Expand **Options** and click **Create an Alarm on this Query**. For more information about service metrics, see Viewing Default Metric Charts on page 2671.

3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:

   **Note:**
   
   To toggle between Basic Mode and Advanced Mode, click **Switch to Advanced Mode** or **Switch to Basic Mode** (to the right of **Define Alarm**).

**Basic Mode (default)**

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**:

  User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

**Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Rendering of the title</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric Name** (optional): The name of the metric. Only one metric can be specified. Example: `CpuUtilization`
  - **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  **Interval values**

  **Note:**

  Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour
  - **1d** - 1 day

  **Note:**

  For alarm queries, the specified `interval` has no effect on the `resolution` of the request. The only valid value of the resolution for an alarm...
query request is 1m. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  Statistic values
  - **COUNT**: The number of observations received in the specified time period.
  - **MAX**: The highest value observed during the specified time period.
  - **MEAN**: The value of Sum divided by Count during the specified time period.
  - **MIN**: The lowest value observed during the specified time period.
  - **P50**: The value of the 50th percentile.
  - **P90**: The value of the 90th percentile.
  - **P95**: The value of the 95th percentile.
  - **P99**: The value of the 99th percentile.
  - **P99.5**: The value of the 99.5th percentile.
  - **RATE**: The per-interval average rate of change.
  - **SUM**: All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  **Dimension fields**
  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

  **Note:**
  Long lists of dimensions are trimmed.
  - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
• To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

• **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.

• **Additional dimension**: Adds another name-value pair for a dimension.

• **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

• **Operator**: The operator used in the condition threshold.

  **Operator values**
  - greater than
  - greater than or equal to
  - equal to
  - less than
  - less than or equal to
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - absent

• **Value**: The value to use for the condition threshold.

• **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

**Advanced Mode**

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See [Monitoring Query Language (MQL) Reference](#) on page 2741.

• **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm. Avoid entering confidential information.

  **Rendering of the title by protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Rendering of the title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Subject line of the email message.</td>
</tr>
<tr>
<td>HTTPS (Custom URL)</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>PagerDuty</td>
<td>Title field of the published message.</td>
</tr>
<tr>
<td>Slack</td>
<td>Not rendered.</td>
</tr>
<tr>
<td>SMS</td>
<td>Not rendered.</td>
</tr>
</tbody>
</table>

• **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.

• **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

• **Tags (optional)**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

• **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.

  • **Compartment**: The *compartment* containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  
  • **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  
  • **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  
  • **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid alarm intervals depend on the frequency at which the metric is emitted. For example, a metric emitted every five minutes requires a 5-minute alarm interval or higher. Most metrics are emitted every minute, which means most metrics support any alarm interval. To determine valid alarm intervals for a given metric, check the relevant service's metric reference.</td>
</tr>
</tbody>
</table>

Example alarm query:

```plaintext
CpuUtilization[1m]
{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
```

For query syntax and examples, see Working with Metric Queries on page 2700.

• **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the Define alarm section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

- **Destinations**
  - **Destination Service**: The provider of the destination to use for notifications.
    - Available options:
      - **Notifications Service**.
  - **Compartment**: The *compartment* storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
  - **Topic**: The *topic* to use for notifications. Each topic supports a *subscription* protocol, such as PagerDuty.
  - **Create a topic**: Sets up a *topic* and *subscription* protocol in the selected compartment, using the specified destination service.
    - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team" for a topic used to notify operations staff of firing alarms. Avoid entering confidential information.
    - **Topic Description**: Description of the new topic.
    - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:
      - **Email subscription**
        - Sends an email message when you publish a *message* to the subscription's parent *topic*.
        - Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.
        - Some message types allow friendly formatting.
          - **Subscription Protocol**: Select Email.
          - **Subscription Email**: Type an email address.
      - **HTTPS (Custom URL) subscription**
        - Sends specified information when you publish a *message* to the subscription's parent *topic*.
        - Endpoint format (URL using HTTPS protocol):
          ```
          https://<anyvalidURL>
          ```
        - Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The
username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select HTTPS (Custom URL).
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

**PagerDuty subscription**

Creates a PagerDuty incident by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select PagerDuty.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

**Slack subscription**

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Message contents and appearance vary by message type. See alarm messages, event messages, and service connector messages.

Sends a message to the specified Slack channel by default when you publish a *message* to the subscription's parent *topic*.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The `<webhook-token>` portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select Slack.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

**SMS subscription**

Sends a text message using Short Message Service (SMS) to the specified phone number when you publish a *message* to the subscription's parent *topic*. Supported endpoint formats: E.164 format.

<table>

</table>

- **Additional destination service**: Adds another destination service and topic to use for notifications.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each alarm is limited to one destination per supported destination service.</td>
</tr>
</tbody>
</table>

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression Description**
  - **Start Time**
  - **End Time**

5. If you want to disable the new alarm, clear Enable This Alarm?.
6. Click Save alarm.

The new alarm is listed on the **Alarm Definitions** page.

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To create a query, use the SummarizeMetricsData operation.

To create an alarm, use the CreateAlarm operation.

### Resource Tags

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate them, report on them, or take bulk actions on them. **Tagging** allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

There are two types of tags:

- **Defined tags** are set up in your tenancy by an administrator. Only users granted permission to work with the defined tags can apply them to resources.

- **Free-form tags** can be applied by any user with permissions on the resource.

For more detailed information about tags and their features, see Tagging Overview on page 3906.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Watch a video to introduce you to the concepts and features of tagging: Introduction to Tagging.</td>
</tr>
</tbody>
</table>
Caution:
Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Working with Resource Tags

To bulk add defined tags
How to add multiple defined tags to existing resources. To apply defined tags, you must have permission to use the namespace.

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Tenancy Explorer.
2. Select the resources to which you want to add tags. Optionally, use the Filter by resource type drop-down menu to narrow the list of resources.
3. In the Actions menu, click Manage Tags.

The Manage Tags page opens. The first table displays the tags currently applied to the selected resources. The second table displays the selected resources.
4. Under the list of existing tags, click + Add New.
   a. Select the Tag Namespace.
   b. Select the Tag Key.
   c. For Value, enter a value.
5. To apply another tag, repeat the previous step. To remove a row, click the Remove (x) button.
6. When you have added all the desired tags, click Next.

A confirmation page opens that lists the actions to take and the resources that the actions apply to.
7. Click Submit.

The Work Request page launches to show you the status of the work request to add tags to the resources.

To add defined tags to one existing resource
To apply a defined tag, you must have permission to use the namespace.

1. Open the Console, go to the details page of the resource you want to tag.

For example, to tag a compute instance: Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances. A list of the instances in your current compartment is displayed. Find the instance that you want to tag, and click its name to view its details page.
2. Click Apply Tags. Depending on the resource, this option might appear in the More Actions menu.
3. In the Apply Tags to the Resource dialog:
   a. Select the Tag Namespace.
   b. Select the Tag Key.
   c. In Value, either enter a value or select one from the list.
   d. To apply another tag, click + Additional Tag.
   e. When finished adding tags, click Apply Tag(s).

To add a free-form tag to an existing resource

1. Open the Console, go to the details page of the resource you want to tag.

For example, to tag a compute instance: Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances. A list of the instances in your current compartment is displayed. Find the instance that you want to tag, and click its name to view its details page.
2. Click Apply Tags. Depending on the resource, this option might appear in the More Actions menu.
3. In the **Apply Tags to the Resource** dialog:
   a. Select *None* (apply a free-form tag).
   b. Enter the *Tag Key*.
   c. Enter a *Value*.
   d. To apply another tag, click **+ Additional Tag**.
   e. When finished adding tags, click **Apply Tag(s)**.

**To add a tag during resource creation**

You can apply tags during resource creation. The location of the **Apply Tag(s)** option in the dialog varies by resource. The general steps are:

1. In the resource Create dialog, click **Apply Tags**.
   
   On some resources, you have to click **Show Advanced Options** to apply a tag.

2. In the **Apply Tags to the Resource** dialog:
   a. Select the **Tag Namespace**, or select *None* to apply a free-form tag.
   b. Select or enter the **Tag Key**.
   c. In **Value**, either enter a value or select one from the list.
   d. To apply another tag, click **+ Additional Tag**.
   e. Click **Apply Tag(s)**.

**To filter a list of resources by a tag**

Open the Console, click the service name and then click the resource you want to view. The left side of the page shows all the filters currently applied to the list.

For example, to view compute instances: Click **Compute** and then click **Instances**, to see the list of instances in your current compartment.

**To filter a list of resources by a defined tag**

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
   a. **Namespace**: Select the tag namespace.
   b. **Key**: Select a specific key.
   c. **Value**: Select from the following:
      • **Match Any Value** - returns all resources tagged with the selected namespace and key, regardless of the tag value.
      • **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same namespace and key, click **+** to display another text box. Enter one value per text box.
   d. Click **Apply Filter**.

**To filter a list of resources by a free-form tag**

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
   a. **Key**: Enter the tag key.
   b. **Value**: Select from the following:
      - **Match Any Value** - returns all resources tagged with the selected free-form tag key, regardless of the tag value.
      - **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same key, click + to display another text box. Enter one value per text box.
   c. Click **Apply Filter**.

### To bulk update defined tags

How to update defined tags applied to one or more resources.

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tenancy Explorer**.
2. Select the resources whose tags you want to update. Optionally, use the **Filter by resource type** drop-down menu to narrow the list of resources.
3. In the **Actions** menu, click **Manage Tags**.
   
   The Manage Tags page opens. The first table displays the tags currently applied to the selected resources. The second table displays the selected resources.
4. In the list of tags, find the tag that you want to update and enter a new value. To revert the change, click the **Undo** button.
5. For **Action**, select **Apply tag to all selected resources**.
6. If desired, update more tag values. Then, click **Next**.
   
   A confirmation page opens that lists the actions to take and the resources that the actions apply to.
7. Click **Submit**.

The Work Request page launches to show you the status of the work request to update the tags on the resources.

### To update a tag applied to a single resource

1. Open the Console, click the service name, and then click the resource you want to view.
   
   For example, to view compute instances: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to update, and click its name to view its details page.
2. Click **Tags**.
   
   The list of tags applied to the resource is displayed.
3. Find the tag you want to update and click the pencil icon next to it.
4. Enter or select a new value.
5. Click **Save**.

### To bulk remove defined tags

How to remove multiple defined tags from resources.

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tenancy Explorer**.
2. Select the resources from which you want to remove tags. Optionally, use the **Filter by resource type** drop-down menu to narrow the list of resources.
3. In the **Actions** menu, click **Manage Tags**.
   
   The Manage Tags page opens. The first table displays the tags currently applied to the selected resources. The second table displays the selected resources.
4. In the list of tags, find the tag that you want to remove. For Action, select **Remove tag from all selected resources**.

5. To remove another tag, repeat the previous step.

6. Click **Next**.

   A confirmation page opens that lists the actions to take and the resources that the actions apply to.

7. Click **Submit**.

The Work Request page launches to show you the status of the work request to remove tags from the resources.

**To remove a tag from a single resource**

1. Open the Console, click the service name and then click the resource you want to view.

   For example, to view a compute instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to remove the tag from, and click its name to view its details page.

2. Click **Tags**.

   The list of tags applied to the resource is displayed.

3. Find the tag you want to remove and click the pencil icon next to it.

4. Click **Remove Tag**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

- To apply a tag to an individual resource using the API, use the appropriate resource's `create` or `update` operation.
- `BulkEditTags` - adds, updates, and removes multiple tag key definitions on the selected resources
- `ListBulkEditTagsResourceTypes` - lists the resource types that support bulk tag editing

**Service Limits**

This topic describes the service limits for Oracle Cloud Infrastructure and the process for requesting a service limit increase.

**About Service Limits and Usage**

When you sign up for Oracle Cloud Infrastructure, a set of service limits is configured for your tenancy. The service limit is the quota or allowance set on a resource. For example, your tenancy is allowed a maximum number of compute instances per availability domain. These limits are generally established with your Oracle sales representative when you purchase Oracle Cloud Infrastructure. If you did not establish limits with your Oracle sales representative, or, if you signed up through the Oracle Store, default or trial limits are set for your tenancy. These limits may be increased for you automatically based on your Oracle Cloud Infrastructure resource usage and account standing. You can also request a service limit increase.

**Compartment Quotas**

Compartment quotas are similar to service limits; the biggest difference is that service limits are set by Oracle, and compartment quotas are set by administrators, using policies that allow them to allocate resources with a high level of flexibility. Compartment quotas are set using `policy statements` written in a simple declarative language that is similar to the IAM policy language.

To learn more, see **Compartment Quotas** on page 243.
Viewing Your Service Limits, Quotas, and Usage

You can view your tenancy's limits, quotas, and usage in the Console. Be aware that:

- The Console might not yet display limits and usage information for all of the Oracle Cloud Infrastructure services or resources.
- The usage level listed for a given resource type could be greater than the limit if the limit was reduced after the resources were created.
- If all the resource limits are listed as 0, this means your account has been suspended. For help, contact Oracle Support.

If you don't yet have a tenancy or a user login for the Console, or if you don't find a particular limit listed in the Console, see Limits by Service on page 218 for the default tenancy limits.

Service Limits API Policy

For the resource availability API (usage) the policy can be at the tenant or compartment level:

Allow group LimitsAndUsageViewers to read resource-availability in tenancy
Allow group LimitsAndUsageViewers to read resource-availability in compartment A

For limit definitions, services, and values APIs (only at the tenant level):

Allow group LimitsAndUsageViewers to inspect resource-availability in tenancy

For limit values APIs (does not include definitions or services), the following policy is also supported:

Allow group LimitsAndUsageViewers to inspect limits in tenancy

To view your tenancy's limits and usage (by region)

Note:

Required Permission

If you're in the Administrators group, you have permission to view the limits and usage. If you're not, here's an example IAM policy that grants the required permission to users in a group called LimitsAndUsageViewers:

Allow group LimitsAndUsageViewers to inspect resource-availability in tenancy

READ resource-availability is required to obtain the resource availability. There are four APIs:

- listServices
- listLimitDefinitions
- listLimitValues
- getResourceAvailability

listServices, listLimitDefinitions, and listLimitValues all require INSPECT at the tenancy level, while
getResourceAvailability requires READ at the compartment level to be able to read the data.

**Note:**
The Console may not display limits and usage information yet for all Oracle Cloud Infrastructure services or resources.

1. Open the Console. Open the navigation menu. Under Governance and Administration, go to Governance and click Limits, Quotas and Usage.

Your resource limits, quotas, and usage for the specific region are displayed, broken out by service. You can use the filter drop-down lists at the top of the list to filter by service, scope, resource, and compartment.

### When You Reach a Service Limit

When you reach the service limit for a resource, you receive an error when you try to create a new resource of that type. You are then prompted to submit a request to increase your limit. You cannot create a new resource until you are granted an increase to your service limit or you terminate an existing resource. Note that service limits apply to a specific scope, and when the service limit in one scope is reached you may still have resources available to you in other scopes (for example, other availability domains).

### Requesting a Service Limit Increase

**Note:**
Government Cloud customers can’t use the procedure here to request a service limit increase. Instead, see Requesting a Service Limit Increase for Government Cloud Tenancies on page 154.

You can submit a request to increase your service limits from within the Console. If you try to create a resource for which limit has been met, you'll be prompted to submit a limit increase request. Additionally, you can launch the request from the service limits page or at any time by clicking the link under the Help menu ( )

This procedure applies to requests for service limit increases. For details about the subscribed region limit and how to request an increase to that limit, see Subscribed Region Limits on page 183.

### To request a service limit increase

1. Open the Help menu ( ), go to Support and click Request service limit increase.
2. Enter the following:
   - **Primary Contact Details:** Enter the name and email address of the person making the request. Enter one email address only. A confirmation will be sent to this address.
   - **Service Category:** Select the appropriate category for your request.
   - **Resource:** Select the appropriate resource.
     - Depending on your selection for resource, additional fields might display for more specific information.
   - **Reason for Request:** Enter a reason for your request. If your request is urgent or unusual, please provide details here.
3. Click Create Request.

After you submit the request, it is processed. A response can take anywhere from a few minutes to a few days. If your request is granted, a confirmation email is sent to the address provided in the primary contact details.

If we need additional information about your request, a follow-up email is sent to the address provided in the primary contact details.
Limits by Service
The following tables list the default limits for each service. Note the scope that each limit applies to (for example, per availability domain, per region, per tenant, etc.).

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Some services have additional limits. For more information, see the overview of each service.</td>
</tr>
</tbody>
</table>

### Analytics Cloud Limits
For Analytics Cloud limits, see Service Limits.

### API Gateway Limits
Limits apply to each tenancy.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>
<td>API gateways per region</td>
<td>10</td>
<td>5</td>
</tr>
<tr>
<td>API resources per region</td>
<td>100</td>
<td>100</td>
</tr>
<tr>
<td>API description length</td>
<td>1 MB</td>
<td>1 MB</td>
</tr>
<tr>
<td>Certificates per region</td>
<td>10</td>
<td>10</td>
</tr>
</tbody>
</table>

### Application Migration Limits
For Application Migration limits, see Service Limits.

### Big Data Limits
For Big Data limits, see Service Limits.

### Block Volume Limits
Volume limits apply to each availability domain. Volume backup limits apply to each region.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Volumes aggregated size</td>
<td>100 TB</td>
<td>30 TB</td>
</tr>
<tr>
<td>Backups</td>
<td>100,000</td>
<td>100,000</td>
</tr>
</tbody>
</table>

### Blockchain Platform Limits
For Blockchain Platform limits, see Service Limits.

### Cloud Guard Limits
Cloud Guard limits are regional.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detector Recipe Count</td>
<td>25</td>
<td>Contact Us</td>
</tr>
</tbody>
</table>
### Service Essentials

<table>
<thead>
<tr>

<td>180</td>
<td>Contact Us</td>
</tr>
<tr>
<td>Total OCPUs (cores) for DVH.Standard2.52 shapes</td>
<td>52</td>
<td>Contact Us</td>
</tr>
</tbody>
</table>

**Note:**
Compute limits used to apply at the individual shape level. These limits have been deprecated. Although you can continue to use the deprecated shape-based limits, the limits are converted to the equivalent OCPU-based (core-based) values.

**Other Compute Resources**

Limits apply to different scopes, depending on the resource.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Scope</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>

<tr>
<td>VM.Standard2 Core</td>
<td>800</td>
<td>60</td>
</tr>
<tr>
<td>VM.Standard E2 Core</td>
<td>200</td>
<td>40</td>
</tr>
</tbody>
</table>

Data Transfer Limits

Data Transfer limits are regional.
Disk-Based Data Import

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-As-You-Go</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transfer package</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>

File a service request at My Oracle Support to increase the service limits for Disk-Based Data Import. See Requesting a Service Limit Increase on page 217 for details.

Appliance-Based Data Import and Data Export

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-As-You-Go</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transfer appliances</td>
<td>2, Request Entitlement</td>
<td>Contact Your CSM</td>
</tr>
</tbody>
</table>

To place an order for the Oracle-provided Data Transfer Appliance used for appliance-based data transfer and data export jobs, request the required entitlement for your tenancy through the Console or CLI. See Requesting Appliance Entitlement on page 1024 for instructions.

The buyer of your tenancy will be required to e-sign a Terms and Conditions document. After Oracle receives the signed document you will have the entitlement to request and use the Data Transfer Appliance. Appliance-Based Data Import and Data Export each come with a service limit of 2. File a service request if you need to increase that number.

Database Limits

Database limits are per availability domain.

See Data Safe Limits on page 221 for information on Data Safe. See MySQL Database Limits on page 226 for information on MySQL Database.

<table>
<thead>
<tr>

</tbody>
</table>

**Note:**

- **Total VM DB Block Storage**: Includes block storage for all VM.Standard1 and VM.Standard2 virtual machine databases.
- **BM.DenseIO1.36**: This DB system shape is available only to monthly universal credit customers with tenancies existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- **Always Free Autonomous Database**: Each of the two Always Free Autonomous Databases available in your tenancy can be provisioned with your choice of Autonomous Transaction Processing or Autonomous Data Warehouse workload types.

**Digital Assistant Limits**

For Digital Assistant limits, see Service Limits.
DNS Limits
DNS limits are global.

<table>
<thead>
<tr>
<th>Resources</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-as-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zones</td>
<td>1,000 zones</td>
<td>1,000 zones</td>
</tr>
<tr>
<td>Records</td>
<td>25,000 per zone</td>

</tbody>
</table>

Email Delivery Limits
Limits apply to each tenant or availability domain on a per-region basis, as specified.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Monthly or Annual Universal Credits</th>
<th>Pay-As-You-Go or Promo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email volume</td>
<td>50,000 unique recipients among all emails sent per day</td>
<td>200 unique recipients among all emails sent per day</td>
</tr>
<tr>
<td>Maximum approved senders</td>
<td>10,000</td>
<td>2,000</td>
</tr>
<tr>
<td>SMTP credentials</td>
<td>2 per user</td>
<td>2 per user</td>
</tr>
<tr>
<td>Sending rate</td>
<td>18,000 emails per minute</td>
<td>10 emails per minute</td>
</tr>
</tbody>
</table>

Note:
The email volume limit applies to unique recipients among all emails sent. For example, a single email sent to 100 recipients would count the same as 100 individual emails each sent to a single recipient.

Note:
Email Delivery supports messages up to 2 MB, inclusive of message headers, body, and attachments. Customers can request this limit to be increased based on their requirement. The maximum size that can be requested is 60 MB.

Events Limits
Events limits are regional.

<table>

<td>Not applicable</td>
<td>Not available</td>
</tr>
<tr>
<td>ESXi hosts</td>
<td>Region</td>
<td>52 cores per host</td>
<td>Not available</td>
</tr>
</tbody>
</table>

**WAF Limits**

WAF limits are global.
### Service Logs

You can enable service logs for some resources. Service logs provide diagnostic information about the resources in your tenancy. When you enable logging on resources, you receive information about the resource in a log file. This information allows you to analyze, optimize, and troubleshoot your resources.

#### Working with Service Logs

Not all resources support Logging. See Supported Services for the list of services with resources that produce logs.

To enable logs on a resource, you must have permission to update the resource and permission to create the log in the log group. See Required Permissions for Working with Logs and Log Groups, and Enabling Logging for a Resource on page 2591.

For more information about Logging, see Overview of the Logging Service.

#### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To enable logging for a resource using the API, use the appropriate resource's create or update operation.

- Logging Management API
- Logging Ingestion API
- Logging Search API

#### Viewing All Resources in a Compartment

This topic describes how you can use the tenancy explorer to get a cross-region view of all resources in a compartment.

#### Tenancy Explorer Highlights

- The tenancy explorer lets you view all your resources in a compartment, across all regions in your tenancy.
- You can choose to view just the resources that reside in the selected compartment, or you can choose to view all the resources in all the subcompartments as well, to get a full view of the compartment tree.
- You can take actions on resources from the tenancy explorer. You can delete or move a single or multiple resources at a time. The tenancy explorer is a convenient option when you need to perform bulk delete or move actions on multiple resources.

The following image highlights these features:
When using the tenancy explorer, be aware of the following:

- If you recently created a resource, it might not show up in the tenancy explorer immediately. Similarly, if you recently updated a resource, your changes might not immediately appear.
- You must be in the same region as the resource to navigate to its details page. The tenancy explorer displays the resource's region. Use the region selector at the top of the Console to change to the same region as the resource to enable these actions.
- When taking bulk actions, you can monitor progress on the Work Requests page.

**Work Requests**

Tenancy explorer is one of the Oracle Cloud Infrastructure features that is integrated with the Work Requests API. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests in the user guide, and the Work Requests API.

**Resources Supported by the Tenancy Explorer**

The tenancy explorer is powered by the Search service and supports the same resource types. Most resources are supported.

**Supported resources**

### Required IAM Policy to Work with Resources in the Tenancy Explorer

The resources that you see in the tenancy explorer depend on the permissions you have in place for the resource type.

You do not necessarily see results for everything in the compartment. For example, if your user account is not associated with a policy that grants you the ability to, at a minimum, inspect the instance resource type, then you can't view instances in the tenancy explorer. For more information about policies, see How Policies Work on page 2136. For information about the permissions required for the list API operation for a specific resource type, see the Policy Reference on page 2167 for the appropriate service.

### Required Permissions to View Work Requests

Work requests inherit the permissions of the operation that spawns the work request. So if you have the permissions to move or delete a resource, you also have permission to see the work requests associated with this action.

To enable users to list all work requests in a tenancy, use a policy like the following:

`Allow group <My_Group> to inspect work-requests in tenancy`

### Navigating to the Tenancy Explorer and Viewing Resources

Open the navigation menu. Under Governance and Administration, go to Governance and click Tenancy Explorer.
The tenancy explorer opens with a view of the root compartment. Select the compartment you want to explore from the compartment picker on the left side of the Console. After you select a compartment, the resources that you have permission to view are displayed. The **Name** and **Description** of the compartment you are viewing are displayed at the top of the page. To also list all resources in the subcompartments of the selected compartment, select **Show resources in subcompartments**. When viewing resources in all subcompartments, it is helpful to use the **Compartment** column in the results list to see the compartment hierarchy where the resource resides.

**Filtering Displayed Resources**

To view only specific resource types, select the resource types you are interested in from the **Filter by resource type** menu. You can select multiple resources to include in the filtered list. You can also filter the list by tags.

**Opening the Resource Details Page**

Detail page navigation is not supported for all resource types. If detail page navigation is not supported, the resource name does not display as a link and the option is grayed out on the Actions menu.

To open the details page for a resource:

1. Locate the resource in the list.
2. Verify that you are in the same region as the resource. The resource's region is listed in the tenancy explorer results. If it is not the same as the region you are currently in (shown at the top of the Console), then select the appropriate region from the **Regions** menu.
3. To open the details page, you can either:
   - Click the name.
   - Click the the Actions icon (three dots) and select **View Details**.

**Moving Resources to a Different Compartment**

Not all resource-types can be moved to a different compartment. If the resource cannot be moved, the option is not selectable on the Actions menu. You must have the appropriate permissions for the resources you want to move in both the original and destination compartments.

**Important:**

Ensure that you understand the impact of moving a resource before you perform this action. See the resource's service documentation for details.

**To move a single resource to a different compartment**

1. Locate the resource in the list.
2. Click the the Actions icon (three dots) and select **Move Resource**.
3. In the dialog, choose the destination compartment from the list.
4. Click **Move Resource**.

**To move multiple resources to a different compartment**

To move multiple resources, the resources must be in the same compartment.

1. Locate and select the resources in the list.
2. Click **Move Selected**.
3. In the dialog, choose the destination compartment from the list.
4. Click **Move Resource**.

The Work Request page launches to show you the status of the work request to move the resources.
Deleting Resources

Not all resource-types can be deleted using the tenancy explorer. If delete is not supported, the option is not selectable on the Actions menu.

Also, if a resource is in use by another resource, you can't delete it. For example, to delete a VCN, it must first be empty and have no related resources or attached gateways.

To delete a single resource

1. Locate the resource in the list.
2. Click the Actions icon (three dots) and select Delete.
3. In the confirmation dialog, click Delete.
4. You are taken to the details page for the deleted resource.

To delete multiple resources

To delete multiple resources, the resources must be in the same compartment.

1. Locate and select the resources in the list.
2. Click Delete Selected.
3. In the confirmation dialog, click Delete.

The Work Request page launches to show you the status of the work request to move the resources.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to move or delete multiple resources at once:

- ListBulkActionResourceTypes - use this API to help you provide the correct resource-type information to the BulkDeleteResources and BulkMoveResources operations. The returned list of resource-types provides the appropriate resource-type name to use as input and the required identifying information for each resource-type. Most resource-types only require the OCID to identity a specific resource, but some resources, such as buckets, require you to provide other identifying information.
- BulkDeleteResources
- BulkMoveResources

Compartment Quotas

This topic describes compartment quotas for Oracle Cloud Infrastructure.

Compartment quotas give tenant and compartment administrators better control over how resources are consumed in Oracle Cloud Infrastructure, enabling administrators to easily allocate resources to compartments using the Console. Along with compartment budgets, compartment quotas create a powerful toolset to manage your spending in Oracle Cloud Infrastructure tenancies.

You can start using compartment quotas from any compartment detail page in the Console.

About Compartment Quotas

Compartment quotas are similar to Service Limits on page 215. The biggest difference is that service limits are set by Oracle, and compartment quotas are set by administrators, using policies that allow them to allocate resources with a high level of flexibility.

Compartment quotas are set using policy statements written in a simple declarative language that is similar to the IAM policy language.
There are three types of quota policy statements:

- **set** - sets the maximum number of a cloud resource that can be used for a compartment
- **unset** - resets quotas back to the default service limits
- **zero** - removes access to a cloud resource for a compartment

The quota policy statements look like this:

```
<table>
<thead>
<tr>
<th>Set statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set family quota name to value in location conditions</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unset statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unset family quota name in location conditions</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Zero statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero family quota name in location conditions</td>
</tr>
</tbody>
</table>
```

The language components for a quota policy statement are:

- The **action** keyword, which corresponds to the type of quota being defined. This can be set, unset, or zero.
- The name of the service family; for example: compute-core.
- The **quota** or **quotas** keyword.
- The name of the quota, which varies by service family. For example, a valid quota in the compute-core family is standard2-core-count.
  - You can also use wildcards to specify a range of names. For example, "/standard*/" matches all Compute quotas that start with the phrase "standard."
- For set statements, the value of the quota.
- The compartment that the quota covers.
- An optional condition. For example where request.region = 'us-phoenix-1'. Currently supported conditionals are request.region and request.ad.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize users, see Common Policies on page 2142. To manage quotas in a compartment, you must belong to a group that has the correct permissions. For example:

```
allow group QuotaAdmins to { QUOTA_READ, QUOTA_CREATE, QUOTA_DELETE, QUOTA_UPDATE, QUOTA_INSPECT } in tenancy
```

For in-depth information on granting users permissions for the Quotas service, see Details for the Quotas Service in the IAM policy reference.
Permissions and Nesting

Compartment quotas can be set on the root compartment. An administrator (who must be able to manage quotas on the root compartment) can set quotas on their own compartments and any child compartments. Quotas set on a parent compartment override quotas set on child compartments. This way, an administrator of a parent compartment can create a quota on a child compartment that cannot be overridden by the child.

Scope

Quotas can have different scopes, and work at the availability domain, the region, or globally. There are a few important things to understand about scope when working with compartment quotas:

- When setting a quota at the availability domain (AD) level, the quota is allocated to each AD. So, for example, setting a quota of 120 X7 OCPUs on a compartment actually sets a limit of 120 OCPUs per AD. To target a specific AD, use the request.ad parameter in the where clause.
- Regional quotas apply to each region. For example, if a quota of 10 functions is set on a compartment, 10 functions will be allocated per region. To target a specific region, use the request.region parameter in the where clause.
- Usage for sub-compartment counts towards usage for the main compartment.

For more information, see Regions and Availability Domains on page 180.

Quota Evaluation and Precedence

The following rules apply when quota statements are evaluated:

- Within a policy, quota statements are evaluated in order, and later statements supersede previous statements that target the same resource.
- In cases where more than one policy is set for the same resource, the most restrictive policy is applied.
- Service limits always take precedence over quotas. Although it is possible to specify a quota for a resource that exceeds the service limit for that resource, the service limit will still be enforced.

Usage Examples

The following example sets the quota for VM.Standard2 and BM.Standard2 compute series to 240 OCPUs (cores) in each AD on compartment MyCompartment in the US West (Phoenix) region:

```bash
set compute-core quota standard2-core-count to 240 in compartment MyCompartment
where request.region = us-phoenix-1
```

The next example shows how to make an allowlist, setting every quota in a family to zero and then explicitly allocating resources:

```bash
zero compute-core quotas in tenancy
set compute-core quota standard2-core-count to 240 in tenancy
```

This example shows how to limit creating dense I/O compute resources to only one region:

```bash
zero compute-core quotas / *dense-io*/ in tenancy
set compute-core quota / *dense-io*/ to 48 in tenancy
where request.region = us-phoenix-1
```

You can clear quotas by using an unset statement, which removes the quota for a resource - any limits on this resource will now be enforced by the service limits:

```bash
zero compute-core quotas in tenancy
unset compute-core quota standard2-core-count in tenancy
```

Using the Console

To create a quota

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Quota Policies.
2. On the Quota Policies screen, click Create Quota.
3. Enter the following:
   - Enter a name for your quota in the **Name** field. Avoid entering confidential information.
   - Enter a description for your quota in the **Description** field.
   - Enter a quota policy string in the **Quota Policy** field.

4. Click **Create Quota Policy**.

   **Note:**
   New policies can take up to 10 minutes to start working.

**To edit a quota**

1. On the **Quota Policies** screen, click the quota you want to edit to display the quota policy details page, then click the **Edit Quota** button.
2. Edit the quota.
3. Click **Save Changes**.

**To delete a quota**

1. There are two ways to delete a quota from the console:
   - On the main **Quota Policies** page, click the context menu to the right of the quota you want to delete, then select **Delete**.
   - Click the quota you want to delete, then from the quota policy detail page click **Delete**.
2. From the **Confirm Delete** dialog, click **Delete** or **Cancel**.

**Available Quotas by Service**

**Analytics Cloud**

For Analytics Cloud quotas and examples, see **Service Quotas**.

**Big Data**

For Big Data quotas and examples, see **Service Quotas**.

**Block Volume Quotas**

Family name: `block-storage`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backup-count</td>
<td>Regional</td>
<td>Total number of block and boot volume backups</td>
</tr>
<tr>
<td>total-storage-gb</td>
<td>Availability domain</td>
<td>Maximum storage space of block and boot volumes, in GB</td>
</tr>
<tr>
<td>volume-count</td>
<td>Availability domain</td>
<td>Total number of block and boot volumes</td>
</tr>
</tbody>
</table>

**Example**

```bash
set block-storage quota volume-count to 10 in compartment MyCompartment
```

**Blockchain Platform Quotas**

For Blockchain Platform quotas and examples, see **Service Quotas**.
Compute Quotas

Compute Instances

Quotas for Compute instances are available per core (OCPU) and per shape.

Core-Based Quotas

Family name: compute-core

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standard1-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard1 and BM.Standard1 series</td>
</tr>
<tr>
<td>standard-b1-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard.B1 and BM.Standard.B1 series</td>
</tr>
<tr>
<td>standard2-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard2 and BM.Standard2 series</td>
</tr>
<tr>
<td>standard-e2-micro-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard.E2.1.Micro series</td>
</tr>
<tr>
<td>standard-e2-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard.E2 and BM.Standard.E2 series</td>
</tr>
<tr>
<td>standard-e3-core-ad-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.Standard.E3 and BM.Standard.E3 series</td>
</tr>
<tr>
<td>dense-io1-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.DenseIO1 and BM.DenseIO1 series</td>
</tr>
<tr>
<td>dense-io2-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the VM.DenseIO2 and BM.DenseIO2 series</td>
</tr>
<tr>
<td>gpu2-count</td>
<td>Availability</td>
<td>Total number of GPUs for shapes in the VM.GPU2 and BM.GPU2 series</td>
</tr>
<tr>
<td>gpu3-count</td>
<td>Availability</td>
<td>Total number of GPUs for shapes in the VM.GPU3 and BM.GPU3 series</td>
</tr>
<tr>
<td>gpu4-count</td>
<td>Availability</td>
<td>Total number of GPUs for shapes in the BM.GPU4 series</td>
</tr>
<tr>
<td>hpc2-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for shapes in the BM.HPC2 series</td>
</tr>
<tr>
<td>dvh-standard2-core-count</td>
<td>Availability</td>
<td>Total number of OCPUs for DVH.Standard2.52 shapes</td>
</tr>
</tbody>
</table>

Example

```
set compute-core quota standard2-core-count to 480 in compartment MyCompartment
```

Shape-Based Quotas

Family name: compute
<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bm-standard1-36-count</td>
<td>Availability domain</td>
<td>Number of BM.Standard1.36 instances</td>
</tr>
<tr>
<td>bm-standard-b1-44-count</td>
<td>Availability domain</td>
<td>Number of BM.Standard.B1.44 instances</td>
</tr>
<tr>
<td>bm-standard2-52-count</td>
<td>Availability domain</td>
<td>Number of BM.Standard2.52 instances</td>
</tr>
<tr>
<td>bm-standard-e2-64-count</td>
<td>Availability domain</td>
<td>Number of BM.Standard.E2.64 instances</td>
</tr>
<tr>
<td>bm-dense-io1-36-count</td>
<td>Availability domain</td>
<td>Number of BM.DenseIO1.36 instances</td>
</tr>
<tr>
<td>bm-dense-io2-52-count</td>
<td>Availability domain</td>
<td>Number of BM.DenseIO2.52 instances</td>
</tr>
<tr>
<td>bm-gpu2-2-count</td>
<td>Availability domain</td>
<td>Number of BM.GPU2.2 instances</td>
</tr>
<tr>
<td>bm-gpu3-8-count</td>
<td>Availability domain</td>
<td>Number of BM.GPU3.8 instances</td>
</tr>
<tr>
<td>bm-hpc2-36-count</td>
<td>Availability domain</td>
<td>Number of BM.HPC2.36 instances</td>
</tr>
<tr>
<td>vm-standard1-1-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.1 instances</td>
</tr>
<tr>
<td>vm-standard1-2-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.2 instances</td>
</tr>
<tr>
<td>vm-standard1-4-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.4 instances</td>
</tr>
<tr>
<td>vm-standard1-8-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.8 instances</td>
</tr>
<tr>
<td>vm-standard1-16-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.16 instances</td>
</tr>
<tr>
<td>vm-standard2-1-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.1 instances</td>
</tr>
<tr>
<td>vm-standard2-2-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.2 instances</td>
</tr>
<tr>
<td>vm-standard2-4-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.4 instances</td>
</tr>
<tr>
<td>vm-standard2-8-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.8 instances</td>
</tr>
<tr>
<td>vm-standard2-16-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.16 instances</td>
</tr>
<tr>
<td>vm-standard2-24-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.24 instances</td>
</tr>
<tr>
<td>vm-standard-e2-1-micro-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard.E2.1.Micro instances</td>
</tr>
<tr>
<td>Name</td>
<td>Scope</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>vm-standard-e2-1-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard.E2.1 instances</td>
</tr>
<tr>
<td>vm-standard-e2-2-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard.E2.2 instances</td>
</tr>
<tr>
<td>vm-standard-e2-4-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard.E2.4 instances</td>
</tr>
<tr>
<td>vm-standard-e2-8-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard.E2.8 instances</td>
</tr>
<tr>
<td>standard-e3-core-ad-count</td>
<td>Availability domain</td>
<td>Total number of OCPUs for shapes in the VM.Standard.E3 and BM.Standard.E3 series</td>
</tr>
<tr>
<td>vm-dense-io1-4-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO1.4 instances</td>
</tr>
<tr>
<td>vm-dense-io1-8-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO1.8 instances</td>
</tr>
<tr>
<td>vm-dense-io1-16-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO1.16 instances</td>
</tr>
<tr>
<td>vm-dense-io2-8-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO2.8 instances</td>
</tr>
<tr>
<td>vm-dense-io2-16-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO2.16 instances</td>
</tr>
<tr>
<td>vm-dense-io2-24-count</td>
<td>Availability domain</td>
<td>Number of VM.DenseIO2.24 instances</td>
</tr>
<tr>
<td>vm-gpu2-1-count</td>
<td>Availability domain</td>
<td>Number of VM.GPU2.1 instances</td>
</tr>
<tr>
<td>vm-gpu3-1-count</td>
<td>Availability domain</td>
<td>Number of VM.GPU3.1 instances</td>
</tr>
<tr>
<td>vm-gpu3-2-count</td>
<td>Availability domain</td>
<td>Number of VM.GPU3.2 instances</td>
</tr>
<tr>
<td>vm-gpu3-4-count</td>
<td>Availability domain</td>
<td>Number of VM.GPU3.4 instances</td>
</tr>
<tr>
<td>dvh-standard2-52-count</td>
<td>Availability domain</td>
<td>Number of DVH.Standard2.52 instances</td>
</tr>
</tbody>
</table>

**Example**

```plaintext
set compute quota vm-dense-io2-8-count to 10 in compartment MyCompartment where request.ad = 'us-phoenix-1-ad-2'
```

**Custom Images**

Family name: `compute`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>custom-image-count</td>
<td>Regional</td>
<td>Number of custom images</td>
</tr>
</tbody>
</table>
Example

```
set compute quota custom-image-count to 15 in compartment MyCompartment
```

**Instance Configurations, Instance Pools, and Cluster Networks**

Family name: `compute-management`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster-network-count</td>
<td>Regional</td>
<td>Number of cluster networks</td>
</tr>
<tr>
<td>config-count</td>
<td>Regional</td>
<td>Number of instance configurations</td>
</tr>
<tr>
<td>pool-count</td>
<td>Regional</td>
<td>Number of instance pools</td>
</tr>
</tbody>
</table>

Example

```
set compute-management quota config-count to 10 in compartment MyCompartment
```

**Autoscaling**

Family name: `auto-scaling`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config-count</td>
<td>Regional</td>
<td>Number of autoscaling configurations</td>
</tr>
</tbody>
</table>

Example

```
Set auto-scaling quota config-count to 10 in compartment MyCompartment
```

**Content and Experience Quotas**

For Content and Experience quotas and examples, see [Service Quotas](#).

**Data Catalog Quotas**

Family name: `data-catalog`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalog-count</td>
<td>Regional</td>
<td>Number of data catalogs</td>
</tr>
</tbody>
</table>

Example

```
set data-catalog quota catalog-count to 1 in compartment <MyCompartment>
```

**Data Integration Quotas**

Family name: `dataintegration`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workspace-count</td>
<td>Regional</td>
<td>Number of workspaces</td>
</tr>
</tbody>
</table>

Example

```
set dataintegration quota workspace-count to 1 in compartment <MyCompartment>
```
Example

```
set dataintegration quota workspace-count to 10 in compartment <compartment_name>
```

### Data Science Quotas

Family name: data-science

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ds-block-volume-count</td>
<td>Regional</td>
<td>Number of block volumes</td>
</tr>
<tr>
<td>ds-block-volume-gb</td>
<td>Regional</td>
<td>Block Volume Size in GB</td>
</tr>
<tr>
<td>ds-gpu2-count</td>
<td>Regional</td>
<td>GPUs for VM.GPU2</td>
</tr>
<tr>
<td>ds-gpu3-count</td>
<td>Regional</td>
<td>GPUs for VM.GPU3</td>
</tr>
<tr>
<td>ds-standard2-core-regional-count</td>
<td>Regional</td>
<td>Number of VM.Standard2 cores</td>
</tr>
<tr>
<td>ds-standard-e2-core-regional-count</td>
<td>Regional</td>
<td>Number of VM.Standard E2 cores</td>
</tr>
<tr>
<td>model-count</td>
<td>Regional</td>
<td>Number of models</td>
</tr>
<tr>
<td>notebook-session-count</td>
<td>Regional</td>
<td>Number of notebook sessions</td>
</tr>
<tr>
<td>project-count</td>
<td>Regional</td>
<td>Number of projects</td>
</tr>
</tbody>
</table>

**Example**

The following example shows how to limit the number of data science projects in a specified compartment:

```
set data-science quota project-count to 10 in compartment MyCompartment
```

### Data Transfer Quotas

Family name: data-transfer

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active-appliance-count</td>
<td>Regional</td>
<td>Number of approved transfer appliances</td>
</tr>
<tr>
<td>appliance-count</td>
<td>Regional</td>
<td>Number of transfer appliances</td>
</tr>
<tr>
<td>job-count</td>
<td>Regional</td>
<td>Number of transfer jobs</td>
</tr>
</tbody>
</table>

**Example**

```
zero data-transfer quota job-count in tenancy
set data-transfer quota job-count to 1 in compartment Finance
set data-transfer quota appliance-count to 3 in compartment Finance
```
# Database Quotas

Family name: database

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adb-free-count</td>
<td>Regional</td>
<td>Number of Always Free Autonomous Databases. Tenancies can have a total of two Always Free Autonomous Databases, and these resources must be provisioned in the home region. For each database, you can choose the workload type (Autonomous Transaction Processing or Autonomous Data Warehouse).</td>
</tr>
<tr>
<td>adw-dedicated-ocpu-count</td>
<td>Availability domain</td>
<td>Number of Autonomous Data Warehouse OCPUs for databases using dedicated Exadata infrastructure. (See note about &quot;n/a&quot; values on the Limits, Quotas and Usage page of the Console.)</td>
</tr>
<tr>
<td>adw-dedicated-total-storage-tb</td>
<td>Availability domain</td>
<td>Amount of storage (in TB) for Autonomous Data Warehouse databases using dedicated Exadata infrastructure. (See note following this table about &quot;n/a&quot; values on the Limits, Quotas and Usage page of the Console.)</td>
</tr>
<tr>
<td>adw-ocpu-count</td>
<td>Regional</td>
<td>Number of Autonomous Data Warehouse OCPUs for databases using shared Exadata infrastructure.</td>
</tr>
<tr>
<td>adw-total-storage-tb</td>
<td>Regional</td>
<td>Amount of storage (in TB) for Autonomous Data Warehouse databases using shared Exadata infrastructure.</td>
</tr>
<tr>
<td>atp-dedicated-ocpu-count</td>
<td>Availability domain</td>
<td>Number of Autonomous Data Warehouse OCPUs for databases using dedicated Exadata infrastructure. (See note following this table about &quot;n/a&quot; values on the Limits, Quotas and Usage page of the Console.)</td>
</tr>
<tr>
<td>atp-dedicated-total-storage-tb</td>
<td>Availability domain</td>
<td>Amount of storage (in TB) for Autonomous Transaction Processing databases using dedicated Exadata infrastructure. (See note following this table about &quot;n/a&quot; values on the Limits, Quotas and Usage page of the Console.)</td>
</tr>
<tr>
<td>atp-ocpu-count</td>
<td>Regional</td>
<td>Number of Autonomous Transaction Processing OCPUs for databases using shared Exadata infrastructure.</td>
</tr>
<tr>
<td>atp-total-storage-tb</td>
<td>Regional</td>
<td>Amount of storage (in TB) for Autonomous Transaction Processing databases using shared Exadata infrastructure.</td>
</tr>
<tr>
<td>bm-dense-io1-36-count</td>
<td>Availability domain</td>
<td>Number of BM.DenseIO1.36 DB systems</td>
</tr>
<tr>
<td>bm-dense-io2-52-count</td>
<td>Availability domain</td>
<td>Number of BM.DenseIO2.52 DB systems</td>
</tr>
<tr>
<td>exadata-base-48-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Base.48 DB systems</td>
</tr>
<tr>
<td>exadata-full1-336-x6-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Full1.336 - X6 DB systems</td>
</tr>
<tr>
<td>exadata-full2-368-x7-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Full2.368 - X7 DB systems and Autonomous Exadata Infrastructure</td>
</tr>
<tr>
<td>exadata-half1-168-x6-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Half1.168 - X6 DB systems</td>
</tr>
<tr>
<td>Name</td>
<td>Scope</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>exadata-half2-184-x7-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Half2.184 - X7 DB systems and Autonomous Exadata Infrastructure</td>
</tr>
<tr>
<td>exadata-quarter1-84-x6-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Quarter1.84 - X6 DB systems</td>
</tr>
<tr>
<td>exadata-quarter2-92-x7-count</td>
<td>Availability domain</td>
<td>Number of Exadata.Quarter2.92 - X7 DB systems and Autonomous Exadata Infrastructure</td>
</tr>
<tr>
<td>vm-block-storage-gb</td>
<td>Availability domain</td>
<td>Total size of block storage attachments across all virtual machine DB systems, in GB</td>
</tr>
<tr>
<td>vm-standard1-ocpu-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard1.x OCPUs</td>
</tr>
<tr>
<td>vm-standard2-ocpu-count</td>
<td>Availability domain</td>
<td>Number of VM.Standard2.x OCPUs</td>
</tr>
</tbody>
</table>

**Note:**

When viewing the Limits, Quotas and Usage page of the Console, you will see the value "n/a" in the Service Limit column for storage and OCPU resources related to Autonomous Transaction Processing and Autonomous Data Warehouse with dedicated Exadata infrastructure. You might also see this value in the Available column for these resources. This is because limits for these resources are based on the capacity of your provisioned Exadata hardware, and are not service limits controlled by Oracle Cloud Infrastructure. If you define compartment quota policies for either of these resources, the Available column will display a value for the amount that is available to be allocated, based on your existing usage in the Exadata hardware.

For information about shapes that are not listed, including non-metered shapes, contact Oracle Support.

**Examples**

The following example shows how to limit the number of Autonomous Data Warehouse resources in a compartment:

```bash
#Limits the Autonomous Data Warehouse CPU core count to 2 in the MyCompartment compartment
set database quota adw-ocpu-count to 2 in compartment MyCompartment
```

This example shows how to set a quota for OCPU cores in an Autonomous Data Warehouse with dedicated Exadata infrastructure:

```bash
#Limits the number of Autonomous Data Warehouse dedicated Exadata infrastructure OCPUs to 20 in the MyCompartment compartment
set database quota adw-dedicated-ocpu-count to 20 in compartment MyCompartment
```

This example shows how to set a quota for Autonomous Exadata Infrastructure quarter rack resources in a compartment:

```bash
#Limits the usage of Exadata.Quarter2.92 X7 shapes to 1 in the MyCompartment compartment
```
To limit the number of virtual machine DB systems in a compartment, you must set a quota for the number of CPU cores and a separate quota for the block storage:

```sql
set database quota exadata-quarter2-92-x7-count to 1 in compartment MyCompartment
```

The following example shows how to prevent the usage of all database resources in the tenancy except for two Exadata full rack X7 resources in a specified compartment:

```sql
zero database quotas in tenancy
set database quota exadata-full2-368-x7-count to 2 in compartment MyCompartment
```

This example of nested quotas shows how to distribute limits for a resource type in a compartment among its subcompartments:

```sql
# Allows usage of 3 Autonomous Data Warehouse OCPUs in parent compartment Compartment1
set database quota adw-ocpu-count to 3 in compartment Compartment1

# Allows usage of 1 Autonomous Data Warehouse OCPU in child compartment Compartment1.1
set database quota adw-ocpu-count to 1 in compartment Compartment1.1

# Allows usage of 2 Autonomous Data Warehouse OCPUs in child compartment Compartment1.2
set database quota adw-ocpu-count to 2 in compartment Compartment1.2
```

**Digital Assistant Quotas**

For Digital Assistant quotas and examples, see Service Quotas.

**DNS Quotas**

Family name: dns

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>global-zone-count</td>
<td>Global</td>
<td>Number of public DNS zones</td>
</tr>
<tr>
<td>steering-policy-count</td>
<td>Global</td>
<td>Number of traffic management steering policies</td>
</tr>
<tr>
<td>steering-policy-attachment-count</td>
<td>Global</td>
<td>Number of traffic management steering policy attachments</td>
</tr>
</tbody>
</table>

**Example**

```sql
zero dns quotas in compartment MyCompartment
zero dns quota global-zone-count in compartment MyCompartment
zero dns quota steering-policy-count in compartment MyCompartment
```
Events Quotas

Family name: events

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule-count</td>
<td>Regional</td>
<td>Number of rules</td>
</tr>
</tbody>
</table>

Example

- Set events quota rule-count to 10 in compartment MyCompartment
- Zero events quota rule-count in compartment MyCompartment

Email Delivery Quotas

Family name: email-delivery

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>approved-sender-count</td>
<td>Regional</td>
<td>Number of approved senders</td>
</tr>
</tbody>
</table>

Example

- Zero email-delivery quota approved-sender-count in compartment MyCompartment

File Storage Quotas

Family name: filesystem

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mount-target-count</td>
<td>Availability domain</td>
<td>Number of mount targets</td>
</tr>
<tr>
<td>file-system-count</td>
<td>Availability domain</td>
<td>Number of file systems</td>
</tr>
</tbody>
</table>

Example

- Set filesystem quota file-system-count to 5 in compartment MyCompartment
- Zero filesystem quota file-system-count in compartment MyCompartment
- Set filesystem quota mount-target-count to 1 in compartment MyCompartment
- Zero filesystem quota mount-target-count in compartment MyCompartment

Management Agent Quotas

Family name: management-agent

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>management-agent-count</td>
<td>Regional</td>
<td>Number of management agents</td>
</tr>
</tbody>
</table>
Examples

The following example limits the number of management agents that users can install in MyCompartment to 200.

```
set management-agent quota management-agent-count to 200 in compartment MyCompartment
```

The following example limits the number of management agent install keys that users can create in MyCompartment to 10.

```
set management-agent quota management-agent-install-key-count to 10 in compartment MyCompartment
```

Networking Quotas

VCN Quotas

Family name: vcn

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vcn-count</td>
<td>Regional</td>
<td>Number of virtual cloud networks</td>
</tr>
<tr>
<td>reserved-public-ip-count</td>
<td>Regional</td>
<td>Number of reserved regional public IP addresses</td>
</tr>
</tbody>
</table>

Example

```
Set vcn quota vcn-count to 10 in compartment MyCompartment
```

NoSQL Database Cloud Quotas

For Oracle NoSQL Database Cloud quotas and examples, see Service Quotas.

Notifications Quotas

Family name: notifications

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>topic-count</td>
<td>Regional</td>
<td>Number of topics</td>
</tr>
</tbody>
</table>

Example

```
set notifications quota topic-count to 10 in compartment MyCompartment
```

Object Storage Quotas

Family name: object-storage
<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>storage-bytes</td>
<td>Regional</td>
<td>Total storage size in bytes</td>
</tr>
</tbody>
</table>

**Examples**

Set object-storage quota storage-bytes to 10000000000 in tenancy

Set object-storage quota storage-bytes to 5000000000 in compartment MyCompartment

Zero object-storage quota storage-bytes in compartment AnotherCompartment

Unset object-storage quota storage-bytes in tenancy

**Resource Manager Quotas**

Family name: resource-manager

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>concurrent-job-count</td>
<td>Regional</td>
<td>Number of concurrent Jobs per compartment</td>
</tr>
<tr>
<td>configuration-source-provider-count</td>
<td>Regional</td>
<td>Number of configuration source providers per compartment</td>
</tr>
<tr>
<td>stack-count</td>
<td>Regional</td>
<td>Number of stacks per compartment</td>
</tr>
<tr>
<td>template-count</td>
<td>Regional</td>
<td>Number of private templates per compartment</td>
</tr>
</tbody>
</table>

**Example**

set resource-manager quota concurrent-job-count to 1 in compartment MyCompartment

zero resource-manager quota stack-count in compartment MyCompartment

set resource-manager quota configuration-source-provider-count to 5 in compartment MyCompartment

set resource-manager quota template-count to 3 in compartment MyCompartment

**Service Connector Hub Quotas**

Family name: service-connector-hub

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service-connector-count</td>
<td>Regional</td>
<td>Number of service connectors</td>
</tr>
</tbody>
</table>

**Example**

set service-connector-hub quota service-connector-count to 10 in compartment MyCompartment

preview
## Streaming Quotas

Family name: `streaming`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>partition-count</code></td>
<td>Regional</td>
<td>Number of partitions</td>
</tr>
</tbody>
</table>

**Example**

```
set streaming quota partition-count to 10 in compartment MyCompartment
```

## Vault Quotas

Family name: `kms`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>virtual-private-vault-count</code></td>
<td>Regional</td>
<td>Number of virtual private vaults</td>
</tr>
</tbody>
</table>

**Example**

```
set kms quota virtual-private-vault-count to 1 in compartment MyCompartment
```

## WAF Quotas

Family name: `waas`

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>waas-policy-count</code></td>
<td>Regional</td>
<td>Number of WAF policies</td>
</tr>
</tbody>
</table>

**Example**

```
zero waas quota waas-policy-count in compartment MyCompartment
```

## Work Requests

This topic describes the work requests feature documented in the Work Requests API. The following Oracle Cloud Infrastructure services are integrated with this API:

- Compute
- Database
- Tenancy Explorer

**Note:**

Some Oracle Cloud Infrastructure services offer work requests supported by the service API rather than the Work Requests API discussed in this topic. For information about work requests in these services, see the following topics:

- **Application Migration:** View the State of a Work Request
- **Blockchain Platform:** Integration: Work Requests
Work requests allow you to monitor long-running operations such as Database backups or the provisioning of Compute instances. When you launch such an operation, the service spawns a work request. A work request is an activity log that enables you to track each step in the operation's progress. Each work request has an OCID that allows you to interact with it programmatically and use it for automation.

If an operation fails, a work request can help you determine which step of the process had an error.

Some operations affect multiple resources. For example, creating an instance pool also affects instances and instance configurations. A work request provides a list of the resources that an operation affects.

For workflows that require sequential operations, you can monitor each operation’s work request and confirm that the operation has completed before proceeding to the next operation. For example, say that you want to create an instance pool with autoscaling enabled. To do this, you must first create the instance pool, and then configure autoscaling. You can monitor the work request for creating the instance pool to determine when that workflow is complete, and then configure autoscaling after it is done.

Work requests are retained for 12 hours.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: Work requests inherit the permissions of the operation that spawns the work request. To enable users to view the work requests, logs, and error messages for an operation, write a policy that grants users permission to do the operation. For example, to let users see the work requests associated with launching instances, write a policy that enables users to launch instances.

To enable users to list all work requests in a tenancy, use the following policy:

```
Allow group SupportTeam to inspect work-requests in tenancy
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Work Request States**

**Note:** Work requests for some services or operations may support only a subset of the following statuses.

**ACCEPTED**

The request is in the work request queue to be processed.

**IN_PROGRESS**

A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.
SUCCEEDED

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.

FAILED

A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

CANCELING

The work request is in the process of canceling.

CANCELED

The work request has been canceled.

Using the Console to View Work Requests

The steps to view a work request are similar for Oracle Cloud Infrastructure services that support work requests.

1. Navigate to resource whose work requests you want to see.

   For example, to see the work requests for a Compute instance: Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.

2. If the resource is displayed in a list view, click the resource name to view the resource details.

3. Under Resources, click Work Requests. The status of all work requests appears on the page.

4. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the More information section.

   For associated resources, you can click the the Actions icon (three dots) next to a resource to copy the resource's OCID.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to monitor the state of work requests:

- ListWorkRequests
- GetWorkRequest
- ListWorkRequestErrors
- ListWorkRequestLogs

Console Announcements

This topic describes the announcements that Oracle Cloud Infrastructure displays in the Console. Console announcements appear at the top of the page to communicate timely, important information about service status. You can also view a list of past and ongoing announcements.

Note:

- If you use Oracle Platform Cloud Services or Oracle Cloud Applications and you have announcements about those service entitlements, the Console displays a banner with a link that you can use to access those announcements. For more information about these announcements, including how to set notification preferences, see Monitoring Notifications.
Types of Announcements

Announcements belong to different categories. An announcement's prefix helps you understand, at a glance, the type and relative severity of the information and whether there's anything you can or must do. Announcement types currently include the following, in order of most important to least:

- **Required action.** You must take specific action within your environment.
- **Emergency change.** There is a time period during which an unplanned, but urgent, change associated with your environment will take place.
- **Recommended action.** You have specific action to take within your environment, but the action is not required.
- **Planned change.** There is a time period during which a planned change associated with your environment will take place.
- **Planned change extended.** The scheduled change period has extended beyond what was previously communicated.
- **Planned change rescheduled.** The planned change to your environment has been postponed to a later time or date.
- **Production event.** An impactful change to your environment either recently occurred or is actively occurring.
- **Planned change completed.** The planned change to your environment has been completed and regular operations have resumed.
- **Information.** There is information that you might find useful, but is not urgent and does not require action on your part.

For announcements that require action and affect Oracle Cloud Infrastructure Compute instances, you will get 30 days of advance notice. If you need to delay the actions described in the announcement, contact support to request one of the alternate dates listed in the announcement. Critical vulnerabilities might not be eligible for delay.

**Required IAM Policy**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Depending on whether you have access, you might not see any announcements. With access to announcements, you can either see only the summary version of any given announcement or you can also view announcement details.

For administrators: for typical policies that give users access to announcements, see Restrict user access to view only summary announcements and Let users view details of announcements. For more information, see Details for the Announcements Service.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Email Delivery**

As part of your service agreement, Oracle Cloud Infrastructure also contacts you with service status announcements through email. These emails help alert you to upcoming changes that will impact your tenancy, such as those involving data centers or instances you use, or about required action on your part. Whenever possible, we try to provide advance notice of impactful events. Oracle sends these announcements to the default tenancy administrator email address on record. You can opt out of emails with operational information that is not urgent and does not require administrator action. (In the Console, these announcements are marked with the type, "Information." For more information about announcement types, see Types of Announcements on page 261.) If you want to change the default tenancy administrator email address on record, contact Oracle Support. For more information, see Contacting Support.
To manage email preferences for announcements

1. Click the Announcements icon (いません).
2. Click Manage Email Preferences.
3. Do one of the following:
   - If you want Oracle to email a copy of all announcements, click Opt in.
   - If you want Oracle to withhold email copies of informational announcements that don't require action on your part, click Opt out.

Viewing Announcements

This section describes how to view announcements. The Console displays announcements as banners that span the width of the top of your browser window. As long as an announcement remains in effect and you have the access to view announcements, the banner announcement displays each time you sign in to the Console until you mark it as read. You can also view all past announcements. The Announcements icon displays a green dot if you have any unread announcements.

To dismiss a banner announcement

- To close a banner announcement until the next time you sign in to the Console, click the X at the far right edge of the banner. If you want to stop seeing an announcement as a banner altogether, you must mark it as read. For more information, see To mark an announcement as read on page 263.

To view the details of an announcement

1. Do one of the following:
   - If you are viewing a banner, click the Show details link near the far right edge of the banner.
   - If you are viewing a list of announcements, under the Summary column, click the announcement summary.
2. On the Announcement Details page, you can view the following information:
   - Description. This describes the issue or event in greater detail than the summary text of the announcement.
   - OCID. This is the announcement's unique, Oracle-assigned identifier.
   - Reference Ticket Number. You can use this number to refer to the issue when talking to Support.
   - Type. This is one of several predefined categories that helps to set expectations about the nature and severity of the issue described.
   - Affected Service. This indicates the Oracle Cloud Infrastructure services affected by the issue or event.
   - Region. This tells you what Oracle Cloud Infrastructure regions are impacted.
   - Start Time. This is when the issue or event was first detected.
   - End Time. This is when the issue or event was resolved.
   - Required After. This is the date after which you must address any required actions described in the announcement.
   - Created. This is when the announcement was created.
   - Updated. This is when the announcement was updated.
   - Additional Information. This includes information such as workarounds or background material.
   - Impacted Resources. This shows the resources that were affected in some way by the event that prompted the announcement.
3. Optionally, if you want to refer to the list of impacted resources later, click Download Impacted Resources List.

To view a list of all announcements

1. Click the Announcements icon (いたします).
2. The **Announcements** page displays all announcements. From this page, you can do the following:

- **Filter.** You can filter announcements by type or by start or end date.
- **Sort.** You can sort announcements by summary, type, event start time, or publish time (which indicates when the announcement was last updated).
- **Mark as read.** You can mark announcements as read if you want stop seeing them as banners in the Console in subsequent sessions.
- **View announcement details.** You can view the details of an announcement.

### To filter a list of announcements

1. Click the Announcements icon (🌐).
2. To filter the list, under **Filters**, do one of the following:
   - Click **Type**, and then click a type from the list.
   - Click **Start Date**, and then choose a date to see only events that started on that date.
   - Click **End Date**, and then choose a date to see only events that ended on that date.
3. To clear a filter on a date, click the X next to the date.

### To sort a list of announcements

1. Click the Announcements icon (🌐).
2. By default, the list displays announcements according to the event start time, from most recent to least. To sort the list another way, do one of the following:
   - Click **Summary.** The list sorts alphabetically, according to the summary of the announcement.
   - Click **Type.** The list sorts according to the importance of the announcement.
   - Click **Start Time.** The list sorts according to the start time of the event described in the announcement. If you begin by viewing the default sort order, the sort order will change to show the oldest announcement at the beginning of the list.
   - Click **Publish Time.** The list sorts according to the time that an announcement was last updated. You might find it helpful to sort by this column if you want to track an ongoing issue or if an announcement requires action on your part.
3. To sort the list again, repeat the previous step.

### To mark an announcement as read

1. Click the Announcements icon (🌐).
2. Find the announcement that you want to mark as read, click the Actions icon (three dots), and then click **Mark As Read.**

### Using the Command Line Interface (CLI)

For information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/usingapi.htm). For a complete list of flags and options available for CLI commands, see the [Command Line Reference](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/usingapi.htm).

### To view the details of an announcement

Open a command prompt and run `oci announce announcements get` to view detailed information about an announcement:

```bash
oci announce announcements get --announcement-id <announcement_OCID>
```

For example:
To view a list of all announcements
Open a command prompt and run `oci announce announcements list` to view a list of all announcements:

```
oci announce announcements list --compartment-id <compartment_OCID>
```

For example:

```
oci announce announcements list --compartment-id ocid1.tenancy.oc1..exampleati4wjo6cbxq4iusld5ltipeskcfy7lr4a6wfauxuwrwed5bsdea
```

To filter a list of announcements
Open a command prompt and run `oci announce announcements list` to filter a list of announcements.
To filter a list of announcements by announcement type:

```
oci announce announcements list --compartment-id <compartment_OCID> --announcement-type <announcement_type>
```

For example:

```
oci announce announcements list --compartment-id ocid1.tenancy.oc1..exampleati4wjo6cbxq4iusld5ltipeskcfy7lr4a6wfauxuwrwed5bsdea --announcement-type ACTION_REQUIRED
```

To sort a list of announcements
Open a command prompt and run `oci announce announcements list` to sort a list of announcements.
To sort a list of announcements in ascending order of time created, from oldest to newest:

```
oci announce announcements list --compartment-id <compartment_OCID> --sort-order ASC
```

For example:

```
oci announce announcements list --compartment-id ocid1.tenancy.oc1..exampleati4wjo6cbxq4iusld5ltipeskcfy7lr4a6wfauxuwrwed5bsdea --sort-order ASC
```

To mark an announcement as read
Open a command prompt and run `oci announce user-status update` to mark an announcement as read:

```
oci announce user-status update --announcement-id <announcement_OCID> --user-status-announcement-id <announcement_OCID> --user-id <user_OCID> --time-acknowledged <date_and_time>
```

For example:
oci announce user-status update --announcement-id ocid1.announcement.region1..examplear73oue4jdywjvietoc6im3cvb6xae4falm3fau5us3iwra3t6q --user-status-announcement-id ocid1.announcement.region1..examplear73oue4jdywjvietoc6im3cvb6xae4falm3fau5us3iwra3t6q --user-id ocid1.user.region1..exampleaorxz3psplonigcvbzy5oaiwiubh7k7ip6zgklfauxic67kksu4oq --time-acknowledged 2019-01-06T20:14:00+00:00

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage announcements:

- GetAnnouncement
- GetAnnouncementUserStatus
- ListAnnouncements
- UpdateAnnouncementUserStatus

Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure

This topic describes procedures that are required by some Oracle Platform Services before you can launch them on Oracle Cloud Infrastructure. The information in this topic applies only to the following services:

- Oracle Database Cloud Service
- Oracle Data Hub Cloud Service
- Oracle Event Hub Cloud Service
- Oracle Java Cloud Service
- Oracle SOA Cloud Service

For a list of all services supported on Oracle Cloud Infrastructure, see Information About Supported Platform Services on page 271.

Accessing Oracle Cloud Infrastructure

Oracle Cloud Infrastructure has a different interface and credential set than your Oracle Platform Services. You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Required Identity and Access Management (IAM) Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

See Common Policies on page 2142 for more information and examples.
Resources Created in Your Tenancy by Oracle

Oracle creates a compartment in your tenancy for Oracle Platform Services. This compartment is specially configured by Oracle for the Oracle Cloud Infrastructure resources that you create through the Platform Services. You can't choose another compartment for Oracle to use.

Along with this compartment, Oracle creates the IAM policies to allow Oracle Platform Services access to the resources.

The compartment that Oracle creates for Oracle Platform Services is named: ManagedCompartmentForPaaS.

The policies that Oracle creates for Oracle Platform Services are:

- **PSM-root-policy**
  
  This policy is attached to the root compartment of your tenancy.

- **PSM-mgd-comp-policy**
  
  This policy is attached to the ManagedCompartmentForPaaS compartment.

Caution: Do not make any changes to these resources. Editing or renaming the policies or the compartment can result in loss of functionality.

Prerequisites for Oracle Platform Services

Before you can create instances of an Oracle Platform Service on Oracle Cloud Infrastructure, you need to have the following resources in your Oracle Cloud Infrastructure tenancy:

- A compartment for your resources
- A virtual cloud network (VCN) with at least one public subnet
- IAM policies to allow Oracle Platform Services to access the VCN
- An Object Storage bucket
- Credentials to use with Object Storage

Some of the Platform Services automatically create some of these resources for you. See details about your service in the following sections.

Setting Up the Prerequisites

Note: To use Autonomous Data Warehouse Cloud, you don't need to set up any of the resources listed in this prerequisites section. However, if you optionally choose to use Oracle Cloud Infrastructure Object Storage for data loading, you need to perform these two tasks:

Create a bucket
Create an auth token

Following are two scenarios with procedure sets. If you need to set up all the required resources, follow Scenario 1. If you already have a VCN in your Oracle Cloud Infrastructure tenancy that you want to use for Oracle Platform Services, follow Scenario 2.

To follow a tutorial on how to set up the prerequisites for Scenario 1, see Creating the Infrastructure Resources Required for Oracle Platform Services.

Scenario 1: I need to create all the prerequisite resources
Scenario 2: I have an existing VCN in Oracle Cloud Infrastructure that I want to use for my Oracle Platform Services instance

You can use an existing VCN. The VCN must have at least one public subnet. Perform these tasks to complete the prerequisites:

Create a compartment

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot use the ManagedCompartmentForPaaS for your VCN and bucket.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments.
2. A list of the existing compartments in your tenancy is displayed.
3. Click Create Compartment.
4. Enter the following:
   - **Name:** For example, PaaSResources. Restrictions for compartment names are: Maximum 100 characters, including letters, numbers, periods, hyphens, and underscores. The name must be unique across all the compartments in your tenancy. Avoid entering confidential information.
   - **Description:** A friendly description.
5. Click Create Compartment.

Set up your virtual cloud network

This procedure creates a VCN with these characteristics:

- A VCN with the CIDR of your choice (example: 10.0.0.0/16).
- A regional public subnet with access to the VCN's internet gateway. You can choose the subnet's CIDR (example: 10.0.0.0/24).
- A regional private subnet with access to the VCN's NAT gateway and service gateway (and therefore the Oracle Services Network). You can choose the subnet's CIDR (example: 10.0.1.0/24).
- Use of the Internet and VCN Resolver for DNS, so your instances can use their hostnames instead of their private IP addresses to communicate with each other.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The following VCN quickstart procedure is useful for getting started and trying out Oracle Platform Services on Oracle Cloud Infrastructure. For production, use the procedure in VCNs and Subnets on page 2821. That topic explains features such as how to specify the CIDR ranges for your VCN and subnets, and how to secure your network. When you use the advanced procedure in that topic, remember that the VCN that you create must have a public subnet for Oracle Platform Services to use.</td>
</tr>
</tbody>
</table>

1. Open the Region menu and select the region in which you want to create the Oracle PaaS service instance.
   - Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).
2. From the Compartment list, select the compartment you created.
3. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
4. Click Networking Quickstart.
5. Select VCN with Internet Connectivity, and then click Start Workflow.
6. Enter the following:
   • **VCN Name:** Enter a name for your cloud network, for example, `<your_initials>_Network`. The name is incorporated into the names of all the related resources that are automatically created. Avoid entering confidential information.
   • **Compartment:** Leave the default value (the compartment you're currently working in). All the resources will be created in this compartment.
   • **VCN CIDR Block:** Enter a valid CIDR block for the VCN. For example 10.0.0.0/16.
   • **Public Subnet CIDR Block:** Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block. For example: 10.0.0.0/24.
   • **Private Subnet CIDR Block:** Enter a valid CIDR block for the subnet. The value must be within the VCN's CIDR block and not overlap with the public subnet's CIDR block. For example: 10.0.1.0/24.
   • Accept the defaults for any other fields.

7. Click **Next**.

8. Review the list of resources that the workflow will create for you. Notice that the workflow will set up security list rules and route table rules to enable basic access for the VCN.

9. Click **Create** to start the short workflow.

**Permit Oracle Platform Services to access resources**

1. In the Console, navigate to the root compartment of your tenancy by clicking your tenancy name in the **Compartment** list.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
3. Click **Create Policy**.
4. Enter the following:
   • **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
   • **Description:** A friendly description. You can change this later if you want to.
   • **Statement:** To allow Oracle Platform Services access to use the network in your compartment, enter the following policy statements. Replace `<compartment_name>` with your compartment name. Click + after each statement to add another.

   ```plaintext
   Allow service PSM to inspect vcns in compartment `<compartment_name>`
   Allow service PSM to use subnets in compartment `<compartment_name>`
   Allow service PSM to use vnics in compartment `<compartment_name>`
   Allow service PSM to manage security-lists in compartment `<compartment_name>`
   ```

   For more information about policies, see **Policy Basics** on page 2137 and also **Policy Syntax** on page 2164.

5. (Optional) If you want to enable the use of an Autonomous Transaction Processing or Oracle Cloud Infrastructure Database instance in your compartment as the infrastructure schema database for your Oracle Java Cloud Service instance, then add the following statements:

   ```plaintext
   Allow service PSM to inspect autonomous-database in compartment `<compartment_name>`
   Allow service PSM to inspect database-family in compartment `<compartment_name>`
   ```

6. Click **Create**.
Create a bucket

1. Open the Region menu and select the region in which you want to create the Oracle PaaS service instance.

   Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).

2. Open the navigation menu. Under Core Infrastructure, click Object Storage.

3. Choose the compartment you created.

4. Click Create Bucket.

5. In the Create Bucket dialog, enter a bucket name, for example: PaasBucket.

   Make a note of the name you enter. You will need it when you create an instance for your Oracle Platform Service later.

6. Click Create Bucket.

Set up credentials to use with Object Storage

For Big Data Cloud, set up an API signing key:

Set up an API signing key

Follow the instructions in this topic: Required Keys and OCIDs on page 4179.

For all other services, create an auth token. Note that your service might refer to this credential as a Swift password. Use the auth token wherever you are asked to provide a Swift password.

Create an auth token

1. View the user's details:

   - If you're creating an auth token for yourself:

     Open the Profile menu ( ) and click User Settings.

   - If you're an administrator creating an auth token for another user: In the Console, click Identity, and then click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click Auth tokens.

3. Click Generate Token.

4. Enter a friendly description for the token and click Generate Token.

   The new token is displayed.

5. Copy the token immediately, because you can't retrieve it again after closing the dialog box. Also, make sure you have this token available when you create your Oracle Platform Services instance.

Permit Oracle Platform Services to access resources

1. In the Console, navigate to the root compartment of your tenancy by clicking your tenancy name in the Compartment list.

2. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.

3. Click Create Policy.
4. Enter the following:
   - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Statement:** To allow Oracle Platform Services access to use the network, enter the following policy. Click + after each statement to add another. In each statement, replace `<compartment_name>` with the name of the compartment where your VCN resides.

   ```sql
   Allow service PSM to inspect vcns in compartment <compartment_name>
   Allow service PSM to use subnets in compartment <compartment_name>
   Allow service PSM to use vnics in compartment <compartment_name>
   Allow service PSM to manage security-lists in compartment <compartment_name>
   ```

   For more information about policies, see **Policy Basics** on page 2137 and also **Policy Syntax** on page 2164.

5. (Optional) If you want to enable the use of an Autonomous Transaction Processing or Oracle Cloud Infrastructure Database instance in your compartment as the infrastructure schema database for your Oracle Java Cloud Service instance, then add the following statements:

   ```sql
   Allow service PSM to inspect autonomous-database in compartment <compartment_name>
   Allow service PSM to inspect database-family in compartment <compartment_name>
   ```

6. Click **Create**.

**Create a bucket**

1. Open the **Region** menu and select the region in which you want to create the Oracle PaaS service instance.
   
   Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).

2. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

3. Choose the compartment you want to create the bucket in.

4. Click **Create Bucket**.

5. In the **Create Bucket** dialog, enter a bucket name, for example: PaasBucket. Make a note of the name you enter. You will need it when you create an instance for your Oracle Platform Service later. Avoid entering confidential information.

6. Click **Create Bucket**.

**Set up credentials to use with Object Storage**

For Big Data Cloud, set up an API signing key:

**Set up an API signing key**

Follow the instructions in this topic: **Required Keys and OCIDs** on page 4179.

For all other services, create an auth token. Note that your service might refer to this credential as a Swift password. Use the auth token wherever you are asked to provide a Swift password.
Create an auth token

1. View the user's details:
   - If you’re creating an auth token for yourself:
     - Open the Profile menu ( ) and click User Settings.
   - If you’re an administrator creating an auth token for another user: In the Console, click Identity, and then click Users. Locate the user in the list, and then click the user’s name to view the details.

2. On the left side of the page, click Auth Tokens.
3. Click Generate Token.
4. Enter a friendly description for the token and click Generate Token.

   The new token is displayed.

5. Copy the auth token immediately, because you can't retrieve it again after closing the dialog box. Also, make sure you have this token available when you create your Oracle Platform Services instance.

Information About Supported Platform Services

Renaming a Cloud Account

This topic describes the process of changing your cloud account name. When you sign up for Oracle Cloud, you get a cloud account and an Oracle Cloud Infrastructure tenancy. Both the cloud account and tenancy have an ID and a name. Oracle assigns the same name to the cloud account and the tenancy, but they each have a unique ID. You need to specify the tenancy name when you sign in to Oracle Cloud Infrastructure Console, so that you arrive at the right account. Any programmatic access uses the tenant ID or cloud account ID, not its name. For example:

- Sample account and tenancy name: "OracleCustomer1"
- Sample cloud account ID: "cacct-7a26a4exampleuniqueID"
- Sample tenancy ID: "ocid1.tenancy.oc1..exampleuniqueID"

You can view your cloud account name in the Tenancy Details page. You might need to rename your cloud account if the name that it was initially given is no longer relevant or correct. For example:

- You created a trial account called MyTrial, and then it became the main account for your company.
- You had an acquisition that is forcing name changes.

Follow these guidelines for a successful rename:

- Plan ahead and inform others that you plan on changing the name.
- Change the name during off-hours to reduce impact on users in your tenancy.
- Notify personnel who use Oracle Cloud when the rename is complete.

Note:

Only an Oracle Identity Cloud Service (IDCS) cloud account administrator can rename the cloud account. After the account name changes, you can’t use the old name to sign in to the Console. Existing sessions keep working, but new sessions need to use the new name. You can’t change an account name back to its old name.

You can change your cloud account name in the My Oracle Services dashboard, which is accessible from the Profile menu's Service User Console option.

Important:

Two methods for signing in are available: by using the oracle.com URL, which always uses IDCS, and by using the Console URL. If you use the Console URL to navigate directly to the Console and sign in, the Service User Console menu option isn't available in the Profile menu. Choose the "oraclecloudidentityservice" option when signing in if you're unsure. For more information, see Signing In to the Console on page 41.

To change a cloud account name

1. Click the Profile icon and select Service User Console. The My Oracle Services dashboard opens in another browser window.
2. From the main menu, select Account.
3. On the Account page, select the Account Management tab.
4. Next to the Account Name field, click the Rename Account button. This button is only available if you are an IDCS cloud account administrator.
5. In the Rename Account dialog box, enter the new account name, and click OK.

After you submit the change, it takes about 15 minutes to rename the account. When the rename is complete, the account admin receives an email, which states that you need to use your existing credentials to sign in.

When you sign in to the Console, you are required to use the new account name (<new_account_name>) when prompted for a cloud account or tenant name.
When you rename an account, all references to the cloud account name and the tenancy name are updated, including the following names:

- IDCS instance name
- Amazon S3 Compatibility API Designated Compartment
- SWIFT API Designated Compartment

The API Designated Compartment names are listed on the Tenancy Information tab of the Tenancy Details page, under Object Storage Settings. The Object Storage Namespace, also shown in the Object Storage Settings area, is not updated. This name is set as the name for older accounts. Newer accounts have a short random string as the namespace.

Billing and Payment Tools Overview

Oracle Cloud Infrastructure provides various billing and payment tools that make it easy to manage your service costs.

**Budgets**

Budgets can be used to set thresholds for your Oracle Cloud Infrastructure spending. You can set alerts on your budget to let you know when you might exceed your budget, and you can view all of your budgets and spending from one single place in the Oracle Cloud Infrastructure console. See Budgets Overview on page 274 for more information.

**Cost Analysis**

Cost Analysis provides easy-to-use visualization tools to help you track and optimize your Oracle Cloud Infrastructure spending. For more information, see Checking Your Expenses and Usage on page 55.

**Cost and Usage Reports**

A cost report is a comma-separated value (CSV) file that is similar to a usage report, but also includes cost columns. The report can be used to obtain a breakdown of your invoice line items at resource-level granularity. As a result, you can optimize your Oracle Cloud Infrastructure spending, and make more informed cloud spending decisions.

A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation.

For more information, see Cost and Usage Reports Overview on page 278.

**Unified Billing**

You can unify billing across multiple tenancies by sharing your subscription between tenancies. For more information, see Unified Billing Overview on page 296.

**Invoices**

You can view and download invoices for your Oracle Cloud Infrastructure usage. For more information, see Viewing Your Subscription Invoice.

**Payment Methods**

The Payment Method section of the Oracle Cloud Infrastructure Console allows you to easily manage how you pay for your Oracle Cloud Infrastructure usage. For more information, see Changing Your Payment Method on page 56.
Budgets Overview

A budget can be used to set soft limits on your Oracle Cloud Infrastructure spending. You can set alerts on your budget to let you know when you might exceed your budget, and you can view all of your budgets and spending from one single place in the Oracle Cloud Infrastructure console.

How Budgets Work

Budgets are set on cost-tracking tags or on compartments (including the root compartment) to track all spending in that cost-tracking tag or for that compartment and its children.

All budgets alerts are evaluated every hour in most regions, and every four hours in IAD. To see the last time a budget was evaluated, open the details for a budget. You will see fields that show the current spend, the forecast and the “Spent in period” field which shows you the time period over which the budget was evaluated. When a budget alert fires, the email recipients configured in the budget alert receive an email.

Budget Concepts

The following concepts are essential to working with budgets:

BUDGET

A monthly threshold you define for your Oracle Cloud Infrastructure spending. Budgets are set on cost-tracking tags or compartments and track all spending in the cost-tracking tag or compartment and any child compartments.

Note:

The budget tracks spending in the specified target compartment, but you need to have permissions to manage budgets in the root compartment of the tenancy to create and use budgets.

ALERT

You can define email alerts that get sent out for your budget. You can send a customized email message body with these alerts. Alerts are evaluated every hour in most regions (every four hours in IAD), and can be triggered when your actual or your forecasted spending hits either a percentage of your budget or a specified set amount.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

To use budgets, you must be in a group that can use "usage-budgets” in the tenancy (which is the root compartment) or be able to use all resources in the tenancy. All budgets are created in the root compartment, regardless of the compartment they are targeting, so IAM policies that grant budget permissions outside of the root will not be meaningful.

<table>
<thead>
<tr>
<th>IAM Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow group accountants to inspect usage-budgets in tenancy</td>
<td>Accountants can inspect budgets including spend.</td>
</tr>
<tr>
<td>Allow group accountants to read usage-budgets in tenancy</td>
<td>Accountants can read budgets including spend (same as list).</td>
</tr>
<tr>
<td>IAM Policy</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Allow group accountants to use usage-budgets in tenancy</td>
<td>Accountants can create and edit budgets and alerts rules.</td>
</tr>
<tr>
<td>Allow group accountants to manage usage-budgets in tenancy</td>
<td>Accountants can create, edit, and delete budgets and alerts rules.</td>
</tr>
</tbody>
</table>

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Creating Automation for Budgets Using the Events Service**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

**Managing Budgets**

This topic discusses how to view and manage your budgets.

**Using the Console**

*To create a budget*

1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Budgets.
2. Click Create Budget at the top of the budgets list. The Create Budget dialog is displayed.
3. Select either Compartment or Cost-Tracking Tag to select the type of target for your budget.
4. Enter a name for your budget in the Name text field. The name can only contain alphanumeric characters, dashes, and the underscore character, and can’t begin with a number. Avoid entering confidential information.
5. Enter a description for the budget. Avoid entering confidential information.
6. Select the target for your budget:
   - For budgets targeting a compartment:
     - Select a target compartment for your budget from the Target Compartment drop-down list. Note that while the budget tracks spending in the specified target compartment, but you need to have permissions to manage budgets in the root compartment of the tenancy to create and use budgets.
   - For budgets targeting a cost-tracking tag:
     - Select a tag namespace.
     - Select a target cost-tracking tag key.
     - Enter a value for the cost-tracking tag.
7. Enter a monthly amount for your budget in the **Monthly Budget Amount** field. The minimum allowed value for your monthly budget is 1; the maximum allowed value is 999,999,999,999.

8. From **Day of the Month to Begin Budget Processing**, select the day of the month that you want budget processing to periodically begin on each month. Setting this value allows you to create a budget that aligns with your billing cycle date, and to receive more meaningful budget alerts. Below this field, **Current Budget Processing Period Based on Selection** reflects the budget processing period, according to the day of the month you chose. When viewing or editing a budget on its details page, the **Budget Processing Period** field also displays this information.

```
Note:
If you select the 29th, 30th, or 31st as the day of the month, budget processing begins on the last day of the month, for months that have fewer than the respective days you have chosen (whether 29, 30, or 31).
```

9. You can optionally create an alert for your budget by creating a budget alert rule. In **Budget Alert Rule** on the **Create Budget** dialog, configure your alert rule:

a. Select a threshold for your alert from the **Threshold Metric** drop-down list. There are two possible values:
   - **Actual Spend** watches the actual amount you spend in your compartment per month;

   **Forecast Spend** watches your resource usage and alert you when it appears that you'll exceed your budget. The forecast algorithm is linear extrapolation and requires at least three days of consumption to trigger.

b. Select a threshold type from the **Threshold Type** drop-down list. You can select either a percentage of your monthly budget (which must be greater than 0 and no greater than 10,000) or a fixed amount.

c. The label of the next text field changes depending on what type of threshold you selected. Enter either a **Threshold %** or a **Threshold Amount**.

d. In the **Email Recipients** field, enter one or more email addresses to receive the alerts. Multiple addresses can be separated using a comma, semicolon, space, tab, or new line.

e. Enter the body of your email alert in the **Email Message** field. The text of the email message cannot exceed 1000 characters. This message will be included with metadata about your budget, including the budget name, the compartment, and the amount of your monthly budget. You can use this message to for things like providing instructions to the recipient that explain how to request a budget increase or reminding users about corporate policies.

10. **Advanced Options (optional)**: Click the **Show advanced options** link to add **Tags** to your budget. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

11. Click the **Create** button to create your budget.

**To view or edit a budget**

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Budgets**.

2. From the list of budgets, click on the budget you want to edit. The budget detail screen will appear.

3. Click the **Edit** button. The **Edit Budget** dialog will appear.

4. You can edit the name of your budget or the budget amount. Avoid entering confidential information.

5. When you are finished, click **Save Changes**.

**To delete a budget**

1. From the list of budgets, select **Delete** from the context menu, or click the **Delete** button at the top of budget detail screen. The **Confirm Delete** dialog will appear.

2. Click the **Confirm** button to delete the budget, or cancel by clicking **Cancel**.

**To manage tags for a budget**

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Budgets**.

2. From the list of budgets, click on the budget you want to tag. The budget detail screen will appear.
3. Click the **Add tag(s)** button to add a tag.
4. Click the **Tags** tab and then click on the pencil icon next to a tag you want to edit or remove.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operation to manage budgets:

- ListBudgets
- GetBudget
- CreateBudget
- DeleteBudget
- UpdateBudget

**Managing Budget Alert Rules**

You can set email alerts on your budgets. You can set alerts that are based on a percentage of your budget or an absolute amount, and on your actual spending or your forecast spending.

This topic covers how to view and manage your budget alert rules.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Using the Console**

*To create a budget alert rule*

1. Click the budget that you want to create an alert for from the budgets list.
2. In the **Budget Alert Rules** panel at the bottom of the screen, click the **Create Budget Alert Rule** button.
3. Configure your alert rule:
   a. Select a threshold for your alert from the **Threshold Metric** drop-down list. There are two possible values:
      - **Actual Spend** will watch the actual amount you spend in your compartment per month;
      - **Forecast Spend** will watch your resource usage and alert you when it appears that you'll exceed your budget. The forecast algorithm is linear extrapolation and requires at least 3 days of consumption to trigger
   b. Select a threshold type from the **Threshold Type** drop-down list. You can select either a percentage of your monthly budget (which must be greater than 0 and no greater than 10,000) or a fixed amount.
   c. The label of the next text field changes depending on what type of threshold you selected. Enter either a **Threshold %** or a **Threshold Amount**.
   d. In the **Email Recipients** field, enter one or more email addresses to receive the alerts. Multiple addresses can be separated using a comma, semicolon, space, tab, or new line.
   e. Enter the body of your email alert in the **Email Message** field. The text of the email message cannot exceed 1000 characters. This message will be included with metadata about your budget, including the budget name, the compartment, and the amount of your monthly budget. You can use this message for things like providing instructions to the recipient that explain how to request a budget increase or reminding users about corporate policies.
4. Click the **Create** button to create your alert.
**To view or edit a budget alert rule**

1. In the list of budget alert rules, click the menu icon at the right side of the list and select **View/Edit** from the context menu.
2. Edit your alert rule.
3. Confirm your changes by clicking **Save Changes**, or dismiss the dialog without saving by clicking the **Cancel** button.

**To delete a budget alert rule**

1. In the list of budget alert rules, click the menu icon at the right side of the list and select **Delete** from the context menu.
2. Confirm or cancel the delete operation in the **Confirm Delete** dialog by clicking either the **Confirm** or **Cancel** button.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use the following operations to manage budget alert rules:

- **ListAlertRules**
- **GetAlertRule**
- **CreateAlertRule**
- **DeleteAlertRule**
- **UpdateAlertRule**

**Cost and Usage Reports Overview**

A **cost report** is a comma-separated value (CSV) file that is similar to a usage report, but also includes cost columns. The report can be used to obtain a breakdown of your invoice line items at resource-level granularity. As a result, you can optimize your Oracle Cloud Infrastructure spending, and make more informed cloud spending decisions.

A **usage report** is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation.

In summary, usage reports indicate the **quantity** of what is consumed, while cost reports indicate the **cost** of resource consumption.

**Note:**

Cost and usage reports do not apply to non-metered tenancies.

**How Cost Reports Work**

The cost report is automatically generated daily, and is stored in an Oracle-owned Object Storage bucket. It contains one row per each Oracle Cloud Infrastructure resource (such as instance, Object Storage bucket, VNIC) per hour along with consumption information (usage, price, cost), metadata, and tags. Cost reports generally contain 24 hours of usage data, although occasionally a cost report may contain late-arriving data that is older than 24 hours.

Cost reports may contain corrections. Corrections are added as new rows to the report, with the `lineItem/isCorrection` column set and the `referenceNo` value of the corrected line populated in the `lineItem/backReference` column.

Cost reports are retained for one year.

The file name for each cost report is appended with an automatically incrementing numerical value.

**Cost Report Schema**

The following table shows the cost report schema.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lineItem/referenceNo</td>
<td>Line identifier. Used for debugging and corrections.</td>
</tr>
<tr>
<td>lineItem/TenantId</td>
<td>The identifier (OCID) for the Oracle Cloud Infrastructure tenant.</td>
</tr>
<tr>
<td>lineItem/intervalUsageStart</td>
<td>The start time of the usage interval for the resource.</td>
</tr>
<tr>
<td>lineItem/intervalUsageEnd</td>
<td>The end time of the usage interval for the resource.</td>
</tr>
<tr>
<td>product/service</td>
<td>The service that the resource is in.</td>
</tr>
<tr>
<td>product/compartmentId</td>
<td>The ID of the compartment that contains the resource.</td>
</tr>
<tr>
<td>product/compartmentName</td>

</tr>
</tbody>
</table>

**How Usage Reports Work**

The usage report is automatically generated daily, and is stored in an Oracle-owned Object Storage bucket. It contains one row per each Oracle Cloud Infrastructure resource (such as instance, Object Storage bucket, VNIC) per hour along with consumption information, metadata, and tags. Usage reports generally contain 24 hours of usage data, although occasionally a usage report may contain late-arriving data that is older than 24 hours.

**Note:**

If you change any cost tracking tags during a particular hour time slot, the last cost tracking tag that is chosen is what gets applied to that hour. For example, if you changed a tag from "AAA" to "BBB" at 10:40, the usage for 10:00-11:00 would reflect "BBB" for the tag. In addition, tags cannot be applied retroactively.

The report may contain corrections. Corrections are added as new rows to the report, with the lineItem/isCorrection column set and the referenceNo value of the corrected line populated in the lineItem/backReference column.

Usage reports are retained for one year.

The file name for each usage report is appended with an automatically incrementing numerical value.

**Usage Report Schema**

The following table shows the usage report schema.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lineItem/referenceNo</td>
<td>Line identifier. Used for debugging and corrections</td>
</tr>
<tr>
<td>lineItem/TenantId</td>
<td>The identifier (OCID) for the Oracle Cloud Infrastructure tenant.</td>
</tr>
<tr>
<td>lineItem/intervalUsageStart</td>
<td>The start time of the usage interval for the resource in UTC.</td>
</tr>
<tr>
<td>lineItem/intervalUsageEnd</td>
<td>The end time of the usage interval for the resource in UTC.</td>
</tr>
<tr>
<td>product/service</td>
<td>The service that the resource is in.</td>
</tr>
<tr>
<td>product/resource</td>
<td>The resource name used by the metering system.</td>
</tr>
<tr>

<tr>
<td>usage/consumedQuantity</td>
<td>The quantity of the resource that has been consumed.</td>
</tr>
<tr>
<td>usage/billedQuantity</td>
<td>The quantity of the resource that has been billed over the usage interval.</td>
</tr>
<tr>
<td>usage/consumedQuantityUnits</td>
<td>The unit for the consumed quantity and billed quantity.</td>
</tr>
</tbody>
</table>
**Accessing Cost and Usage Reports**

Cost and usage reports are comma-separated value (CSV) files that are generated daily and stored in an Object Storage bucket. This topic describes how to access these reports.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

To use cost and usage reports, the following policy statement is required:

```
define tenancy usage-report as
  ocid1.tenancy.oc1..aaaaaaaaaned4fkpksbwjl56u7cj63lf3wffbilvqknstgtvzub7vhkqggq
endorse group <group> to read objects in tenancy usage-report
```

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Using the Console**

To download a cost or usage report:

1. Open the navigation menu. Under Governance and Administration, go to Account Management and select Cost and Usage Reports.
2. Click the report you want to download from the list, and follow your browser's instructions for downloading.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Service Essentials

To download a cost or usage report, use the Object Storage APIs. The reports are stored in the tenancy's home region.
The Object Storage namespace used for the reports is bling; the bucket name is the tenancy OCID.
The following example shows how to download a cost report, usage report (or both) using a Python script:

import oci
import os
# This script downloads all of the cost, usage, (or both) reports for a
tenancy (specified in the config file).
#
# Pre-requisites: Create an IAM policy to endorse users in your tenancy to
read cost reports from the OCI tenancy.
#
# Example policy:
# define tenancy reporting as
ocid1.tenancy.oc1..aaaaaaaaned4fkpkisbwjlr56u7cj63lf3wffbilvqknstgtvzub7vhqkggq
# endorse group group_name to read objects in tenancy reporting
#
# Note - The only value you need to change is the group name. Do not change
the OCID in the first statement.
reporting_namespace = 'bling'
# Download all usage and cost files.
specific need:
prefix_file = ""
# prefix_file = "reports/cost-csv"
# prefix_file = "reports/usage-csv"

You can comment out based on the
#
#
#

For cost and usage files
For cost
For usage

# Update these values
destintation_path = 'downloaded_reports'
# Make a directory to receive reports
if not os.path.exists(destintation_path):
os.mkdir(destintation_path)
# Get the list of reports
config = oci.config.from_file(oci.config.DEFAULT_LOCATION,
oci.config.DEFAULT_PROFILE)
reporting_bucket = config['tenancy']
object_storage = oci.object_storage.ObjectStorageClient(config)
report_bucket_objects = object_storage.list_objects(reporting_namespace,
reporting_bucket, prefix=prefix_file)
for o in report_bucket_objects.data.objects:
print('Found file ' + o.name)
object_details = object_storage.get_object(reporting_namespace,
reporting_bucket, o.name)
filename = o.name.rsplit('/', 1)[-1]
with open(destintation_path + '/' + filename, 'wb') as f:
for chunk in object_details.data.raw.stream(1024 * 1024,
decode_content=False):
f.write(chunk)
print('----> File ' + o.name + ' Downloaded')

Cost Analysis Overview
Cost Analysis is an easy-to-use visualization tool to help you track and optimize your Oracle Cloud Infrastructure
spending, allows you to generate charts, and download accurate, reliable tabular reports of aggregated cost data on

Oracle Cloud Infrastructure User Guide

282


your Oracle Cloud Infrastructure consumption. Use the tool for spot checks of spending trends and for generating reports. Common scenarios you might be interested in include:

- Show monthly costs for compartment X and its children, grouped by service or by tag.
- Show daily costs for tag key A and tag key B, values X, Y and Z, grouped by service and product description (SKU).
- Show hourly costs for service = compute or database, grouped by compartment name.

You can choose the dates you’re interested in. Filter to the specific tags, compartments, services, or filter you want, and pick how you want it grouped. As a result, a chart and corresponding data table are generated, and can also be downloaded as a data table.

If you want to re-create the breakdown provided by the former Classic Version of the Cost Analysis tool, apply the SKU (Part Number) grouping dimension in the current version of Cost Analysis. To explore your costs in new ways, we recommended viewing your costs based on Service, or Service and Product Description. If you are doing cost tracking, we recommended grouping by Compartment or Tag.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>

<tbody>
<tr>
<td>All tags, not only cost tracking tags, are supported.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Costs for tags are based on the date at which the tag was associated with a resource. It does not work retroactively for resources on which these tags are applied.</td>
</tr>
</tbody>
</table>

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

To use Cost Analysis, the following policy statement is required:

```
Allow group <group_name> to read usage-report in tenancy
```

### Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

### Cost Analysis Query Fields

The following table describes the Cost Analysis query fields.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Time Period (UTC)       | Allows you to query predefined time ranges for data available in the usage store. Other time ranges can be queried using the Classic Version. The available options in the drop-down (for example, **This Month, Last Month**) are according to the UTC time zone, and are based on the calendar year. The actual time ranges are indicated in parentheses. When changing the time period, it is also indicated just above the chart. Granularity (hourly, daily, monthly) is based on the requested date range size. The logic is the following:  
  - Hourly: 48 hours or less  
  - Daily: > 48 hours, <= 2 months  
  - Monthly: > 2 months  
  **Note:** Historical data is currently being back-filled for tenancies and may not appear immediately. As that process completes, up to twelve months of past consumption data will become available. |
| Show                    | Allows you to view the report in terms of **Cost** (the default) or **Usage**. To view **Usage** you must apply a filter for a unit, by selecting one from the **Filters** field, then via the **Show Usage Info** dialog box. Oracle Cloud Infrastructure services have unit measures that span from GBs/month to CPU/hours to API requests. When selecting **Usage**, a dialog appears, which prompts you to add a filter for a unit to view usage data.  
  **Note:** For **Usage**, unit filtering is the only possible selection, and you can only choose one value for the unit. |
| Cumulative              | Select this option to modify the values so that they’re cumulative for the selected time period selected. For example, consider if you were looking at 10 days of data, cumulatively, and the values for each day are $5. In such a case, selecting **Cumulative** displays values of 5, 10, 15, 20, 25, 30, 35, 40, 45, and 50 across the 10 days, respectively. In a non-cumulative chart, the values display as 5, 5, 5, 5, 5, 5, 5, 5, 5.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Filters    | Allows filtering on the following:  
  • Availability domain  
  • Compartment  

  **Note:**  
  Filtering by compartment displays usage and costs attributed to all resources in the selected compartments, and their child compartments.  
  • By OCID  
  • By Name  
  • By Path (for example, root/compartmentname/compartmentname)  
  • Platform (Gen-1 are services which are not OCI native. Gen-2 includes all OCI native services)  
  • Tag  
  • By Tag Namespace  
  • By TagKey + Value  
  • Region  
  • Service  
  • Product description (the human-readable corresponding name)  
  • SKU - Part Number (for example, B91444)  
  • Unit  

  See Filters for more information on adding, editing, and removing filters, and filter logic. |
**Field Name** | **Description**
---|---
Grouping Dimensions | Allows visualizing the data in terms of the particular grouping. A grouping dimension by **Service** is displayed by default. You can view only one grouping dimension at a time.

- **Availability domain**
- **Compartment.** When you choose to group by compartment, you can pick the display name value, and a compartment depth. The compartment depth corresponds to the lowest level you want the compartments to be grouped by. All levels above that grouping level return just what is directly in those compartments. The grouping level returns values for all resources in those compartments, plus all resources in compartments below it.

- **Display As**
  - Display as Compartment Name
  - Display as Compartment OCID
  - Display as Compartment Path

**Note:**
If Compartment OCID or Compartment Name are chosen, you cannot view Compartment Level.

- **Compartment Level**
  - **All** (the default): Every compartment is displayed. Values would display usage/spend associated only with the resources in that specific compartment.
  - **Level 1** (root only): Only 1 column is returned (root), and values for resources contained in root and every child compartment are displayed.
  - **Level 2** (root/<value>): Displays root, with values for root equaling only those resources in root. All compartments that are direct children of root are also returned. The values for each of those compartments is the sum of all resources therein, or within any children of those compartments.
  - **Level 3** (root/<value>/<value>): Returns root, with values for root equaling only those resources in root. All Level 2 compartments are also returned, but with values only equal to the resources contained in each of those specific compartments. The first child level of the level 2 compartments are also returned. The values for the third level of compartment (root/child1/child2 <<) would be equal to the resources in those compartments, plus all the resources in all the children of those compartments.
  - **Level 4** (root/<value>/<value>/<value>)
  - **Level 5** (root/<value>/<value>/<value>/<value>)

- **Platform** (Gen-1 are services which are not Oracle Cloud Infrastructure native, while Gen-2 includes all native Oracle Cloud Infrastructure services)
- **Region**
- **Resource OCID**
- **Service**
- **Service and Product Description**
- **SKU - Part Number**
- **SKU - Product Description**
- **Tag**
- **Unit**

See Grouping Dimensions for more information on viewing and changing grouping dimensions.
**Viewing and Working with the Chart Data**

When the Cost Analysis page first loads, the default view is to show a grouping of services for the **This Month** time period, grouped by **Service**. The Cost Analysis chart is organized in terms of time (UTC) on the X-axis, and the cost amount on the Y-axis. When viewing a chart, you can hover the mouse over a data point in the chart to see more information about it. The tooltip shows the cost value summary for the particular Y-axis item at a particular time, whether you are viewing the chart as either a **Bars** (the default), **Lines**, or **Stacked Lines** chart.

To the right of the chart, the **Legend** box shows all the data by default, and each item is color-coded. You can click the eye icon next to any of the **Legend** items to toggle the chart data on or off. For example, when viewing a chart with various services and their costs, the **Legend** box includes all the impacted services related to the query. Toggling one or more of the services shows or hides them dynamically from the chart output. Toggling the **Legend** data, however, does not change the data shown in the table view, or what is downloaded.

When viewing a chart, you can also add filters or grouping dimensions (or both), to view the cost data according to one or more filters, or in terms of both filters and a single grouping dimension.

A tabular view of the chart is also provided under the chart, which is updated as you apply different time period, filtering, and grouping dimension options. When viewing the table data, you can click the column header to sort in ascending or descending order.

**Note:**

Data can take up to 48 hours to appear in Cost Analysis.

**Filters**

See the following for instructions on how to add, edit, and remove filters, as well filter logic.

**To add filters**

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Cost Analysis**.

2. From **Time Period (UTC)**, select a time period.

3. From **Show**, select whether you want to view **Cost** or **Usage**.

4. Choose from three chart types, whether **Bars** (the default), **Lines**, or **Stacked Lines**.

5. From **Filters**, select a filter. A dialog specific to the chosen filter is displayed. For example, if you chose **Service**, select a service from the drop-down menu. You can add multiple services if preferred, or click the **X** icon to remove service filters. Click **Select** when you are finished selecting filtering criteria.

6. Click **Apply** to apply the changes and reload the chart and table with the selected filters.

**To edit a filter**

1. To edit the filter after it has already been applied to the chart, click the filter. The filter's dialog box is displayed.

2. From the filter dialog drop-down menu, select one or more filters, and click **Select**.

3. Click **Apply** to apply the changes and reload the chart and table with the selected filters.

**To remove a filter**

1. To remove the filter after it has been applied to the chart, click **Clear All Filters**, or click the filter's **X** icon under **Filters**.

2. Click **Apply** to apply the changes and reload the chart and table without the selected filters.

**Filter Logic**

Filters are ORed within each specific filter, and ANDed between filters. For example, a filter for **Service** = Compute, Block Storage, Object Storage, Database, and **Tag** = **Tag Key** "MyKey" displays data that is for (Compute OR Block Storage OR Object Storage OR Database) AND **Tag Key** "MyKey".

The Tag filter, however, is a unique case. You can add multiple Tag filters, which function as a joined OR.
Using Multiple Filters to View Costs

You can start by filtering the Cost Analysis chart data based on a single filter, and then add additional filters. For example:

1. Set your Grouping Dimensions on page 288 to Service, to view your costs by service.
2. From Filters, add a filter by Tag.
3. Select a Tag Namespace (this example uses "Financial" as the selected namespace).
4. Select a Tag Key (this example uses "Owner" as the selected key).
5. Specify whether to Match any value (AND condition), or Match any of the following (OR condition).

For example, assuming the value "alpha" is the value, and if Match any of the following is chosen, it means show all services that have "alpha" as the owner. Conversely, assuming multiple values "alpha" and "beta" are chosen, and if Match any of the following is selected, this corresponds to an OR condition (meaning, filter to show the costs from all the services from the "Financial" namespace, with the Tag Key "Owner", that matches either the "alpha" or "beta" values).

6. Click Select, then Apply to reload the Cost Analysis chart with the filtered information.

You can also add another filter by tag, to break the data down further. For example:

1. From Filters, add a filter by Tag.
2. Select a Tag Namespace (for example, the "Cost Center" namespace).
3. Select Match any of the following, and for example, filter for any "Cost Center" values of "1234" or "5678".

After clicking Select, then Apply, this filter shows the costs from all the services with the previous tag filter, plus this second tag filter ("Financial" namespace, Tag Key "Owner", "alpha" or "beta" values + "Cost Center" namespace with the values of "1234" or "5678"). The two tag filters together amount to an AND with the previous filter (the two filters are shown adjacent to the Add Filter drop-down list).

Alternatively, instead of this second tag filter ("Cost Center" namespace with the values of "1234" or "5678"), you could add a service filter (NETWORK), and that would show the costs from all the services from the "Financial" namespace, with the Tag Key "Owner", that matches both the "alpha" or "beta" values, and is filtered by the NETWORK service type.

Grouping Dimensions

See the following for instructions on how to view and change grouping dimensions. Grouping dimensions change the way data is aggregated, but does not change the sum. If a resource does not have a value for a particular field, a "no value" column is displayed, which reflects the sum of those resources. Specifically, products which are Gen-1 often do not have an Availability Domain, Compartment, or Resource ID.

To view grouping dimensions

1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Cost Analysis.
2. From Time Period (UTC), select a time period.
3. From Show, select whether you want to view Cost or Usage.
4. Choose from three chart types, whether Bars (the default), Lines, or Stacked Lines.
5. From Grouping Dimensions, select the preferred grouping dimension. If Compartment or Tag is chosen, additional Compartment or Tag selection fields appear.
6. Click Apply to apply the changes and reload the chart and table with the selected grouping dimension.

To change a grouping dimension

1. To change the grouping dimension, select it from Grouping Dimensions.
2. Click **Apply** to apply the changes and reload the chart and table with the new grouping dimension.

**Identifying a Resource that is Consuming Costs**

If you have noticed a large amount of, for example, Database service usage that has appeared in a chart, and you wanted to identify which resource was responsible, you can group by **Resource OCID** from the **Grouping Dimensions** drop-down list. Next, from **Filters**, add a filter for the service type (**Database** in this example), and click **Apply** to reload the chart.

The chart reloads to show which resource OCIDs were driving the Database cost, both when hovering over the data point in the chart, and in the **Legend** box. These resource OCIDs are also displayed in the data table below the chart. If desired, you can save this information by clicking **Download**, and then selecting **Download Table as CSV**.

**Tip:**

The **Legend** box is set to a default size when the charts first loads, but you can click and drag the box to more easily read lengthy items within it (such as OCIDs).

To find more information about the resource, copy the OCID and enter it in the Console’s Search box, to pinpoint which resource is driving costs.

**Grouping by Service and SKU, or Service and Product Description to Identify Costs**

In some instances you may see multiple SKU numbers for a service. When grouping by **Service and SKU (Part Number)**, multiple SKU numbers for the same service appear in the **Legend** box. For example, if you had multiple Compute entries in the **Legend** box but they have different SKUs, it means there is one resource using multiple underlying infrastructure components. This case is actually most common for Block Storage (where multiple Block Storage entries appear with different SKUs). Specifically, for the Block Storage case, you are charged for storage itself, but you are also charged for any data transfers out of Block Storage. As a result, you will see multiple "Block Storage" items listed with different SKU numbers in the **Legend** box. For example:

```
Block Storage / <SKU number 1>
Block Storage / <SKU number 2>
Block Storage / <SKU number 3>
Block Storage / <SKU number 4>
```

Another way of looking at this same type of data is to use the **Service and Product Description** grouping dimension. The **Legend** box is sorted in the same manner, but presents the data differently. That is, according to the actual product descriptions, versus the SKUs that these are associated with. For example:

```
Block Storage / Block Volume - Backup
Block Storage / Block Volume - Free
Block Storage / Block Volume - Performance Units
Block Storage / Block Volume - Storage
```

**Tip:**

By default, these longer descriptions may not be visible, and so you should resize the **Legend** box to view them.

The Database service is also a useful example. There could be different instances of a database and you could also be charged for Block Storage within the Database service. For example, this entry could appear in the **Legend** for such a case:

```
Database / DBaaS - Attached Block Storage Volume - Standard Performance
```

You could also be charged in the Database service for network transfer. For example:

```
Database / Oracle Autonomous Data Warehouse - Exadata Storage
```

Charges for licensing of the application version can also occur:
Cost and Usage reports are a good way to further slice such information you have noticed in the Cost Analysis charts. For example, in a cost report you might notice a SKU number that's associated with Compute, and also see the same SKU number that's associated with Block Storage. As a result, you may wonder if you were double-billed (though this is actually not the case). To investigate the actual cost, you can first filter the cost CSV spreadsheet by the SKU. Once you have applied a filter to the CSV using a particular SKU, you can see which services are consuming from the product/Description column. For example, a SKU could be using a lot of "Block Volume - Performance Units", but you also notice that "DBaaS - Attached Block Storage Volume" appears in this column.

A way to further segment the data would be to copy the resource ID from the product/resourceid column, of say the "DBaaS - Attached Block Storage Volume" entry you noticed amongst all the "Block Volume - Performance Units", and remove the SKU filter you applied previously. Next, filter the spreadsheet based on the resource ID instead. This then shows all the components (indicated in the product/Description column) that the particular resource ID is consuming.

Note:
When viewing a cost report, the cost/productSku and product/description columns map to one another, and are adjacent columns in the CSV. For more information on these fields and other fields that appear in the reports, see Cost and Usage Reports Overview on page 278.

Similarly, you can use Cost Analysis to do a Resource OCID grouping dimension, with a Product description filter, to show all the resources that are using a particular product. For example, if you choose Block Volume - Performance Units as the filter, the Cost Analysis chart shows which resources are using "Block Volume - Performance Units". See Identifying a Resource that is Consuming Costs on page 289 for more information on identifying the particular resource(s).

Download Your Data
Click the Download button to download a CSV file of the data, or a PNG file of the chart. Downloading generates a file that corresponds to the chart or table on the Cost Analysis page, inclusive of applied filters, sorting, and grouping dimensions.

Using the Usage API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage usage:
• UsageSummary
• RequestSummarizedUsages

The Usage API allows retrieval of usage and cost data. You can:
• Query based on different granularity, for example, MONTHLY or DAILY.
• Specify queryType, for example, COST, USAGE.
• Filter and group by different dimension/tags, functioning like an SQL query.
• Use up to four groupBy parameters.

The following is a sample Usage endpoint URI that conforms to the schema:
• https://usageapi.<region>.oci.oraclecloud.com/20200107/usage

For more information about the API and to view the full list of endpoints, see the Usage API.
Using granularity

The Usage API supports: MONTLY, DAILY, and HOURLY granularity. All startTime are inclusive, and endTime are exclusive, the same as a Java substring.

- For HOURLY, only a maximum 36-hour time period is supported, with no more precision than an hour. This means no minutes or seconds in the input time.
- For MONTHLY, only the first date of the month to another first date of the month is supported. For example, 2020-06-01T00:00:00Z, a maximum 12-month period.
- For DAILY, no more precision than a day is supported, with a maximum 90-day period. You must enter this as 00:00:00. For example, 2020-06-01T00:00:00Z.

Using groupBy

In an API response, dimension is only shown in terms of groupBy. For example, if "service" isn't in groupBy, the "service" field in the response will be empty.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only four groupBy parameters can be used at a time.</td>
</tr>
</tbody>
</table>

In addition:

- If a groupBy list is empty, "currency" will be added into groupBy.
- If the queryType is "Usage", "unit" will be add into groupBy.
- If the queryType is "COST" or "empty", "currency" will be add into groupBy.
- computedAmount works as expected only when "currency" is in groupBy.
- computedQuantity works as expected only when "unit" is in groupBy.

Using queryType

The API can query USAGE or COST. computedQuantity represents usage and computedAmount represents cost. For getting the expected usage, you need to set queryType to USAGE or add "unit" in groupByKey. This is due to the fact that usage is aggregated/grouped correctly when grouping by unit.

Using filtering

Nested filtering in API requests is supported. The list of filters are evaluated by the operator. In each filter, all dimensions and tags are evaluated by the operator. Simultaneous evaluation of the filter list and dimension/tags is not supported, which means dimensions or tags and the filter list can't be non-empty at the same time.

Supported operators are AND, OR. These two filters below are equal:

```
"filter": {
  "operator": "AND",
  "dimensions": [
    {
      "key": "service",
      "value": "compute"
    },
    {
      "key": "compartmentPath",
      "value": "abc/cde"
    }
  ],
  "tags": [
    {
      "namespace": "compute",
      "key": "created",
      "value": "string"
    }
  ]
```

Invalid example because dimensions and filters are non-empty at the same time:

```
"filter": {
  "operator": "AND",
  "dimensions": [{
    "key": "compartmentPath",
    "value": "abc/cde"
  }],
  "tags": [],
  "filters": [
    {
      "operator": "AND",
      "dimensions": [{
        "key": "service",
        "value": "compute"
      }],
      "tags": null,
      "filters": null
    },
    {
      "operator": "AND",
      "dimensions": [{
        "key": "compartmentPath",
        "value": "abc/cde"
      }],
      "tags": null,
      "filters": null
    },
    {
      "operator": "AND",
      "dimensions": null,
      "tags": [{
        "namespace": "compute",
        "key": "created",
        "value": "string"
      }],
      "filters": null
    }
  ]
}
```
Querying with tags

As mentioned previously, we only show the field in `groupBy`. So you need to add tag related fields in `groupBy`. For example:

```
"tagNamespace", "tagKey", "tagValue"
```

If you add `tagKey`, all items in the response will have a `tagKey`. `tagKey` also can be empty even if you add a `tagKey`. This is because some of your resources don't have a `tagKey`. We suggested adding all three of these in `groupBy`, so you can see a complete tag in the response:

```
"tagNamespace", "tagKey", "tagValue"
```

If you want to filter by tag, you need to add the tag in the filter object. This can be filtered by any `tagKey/_namespace/value` combination of any `tagKey/namespace/value`.

**Valid `groupBy` example**

```
"tagNamespace", "tagKey", "tagValue", "service", "skuName", "skuPartNumber", "unit", "compartmentName", "compartmentPath", "compartmentId", "platform", "region", "logicalAd", "resourceId", "tenantId", "tenantName"
```

**Note:**

Only up to four `groupBy` parameters can be used in an API call.

"tenantId" and "tenantName" are not currently supported.

**Valid filter dimension example**

```
"service", "skuName", "skuPartNumber", "unit", "compartmentName", "compartmentPath", "compartmentId", "platform", "region", "logicalAd", "resourceId", "tenantId", "tenantName"
```

This is case-sensitive. "tenantId" and "tenantName" are not currently supported.

**How to `groupBy` compartment?**

`groupBy` compartment-related keys ("compartmentName", "compartmentPath", "compartmentId") are different than the other `groupBy` keys.

To get an expected result, you must request with `compartmentDepth`. `compartmentDepth` is >=1 and <=6.

`groupBy` compartment means all compartments usage or costs with a higher depth will be aggregated to the compartment with the given depth. For example:

<table>
<thead>
<tr>
<th>Compartment</th>
<th>Depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root</td>
<td>1</td>
</tr>
<tr>
<td>B</td>
<td>C</td>
</tr>
</tbody>
</table>
If the depth is 1, it means all usage or costs are grouped to the root compartment.

If the depth is 2, it means all compartments with depth 2 will contain the usage or costs with all its children. In the response, the root will contain its own usage, B will aggregate (B, D, E, F), and C will contain C.

**Why are some fields in a response empty?**

The fields will show up only when the fields are in `groupBy`. Not all fields in the response are currently available. Only the fields mentioned in [Valid groupBy example](#) on page 293 are supported.

**What is nextPageToken?**

This can be set as null. Currently not supported.

**Example request body**

The best way to understand how the API works is checking how the Console uses the API. You can find the request body in the web browser's debug mode.

```json
{
    "tenantId": "oci1.tenancy.oc1..<unique_ID>",
    "timeUsageStarted": "2020-04-01T00:00:00.000Z",
    "timeUsageEnded": "2020-07-01T00:00:00.000Z",
    "granularity": "MONTHLY",
    "queryType": "COST",
    "groupBy": [
        "tagNamespace",
        "tagKey",
        "tagValue",
        "service",
        "compartmentPath"
    ],
    "compartmentDepth": 2,
    "filter": null
}
```

After you make a request without any filter, you can see what the dimension/tags' value can be. Subsequently, you can make a request with a filter and a correct dimension value.

```json
{
    "tenantId": "oci1.tenancy.oc1..<unique_ID>",
    "timeUsageStarted": "2020-04-01T00:00:00.000Z",
    "timeUsageEnded": "2020-07-01T00:00:00.000Z",
    "granularity": "MONTHLY",
    "groupBy": ["tagNamespace","tagKey","tagValue","service","compartmentPath"],
    "compartmentDepth": 2,
    "filter": {
        "operator": "AND",
        "dimensions": [],
        "tags": [],
        "filters": [
            {
                "operator": "AND",
                "dimensions": [
                    {"key": "service",
                     "value": "compute"
                    }],
                "tags": null,
```
Using customized scripts, CLI, and SDK

If you write a customized script, Oracle does not support or assist with debugging your script. Only the CLI, SDK, and Terraform are supported. See 3. Create and Configure a Copy of oci-curl on page 2050 for more information on using customized scripts, and Command Line Interface (CLI) on page 4192 for more information. For example:

```bash
--request-body
file:///<system_path>/SimpleRequestSummarizedUsagesDetails.json
--config-file ~/Downloads/clitest.conf
```

**SimpleRequestSummarizedUsagesDetails.json:**

```json
{
    "tenantId": "oci1.tenancy.oc1..<unique_ID>",
    "timeUsageStarted": "2020-03-19T17:00:00.000000-07:00",
    "timeUsageEnded": "2020-03-21T00:00:00Z",
    "granularity": "DAILY",
    "groupBy": [],
    "compartmentDepth": null,
    "filter": null,
    "nextPageToken": "string"
}
```

**clitest.conf:**

```ini
[DEFAULT]
user=oci1.user.oc1..<unique_ID>
fingerprint=<MAC_ID>
key_file=<system_path>/oci_api_key.pem
#tenancy=oci1.tenancy.oc1..<unique_ID>
tenancy=oci1.tenancy.oc1..<unique_ID>
region=us-ashburn-1
```

Unified Billing Overview

This topic describes how you can unify billing across multiple tenancies by sharing your subscription. You should consider sharing your subscription if you want to have multiple tenancies to isolate your cloud workloads, but you want to have a single Universal Credits commitment. For example, you have a subscription with a $150,000 commitment, but you want to have three tenancies, because the credits are going to be used by three distinct groups that require strictly isolated environments.

Two types of tenancies are involved when sharing a subscription in the Console:

- The parent tenancy (the one that is associated with the primary funded subscription).
- Child tenancies (those that are consuming from a subscription that is not their own).

Notable benefits of sharing a subscription includes:

- Sharing a single commitment helps to avoid cost overages and allows consolidating your billing.
- Enabling multi-tenancy cost management. You can analyze, report, and monitor across all linked tenancies. The parent tenancy has the ability to analyze and report across each of your tenancies through Cost Analysis and Cost and usage reports, and you can receive alerts through Budgets.
- Isolation of data. Customers with strict data isolation requirements can use a multi-tenancy strategy to continue restricting resources across their tenancies.

The remainder of this topic provides an overview of how to share your subscription between tenancies, and provides best practices on how to isolate workloads, in order to help you determine if you should use a single-tenancy or multi-tenancy strategy.

Planning Considerations

Before you get additional tenancies you should evaluate your needs to make sure that a multi-tenancy approach is best for your workloads. The main reason to have multiple tenancies is for strong isolation. By default, each parent and child tenancy comes with:

- A distinct set of IAM users (which can be federated to another identity system).
- A distinct set of IAM policies (permissions).
- Its own service limits.
- Isolated Virtual Cloud Networks (VCNs).
- Separate security and governance settings.

The main point to be aware of is that multiple tenancies make it easier to isolate workloads, but that comes at the cost of needing to manage multiple tenancies. Additional tenancies, however, do create additional management overhead, so you need to ensure that the isolation is worth it. If you don't require a strong level of isolation, you should consider using compartments to separate workloads.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

To use subscription sharing, the following policy statements are required:

- Allow group linkUsers to use organizations-family in tenancy
- Allow group linkAdmins to manage organizations-family in tenancy

To accept an invitation but not create one use the following:

- allow group linkAccepters to manage organizations-recipient-invitations in tenancy
Subscription Sharing Overview

Depending on whether or not you already have multiple tenancies, there are two approaches:

If you don't already have an additional tenancy

1. Sign up for a new PAYG (pay as you go) subscription to get a new tenancy. You do not incur any charges against the PAYG subscription, as long as you link it with your existing subscription before creating any billable resource. There are two ways to get a new PAYG subscription:
   a. Self-service: Sign up for a new trial using http://signup.oracle.com, and upgrade the trial to a paid account.
   b. Through sales: Work with your Oracle sales team to book a new PAYG order.
2. Take note of the tenancy OCID in the new tenancy. You can find it on the Tenancy Details page in the Console. This page can be accessed by opening the Profile menu and then selecting Tenancy: <your_tenancy_name>. See the OCID field on the Tenancy Information tab.
3. From the tenancy that owns the primary subscription, invite the new tenancy to share the subscription (described in To Share a Subscription).

If you already have multiple tenancies

There are two paths you can take:

• If you have one primary tenancy that has a Universal Credits Flex (commitment) subscription and your subsequent tenancies have a PAYG subscription, you can follow the steps in If you don't already have an additional tenancy to get a new tenancy.
• If your tenancies have multiple Universal Credits Flex (commitment), you will need to work with your Oracle sales team to rebalance your commitment balances.

To Share a Subscription

Important:
Ensure that you understand the terms of your contract before sharing your subscription with another tenancy. Your contract specifies how your subscription can be used, and which end users are allowed to use it.

Note:
Rebalancing subscriptions is a manual process that needs to be coordinated, and rebalancing will not be available under all circumstances. Your sales team will work with you to rebalance your subscriptions and set up the parent-child billing relationship.

1. Sign in to the sender tenancy that will send the invitation, as a user that has permissions to manage subscription sharing.
2. Open the navigation menu. Under Governance and Administration, go to Account Management and click Subscription Sharing. The Subscription Sharing page is displayed.
3. Click Invite Tenancy. The Invite Tenancy panel is displayed.
4. Enter the invitation details. You will need to specify the following:
   • The invitation name in Invitation Name. For the invitation name, it can be helpful to use notation that signifies the direction and number of sending invitation attempts. For example, entering a1 to b1 v1 can
signify that tenancy a1 is sending an invitation to b1 and v1 as the first attempt. Such a convention allows the invitations to be more readable to the Console user, without having to access the Invitation Detail page to view sender and recipient details.

- The child tenancy OCID in Recipient Tenancy OCID.
- Optionally, an email address in Recipient Email, to notify that a sharing invitation has been sent.

**Note:**
The recipient needs to have the proper permissions to manage subscription sharing in the child tenancy, in order to accept the invitation. For more information, see Required IAM Policy on page 296.

- Optionally, enter tagging information.

5. Click Send Invitation. The invitation is sent to the tenancy you are inviting to share the subscription with.

**Note:**
Parent tenancies and tenancies that are not already in a sharing relationship can send invitations. Child tenancies cannot send invitations.

6. On the recipient (child) tenancy: Open the navigation menu. Under Governance and Administration, go to Account Management and click Subscription Sharing. The Subscription Sharing page is displayed.

7. The invitation from the other tenancy is displayed in the list, with the following information:

- **Invitation Name**: Click this linked name to go to the Invitation Detail page.
- **Status**: Displays the invitation status. For example, it is Active when the invitation is received but not yet accepted. From the parent tenancy, this field shows Pending for an invitation that has been sent but not yet accepted.

The possible status states for a sender and recipient invitation are the following:

<table>
<thead>
<tr>
<th>Sender Invitation</th>
<th>Recipient Invitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PENDING</td>
<td>PENDING</td>
</tr>
<tr>
<td>CANCELED</td>
<td>CANCELED</td>
</tr>
<tr>
<td>ACCEPTED</td>
<td>ACCEPTED</td>
</tr>
<tr>
<td>EXPIRED</td>
<td>IGNORED</td>
</tr>
<tr>
<td>FAILED</td>
<td>EXPIRED</td>
</tr>
<tr>
<td></td>
<td>FAILED</td>
</tr>
</tbody>
</table>

- **Type**: The invitation type, whether Sent or Received.
- **Created**: The UTC creation date and time of the invitation.

8. Click the Actions icon (three dots) and select Accept Sharing Invitation. An confirmation acceptance message is displayed, which indicates that you are about to accept a subscription sharing invitation from tenancy <OCID>.

After clicking Accept, the invitation is processed, and the invitation's Status field changes to Updating. The tenancy then becomes a child tenancy.

After the sharing invitation is accepted, it will take one to two hours for metering to start flowing to the subscription in the parent tenancy. From that time onwards, however, all usage in the child tenancy will be metered against the parent tenancy's subscription. In addition, after linking tenancies, we recommend you wait
for a few hours before launching resources, that is, if you want to be sure all spending will accrue against the subscription of the parent tenancy.

If there is a remaining subscription balance, contact your sales representative to move it to a primary subscription in the sending tenancy.

Note:
Once the tenancy becomes a child tenancy, it cannot invite another tenancy to become a child tenancy. The Invite Tenancy button on the Subscription Sharing page becomes disabled to reflect this state.

9. Open the child tenancy's Linked Tenancies page, where you can view the linking between the child and parent tenancy. The following information is displayed:

- **Tenancy OCID**: The tenancy OCID.
- **Status**: Displays the invitation status.
- **Established**: The UTC date and time that the subscription sharing began.
- **Terminated**: The UTC date and time that the subscription sharing began. This field is empty if the sharing is still active.

Meanwhile on the parent tenancy's Linked Tenancies page, you can view the (child) tenancies that are being metered against your subscription.

**To Revoke a Subscription Sharing Invitation**

1. Sign in to the primary tenancy as a user that has permissions to manage subscription sharing.
2. Open the navigation menu. Under Governance and Administration, go to Account Management and click Subscription Sharing. The Subscription Sharing page is displayed.
3. For the invitation you want to revoke, click the Actions icon (three dots) and select Revoke Invitation. A Revoke Invitation confirmation is displayed. Click Revoke to cancel the sharing invitation.
4. On the Subscription Sharing page, the invitation’s Status changes to Canceled.

**Viewing Invitation Details**

Invitation details can be viewed from both the parent and child tenancy. To view invitation details:

1. Open the navigation menu. Under Governance and Administration, go to Account Management and click Subscription Sharing. The Subscription Sharing page is displayed.
2. Click the linked invitation name from the Invitation Name field, or click the Actions icon (three dots) and select View Invitation Details. The Invitation Detail page is displayed.
3. This page displays the invitation status, along with the following details on the Invitation Information tab:
   - Sent from Tenancy OCID
   - Type
   - Last Status Change
   - Sent to Tenancy OCID
   - Sent Date

   You can also click Add Tags to add tagging information, and view it on the Tags tab. See Resource Tags on page 211 for more information.

**Using the Organizations API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations in the Organizations API to manage subscription sharing:

- **Link**
Service Essentials

- RecipientInvitation
- SenderInvitation
- WorkRequest
- WorkRequestError
- WorkRequestLogEntry

Cost Reporting

Once a subscription is shared, the behavior of cost reporting tools changes. All spending against the subscription (in the parent and all child tenancies) is included in cost reporting in the parent tenancy, and child tenancies are limited to seeing spending in their own tenancy. Cost and usage reports are generated only in the parent tenancy, and include all usage for the parent and all of its children. Budgets are only supported in the parent tenancy. The following table describes the impact of subscription sharing on cost reporting.

<table>
<thead>
<tr>
<th></th>
<th>Parent Tenancy</th>
<th>Child Tenancies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cost Analysis</td>
<td>Reports on all usage and cost in the parent, and all children with the ability to group and filter by tenancy.</td>
<td>Reports on all usage and cost in the child tenancy.</td>
</tr>
<tr>
<td>Note:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If a child tenancy wants to use Cost Analysis from the Console, you must subscribe to the parent’s home region.</td>
</tr>
<tr>
<td>Cost and usage reports (CSVs)</td>
<td>Includes all usage and costs in the parent and all children.</td>
<td>Not available.</td>
</tr>
<tr>
<td>Budgets</td>
<td>Budgets can be created against compartments or tags in the primary tenancy but not against child tenancies.</td>
<td>Not supported.</td>
</tr>
</tbody>
</table>

Support

Depending on how you created your tenancy, you will either have separate CSI (Customer Support Identifier) numbers, and support accounts for each tenancy, or they will be combined. If you want to make sure that you get multiple CSI numbers, ensure that you work with your account team to create tenancies in a way that will create new CSIs.

My Services Use Cases

**Important:**
The My Services dashboard and APIs are deprecated.

To interact programmatically with My Services, you can use the Oracle Cloud My Services API. To help you get started, here are some use cases:

- Service Discovery Use Case on page 300
- Exadata Use Cases on page 303
- Managing Exadata Instances on page 314
- Using Access Token Authorization with My Services API on page 328

Service Discovery Use Case

This use case shows how you can get the list of your service entitlement IDs.
Important:
The My Services dashboard and APIs are deprecated.

Discover Current Service Entitlement IDs

Many of the My Services API operations require you to specify the `serviceEntitlementId`. To get the list of all your service entitlement IDs, use the `GET ServiceEntitlements` operation. This operation returns information that you can use to make more specific requests using the Oracle Cloud My Services API.

Example:

```
GET /itas/<domain>/myservices/api/v1/serviceEntitlements
```

**Note:**

In the examples, `<domain>` is the identity domain ID. An identity domain ID can be either the `IDCS GUID` that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the `Identity Domain name` for a traditional Cloud Account.

Example payload returned for this request:

```
{
   "items": [
      {
         "id": "cesi-511202718", // Unique ServiceEntitlementId
         "purchaseEntitlement": { // Purchase Entitlement is the entity bought by a customer
            "subscriptionId": "511203590",
            "id": "511203590",
            "canonicalLink": "/itas/<domain>/myservices/api/v1/purchaseEntitlements/511203590"
         },
         "serviceDefinition": { // The customer is entitled to use the Storage Service
            "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceDefinitions/500089778",
            "id": "500089778",
            "name": "Storage"
         },
         "createdAt": "2017-12-20T16:23:23.326Z",
         "createdBy": "paul.smith@oracle.com",
         "modifiedAt": "2017-12-20T18:35:40.628Z",
         "modifiedBy": "paul.smith@oracle.com",
         "identityDomain": { // Identity Domain to which the Service Entitlement is associated
            "id": "511203592",
            "name": "myenvironment",
            "displayName": "myenvironment"
         },
         "cloudAccount": { // Cloud Account to which the Service Entitlement is associated
            "id": "cacct-be7475efc2c54995bc842d3379d35812",
            "name": "myenvironment",
            "canonicalLink": "/itas/<domain>/myservices/api/v1/cloudAccounts/cacct-be7475efc2c54995bc842d3379d35812"
         },
         "status": "ACTIVE", // Current Status
      }
   ]
}
```
"serviceConfigurations": { }

Service Essentials

"serviceConfigurations": { // Specific configuration information such as Exadata configuration
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-511202718/serviceConfigurations",
},
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-511202718"
},
{
  "id": "cesi-511202719",
  "purchaseEntitlement": {
    "subscriptionId": "511203590",
    "id": "511203590",
    "canonicalLink": "/itas/<domain>/myservices/api/v1/purchaseEntitlements/511203590"
  },
  "serviceDefinition": {
    "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceDefinitions/500123193",
    "id": "500123193",
    "name": "Compute" // The customer is entitled to use the Compute Service
  },
  "createdOn": "2017-12-20T16:23:23.326Z",
  "createdBy": "paul.smith@oracle.com",
  "modifiedOn": "2017-12-20T18:35:40.628Z",
  "modifiedBy": "paul.smith@oracle.com",
  "identityDomain": {
    "id": "511203592",
    "name": "myenvironment",
    "displayName": "myenvironment"
  },
  "cloudAccount": {
    "id": "cacct-be7475efc2c54995bc842d3379d35812",
    "name": "myenvironment",
    "canonicalLink": "/itas/<domain>/myservices/api/v1/cloudAccounts/cacct-be7475efc2c54995bc842d3379d35812"
  },
  "status": "ACTIVE",
  "serviceConfigurations": {
    "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-511202719/serviceConfigurations",
  },
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-511202719"
}, ...

Service Entitlements could be displayed

To obtain the IDCS GUID

Go to the Users page in My Services dashboard and click Identity Console. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

https://idcs-105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v1/adminconsole/?root=users
In the above URL, idcs-105bbdfe5644611bf7ce04496073adf is the IDCS GUID for your identity domain.

**Exadata Use Cases**

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The My Services dashboard and APIs are deprecated.</td>
</tr>
</tbody>
</table>

The following use case examples can get you started working with the Exadata operations available in the Oracle Cloud My Services API.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>These procedures are for use with Oracle Database Exadata Cloud@Customer ONLY. For more information, see Administering Oracle Database Exadata Cloud at Customer. These procedures DO NOT apply to the Exadata Cloud Service available in Oracle Cloud Infrastructure.</td>
</tr>
</tbody>
</table>

**Exadata Firewall Allowlisting**

To enable access to your Exadata Cloud Service instance, you can configure security rules and associate them with your instance. The security rules define an allowlist of allowed network access points.

The firewall provides a system of rules and groups. By default, the firewall denies network access to the Exadata Cloud Service instance. When you enable a security rule, you enable access to the Exadata Cloud Service instance. To enable access you must:

- Create a security group and create security rules that define specific network access allowances.
- Assign the security group to your Exadata Cloud Service instance.

You can define multiple security groups, and each security group can contain multiple security rules. You can associate multiple security groups with each Exadata Cloud Service instance, and each security group can be associated with multiple Exadata Cloud Service instances. You can dynamically enable and disable security rules by modifying the security groups that are associated with each Exadata Cloud Service instance.

To enable access to an Exadata Cloud Service instance:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the following examples, &lt;domain&gt; is the identity domain ID. An identity domain ID can be either the IDCS GUID that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the Identity Domain name for a traditional Cloud Account.</td>
</tr>
</tbody>
</table>

1. Get the service instance IDs.

   **Operation:** GET ServiceInstances

   **Example**

   **Example request:**

   GET /itas/<domain>/myservices/api/v1/serviceInstances?
   serviceDefinitionNames=Exadata&statuses=ACTIVE

   **Example payload returned for this request:**

   ```json
   {
   "items": [
   {
   "id": "csi-585928949", // Unique ServiceInstanceID
   "serviceEntitlement": {
   ```
This example payload returns the service instance ID csi-585928949, which is part of the service entitlement ID cesi-585927251.

2. Get the service configuration IDs.

Operation: GET SIServiceConfigurations

Example

Example request, using the service instance ID csi-585928949:

GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations

Example payload returned for this request:

```json
{
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations",
  "items": [
    {
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata",
      "exadata": {
        "bursting": {
          "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/bursting"
        },
        "id": "Exadata",
        "securityGroupAssignments": {
          "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments"
        }
      }
    }
  ],
  "hasMore": false,
  "limit": 25,
  "offset": 0
}
```
This example payload shows that /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments is used for Exadata Firewall.

3. Get the current security groups for the service entitlement.

   Operation: GET SEExadataSecurityGroups

   Example

   Example request, using the service entitlement ID cesi-585927251:

   ```
   GET /itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-585927251/serviceConfigurations/Exadata/securityGroups
   ```

   Example payload returned for this request:

   ```
   {
   "items": [
   {
   "id": "1",
   "customerId": "585927251",
   "name": "SecGroup 1",
   "description": "My first Security group",
   "version": 10,
   "rules": [
   {
   "direction": "ingress",
   "proto": "tcp",
   "startPort": 1159,
   "endPort": 1159,
   "ipSubnet": "0.0.0.0/0",
   "ruleInterface": "data"
   }
   ],
   "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/1"
   },
   {
   "id": "2",
   "customerId": "585927251",
   "name": "SecGroup 2",
   "description": "My second Security group",
   "version": 3,
   "rules": [
   {
   "direction": "egress",
   "proto": "tcp",
   "startPort": 8123,
   "endPort": 8123,
   "ipSubnet": "192.168.1.0/28",
   "ruleInterface": "data"
   }
   ],
   "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/2"
   }]
   ```
This example payload shows two security groups defined for the specified service entitlement ID.

4. Get the current security group assignments for the service instance

Operation: GET SIExadataSecurityGroupAssignments

Example

Example request, using the service instance ID csi-585928949:

GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments

Example payload returned for this request:

```
{
  "items": [
    {
      "id": "11",
      "securityGroup": {
        "id": "1",
        "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/1",
        "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments/11"
      },
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments"
    }
  ],
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments"
}
```

This example payload shows one security group assigned to the service instance csi-585928949.

5. Create a security group with security rules.

Operation: POST SExadataSecurityGroups

Example

Example request, using the service entitlement ID cesi-585927251:

POST /itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-585927251/serviceConfigurations/Exadata/securityGroups
{
  "customerId": "585927251",
  "name": "SecGroup 1",
  "description": "My third Security group",
  "version": 1,
  "rules": [
    {
      "direction": "ingress",
      "proto": "tcp",
      "startPort": 30,
      "endPort": 31,
      "ipSubnet": "100.100.100.255",
      "ruleInterface": "admin"
    }
  ]
}
"direction": "egress",
"proto": "tcp",
"startPort": 32,
"endPort": 32,
"ipSubnet": "100.100.255.0/16",
"ruleInterface": "admin"
}
]

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>customerId</td>
<td>Required: Yes&lt;br&gt;String&lt;br&gt;This must be the same as the &lt;serviceEntitlementId&gt;</td>
</tr>
<tr>
<td>direction</td>
<td>Required: Yes&lt;br&gt;String&lt;br&gt;Allowed values: [ingress</td>
</tr>
<tr>
<td>proto</td>
<td>Required: Yes&lt;br&gt;String&lt;br&gt;Allowed values: [tcp</td>
</tr>
<tr>
<td>startPort</td>
<td>Required: Yes&lt;br&gt;Integer&lt;br&gt;startPort defines the beginning of a range of ports to open/white-list [0 - 65535].</td>
</tr>
<tr>
<td>endPort</td>
<td>Required: Yes&lt;br&gt;Integer&lt;br&gt;endPort defines the ending of a range of ports to open/white-list [0 - 65535].</td>
</tr>
<tr>
<td>ipSubnet</td>
<td>Required: Yes&lt;br&gt;String&lt;br&gt;Single IP address or range specified in CIDR notation.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| ruleInterface | Required: Yes  
String  
Allowed values: [admin | client | backup] where:  
• admin — specifies that the rule applies to network communications over the administration network interface. The administration network is typically used to support administration tasks by using terminal sessions, monitoring agents, and so on.  
• client — specifies that the rule applies to network communications over the client access network interface, which is typically used by Oracle Net Services connections.  
• backup — specifies that the rule applies to network communications over the backup network interface, which is typically used to transport backup information to and from network-based storage that is separate from Exadata Cloud Service. |

If successful, the POST request will return the unique ID of the newly created security group. For the next step, we'll assume that the newly created security group ID is 3.

**Note:**
A security group can also be modified or deleted. See Oracle Cloud My Services API.

6. Assign the security group to a service instance.

Operation: POST SIExadataSecurityGroupAssignments

Example

Example request, using the service instance csi-585928949 and the security group ID 3:

```json
POST /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments

{
   "securityGroup": {
      "id": "3",
      "customerId": "585927251",
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/3"
   }
}
```
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| customerId | Required: Yes  
|          | String  
|          | This must be the same as the serviceEntitlementId. |

If successful, the POST request will return the unique Id of the newly created security group assignment.

**Note:**
A security group assignment can also be deleted. See [Oracle Cloud My Services API](#).

You can now verify all your security groups and assignments. See:

- Get the current security groups for the service entitlement.
- Get the current security group assignments for the service instance.

**To obtain the IDCS GUID**

Go to the Users page in My Services dashboard and click **Identity Console**. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

https://idcs-105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v1/adminconsole/?root=users

In the above URL, `idcs-105bbbdfe5644611bf7ce04496073adf` is the IDCS GUID for your identity domain.

**Exadata Scaling with Bursting**

You can temporarily modify the capacity of your Exadata environment by configuring bursting. Bursting is a method you can use to scale Exadata Cloud Service non-metered instances within an Exadata system.

To scale up your non-metered instances, increase the number of compute nodes by modifying the `burstOcpu` attribute of the host. When you no longer need the additional nodes, update the `burstOcpu` attribute back to its original setting.

**Note:**

In the following examples, `<domain>` is the identity domain ID. An identity domain ID can be either the IDCS GUID that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the Identity Domain name for a traditional Cloud Account.
1. Get the service instance IDs.
   Operation: GET ServiceInstances
   Example
   Example request:
   ```
   GET /itas/<domain>/myservices/api/v1/serviceInstances?
   serviceDefinitionNames=Exadata&statuses=ACTIVE
   ```
   Example payload returned for this request:
   ```
   {
   "items": [
   {
   "id": "csi-585928949",              // Unique ServiceInstanceId
   "serviceEntitlement": {
   "id": "cesi-585927251",
   "canonicalLink": "/itas/<domain>/myservices/api/v1/
   serviceEntitlements/cesi-585927251"
   },
   "serviceDefinition": {
   "canonicalLink": "/itas/<domain>/myservices/api/v1/
   serviceDefinitions/502579309",
   "id": "502579309",
   "name": "Exadata"                // The customer is entitled to use
   the Exadata Service
   },
   "cloudAccount": {
   "canonicalLink": "/itas/<domain>/myservices/api/v1/cloudAccounts/
   cacct-fd7a122448aaaa",
   "id": "cacct-fd7a122448aaaa",
   "name": "myAccountName"
   },
   ...
   "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/
   csi-585928949"
   }
   ...
   // More Service Instances
could be displayed
   },
   "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances",
   "hasMore": false,
   "limit": 25,
   "offset": 0
   }
   ```
   This example payload returns the service instance ID csi-585928949.

2. Get the service configuration IDs.
   Operation: GET SIServiceConfigurations
   Example
   Example request, using the service instance ID csi-585928949:
   ```
   GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/
serviceConfigurations
   ```
   Example payload returned for this request:
   ```
   {
   ```
This example payload shows that `/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments` is used for Bursting.

3. Get the current compute node configuration.

   **Operation:** GET SIExadataBursting

   **Example**

   Example request, using the service instance ID `csi-585928949`:

   ```
   GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/bursting
   ```

   Example payload returned for this request:

   ```
   {  
     "ocpuOpInProgress": false,  
     "exaunitId": 50,  
     "ocpuAllocations": [  
       {  
         "nodeName": "host1.oraclecloud.com",  
         "subscriptionOcpu": 11,  
         "meteredOcpu": 0,  
         "burstOcpu": 0,  
         "minOcpu": 11,  
         "maxOcpu": 42,  
         "maxBurstOcpu": 11,  
         "maxSubOcpu": 38,  
         "maxMetOcpu": 0
         },  
       {  
         "nodeName": "host2.oraclecloud.com",  
         "subscriptionOcpu": 11,  
         "meteredOcpu": 0,  
         "burstOcpu": 0,  
         "minOcpu": 11,  
         "maxOcpu": 42,  
         "maxBurstOcpu": 11,  
         "maxSubOcpu": 38,  
         "maxMetOcpu": 0
         }  
     ]
   }  
   ```
4. **Modify the values for burstOcpu.**

Operation: PUT SIE\text{ExadataBursting}

You can modify \text{burstOcpu} to a value that is up to the value of \text{maxBurstOcpu}. This example adds two compute nodes to each host.

Example

Example request, using the service instance csi-585928949:

```json
PUT /itas/\text{<domain>}/myservices/api/v1/serviceInstances/csi-585928949/
    serviceConfigurations/Exadata/bursting/
{
    "ocpuOpInProgress": false,
    "exaunitId": 50,
    "ocpuAllocations": [
        {
            "hostName": "host1.oraclecloud.com",
            "subscriptionOcpu": 11,
            "meteredOcpu": 0,
            "burstOcpu": 2,
            "minOcpu": 11,
            "maxOcpu": 42,
            "maxBurstOcpu": 11,
            "maxSubOcpu": 38,
            "maxMetOcpu": 0
        },
        {
            "hostName": "host2.oraclecloud.com",
            "subscriptionOcpu": 11,
            "meteredOcpu": 0,
            "burstOcpu": 2,
            "minOcpu": 11,
            "maxOcpu": 42,
            "maxBurstOcpu": 11,
            "maxSubOcpu": 38,
            "maxMetOcpu": 0
        }
    ]
}
```
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| burstOcpu | Required: Yes  
|          | Type: Integer, Minimum Value: 0, Maximum Value:       |
|          | maxBurstOcpu                                         |
|          | Number of additional cores                           |

Note:  
This action may take a few minutes to complete.

5. Verify the new compute node configuration.

Operation: GET SIExadataBursting

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/
    serviceConfigurations/Exadata/bursting
```

Example payload returned for this request:

```
{
    "ocpuOpInProgress": false,
    "exaunitId": 50,
    "ocpuAllocations": [
        {
            "hostName": "host1.oraclecloud.com",
            "subscriptionOcpu": 11,
            "meteredOcpu": 0,
            "burstOcpu": 2, // New Burst value
            "minOcpu": 11,
            "maxOcpu": 42,
            "maxBurstOcpu": 11,
            "maxSubOcpu": 38,
            "maxMetOcpu": 0
        },
        {
            "hostName": "host2.oraclecloud.com",
            "subscriptionOcpu": 11,
            "meteredOcpu": 0,
            "burstOcpu": 2, // New Burst value
            "minOcpu": 11,
            "maxOcpu": 42,
            "maxBurstOcpu": 11,
            "maxSubOcpu": 38,
            "maxMetOcpu": 0
        }
    ],
    "status": 200,
    "op": "exaunit_coreinfo",
    "additionalNumOfCores": "0",
    "additionalNumOfCoresHourly": "0",
    "coreBursting": "Y"
}
```
To obtain the IDCS GUID

Go to the Users page in My Services dashboard and click Identity Console. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

https://idcs-105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v1/adminconsole/?root=users

In the above URL, idcs-105bbbdfe5644611bf7ce04496073adf is the IDCS GUID for your identity domain.

Managing Exadata Instances

Important:
The My Services dashboard and APIs are deprecated.

The following procedures walk you through creating, modifying, and deleting Exadata instances used with the Oracle Cloud My Services API.

Important:
These procedures are for use with Oracle Database Exadata Cloud@Customer ONLY. For more information, see Administering Oracle Database Exadata Cloud at Customer. These procedures DO NOT apply to the Exadata Cloud Service available in Oracle Cloud Infrastructure.

Prerequisites

Before you can manage Exadata instances, you need to:

- Subscribe to an Oracle Cloud service
- Obtain account credentials with required roles assigned
- Determine your API endpoint

To subscribe to an Oracle Cloud service

To access Oracle Cloud My Services API, you must request a trial or paid subscription to an Oracle Cloud service.

To obtain account credentials and role assignments

Ask your account administrator for the following items to access Oracle Cloud My Services API:

- Account credentials:
  - User name and password
  - Identity domain ID

  An identity domain ID can be either the IDCS GUID that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the Identity Domain name for a traditional Cloud Account.

- Required roles assigned to above user name

To determine your API endpoint

Insert the identity domain ID provided by the account administrator (<domain>) between /itas/ and /myservices/.

Example:

https://itra.oraclecloud.com/itas/<domain>/myservices/api/v1/serviceEntitlements
Creating Exadata Instances

This section covers how to create a basic Exadata instance, an instance with custom IP network configuration, and an instance with multi-VM support.

To create a basic Exadata instance

Post a request with the required payload to create a new instance for a given service entitlement (Exadata in our case). In the following example, `<domain>` is the identity domain ID.

```json
POST /itas/<domain>/myservices/api/v1/operations
{
    "operationItems": [
    {
        "attributes": [
        {
            "name": "requestPayload.name",
            "value": "newinstanceName"
        },
        {
            "name": "requestPayload.serviceEntitlementId",
            "value": "500073421"
        },
        {
            "name": "requestPayload.size",
            "value": "CUSTOM"
        },
        {
            "name": "requestPayload.serviceType",
            "value": "Exadata"
        },
        {
            "name": "requestPayload.adminUserName",
            "value": "john.smith@example.com"
        },
        {
            "name": "requestPayload.adminEmail",
            "value": "john.smith@example.com"
        },
        {
            "name": "requestPayload.adminFirstName",
            "value": "John"
        },
        {
            "name": "requestPayload.adminLastName",
            "value": "Smith"
        },
        {
            "name": "requestPayload.invokerAdminUserName",
            "value": "john.smith@example.com"
        },
        {
            "name": "requestPayload.invokerAdminEmail",
            "value": "john.smith@example.com"
        },
        {
            "name": "requestPayload.invokerAdminFirstName",
            "value": "John"
        },
        {
            "name": "requestPayload.invokerAdminLastName",
            "value": "Smith"
        }
    ],
}
```
Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestPayload.name</td>
<td>Required: Yes&lt;br&gt;Type: String&lt;br&gt;Name of the Exadata instance. This name:&lt;br&gt;• Must not exceed 25 characters.&lt;br&gt;• Must start with a letter.&lt;br&gt;• Must contain only lower case letters and numbers.&lt;br&gt;• Must not contain spaces or any other special characters.&lt;br&gt;• Must be unique within the identity domain.</td>
</tr>
<tr>
<td>requestPayload.serviceEntitlementId</td>
<td>Required: Yes&lt;br&gt;Type: String&lt;br&gt;Service Entitlement for the Exadata instance. See “Exadata Service Entitlement discovery”. Note that any “cesi-“ or “sub-“ prefix should not be included.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>

<td>isBYOL</td>
<td>Required: Yes Type: String &quot;Y&quot; to indicate that the Exadata Cloud Service instance uses Oracle Database licenses that are provided by you rather than licenses that are provided are part of the service subscription, else &quot;N&quot;. This option only affects the billing that is associated with the service instance. It has no effect on the technical configuration of the Exadata Cloud Service instance.</td>
</tr>
<tr>
<td>requestPayload.</td>
<td></td>
</tr>
<tr>
<td>customAttributes.</td>
<td></td>
</tr>
<tr>
<td>PickRackSize</td>
<td>Required: Yes Type: String Specify the rack configuration for your service instance. Exact allowed values depend on your purchase. Typical values are like &quot;Full Rack&quot;, &quot;Half Rack&quot;, &quot;Quarter Rack&quot; or &quot;Eighth Rack&quot;.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
requestPayload. | Required: Yes  
Type: String  
Data center that will host your Exadata Cloud Service instance. See “Exadata Service Entitlement discovery” to obtain the Eligible Data Center IDs.
customAttributes. |  
SELECTED_DC_ID |  

**To create an Exadata instance with custom IP network configuration**

Post a request with the attributes ClientNetwork and BackupNetwork as part of the payload. The following example includes these optional attributes as well as required attributes.

In the following example, `<domain>` is the identity domain ID.

```json
POST /itas/<domain>/myservices/api/v1/operations
{
   "operationItems": [
   {
      "attributes": [
      {
         "name": "requestPayload.name",
         "value": "newinstanceName"
      },
      {
         "name": "requestPayload.serviceEntitlementId",
         "value": "500073421"
      },
      {
         "name": "requestPayload.size",
         "value": "CUSTOM"
      },
      {
         "name": "requestPayload.serviceType",
         "value": "Exadata"
      },
      {
         "name": "requestPayload.adminUserName",
         "value": "john.smith@example.com"
      },
      {
         "name": "requestPayload.adminEmail",
         "value": "john.smith@example.com"
      },
      {
         "name": "requestPayload.adminFirstName",
         "value": "John"
      },
      {
         "name": "requestPayload.adminLastName",
         "value": "Smith"
      },
      {
         "name": "requestPayload.invokerAdminUserName",
         "value": "john.smith@example.com"
      },
      {
         "name": "requestPayload.invokerAdminEmail",
         "value": "john.smith@example.com"
      }
   ]
}
Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| requestPayload.customAttributes.ClientNetwork     | Required: Yes  
Type: Url  
IP network definitions for the network that is primarily used for client access to the database servers. Applications typically access databases on Exadata Cloud Service through this network using Oracle Net Services in conjunction with Single Client Access Name (SCAN) and Oracle RAC Virtual IP (VIP) interfaces. |
| requestPayload.customAttributes.SELECTED_DC_ID    | US001                                                                 |
| requestPayload.customAttributes.BackupNetwork     | /root/root/1/ipnetwork2                                                   |
| requestPayload.customAttributes.CreateSparse       | N                                                                     |
| requestPayload.customAttributes.BackupToDisk       | N                                                                     |
| requestPayload.customAttributes.isBYOL             | N                                                                     |
| requestPayload.customAttributes.PickRackSize       | Quarter Rack                                                            |
| requestPayload.invokerAdminFirstName               | John                                                                    |
| requestPayload.invokerAdminLastName                | Smith                                                                   |
| requestPayload.customAttributes.ExaUnitName        | systemname                                                              |

#### To create an Exadata instance with multi-VM support

If your Exadata system environment is enabled to support multiple virtual machine (VM) clusters, then you can define up to eight clusters and specify how the overall Exadata system resources are allocated to them.

In a configuration with multiple VM clusters, each VM cluster is allocated a dedicated portion of the overall Exadata system resources, with no over-provisioning or resource sharing. On the compute nodes, a separate VM is defined for each VM cluster, and each VM is allocated a dedicated portion of the available compute node CPU, memory, and local disk resources. Each VM cluster is also allocated a dedicated portion of the overall Exadata storage.

Post a request with the attributes EXAUNIT_ALLOCATIONS and MULTIVM_ENABLED as part of the payload. The following example includes these optional attributes as well as required attributes.

In the following example, <domain> is the identity domain ID and <base64_encoded_string> is a base64 encoding of the payload following the example.

**Example payload for request:**

```json
POST /itas/<domain>/myservices/api/v1/operations
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "requestPayload.name",
          "value": "newinstanceName"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.adminUserName",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminEmail",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminFirstName",
          "value": "John"
        },
        {
          "name": "requestPayload.adminLastName",
          "value": "Smith"
        }
      ]
    }
  ]
}
Payload for <base64_encoded_string>:

```
{
  ExaunitProperties: [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d2a0},
    ...
  ]
}
```
Service Essentials

```javascript
{name:Operation, value:AddCluster},
{name:TotalNumOfCoresForCluster, value:4},
{name:TotalMemoryInGb, value:30},
{name:StorageInTb, value:3},
{name:OracleHomeDiskSizeInGb, value:60},
{name:ClientNetwork, value:/root/root/1/ipnetwork1},  // Only if Higgs is also required
{name:BackupNetwork, value:/root/root/1/ipnetwork2},  // Only if Higgs is also required
{name:ExaUnitName, value:systemname},
{name:CreateSparse, value:N},
{name:BackupToDisk, value:N}
```

### Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</thead>
</table>
| requestId             | Required: Optional  
|                       | Type: String  
|                       | Unique UUID  |
| TotalNumOfCoresForCluster | Required: Yes  
|                       | Type: String  
|                       | The number of CPU cores that are allocated to the VM cluster. This is the total number of CPU cores that are allocated evenly across all of the compute nodes in the VM cluster. Must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.  |
| TotalMemoryInGb       | Required: Yes  
|                       | Type: String  
|                       | The amount of memory (in GB) that is allocated to the VM cluster. This is the total amount of memory that is allocated evenly across all of the compute nodes in the VM cluster. Must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.  |
| StorageInTb           | Required: Yes  
|                       | Type: String  
|                       | The total amount of Exadata storage (in TB) that is allocated to the VM cluster. This storage is allocated evenly from all of the Exadata Storage Servers.  |
| OracleHomeDiskSizeInGb | Required: Yes  
|                       | Type: String  
|                       | The amount of local disk storage (in GB) that is allocated to each database server in the first VM cluster.  |
Modifying Exadata Instances

This section covers how to add a cluster to an existing instance, reshape a cluster, and delete a cluster.

To add a cluster to an existing instance

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of AddCluster.

In the following example, <domain> is the identity domain ID, <instanceId> and <serviceEntitlementId> are returned from iTAS serviceInstances, and <base64_encoded_string> is a base64 encoding of the payload following the example.

Example payload for request:

```json
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
    "operationItems": [
        {
            "attributes": [
                {
                    "name": "instanceId",
                    "value": "<instanceId>"
                },
                {
                    "name": "requestPayload.serviceEntitlementId",
                    "value": "<serviceEntitlementId>"
                },
                {
                    "name": "requestPayload.size",
                    "value": "CUSTOM"
                },
                {
                    "name": "requestPayload.serviceType",
                    "value": "Exadata"
                },
                {
                    "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
                    "value": "<base64_encoded_string>"
                },
                {
                    "name": "requestPayload.customAttributes.MULTIVM_ENABLED",
                    "value": "true"
                }
            ],
            "operationItemDefinition": {
                "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
            }
        }
    ]
}
```

Payload for <base64_encoded_string>:

```json
{
    "ExaunitProperties": {
        {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d2a0},
        {name:Operation, value:AddCluster},
        {name:TotalNumOfCoresPerCluster, value:4},
        {name:TotalMemoryInGb, value:30},
        {name:StorageInTb, value:3},
        {name:OracleHomeDiskSizeInGb, value:60},
        {name:ClientNetwork, value:/root/root/1/ipnetwork1}, // Only if Higgs is also required
```
To reshape a cluster

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of ReshapeCluster.

In the following example, <domain> is the identity domain ID and <base64_encoded_string> is a base64 encoding of the payload following the example.

Example payload for request:

```json
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "instanceId",
          "value": "500076173"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
          "value": "<base64_encoded_string>"
        },
        {
          "name": "requestPayload.customAttributes.MULTIVM_ENABLED",
          "value": "true"
        }]
    },
    "operationItemDefinition": {
      "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
    }
  ]
}
```

Payload for <base64_encoded_string>:

```json
{
  "ExaunitProperties": [
    {
      "name": "requestId",
      "value": "27ac0ee3-0c72-4493-b02b-40038f07d2a0"
    },
    {
      "name": "ExaunitID",
      "value": "1" // From ecra/endpoint/exaservice/serviceInstance/resourceinfo
    },
    {
      "name": "Operation",
      "value": "ReshapeCluster"
    }
  ]
}
```
Important:

- Only one attribute can be modified per Reshape request. The payload should contain only the modified attribute. Example:

```json
{ExaunitProperties :
 [{name:Operation,value :
 ReshapeCluster),
 { name:ExaunitID,value:5
 },
 name:TotalNumOfCoresForCluster
 ,
 value:6}]
}
```

- When doing a Reshape with the OracleHomeDiskSizeInGb attribute, use the name OhomePartitionInGB.
- The value for TotalNumOfCoresForCluster must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.
- The value for TotalMemoryInGb must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.

To delete a cluster

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of DeleteCluster.

In the following example, `<domain>` is the identity domain ID and `<base64_encoded_string>` is a base64 encoding of the payload following the example.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
```
"operationItems": [
  {
    "attributes": [
      {
        "name": "instanceId",
        "value": "500076173"
      },
      {
        "name": "requestPayload.serviceEntitlementId",
        "value": "500073421"
      },
      {
        "name": "requestPayload.size",
        "value": "CUSTOM"
      },
      {
        "name": "requestPayload.serviceType",
        "value": "Exadata"
      },
      {
        "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
        "value": "<base64_encoded_string>"
      },
      {
        "name": "requestPayload.customAttributes.MULTIVM_ENABLED",
        "value": "true"
      }
    ],
    "operationItemDefinition": {
      "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
    }
  }
],
"Payload for <base64_encoded_string>:"
{
  "ExaunitProperties": [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d202},  // Optional
    {name:ExaunitID, value:2},
    {name:Operation, value:DeleteCluster}
  ]
}

**Deleting Exadata Instances**

This section covers how to delete Exadata instances.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete all existing multi-VM clusters before deleting the Exadata instance. Following this guidance prevents the instance ending up in an invalid state.</td>
</tr>
</tbody>
</table>

**To delete an instance**

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-DELETE.

In the following example, `<domain>` is the identity domain ID.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
```
Discovering Entitlements and Instances

This section describes how to discover service entitlements and service instances.

To discover service entitlements

Send the following request:

```
GET /itas/<domain>/myservices/api/v1/serviceEntitlements?
serviceDefinitionNames=Exadata
```

Example payload returned for this request:

```
{
   "items": [
      {
         "id": "cesi-585927251", // Unique ServiceEntitlementId
         "serviceDefinition": {
            "canonicalLink": "/itas/a517289/myservices/api/v1/
            serviceDefinitions/502579309",
            "id": "502579309",
            "name": "Exadata" // The customer is entitled to
            use the Exadata Service
         },
         "status": "ACTIVE",
         "canonicalLink": "/itas/a517289/myservices/api/v1/serviceInstances/
            csi-585928949"
      } // More Service
   Entitlements could be displayed
   ]
```

Eligible Data Centers:
Use:

/itas/<domain>/myservices/api/v1/serviceEntitlements/{ServiceEntitlementId}?expands=serviceInstancesEligibleDataCenters

where `{ServiceEntitlementId}` is a service entitlement ID such as cesi-500074601. This will provide additional information such as:

```
"serviceInstancesEligibleDataCenters": [  
  {  
    "id": "US001"
  }  
],
```

To discover service instances

Send the following request:

GET /<domain>/myservices/api/v1/serviceInstances?

serviceDefinitionNames=Exadata

Example payload returned for this request:

```json
{
  "items": [  
    {  
      "id": "csi-585928949",             // Unique ServiceInstanceId
      "serviceEntitlement": {  
        "id": "cesi-585927251",         // Related ServiceEntitlementId
        "canonicalLink": "/itas/a517289/myservices/api/v1/serviceEntitlements/cesi-585927251"
      },  
      "serviceDefinition": {  
        "canonicalLink": "/itas/a517289/myservices/api/v1/serviceDefinitions/502579309",
        "id": "502579309",
        "name": "Exadata"                 // The customer is entitled to use the Exadata Service
      },
      "canonicalLink": "/itas/a517289/myservices/api/v1/serviceInstances/csi-585928949"
    }
  ],
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements",
  "hasMore": false,
  "limit": 25,
  "offset": 0
}
```

Using Access Token Authorization with My Services API

**Important:**

The My Services dashboard and APIs are deprecated.
This topic explains how to set up and use access token authorization with the Oracle Cloud My Services API. Access token authorization allows a developer to access programmatic endpoints (APIs) to obtain some information (for example, entitlements, instances, or metering data) for your cloud account.

**About Access Tokens**

An access token contains the information required to allow a developer to access information on your cloud account. A developer presents the token when making API calls. The allowed actions and endpoints depend on the scopes (permissions) that you select when you generate the token. An access token is valid for about an hour.

A refresh token allows the developer to generate a new access token without having to contact an administrator. A refresh token is valid for about one year.

**Process Overview**

**Setup steps for the Administrator:**

1. Create an Identity Cloud Service client application with the specific privileges you want to grant to developers.
2. Generate an access token that contains the required privileges for the intended developer.
3. Provide the access token and required information to the developer.
4. Configure Identity Cloud Service for access token validation.

**Steps for developer to use the token:**

1. Issue requests against My Services API endpoints. Include the access token for the authorization parameter.
2. When the access token expires, refresh the access token without administrator intervention until the privilege is terminated.

**Administrator Tasks to Set Up Token Validation**

Perform the following tasks to enable developer access with an access token:

**Create the IDCS client application**

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Click the Applications tile. A list of the applications is displayed.
3. Click + Add to create a new application.
4. Click Confidential Application as the type of application.
5. In the App Details section, enter a Name and Description. Avoid entering confidential information.
6. Click Next.
7. In the Client section:
   a. Select Configure this application as a client now.
   b. Under Authorization, for Allowed Grant Types, select the following options:
      - JWT Assertion
      - Refresh Token
9. In the Select Scope dialog, select CloudPortalResourceApp and click the arrow to select scopes for the resource.
10. Select the box next to each authorization that you might want to give the developers to whom you will provide an Access Token. (The permissions are assigned in another step.)
11. Click Add to close the dialog. Your selections are displayed.
12. Click Next.
13. In the Resources section, accept the default and click Next.
14. In the Web Tier Policy section, accept the default and click Next.
15. In the **Authorization** section, click **Finish**.

The **Application Added** notification displays the new Client ID and Client Secret for the application.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy and store the Client ID and Client Secret in a safe place and then click <strong>Close</strong>. The Client ID and Client Secret are credentials that are specific to the application that you just created. You will need these credentials later.</td>
</tr>
</tbody>
</table>

16. To complete the creation process, click **Activate** at the top of the page.

**Generate an access token**

1. Navigate to the IDCS application that you created in the preceding task and select the **Details** tab.
2. Click **Generate Access Token**.
3. On the **Generate Token** dialog, select **Customized Scopes**, then select **Invokes Other APIs**.
4. Select the scopes that you want to give to the developer who will receive this access token.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle recommends that you provide only the minimum required privileges.</td>
</tr>
</tbody>
</table>

5. Select **Include Refresh Token**.
6. Click **Download Token**. Your browser will prompt you to download a token file (.tok). The token file contains an access token and a refresh token.
7. Provide this file to the developer.

**Send the access information to a developer**

To call API endpoints, the developer needs:

- A token file that you generated.
- The Client ID and Client Secret for the IDCS application used to generate the token file. The Client ID and Secret are required for the developer to generate a new access token from the refresh token.
- The endpoints for the APIs.
  - End points related to the itas:myservices scopes are: https://itra.oraclecloud.com/itas/<tenant-IDCS-ID>/myservices/api/v1
  - End points related to the itas:metering scopes are: https://itra.oraclecloud.com/metering/api/v1

Make sure that you send the above information in a secure way. If you think that this information has been compromised, see Revoking a Developer's Ability to Refresh Access Tokens on page 331.

**Configure Identity Cloud Service for access token validation**

To allow clients to access the tenant signing certificate without logging in to Oracle Identity Cloud Service:

1. Sign in to the Oracle Identity Cloud Services admin console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Open the navigation menu. Under **Settings** select **Default Settings**.
3. Set the **Access Signing Certificate** toggle button to on.

**Using the Access Token**

The token file has a .tok extension. The file contains the access token and the refresh token. The content looks like:

```json
{"app_access_token":"eyJ4N...aabb...CpNwA","refresh_token":"AQID...9NCA"}
```

To use the token with the My Services API:
1. Open the token file.
2. Issue a request to a valid endpoint, inserting the access token for the Authorization parameter.

For example:

```sh
```

### Requesting a New Access Token from a Refresh Token

An access token is valid for about one hour. When the token is no longer valid you will get a 401 response code and an Error Message (“errorMessage”) value containing “Expired”.

You can generate a new short-lived access token from the refresh token. You'll need the Client ID and Client Secret to generate the new token. You can only generate tokens with the same or lower access (scopes) as your original token.

Example using the curl command:

```sh
```

Using the sample token file from the previous section, the value for `<refresh-token>` would be AQID...9NCA=.

Sample response:

```
{ "access_token": "eyJraWQiO....2nqA", "token_type": "Bearer", "expires_in": 3600, "refresh_token": "AQIDBAUn...VkxNCB7djF9NCA=" }`
```

**Note:**

When a developer generates a new access token and refresh token, the previous refresh token becomes invalid.

### Revoking a Developer's Ability to Refresh Access Tokens

If you need to revoke a developer's ability to refresh access tokens, you can either invalidate the existing refresh token by generating a new Client Secret for the token; or, you can temporarily revoke access by deactivating the application.

**Important:**

Taking either of these actions will terminate or suspend the ability of all developers using the current Client Secret or application. When generating tokens for multiple developers, consider creating more than one IDCS application to isolate developers from each other.

**To terminate a developer's ability to refresh their access token**

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See [How to Access Oracle Identity Cloud Service](#) if you need help signing in.
2. Click the Applications tile. A list of the applications is displayed.
3. Click the application used to generate the token to view its details.
4. Click Configuration.
5. Under General Information, next to Client Secret, click Regenerate to generate a new Client Secret.

To restore the ability for the developer to generate an access token from a refresh token, generate a new access token. Then provide the token along with the new Client Secret to the developer.
To temporarily suspend a developer's ability to refresh their access token

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Click the Applications tile. A list of the applications is displayed.
3. Click the application used to generate the token to view its details.
4. In the upper right corner of the page, click Deactivate.
5. At the prompt, click Deactivate Application.

To re-enable developers to use the same tokens, click Activate.
Chapter 6

API Gateway

This chapter explains how to use the API Gateway service to create protected RESTful API endpoints for Oracle Functions, Container Engine for Kubernetes, and other services running on Oracle Cloud Infrastructure and beyond.

Overview of API Gateway

The API Gateway service enables you to publish APIs with private endpoints that are accessible from within your network, and which you can expose with public IP addresses if you want them to accept internet traffic. The endpoints support API validation, request and response transformation, CORS, authentication and authorization, and request limiting.

Using the API Gateway service, you create one or more API gateways in a regional subnet to process traffic from API clients and route it to back-end services. You can use a single API gateway to link multiple back-end services (such as load balancers, compute instances, and Oracle Functions) into a single consolidated API endpoint.

You can access the API Gateway service to define API gateways and API deployments using the Console and the REST API.

The API Gateway service is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality.

To get set up and running quickly with the API Gateway service, see the Quick Start Guide. A number of related Developer Tutorials are also available.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.
API Gateway

Authentication and Authorization
Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

API Gateway Capabilities and Limits
The number of API gateways, API resources, and certificate resources you can define in a region is controlled by API Gateway service limits (see API Gateway Limits on page 218). The default service limits vary according to your payment method. If you need more capacity, you can submit a request to increase the default service limits (see Requesting a Service Limit Increase on page 217).

Some other API Gateway capabilities and limits are also fixed. However, there are also a number that you can change. See API Gateway capabilities and limits on page 476.

Required IAM Service Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for the API Gateway service, see:

- Create Policies to Control Access to Network and API Gateway-Related Resources on page 342
- Details for API Gateway on page 2173

API Gateway Concepts
This topic describes key concepts you need to understand when using the API Gateway service.

API Gateways
In the API Gateway service, an API gateway is a virtual network appliance in a regional subnet. Private API gateways can only be accessed by resources in the same subnet. Public API gateways are publicly accessible, including from the internet.

An API gateway routes inbound traffic to back-end services including public, private, and partner HTTP APIs, as well as Oracle Functions. Each API gateway is a private endpoint that you can optionally expose over a public IP address as a public API gateway.

To ensure high availability, you can only create API gateways in regional subnets (not AD-specific subnets). You can create private API gateways in private or public subnets, but you can only create public API gateways in public subnets.

An API gateway is bound to a specific VNIC.

You create an API gateway within a compartment in your tenancy. Each API gateway has a single front end, zero or more back ends, and has zero or more APIs deployed on it as API deployments.
APIs

In the API Gateway service, an API is a set of back-end resources, and the methods (for example, GET, PUT) that can be performed on each back-end resource in response to requests sent by an API client.

To enable an API gateway to process API requests, you must deploy the API on the API gateway by creating an API deployment.

To deploy an API on an API gateway, you have the option to create an API resource in the API Gateway service. An API resource includes an API description that defines the API resource. Note that creating an API resource is optional. You can deploy an API on an API gateway without creating an API resource in the API Gateway service.

API Deployments

In the API Gateway service, an API deployment is the means by which you deploy an API on an API gateway. Before the API gateway can handle requests to the API, you must create an API deployment.

When you create an API deployment, you set properties for the API deployment, including an API deployment specification. Every API deployment has an API deployment specification.

You can deploy multiple APIs on the same API gateway, so a single API gateway can host multiple API deployments.

API Deployment Specifications

In the API Gateway service, an API deployment specification describes some aspects of an API deployment.

When you create the API deployment, you set properties for the API deployment, including an API deployment specification. Every API deployment has an API deployment specification. You can create an API deployment specification:

- by using dialogs in the Console
- by using your preferred JSON editor to create a JSON file
- by using an API description that you've uploaded from an API description file written in a supported language (for example, OpenAPI Specification version 3.0)

Each API deployment specification describes one or more back-end resources, the route to each back-end resource, and the methods (for example, GET, PUT) that can be performed on each resource. The API deployment specification describes how the API gateway integrates with the back end to execute those methods. The API deployment specification can also include request and response policies.

API Resources and API Descriptions

In the API Gateway service, you have the option to create an API resource. An API resource is the design-time representation of an API. You can use an API resource to deploy an API on an API gateway.

An API description defines an API resource, including:

- available endpoints
- available operations on each endpoint
- parameters that can be input and output for each operation
- authentication methods

If you use an API resource to deploy an API on an API gateway, its API description pre-populates some of the properties of the API deployment specification.

You import the API description from a file (sometimes called an 'API specification', or 'API spec') written in a supported language. Currently, OpenAPI Specification version 2.0 (formerly Swagger Specification 2.0) and version 3.0 are supported.

Note that creating an API resource in the API Gateway service is optional. You can deploy an API on an API gateway without creating an API resource in the API Gateway service. Note also that you can create an API resource that doesn't have an API description initially, and then add an API description later.
Front ends
In the API Gateway service, a front end is the means by which requests flow into an API gateway. An API gateway can have either a public front end or a private front end:

- A public front end exposes the APIs deployed on an API gateway via a public IP address.
- A private front end exposes the APIs deployed on an API gateway to a VCN via a private endpoint.

Back ends
In the API Gateway service, a back end is the means by which a gateway routes requests to the back-end services that implement APIs. If you add a private endpoint back end to an API gateway, you give the API gateway access to the VCN associated with that private endpoint.

You can also grant an API gateway access to other Oracle Cloud Infrastructure services as back ends. For example, you could grant an API gateway access to Oracle Functions, so you can create and deploy an API that is backed by a serverless function.

API Providers, API Consumers, API Clients, and End Users
An API provider is a person or team who designs, implements, delivers, and operates APIs. These users interact with interfaces such as the Oracle Cloud Infrastructure Console, SDK, CLI, and Terraform provider. They use API Gateway to deploy, monitor, and operate APIs. Some organizations segment the API provider role further, for example into:

- API developers, with responsibility for building APIs and deploying them on API gateways
- API Gateway managers, with responsibility for monitoring and managing API gateways, typically in production

An API consumer is a person or team who builds apps and services (API clients) and wants to leverage one or more APIs offered by an API provider. The API consumer is typically not sharing an Oracle Cloud Infrastructure tenancy with the API provider. The API consumer is a customer of the API provider.

An API client is an application or device created by an API consumer. The API client invokes the API at runtime by sending requests to the API gateway on which the API is deployed. API clients typically authenticate with the API using OAuth, Basic Auth, mTLS and might use some other token such as an API key for metering and monetization.

An end user is a user of an API client, and is sometimes referred to as the "resource-owner" in terms of authorization. The end user only ever interacts with an API using the API client, and is typically unaware of the API itself. The end user is a customer of the API consumer.

Routes
In the API Gateway service, a route is the mapping between a path, one or more methods, and a back-end service. Routes are defined in API deployment specifications.

Policies
In the API Gateway service, there are different types of policy:

- a request policy describes actions to be performed on an incoming request from an API client before it is sent to a back end
- a response policy describes actions to be performed on a response returned from a back end before it is sent to an API client
- a logging policy describes how to store information about requests and responses going through an API gateway, and information about processing within an API gateway

You can use request policies and/or response policies to:

- limit the number of requests sent to back-end services
- enable CORS (Cross-Origin Resource Sharing) support
- provide authentication and authorization
• modify incoming requests and outgoing responses

You can add policies to an API deployment specification that apply globally to all routes in the API deployment specification, as well as policies that apply only to particular routes.

Note that API Gateway policies are different to IAM policies, which control access to Oracle Cloud Infrastructure resources.

Preparing for API Gateway

Before you can use the API Gateway service to create API gateways and deploy APIs on them as API deployments:

• You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which API Gateway is available (see Availability by Region on page 338).
• Your tenancy must have sufficient quota on API Gateway-related resources (see Service Limits on page 215).
• Within your tenancy, there must already be a compartment to own the necessary network resources. If such a compartment does not exist already, you will have to create it. See Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don't exist already on page 340.
• The compartment that owns network resources must contain a VCN, a public or private regional subnet, and other resources (such as an internet gateway, a route table, security lists). To ensure high availability, API gateways can only be created in regional subnets (not AD-specific subnets). Note that an API gateway must be able to reach the back ends defined in the API deployment specification. For example, if the back end is on the public internet, the VCN must have an internet gateway to enable the API gateway to route requests to the back end.
• The VCN must have a set of DHCP options that includes an appropriate DNS resolver to map host names defined in an API deployment specification to IP addresses. If such a DHCP options set does not exist in the VCN already, you will have to create it. Select the DHCP options set for the API gateway's subnet as follows:
  • If the host name is publicly published on the internet, or if the host name belongs to an instance in the same VCN, select a DHCP options set that has the Oracle-provided Internet and VCN Resolver as the DNS Type. This is the default if you do not explicitly select a DHCP options set.
  • If the host name is on your own private or internal network (for example, connected to the VCN by FastConnect), select a DHCP options set that has Custom Resolver as the DNS Type, and has the URL of a suitable DNS server that can resolve the host name to an IP address.

Note that you can change the DNS server details in the DHCP options set specified for an API gateway's subnet. The API gateway will be reconfigured to use the updated DNS server details within two hours. For more information about resolving host names to IP addresses, see DNS in Your Virtual Cloud Network on page 2910 and DHCP Options on page 2917.
• Within your tenancy, there must already be a compartment to own API Gateway-related resources (API gateways, API deployments). This compartment can be, but need not be, the same compartment that contains the network resources. See Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don't exist already on page 340. Note that the API Gateway-related resources can reside in the root compartment. However, if you expect multiple teams to create API gateways, best practice is to create a separate compartment for each team.
• To create API gateways and deploy APIs on them, you must belong to one of the following:
  • The tenancy's Administrators group.
  • A group to which policies grant the appropriate permissions on network and API Gateway-related resources. See Create Policies to Control Access to Network and API Gateway-Related Resources on page 342.
  • Policies must be defined to give the API gateways you create access to additional resources, if necessary. See Create a Policy to Give API Gateways Access to Functions on page 345.

Availability by Region

The API Gateway service is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 180. Refer to that topic to see region identifiers, region keys, and availability domain names.
Configuring Your Tenancy for API Gateway Development

Before you can start using the API Gateway service to create API gateways and deploy APIs on them, you have to set up your tenancy for API gateway development.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. API Gateway service users are typically not members of the Administrators group, and do not have to be. However, a member of the Administrators group does need to perform a number of administrative tasks to enable users to use the API Gateway service.

To set up your tenancy for API gateway development, you have to complete the following tasks in the order shown in this checklist (the instructions in the topics below assume that you are a tenancy administrator):

<table>
<thead>
<tr>
<th>Task #</th>
<th>Tenancy Configuration Task</th>
<th>Done?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Create Groups and Users to Use API Gateway, if these don't exist already on page 339</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don't exist already on page 340</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Create a VCN to Use with API Gateway, if one doesn't exist already on page 340 See Example Network Resource Configurations on page 346 for details of typical network configurations.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Create Policies to Control Access to Network and API Gateway-Related Resources on page 342, and more specifically: • Create a Policy to Give API Gateway Users Access to API Gateway-Related Resources on page 342 • Create a Policy to Give API Gateway Users Access to Network Resources on page 343 • Create a Policy to Give API Gateway Users Access to Functions on page 344 • Create a Policy to Give API Gateways Access to Functions on page 345</td>
<td></td>
</tr>
</tbody>
</table>

Click each of the links in turn, and follow the instructions.

Create Groups and Users to Use API Gateway, if these don't exist already

Before users can start using the API Gateway service to create API gateways and deploy APIs on them, as a tenancy administrator you have to create Oracle Cloud Infrastructure user accounts, along with a group to which the user accounts belong. Later on, you'll define policies to give the group (and the user accounts that belong to it) access to API Gateway-related resources. If a suitable group and user accounts already exist, there's no need to create new ones.

To create groups and users to use the API Gateway service:

1. Log in to the Console as a tenancy administrator.
2. If a suitable group for API Gateway users doesn't exist already, create such a group as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Groups. A list of
      the groups in your tenancy is displayed.
   b. Click Create Group and create a new group (see To create a group on page 2420). Give the group a
      meaningful name (for example, api-gateway-developers) and description. Avoid entering confidential
      information.
3. If suitable user accounts for API Gateway users don't exist already, create users as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of
      the users in your tenancy is displayed.
   b. Click Create User and create one or more new users (see To create a user on page 2417).
4. If they haven't been added already, add users to the group to use the API Gateway service as follows:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Users. A list of
      the users in your tenancy is displayed.
   b. Select one or more users and add them to the group authorized to use the API Gateway service (see To add a
      user to a group on page 2417).

Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don't exist already

Before users can start using the API Gateway service to create API gateways and deploy APIs on them, as a tenancy
administrator you have to create:

- a compartment to own network resources (a VCN, a public or private regional subnet, and other resources such as
  an internet gateway, a route table, security lists)
- a compartment to own API Gateway resources (API gateways, API deployments)

Note that the same compartment can own both network resources and API Gateway-related resources. Alternatively,
you can create two separate compartments for network resources and API Gateway-related resources.

If suitable compartments already exist, there's no need to create new ones.

To create a compartment to own network resources and/or API Gateway-related resources in the tenancy:

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under Governance and Administration, go to Identity and click Compartments. A
   list of the compartments in your tenancy is displayed.
3. Click Create Compartment and create a new compartment (see To create a compartment on page 2442). Give
   the compartment a meaningful name (for example, acme-network, acme-api-gateway-compartment,) and
   description. Avoid entering confidential information.

Tip:

Normally, API gateways and API deployments are created in the same compartment. However, in large development teams with many API
developers, you might find it useful to create separate compartments for
API gateways and for API deployments. Doing so will enable you to give
different groups of users appropriate access to those resources.

Create a VCN to Use with API Gateway, if one doesn't exist already

Before users can start using the API Gateway service to create API gateways and deploy APIs on them, as a tenancy
administrator you have to create one or more VCNs containing a public or private regional subnet in which to create
API gateways.

The VCN can be, but need not be, owned by the same compartment to which other API Gateway-related resources
will belong. To ensure high availability, API gateways can only be created in regional subnets (not AD-specific
subnets). Note that an API gateway must be able to reach the back ends defined in the API deployment specification.
For example, if the back end is on the public internet, the VCN must have an internet gateway to enable the API...
gateway to route requests to the back end. The VCN must have a set of DHCP options that includes an appropriate DNS resolver to map host names defined in an API deployment specification to IP addresses.

The public or private regional subnet in which to create API gateways must have a CIDR block that provides a minimum of 32 free IP addresses. Note that Oracle strongly recommends the CIDR block provides more than the minimum.

To support the largest possible number of concurrent connections, Oracle also strongly recommends that the security lists used by the subnet only have stateless rules.

If a suitable VCN already exists, there's no need to create a new one.

If you do decide to create a new VCN, you have several options, including the following:

- You can create just the VCN initially, and then create the regional subnets and other related resources later (as described in this topic). In this case, you can choose whether to create a public regional subnet and an internet gateway (see Internet Gateway on page 3243), or a private regional subnet and a service gateway (see Access to Oracle Services: Service Gateway on page 3256). For example, if you don't want to expose traffic over the public internet, create a private regional subnet and a service gateway.
- You can create the new VCN and have related resources created automatically at the same time by selecting the Start VCN Wizard option. In this case, a public regional subnet and a private regional subnet are created, along with an internet gateway, a NAT gateway, and a service gateway. Although a default security list is also created, you have to add a new stateful ingress rule for the regional subnet to allow traffic on port 443. That's because API Gateway communicates on port 443, and port 443 is not open by default (see the corresponding step in this topic).

See Example Network Resource Configurations on page 346 for details of typical network configurations.

To create a VCN to use with API Gateway:

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under Core Infrastructure, go to Networking and click Virtual Cloud Networks.
3. Choose the compartment that will own the network resources (on the left side of the page). For example, acme-network.
   
   The VCN can be, but need not be, owned by the same compartment to which API Gateway-related resources will belong. The page updates to display only the resources in the compartment you select.

4. Click Create Virtual Cloud Network to create a new VCN.

5. In the Create Virtual Cloud Network dialog box, enter the following:

   - Name: A meaningful name for the VCN, such as acme-api-gw-vcn. The name doesn't have to be unique, but you cannot change it later using the Console (although you can change it using the API). Avoid entering confidential information.
   - Other details for the VCN (see To create a VCN on page 2825).

6. Click Create Virtual Cloud Network to create the VCN.

   The VCN is created and displayed on the Virtual Cloud Networks page in the compartment you chose.

7. On the Virtual Cloud Networks page, click Create Subnet.

8. In the Create Subnet dialog box, enter the following:

   - Name: A meaningful name for the subnet, such as acme-api-gw-subnet. The name doesn't have to be unique, but you cannot change it later using the Console (although you can change it using the API). Avoid entering confidential information.
   - Subnet Type: Select Regional (Recommended). To ensure high availability, API gateways can only be created in regional subnets (not AD-specific subnets).
   - CIDR Block: A CIDR block that provides a minimum of 32 free IP addresses.
   - DHCP Options: (Optional) Select a set of DHCP options that includes an appropriate DNS resolver to map host names defined in an API deployment specification to IP addresses. If you do not explicitly specify a DHCP options set, the default DHCP options set uses the Oracle-provided Internet and VCN Resolver to
API Gateway communicates on port 443, which is not open by default. You have to add a new stateful ingress rule for the regional subnet to allow traffic on port 443.

10. Click the name of the regional subnet, then the name of the default security list, and then click Add Ingress Rules and enter the following:

- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 443

11. Click Add Ingress Rules to add the new rule to the default security list.

### Create Policies to Control Access to Network and API Gateway-Related Resources

Before users can start using the API Gateway service to create API gateways and deploy APIs on them, as a tenancy administrator you have to create a number of Oracle Cloud Infrastructure policies to grant access to API Gateway-related and network resources.

To grant access to API Gateway-related and network resources, you have to:

- Grant users access to API Gateway-related resources, network resources, and (optionally) function resources. More specifically, you have to:
  - Create a Policy to Give API Gateway Users Access to API Gateway-Related Resources on page 342
  - Create a Policy to Give API Gateway Users Access to Network Resources on page 343
  - Create a Policy to Give API Gateway Users Access to Functions on page 344

- Grant API gateways access to functions defined in Oracle Functions, if required. If API Gateway users define a new API gateway with a serverless function in Oracle Functions as an API back end, the API Gateway service verifies that the new API gateway will have access to the specified function. To provide access, you have to create a policy that grants API gateways access to functions defined in Oracle Functions. See Create a Policy to Give API Gateway Users Access to Functions on page 345.

See Details for API Gateway on page 2173 for more information about policies.

### Create a Policy to Give API Gateway Users Access to API Gateway-Related Resources

When API Gateway users define a new API gateway and new API deployments, they have to specify a compartment for those API Gateway-related resources. Users can only specify a compartment that the groups to which they belong have been granted access. To enable users to specify a compartment, you must create an identity policy to grant the groups access.

To create a policy to give users access to API Gateway-related resources in the compartment that will own those resources:

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed.
3. Select the compartment that will own API Gateway-related resources from the list on the left.
4. Click Create Policy.
5. Enter the following:

- **Name:** A meaningful name for the policy (for example, acme-apigw-developers-manage-access). The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
- **Description:** A meaningful description (for example, Gives api-gateway developers access to all resources in the acme-apigw-compartment). You can change this later if you want to.
- **Statement:** The following policy statement to give the group access to all API Gateway-related resources in the compartment:

As **Statement 1:** enter the following policy statement to give the group access to all API Gateway-related resources in the compartment:

```
Allow group <group-name> to manage api-gateway-family in compartment <compartment-name>
```

For example:

```
Allow group acme-apigw-developers to manage api-gateway-family in compartment acme-apigw-compartment
```

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. Click **Create** to create the policy giving API Gateway users access to API Gateway-related resources in the compartment.

**Tip:**

Normally, API gateways and API deployments are created in the same compartment. However, in large development teams with many API developers, you might find it useful to create separate compartments for API gateways and for API deployments. Doing so will enable you to give different groups of users appropriate access to those resources.

**Create a Policy to Give API Gateway Users Access to Network Resources**

When API Gateway users define a new API gateway, they have to specify a VCN and a subnet in which to create the API gateway. Users can only specify VCNs and subnets that the groups to which they belong have been granted access. To enable users to specify a VCN and subnet, you must create an identity policy to grant the groups access. In addition, if you want to enable users to create public API gateways, the identity policy must allow the groups to manage public IP addresses in the compartment that owns the network resources.

To create a policy to give API Gateway users access to network resources:

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you’re viewing is displayed.
3. Select the compartment that owns the network resources from the list on the left.
4. Click **Create Policy**.
5. Enter the following:

- **Name**: A meaningful name for the policy (for example, `acme-apigw-developers-network-access`). The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.

- **Description**: A meaningful description (for example, `Gives api-gateway developers access to all network resources in the acme-network compartment`). You can change this later if you want to.

- **Statement**: The following policy statement to give the group access to network resources in the compartment (including the ability to manage public IP addresses):

  ```
  Allow group <group-name> to manage virtual-network-family in compartment <compartment-name>
  ```

  For example:

  ```
  Allow group acme-apigw-developers to manage virtual-network-family in compartment acme-network
  ```

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. Click **Create** to create the policy giving API Gateway users access to network resources and public IP addresses in the compartment.

---

### Create a Policy to Give API Gateway Users Access to Functions

When API Gateway users define a new API gateway, one option is to specify a serverless function defined in Oracle Functions as the API back end. Users can only specify functions that the groups to which they belong have been granted access. If you want to enable users to specify functions as API back ends, you must create an identity policy to grant the groups access. Note that in addition to this policy for the user group, to enable users to specify functions as API back ends you also have to create a policy to give API gateways access to Oracle Functions (see [Create a Policy to Give API Gateways Access to Functions](#) on page 345).

Another reason to create an identity policy that grants groups access to Oracle Functions is if you want to enable users to use the Console (rather than a JSON file) to define an authentication request policy and specify an authorizer function defined in Oracle Functions (see [Using Authorizer Functions to Add Authentication and Authorization to API Deployments](#) on page 431).

To create a policy to give API Gateway users access to functions defined in Oracle Functions:

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
3. Select the compartment that owns the functions from the list on the left.
4. Click **Create Policy**.
5. Enter the following:
   - **Name:** A meaningful name for the policy (for example, acme-apigw-developers-functions-access). The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description:** A meaningful description (for example, Gives api-gateway developers access to all functions in the acme-functions-compartment). You can change this later if you want to.
   - **Statement:** The following policy statement to give the group access to the functions in the compartment:

   ```plaintext
   Allow group <group-name> to use functions-family in compartment <compartment-name>
   ```

   For example:

   ```plaintext
   Allow group acme-apigw-developers to use functions-family in compartment acme-functions-compartment
   ```

   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. Click **Create** to create the policy giving API Gateway users access to functions in the compartment.

   **Create a Policy to Give API Gateways Access to Functions**

   When API Gateway users define a new API gateway, one option is to specify a serverless function defined in Oracle Functions as the API back end. Before creating the API gateway, the API Gateway service verifies that the new API gateway will have access to the specified function through an IAM policy.

   Note that in addition to this policy for API gateways, to enable users to specify functions as API back ends you also have to create a policy to give users access to Oracle Functions (see **Create a Policy to Give API Gateway Users Access to Functions** on page 344).

   To create a policy to give API gateways access to functions defined in Oracle Functions:

   1. Log in to the Console as a tenancy administrator.
2. Create a new policy to give API gateways access to functions defined in Oracle Functions:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   b. Select the compartment containing the function-related resources to which you want to grant access. If the resources are in different compartments, select a common parent compartment (for example, the tenancy's root compartment).
   c. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-apigw-gateways-functions-policy).
   d. Enter a policy statement to give API gateways access to the compartment containing functions defined in Oracle Functions:

   ```allow any-user to use functions-family in compartment <functions-compartment-name> where ALL {request.principal.type='ApiGateway', request.resource.compartment.id='<api-gateway-compartment-OCID>'}`

   where:
   • `<functions-compartment-name>` is the name of the compartment containing the functions you want to use as back ends for API gateways.
   • `<api-gateway-compartment-OCID>` is the OCID of the compartment containing the API gateways that you want to have access to the functions.

   For example:

   ```allow any-user to use functions-family in compartment acme-functions-compartment where ALL {request.principal.type='ApiGateway', request.resource.compartment.id='ocid1.compartment.oc1..aaaaaaaa7______ysq'}`

   e. Click Create to create the policy giving API gateways access to functions defined in Oracle Functions.

Example Network Resource Configurations

Before you can use the API Gateway service to create API gateways and deploy APIs on them as API deployments:
   • You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which API Gateway is available (see Availability by Region on page 338).
   • Your tenancy must have sufficient quota on API Gateway-related resources (see Service Limits on page 215).
   • Within your tenancy, there must already be a compartment to own the necessary network resources. If such a compartment does not exist already, you will have to create it. See Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don't exist already on page 340.
   • The compartment that owns network resources must contain a VCN, a public or private regional subnet, and other resources (such as an internet gateway, a route table, security lists). To ensure high availability, API gateways can only be created in regional subnets (not AD-specific subnets). Note that an API gateway must be able to reach the back ends defined in the API deployment specification. For example, if the back end is on the public internet, the VCN must have an internet gateway to enable the API gateway to route requests to the back end.
   • The VCN must have a set of DHCP options that includes an appropriate DNS resolver to map host names defined in an API deployment specification to IP addresses. If such a DHCP options set does not exist in the VCN already, you will have to create it. Select the DHCP options set for the API gateway's subnet as follows:
     • If the host name is publicly published on the internet, or if the host name belongs to an instance in the same VCN, select a DHCP options set that has the Oracle-provided Internet and VCN Resolver as the DNS Type. This is the default if you do not explicitly select a DHCP options set.
     • If the host name is on your own private or internal network (for example, connected to the VCN by FastConnect), select a DHCP options set that has Custom Resolver as the DNS Type, and has the URL of a suitable DNS server that can resolve the host name to an IP address.

   Note that you can change the DNS server details in the DHCP options set specified for an API gateway's subnet. The API gateway will be reconfigured to use the updated DNS server details within two hours. For more
information about resolving host names to IP addresses, see DNS in Your Virtual Cloud Network on page 2910 and DHCP Options on page 2917.

- Within your tenancy, there must already be a compartment to own API Gateway-related resources (API gateways, API deployments). This compartment can be, but need not be, the same compartment that contains the network resources. See Create Compartments to Own Network Resources and API Gateway Resources in the Tenancy, if they don’t exist already on page 340. Note that the API Gateway-related resources can reside in the root compartment. However, if you expect multiple teams to create API gateways, best practice is to create a separate compartment for each team.

- To create API gateways and deploy APIs on them, you must belong to one of the following:
  - The tenancy’s Administrators group.
  - A group to which policies grant the appropriate permissions on network and API Gateway-related resources. See Create Policies to Control Access to Network and API Gateway-Related Resources on page 342.
  - Policies must be defined to give the API gateways you create access to additional resources, if necessary. See Create a Policy to Give API Gateways Access to Functions on page 345.

This topic gives examples of how you might configure network resources for API gateways with a serverless function as a back end:

- for a public API gateway in a public subnet (see Example 1: Example Network Resource Configuration for a Public API Gateway in a Public Subnet with a Serverless Function as an HTTP Back End on page 347)
- for a private API gateway in a private subnet (see Example 2: Network Resource Configuration for a Private API Gateway in a Private Subnet with a Serverless Function as an HTTP Back End on page 350)

These examples assume the default helloworld function has been created and deployed in Oracle Functions with the name helloworld-func and belonging to the helloworld-app application (see Creating, Deploying, and Invoking a Helloworld Function on page 2059).

**Example 1: Example Network Resource Configuration for a Public API Gateway in a Public Subnet with a Serverless Function as an HTTP Back End**

This example assumes you want a public API gateway that can be accessed directly from the internet, with a serverless function as an HTTP back end.
To achieve this example configuration, you create the following resources in the sequence shown, with the properties shown in the Example Resource Configuration table below:

1. A VCN named 'acme-vcn1'.
2. An internet gateway named 'acme-internet-gateway'.
3. A route table named 'acme-routetable-public'.
4. A security list named 'acme-security-list-public', with an ingress rule that allows public access to the API gateway and an egress rule that allows access to Oracle Functions.
5. A public subnet named 'acme-public-subnet'.
6. An API gateway named 'acme-public-gateway', with an API deployment named 'acme-public-deployment'.

Issuing a curl command from the public internet against the API deployment returns the response shown:

```
[user@machinename ~]$ curl -X GET https://lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com/marketing/hello
Hello, world!
```

</tr>
<tr>
<td></td>
<td>• <strong>Hostname</strong>: (for the purpose of this example, the hostname is lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com)</td>
</tr>
</tbody>
</table>
One API deployment created and defined as follows:

- **Name**: acme-public-deployment
- **Path Prefix**: /marketing
- **API Request Policies**: None specified
- **API Logging**: None specified
- **Route**:
  - **Path**: /hello
  - **Methods**: GET
  - **Type**: Oracle Functions
  - **Application**: helloworld-app
  - **Function Name**: helloworld-func

**Example 2: Network Resource Configuration for a Private API Gateway in a Private Subnet with a Serverless Function as an HTTP Back End**

This example assumes you want a private API gateway that can only be accessed via a bastion host (rather than accessed directly from the internet), with a serverless function as an HTTP back end.

To achieve this example configuration, you create the following resources in the sequence shown, with the properties shown in the Example Resource Configuration table below:

1. A VCN named acme-vcn2
2. An internet gateway named acme-internet-gateway
3. A service gateway named acme-service-gateway. (In this example, you only need to create a service gateway, because the API gateway only has an Oracle Functions back end. However, if the API gateway has both an Oracle Functions back end and also an HTTP back end on the public internet, you could create a NAT gateway instead to access both back ends.)

4. A route table named acme-routetable-private

5. A security list named acme-security-list-private, with an ingress rule that allows the bastion host to access the API gateway and an egress rule that allows access to Oracle Functions.

6. A private subnet named acme-private-subnet

7. An API gateway named acme-private-gateway, with an API deployment named acme-private-deployment

8. A route table named acme-routetable-bastion

9. A security list named acme-security-list-bastion, with an ingress rule that allows public SSH access to the bastion host and an egress rule that allows the bastion host to access the API gateway.

10. A public subnet named acme-bastion-public-subnet

11. A compute instance with a public IP address to act as the bastion host, called acme-bastion-instance

Having SSH'd into the bastion host, issuing a curl command against the API deployment returns the response shown:

```
[user@machinename ~]$ ssh opc@198.51.100.254
[opc@acme-bastion-instance ~]$ curl -X GET https://pwa...djt.apigateway.us-phoenix-1.oci.customer-oci.com/marketing-private/hello
Hello, world!
```

**Configuring Your Client Environment for API Gateway Development**

When using the API Gateway service to create API gateways and API deployments, you can perform many operations using the Console. However, as well as using the Console, you'll typically also want to create and manage API gateways and API deployments programmatically using the API Gateway service's REST API.

You can use the API Gateway REST API using the Oracle Cloud Infrastructure CLI (for more information and configuration instructions, see Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).

**Configuring Your Client Environment to use the CLI for API Gateway Development**

In addition to using the Console to create API gateways and API deployments, you'll typically also want to create and manage API gateways and API deployments programmatically using the API Gateway service's REST API.

One way to use the API Gateway REST API is to use the Oracle Cloud Infrastructure CLI.

Before you can start using the Oracle Cloud Infrastructure CLI to create and manage API gateways and API deployments programmatically using the API Gateway REST API, you have to set up your client environment appropriately. Note that prior to setting up your client environment, you must already have set up your tenancy (see Configuring Your Tenancy for API Gateway Development on page 339).

To set up your client environment for API development using the Oracle Cloud Infrastructure CLI, you have to complete the following tasks in the order shown in this checklist:

<table>
<thead>
<tr>
<th>Task #</th>
<th>Development Environment Configuration Task</th>
<th>Done?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Installing the CLI on page 4195</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Setting up the Config File on page 4197</td>
<td></td>
</tr>
</tbody>
</table>

Click each of the links in the checklist in turn, and follow the instructions.

**Creating an API Gateway**

You can create one or more API gateways to process traffic from API clients and route it to back-end services. Having created an API gateway, you then deploy an API on the API gateway by creating an API deployment.

You can use a single API gateway as the front end for multiple back-end services by:

- Creating a single API deployment on the API gateway, with an API deployment specification that defines multiple back-end services.
- Creating multiple API deployments on the same API gateway, each with an API deployment specification that defines one (or more) back-end services.
Having a single API gateway as a front end enables you to present a single cohesive API to API consumers and API clients, even if the API is actually comprised of smaller microservices written by different software teams using different programming languages or technologies.

**Using the Console**

To create an API gateway:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **API Gateway**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Gateways** page, click **Create Gateway** and specify:
   - **Name**: The name of the new API gateway. Avoid entering confidential information.
   - **Type**: The type of API gateway to create. Select Private if you want the API gateway (and the APIs deployed on it) to be accessible only from the same subnet in which the API gateway is created. Select Public if you want the API gateway (and the APIs deployed on it) to be accessible from the internet. In the case of a public API gateway, an internet gateway must exist to give access to the VCN.
   - **Compartment**: The compartment to which the new API gateway is to belong.
   - **Custom DNS**: Use this option to determine the TLS certificate (and associated domain name) that the API gateway uses.

   Do not select this option if you want the domain name to be generated automatically for you, and you want the API gateway to use a TLS certificate obtained by the API Gateway service (the default behavior). The auto-generated domain name will comprise a random string of characters followed by \`apigateway.<region-identifier>.oci.customer-oci.com\`. For example, `laksjd.apigateway.us-phoenix-1.oci.customer-oci.com`.

   Do select this option if you want the API gateway to use a custom TLS certificate (and associated custom domain name). In this case, specify the name of the default API Gateway certificate resource containing details of the custom TLS certificate (and associated custom domain name) that you want the API gateway to use.

   Note that for public or production systems, Oracle recommends using custom TLS certificates. Oracle recommends only using TLS certificates obtained by the API Gateway service for private or non-production systems (for example, for development and testing).

   See [Setting Up Custom Domains and TLS Certificates](#) on page 371.
   - **VCN in `<compartment-name>`**: The VCN in which to create the API gateway. The VCN can belong to the same compartment as the new API gateway, but does not have to.
   - **Subnet in `<compartment-name>`**: The name of a public or private regional subnet in which to create the API gateway. If you want to create a public API gateway, you must specify a public regional subnet.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

4. Click **Create** to create the new API gateway.

   Note that it can take a few minutes to create the new API gateway. While it is being created, the API gateway is shown with a state of Creating on the **Gateways** page. When it has been created successfully, the new API gateway is shown with a state of Active.

5. If you have waited more than a few minutes for the API gateway to be shown with an Active state (or if the API gateway creation operation has failed):
   a. Click the name of the API gateway, and click **Work Requests** to see an overview of the API gateway creation operation.
   b. Click the **Create Gateway** operation to see more information about the operation (including error messages, log messages, and the status of associated resources).
   c. If the API gateway creation operation has failed and you cannot diagnose the cause of the problem from the work request information, see [Troubleshooting API Gateway](#) on page 474.
Having successfully created an API gateway, you can deploy an API on it (see Deploying an API on an API Gateway by Creating an API Deployment on page 363).

**Using the CLI**

To create a new API gateway using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. Open a command prompt and run `oci api-gateway gateway create` to create the API gateway:

   ```
   oci api-gateway gateway create --display-name "<gateway-name>" --compartment-id <compartment-ocid> --endpoint-type "<gateway-type>" --subnet-id <subnet-ocid> --certificate-id <certificate-ocid>
   ```

   where:
   - `<gateway-name>` is the name of the new API gateway. Avoid entering confidential information.
   - `<compartment-ocid>` is the OCID of the compartment to which the new API gateway will belong.
   - `<gateway-type>` is the type of API gateway to create. Specify `PRIVATE` if you want the API gateway (and the APIs deployed on it) to be accessible only from the same subnet in which the API gateway is created. Specify `PUBLIC` if you want the API gateway (and the APIs deployed on it) to be accessible from the internet.
   - `<subnet-ocid>` is the OCID of a public or private regional subnet in which to create the API gateway. If you want to create a public API gateway, you must specify a public regional subnet.
   - `<certificate-ocid>` (optional) is the OCID of the API Gateway certificate resource created for the API gateway's custom TLS certificate. See Setting Up Custom Domains and TLS Certificates on page 371.

   For example:

   ```
   oci api-gateway gateway create --display-name "Hello World Gateway" --compartment-id ocid1.compartment.oc1..aaaaaaaa7_____ysq --endpoint-type "PRIVATE" --subnet-id ocid1.subnet.oc1.iad.aaaaaaaaz______rca
   ```

   The response to the command includes:
   - The API gateway's OCID.
   - The host name, as the domain name to use when calling an API deployed on the API gateway. If you didn't specify an API Gateway certificate resource when creating the API gateway, a domain name is automatically generated in the format `<gateway-identifier>.apigateway.<region-identifier>.oci.customer-oci.com`, where:
     - `<gateway-identifier>` is a string of characters that identifies the API gateway. For example, lak...sjd (abbreviated for readability).
     - `<region-identifier>` is the identifier of the region in which the API gateway has been created. See Availability by Region on page 338.
   - For example, lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com.
   - The lifecycle state (for example, ACTIVE, FAILED).
   - The id of the work request to create the API gateway (details of work requests are available for seven days after completion, cancellation, or failure).

   If you want the command to wait to return control until the API gateway is active (or the request has failed), include either or both the following parameters:
   - `--wait-for-state ACTIVE`
   - `--wait-for-state FAILED`

   For example:

   ```
   oci api-gateway gateway create --display-name "Hello World Gateway" --compartment-id ocid1.compartment.oc1..aaaaaaaa7_____ysq --endpoint-type
   ```
Note that you cannot use the API gateway until the work request has successfully created it and the API gateway is active.

3. (Optional) To see the status of the API gateway, enter:

```
oci api-gateway gateway get --gateway-id <gateway-ocid>
```

4. (Optional) To see the status of the work request that is creating the API gateway, enter:

```
oci api-gateway work-request get --work-request-id <work-request-ocid>
```

5. (Optional) To view the logs of the work request that is creating the API gateway, enter:

```
oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

6. (Optional) If the work request that is creating the API gateway fails and you want to review the error logs, enter:

```
oci api-gateway work-request-error --work-request-id <work-request-ocid>
```

For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the CreateGateway operation to create an API gateway.

**Creating an API Resource with an API Description**

When using the API Gateway service, you have the option to create an API resource. You can use the API resource to deploy an API on an API gateway. The API resource has an API description that describes the API.

If you use an API resource to deploy an API on an API gateway, its API description pre-populates some of the properties of the API deployment specification.

You import the API description from a file (sometimes called an 'API specification', or 'API spec') written in a supported language. Currently, OpenAPI Specification version 2.0 (formerly Swagger Specification 2.0) and version 3.0 are supported.

Note that creating an API resource in the API Gateway service is optional. You can deploy an API on an API gateway without creating an API resource in the API Gateway service. Note also that you can create an API resource that doesn't have an API description initially, and then add an API description later.

**Using the Console**

To create an API resource, optionally with an API description created from an uploaded API description file, using the Console:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Choose a Compartment you have permission to work in.
3. On the APIs page, click **Create API Resource** and specify:
   - **Name**: The name of the new API resource. Avoid entering confidential information.
   - **Compartment**: The compartment to which the new API resource is to belong.
   - **Upload API Description File**: (optional) A file containing an API description (in a supported language) to upload and from which to create the API description. The file can be up to 1MB in size. The file is parsed to confirm that it is in a supported language and correctly formatted. Currently, OpenAPI Specification version 2.0 (formerly Swagger Specification 2.0) and version 3.0 files are supported.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

4. Click **Create** to create the new API resource.
   
   If you uploaded an API description file, an API description is created and validated. Note that it can take a few minutes to validate the API description. While it is being validated, the API description is shown with a state of Validating on the Validations page. When the API description has been validated successfully:
   - The Validations page shows successful validation.
   - The API description page shows the API description created from the API description file.
   - The API Deployment Specification page shows any additional information about the default API deployment specification created from the API description.

5. If you have waited more than a few minutes for the API description to be shown as Valid (or if the API description validation operation has failed):
   
   a. Click **Work Requests** to see an overview of the API description validation operation.
   b. Click the **Validate API** operation to see more information about the operation (including error messages, log messages, and the status of associated resources).
   c. If the API description validation operation has failed and you cannot diagnose the cause of the problem from the work request information, see Troubleshooting API Gateway on page 474.

6. If you don't upload an API description file when you first create an API resource, or if you subsequently want to upload a different API description file:
   
   a. On the APIs page, select **Edit** from the Actions menu beside the API resource.
   b. Provide details of the API description file from which to create the API description.

Having successfully created an API resource with an API description, you can deploy it on an API gateway (see Using the Console to Create an API Deployment from an API Resource on page 366).

**Using the CLI**

To create an API resource, optionally with an API description created from an uploaded API description file, using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. Open a command prompt and run `oci api-gateway api create` to create the API resource:

```
oci api-gateway api create --display-name "<api-name>" --compartment-id <compartment-ocid> --content "<api-description>"
```

where:

- `<api-name>` is the name of the new API resource. Avoid entering confidential information.
- `<compartment-ocid>` is the OCID of the compartment to which the new API resource will belong.
- `<api-description>` is optionally an API description (in a supported language). The value you specify for `<api-description>` can be:
  - The entire API description, enclosed within double quotes. Inside the description, each double quote must be escaped with a backslash (`\`) character. For example (and abbreviated for readability), `--content "swagger:2.0",title:"Sample API",..."`
  - The name and location of an API description file, enclosed within double quotes and in the format `"$<path>/<filename>.yaml"`. For example, `--content "$<path>/api.yaml"`

The description is parsed to confirm that it is in a supported language and correctly formatted. Currently, OpenAPI Specification version 2.0 (formerly Swagger Specification 2.0) and version 3.0 files are supported.

For example:

```
oci api-gateway api create --display-name "Hello World API Resource" --compartment-id ocid1.compartment.oc1..aaaaaaa7____ysq --content "swagger:2.0",title:"Sample API",..."
```

The response to the command includes:

- The API resource's OCID.
- The lifecycle state (for example, SUCCEEDED, FAILED).
- The id of the work request to create the API resource (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API resource has been created (or the request has failed), include either or both the following parameters:

- `--wait-for-state SUCCEEDED`
- `--wait-for-state FAILED`

For example:

```
oci api-gateway api create --display-name "Hello World API Resource" --compartment-id ocid1.compartment.oc1..aaaaaaa7____ysq --content "swagger:2.0",title:"Sample API",..." --wait-for-state SUCCEEDED
```

Note that you cannot use the API resource until the work request has successfully created it.

3. (Optional) To see the status of the work request that is creating the API resource, enter:

```
oci api-gateway work-request get --work-request-id <work-request-ocid>
```

4. (Optional) To view the logs of the work request that is creating the API resource, enter:

```
oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

5. (Optional) If the work request that is creating the API resource fails and you want to review the error logs, enter:

```
oci api-gateway work-request-error --work-request-id <work-request-ocid>
```
For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the CreateAPI operation to create an API resource.

### Creating an API Deployment Specification

Before you can deploy an API on an API gateway, you have to create an API deployment specification. Every API deployment has an API deployment specification.

Each API deployment specification describes a set of resources, and the methods (for example, GET, PUT) that can be performed on each resource.

You can use a single API gateway as the front end for multiple back-end services by:

- Creating a single API deployment on the API gateway, with an API deployment specification that defines multiple back-end services.
- Creating multiple API deployments on the same API gateway, each with an API deployment specification that defines one (or more) back-end services.

Typically, back-end services will be in the same VCN as the API gateway on which you deploy an API. However, they don't have to be. In the API deployment specification, you can describe back-end services that are on a private or public subnet in your tenancy, as well as services outside your tenancy (including on the public internet). Wherever they are located, the back-end services must be routable from the subnet containing the API gateway on which the API is deployed. For example, if the back-end service is on the public internet, the VCN must have an internet gateway to enable the API gateway to route requests to the back-end service.

You can create an API deployment specification:

- Using dialogs in the Console whilst creating an API deployment.
- Using your preferred JSON editor to create a separate JSON file. You can then specify the JSON file when using the Console, the CLI, or the API to create an API deployment.
- Using an API description file you upload for an API resource. The API description file provides some initial values for the API deployment specification, which you can modify and extend when deploying the API resource on an API gateway. See Creating an API Resource with an API Description on page 358.

The instructions in this topic show a basic API deployment specification with a single backend, only one route, and no request or response policies. See Example API Deployment Specification with Multiple Back Ends on page 363 for a more typical API deployment specification that includes multiple back ends, each with one or more routes.

In addition, you can add request and response policies that apply to routes in an API deployment specification (see Adding Request Policies and Response Policies to API Deployment Specifications on page 417).

### Using the Console to Create an API Deployment Specification

To create an API deployment specification whilst creating an API deployment using dialogs in the Console, see Using the Console to Create an API Deployment from Scratch on page 364.

### Using a JSON Editor to Create an API Deployment Specification in a Separate JSON File

To create an API deployment specification in a JSON file:

1. Using your preferred JSON editor, create the API deployment specification in a JSON file in the format:

   ```json
   {
     "requestPolicies": {},
   }
   ```
"routes": [
  {
    "path": "<api-route-path>",
    "methods": ["<method-list>"],
    "backend": {
      "type": "<backend-type>",
      "<backend-target>": "<identifier>"
    },
    "requestPolicies": {}
  }
]

where:

- "requestPolicies" specifies optional policies to control the behavior of an API deployment. If you want to apply policies to all routes in an API deployment specification, place the policies outside the routes section. If you want to apply the policies just to a particular route, place the policies inside the routes section. See Adding Request Policies and Response Policies to API Deployment Specifications on page 417.

- <api-route-path> specifies a path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  - is relative to the deployment path prefix (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)
  - must be preceded by a forward slash (/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters \$ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)

- <method-list> specifies one or more methods accepted by the back-end service, separated by commas. For example, "GET, PUT".

- <backend-type> specifies the type of the back-end service. Valid values are ORACLE_FUNCTIONS_BACKEND, HTTP_BACKEND, and STOCK_RESPONSE_BACKEND.

- <backend-target> and <identifier> specify the back-end service. Valid values for <backend-target> and <identifier> depend on the value of <backend-type>, as follows:
  - If you set <backend-type> to ORACLE_FUNCTIONS_BACKEND, then replace <backend-target> with functionId, and replace <identifier> with the OCID of the function. For example, "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab5b...". See Adding a Function in Oracle Functions as an API Gateway Back End on page 410.
  - If you set <backend-type> to HTTP_BACKEND, then replace <backend-target> with url, and replace <identifier> with the URL of the back-end service. For example, "url": "https://api.weather.gov". See Adding an HTTP or HTTPS URL as an API Gateway Back End on page 406.
  - If you set <backend-type> to STOCK_RESPONSE_BACKEND, then replace <backend-target> and <identifier> with appropriate key-value pairs. See Adding Stock Responses as an API Gateway Back End on page 413.

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
```
For a more complex example that defines multiple back ends, see Example API Deployment Specification with Multiple Back Ends on page 363.

2. Save the JSON file containing the API deployment specification.

3. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363.

Using an API Description File to Create an API Deployment Specification

To create an API deployment specification based on an API description file you upload for an API resource, see Creating an API Resource with an API Description on page 358

The API description file provides some initial values for the API deployment specification, which you can modify and extend when deploying the API resource on an API gateway.

Example API Deployment Specification with Multiple Back Ends

You can create a single API deployment on an API gateway, with an API deployment specification that defines multiple back-end services.

For example, the following API deployment specification defines a simple Hello World serverless function in Oracle Functions as one back end, and the National Weather Service API as a second back end.

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab________xmq"
            }
        },
        {
            "path": "/weather",
            "methods": ["GET"],
            "backend": {
                "type": "HTTP_BACKEND",
                "url": "https://api.weather.gov"
            }
        }
    ]
}
```

Deploying an API on an API Gateway by Creating an API Deployment

Having created an API gateway, you deploy an API on the API gateway by creating an API deployment. When you create an API deployment, you include an API deployment specification that defines the API. The API Gateway service inspects the API deployment specification to confirm that it is valid.

You can use a single API gateway as the front end for multiple back-end services by:
• Creating a single API deployment on the API gateway, with an API deployment specification that defines multiple back-end services.
• Creating multiple API deployments on the same API gateway, each with an API deployment specification that defines one (or more) back-end services.

**Using the Console to Create an API Deployment from Scratch**

To use the Console to create an API deployment, entering the API deployment specification in dialogs in the Console as you go:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **API Gateway**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Gateways** page, click the name of the API gateway on which you want to deploy the API to show the **Gateway Details** page.
4. On the **Gateway Details** page, select **Deployments** from the **Resources** list, and then click **Create Deployment**.
5. Click **From Scratch** and in the **Basic Information** section, specify:
   - **Name**: The name of the new API deployment. Avoid entering confidential information.
   - **Path Prefix**: A path on which to deploy all routes contained in the API deployment specification. For example:
     - /v1
     - /v2
     - /test/20191122
     Note that the deployment path prefix you specify:
     - must be preceded by a forward slash ( / )
     - can contain multiple forward slashes (provided they are not adjacent), but must not end with a forward slash
     - can include alphanumeric uppercase and lowercase characters
     - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
     - cannot include parameters and wildcards
   - **Compartment**: The compartment in which to create the new API deployment.
6. (Optional) In the **API Request Policies** section, optionally specify request policy details to provide support for:
   - **Authentication**: Click **Add** and enter details for an authentication request policy (see **Adding Authentication and Authorization to API Deployments** on page 431).
   - **CORS**: Click **Add** and enter details for a CORS request policy (see **Adding CORS support to API Deployments** on page 424).
   - **Rate Limiting**: Click **Add** and enter details for a rate limiting request policy (see **Limiting the Number of Requests to API Gateway Back Ends** on page 421).
7. (Optional) In the **API Logging Policies** section, optionally specify an execution log level to record information about processing within the API gateway. See **Adding Logging to API Deployments** on page 397.
8. (Optional) Click **Show Advanced Options** and optionally specify:
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
9. Click **Next** to enter details of the routes in the API deployment.
10. In the **Route 1** section, specify the first route in the API deployment that maps a path and one or more methods to a back-end service:

- **Path:** A path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  - is relative to the deployment path prefix
  - must be preceded by a forward slash (/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)
- **Methods:** One or more methods accepted by the back-end service, separated by commas. For example, GET, PUT.
- **Type:** The type of the back-end service, as one of:
  - **HTTP:** For an HTTP back end, you also need to specify a URL, timeout details, and whether to disable SSL verification (see Adding an HTTP or HTTPS URL as an API Gateway Back End on page 406).
  - **Oracle Functions:** For an Oracle Functions back end, you also need to specify the application and function (see Adding a Function in Oracle Functions as an API Gateway Back End on page 410).
  - **Stock Response:** For a stock response back end, you also need to specify the HTTP status code, the content in the body of the response, and one or more HTTP header fields (see Adding Stock Responses as an API Gateway Back End on page 413).

11. (Optional) Click **Another Route** to enter details of additional routes.

12. Click **Next** to review the details you entered for the new API deployment.

13. Click **Create** to create the new API deployment.

   Note that it can take a few minutes to create the new API deployment. While it is being created, the API deployment is shown with a state of Creating on the **Gateway Details** page. When it has been created successfully, the new API deployment is shown with a state of Active.

14. If you have waited more than a few minutes for the API deployment to be shown with an Active state (or if the API deployment creation operation has failed):

   a. Click the name of the API deployment, and click **Work Requests** to see an overview of the API deployment creation operation.
   b. Click the **Create Deployment** operation to see more information about the operation (including error messages, log messages, and the status of associated resources).
   c. If the API deployment creation operation has failed and you cannot diagnose the cause of the problem from the work request information, see Troubleshooting API Gateway on page 474.

15. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

### Using the Console to Create an API Deployment from a JSON File

To use the Console to create an API deployment, uploading the API deployment specification from a JSON file:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **API Gateway**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Gateways** page, click the name of the API gateway on which you want to deploy the API to show the **Gateway Details** page.
4. On the **Gateway Details** page, select **Deployments** from the **Resources** list, and then click **Create Deployment**.
5. Click **Upload an existing API**.
6. In the **Upload Information** section, specify:
   - **Name**: The name of the new API deployment. Avoid entering confidential information.
   - **Path Prefix**: A path on which to deploy all routes contained in the API deployment specification. For example:
     - `/v1`
     - `/v2`
     - `/test/20191122`

   Note that the deployment path prefix you specify:
   - must be preceded by a forward slash (`/`)  
   - can contain multiple forward slashes (provided they are not adjacent), but must not end with a forward slash
   - can include alphanumeric uppercase and lowercase characters
   - can include the special characters `$_+!*()%,@&=`
   - cannot include parameters and wildcards

   - **Compartment**: The compartment in which to create the new API deployment.
   - **Specification**: The JSON file containing the API deployment specification, either by dragging and dropping the file, or by clicking **select one**. See **Creating an API Deployment Specification** on page 361.

7. (Optional) Click **Show Advanced Options** and optionally specify:
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

8. Click **Next** to review the details you entered for the new API deployment.

9. Click **Create** to create the new API deployment.

   Note that it can take a few minutes to create the new API deployment. While it is being created, the API deployment is shown with a state of Creating on the **Gateway Details** page. When it has been created successfully, the new API deployment is shown with a state of Active.

10. If you have waited more than a few minutes for the API deployment to be shown with an Active state (or if the API deployment creation operation has failed):
    a. Click the name of the API deployment, and click **Work Requests** to see an overview of the API deployment creation operation.
    b. Click the **Create Deployment** operation to see more information about the operation (including error messages, log messages, and the status of associated resources).
    c. If the API deployment creation operation has failed and you cannot diagnose the cause of the problem from the work request information, see **Troubleshooting API Gateway** on page 474.

11. (Optional) Confirm the API has been deployed successfully by calling it (see **Calling an API Deployed on an API Gateway** on page 384).

### Using the Console to Create an API Deployment from an API Resource

You can create an API deployment from an existing API resource, using the API resource's API description. In this case, the API description is based on an API description file you've uploaded for the API resource (see **Creating an API Resource with an API Description** on page 358). The API description file provides some initial values for the API deployment specification, which you can modify and extend when creating the API deployment. In particular, a default route is created for each path and associated method in the API description.

To use the Console to create an API deployment from an existing API resource, using an API deployment specification derived from an API description file:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **API Gateway**.
2. Choose a **Compartment** you have permission to work in.
3. On the **APIs** page, click the name of the API resource that you want to deploy.

4. (Optional) On the **API Details** page, select **API Deployment Specification** from the **Resources** list to confirm that a valid API deployment specification has been created for the API resource from an uploaded API description file. If no API deployment specification is available, see **Creating an API Resource with an API Description** on page 358.

5. On the **API Details** page, click **Deploy API Gateway** to use the Console dialogs for creating an API deployment.

Some of the initial values for the API deployment specification properties shown in the Console dialogs are derived from the API description file.

The **API Information** section shows details about the API resource from which to create the API deployment.

6. In the **Gateway** section, select the API gateway on which to create the API deployment. If a suitable API gateway does not already exist, click **Create Gateway** to create one (see **Creating an API Gateway** on page 355).

7. In the **Basic Information** section, specify:
   - **Name**: The name of the new API deployment. Avoid entering confidential information.
   - **Path Prefix**: A path on which to deploy all routes contained in the API deployment specification.
     
     For example:
     - `/v1`
     - `/v2`
     - `/test/20191122`
     
     Note that the deployment path prefix you specify:
     - must be preceded by a forward slash (`/`)
     - can contain multiple forward slashes (provided they are not adjacent), but must not end with a forward slash
     - can include alphanumeric uppercase and lowercase characters
     - can include the special characters `$_.+!*()%,@&=`
     - cannot include parameters and wildcards
   - **Compartment**: The compartment in which to create the new API deployment.

8. (Optional) In the **API Request Policies** section, optionally specify request policy details to provide support for:
   - **Authentication**: Click **Add** and enter details for an authentication request policy (see **Adding Authentication and Authorization to API Deployments** on page 431).
   - **CORS**: Click **Add** and enter details for a CORS request policy (see **Adding CORS support to API Deployments** on page 424).
   - **Rate Limiting**: Click **Add** and enter details for a rate limiting request policy (see **Limiting the Number of Requests to API Gateway Back Ends** on page 421).

9. (Optional) In the **API Logging Policies** section, optionally specify an execution log level to record information about processing within the API gateway. See **Adding Logging to API Deployments** on page 397.

10. (Optional) Click **Show Advanced Options** and optionally specify:
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

11. Click **Next** to review and enter details of the routes in the API deployment.

    By default, a route is created for every path and associated method that is present in the API description. Initially, each of these default routes is created with a stock response back end. The HTTP status code, the content in the body of the response body content, and the header are obtained from the details in the API description. If the API description does not include response information for a particular path and associated method, a default stock response back end is created for that route with 501 as the HTTP status code.
12. Review each default route in turn, modifying its configuration if necessary to meet your requirements, and adding request, response, and logging policies:

- **Path**: A path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  - is relative to the deployment path prefix
  - must be preceded by a forward slash (\/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)

- **Methods**: One or more methods accepted by the back-end service, separated by commas. For example, GET, PUT.

- **Type**: The type of the back-end service, as one of:
  - **HTTP**: For an HTTP back end, you also need to specify a URL, timeout details, and whether to disable SSL verification (see Adding an HTTP or HTTPS URL as an API Gateway Back End on page 406).
  - **Oracle Functions**: For an Oracle Functions back end, you also need to specify the application and function (see Adding a Function in Oracle Functions as an API Gateway Back End on page 410).
  - **Stock Response**: For a stock response back end, you also need to specify the HTTP status code, the content in the body of the response, and one or more HTTP header fields (see Adding Stock Responses as an API Gateway Back End on page 413).

- **Show Route Request Policies**: and **Show Route Response Policies**: Review and optionally update the request policies and response policies that apply to the route. See Adding Request Policies and Response Policies to API Deployment Specifications on page 417.

- **Show Route Logging Policies**: Review and optionally update the logging policy that applies to the route. See Adding Logging to API Deployments on page 397.

13. (Optional) Click **Another Route** to enter details of more routes, in addition to those created by default from the API description.

14. Click **Next** to review the details you entered for the new API deployment.

15. Click **Create** to create the new API deployment.

Note that it can take a few minutes to create the new API deployment. While it is being created, the API deployment is shown with a state of Creating on the Gateway Details page. When it has been created successfully, the new API deployment is shown with a state of Active.

16. If you have waited more than a few minutes for the API deployment to be shown with an Active state (or if the API deployment creation operation has failed):
   a. Click the name of the API deployment, and click **Work Requests** to see an overview of the API deployment creation operation.
   b. Click the **Create Deployment** operation to see more information about the operation (including error messages, log messages, and the status of associated resources).
   c. If the API deployment creation operation has failed and you cannot diagnose the cause of the problem from the work request information, see Troubleshooting API Gateway on page 474.

17. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

**Using the CLI**

To create a new API deployment using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. Open a command prompt and run `oci api-gateway deployment create` to create the deployment:

```
oci api-gateway deployment create --compartment-id <compartment-ocid>
--display-name <api-name> --gateway-id <gateway-ocid> --path-prefix "/<deployment-path-prefix>"
--specification file:///<filename>
```

where:

- `<compartment-ocid>` is the OCID of the compartment in which to create the new API deployment.
- `<api-name>` is the name of the new API deployment. Avoid entering confidential information.
- `<gateway-ocid>` is the OCID of the existing gateway on which to deploy the API. To find out the API gateway's OCID, see Listing API Gateways and API Deployments on page 386.
- `/<deployment-path-prefix>` is a path on which to deploy all routes contained in the API deployment specification.

Note that the deployment path prefix you specify:

- must be preceded by a forward slash (`/`) in the JSON file
- can contain multiple forward slashes (provided they are not adjacent), but must not end with a forward slash
- can include alphanumeric uppercase and lowercase characters
- can include the special characters `$ - _ . + ! * ' ( ) , % ; : @ & =`
- cannot include parameters and wildcards
- `<filename>` is the API deployment specification, including a path, one or more methods, and a back end definition. See Creating an API Deployment Specification on page 361.

For example:

```
oci api-gateway deployment create --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --display-name "Marketing Deployment" --gateway-id ocid1.apigateway.oc1..aaaaaaaab_____hga
```
The response to the command includes:

- The API deployment's OCID.
- The host name on which the API deployment has been created, as a domain name in the format `<gateway-identifier>.apigateway.<region-identifier>.oci.customer-oci.com`, where:
  - `<gateway-identifier>` is the string of characters that identifies the API gateway. For example, lak...sja (abbreviated for readability).
  - `<region-identifier>` is the identifier of the region in which the API deployment has been created. See Availability by Region on page 338.

For example, lak...sja.apigateway.us-phoenix-1.oci.customer-oci.com.

- The lifecycle state (for example, ACTIVE, FAILED).
- The id of the work request to create the API deployment (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API deployment is active (or the request has failed), include either or both the following parameters:

- `--wait-for-state ACTIVE`
- `--wait-for-state FAILED`

For example:

```bash
oci api-gateway deployment create --compartment-id ocid1.compartment.oc1..aaaaaaaa7_____ysq --display-name "Marketing Deployment" --gateway-id ocid1.apigateway.oc1..aaaaaaaab_____hga --path-prefix "/marketing" --specification file:///Users/jdoe/work/deployment.json --wait-for-state ACTIVE
```

Note that you cannot use the API deployment until the work request has successfully created it and the API deployment is active.

3. (Optional) To see the status of the API deployment, enter:

```bash
oci api-gateway deployment get --deployment-id <deployment-ocid>
```

4. (Optional) To see the status of the work request that is creating the API deployment, enter:

```bash
oci api-gateway work-request get --work-request-id <work-request-ocid>
```

5. (Optional) To view the logs of the work request that is creating the API deployment, enter:

```bash
oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

6. (Optional) If the work request that is creating the API deployment fails and you want to review the error logs, enter:

```bash
oci api-gateway work-request-error --work-request-id <work-request-ocid>
```

For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use the `CreateDeployment` operation to create an API deployment.

### Setting Up Custom Domains and TLS Certificates

The API gateways you create with the API Gateway service are TLS-enabled, and therefore require TLS certificates (formerly SSL certificates) issued by a Certificate Authority to secure them. To specify a particular custom domain name for an API gateway, you must obtain a custom TLS certificate from a Certificate Authority yourself, rather than have the API Gateway service obtain a TLS certificate for you.

When you create an API gateway, you specify that the API gateway uses one of the following:

- A TLS certificate that the API Gateway service obtains for you (the default behavior). In this case, the API Gateway service requests a TLS certificate from an Oracle-designated Certificate Authority.
- A custom TLS certificate that you obtain from your chosen Certificate Authority yourself. Your request to the Certificate Authority includes the custom domain name. The Certificate Authority returns a file containing the custom TLS certificate, and typically one or more files containing intermediate certificates forming a certificate chain from the TLS certificate back to the Certificate Authority.

To enable API gateways to use a custom TLS certificate, you create an API Gateway certificate resource comprising the custom TLS certificate, any intermediate certificates, and the private key used to generate the TLS certificate. You then specify that API Gateway certificate resource when creating a new API gateway.

The way in which the TLS certificate is obtained determines how much control you have over the API gateway's domain name:

- If the API Gateway service obtains a TLS certificate for you, the API Gateway service gives the API gateway an auto-generated domain name. The auto-generated domain name comprises a random string of characters followed by `.apigateway.<region-identifier>.oci.customer-oci.com`. For example, `lakjsd.apigateway.us-phoenix-1.oci.customer-oci.com`.
- If you obtain a custom TLS certificate yourself, the API Gateway service gives the API gateway the custom domain name you specified in your request to the Certificate Authority.

The way in which the TLS certificate is obtained also determines responsibility for recording the mapping between the API gateway's domain name and its public IP address with a DNS provider:

- If the API Gateway service obtains a TLS certificate for you, the API Gateway service takes responsibility for recording the mapping between the API gateway's auto-generated domain name and its public IP address with the Oracle Cloud Infrastructure DNS service.
- If you obtain a custom TLS certificate yourself, you are responsible for recording the mapping between the API gateway's custom domain name and its public IP address with your chosen DNS provider as an A record.

Similarly, the handling of TLS certificate expiry and renewal is determined by how the TLS certificate is originally obtained:

- If the API Gateway service obtains a TLS certificate for you, the API Gateway service automatically renews the TLS certificate with the Oracle-designated Certificate Authority before it expires.
- If you obtain a custom TLS certificate yourself, you are responsible for renewing the TLS certificate with your chosen Certificate Authority before it expires. Having received a new custom TLS certificate from the Certificate Authority, you create a new API Gateway certificate resource with the details of the new custom TLS certificate. You then update any API gateways that used the original API Gateway certificate resource to use the new certificate resource instead.

For some customers, use of custom domains and custom TLS certificates is obligatory. For example, if you are using Oracle Cloud Infrastructure Government Cloud, you are required to:

- only obtain a TLS certificate from a particular, approved Certificate Authority
- only use a particular, approved DNS provider

For other customers, use of custom domains is likely to be driven by commercial requirements. For example, typically you'll want to include your company name in the API gateway's domain name, rather than using the auto-generated random string of characters followed by `.apigateway.<region-identifier>.oci.customer-oci.co`. 
Note the following:

- You cannot delete an API Gateway certificate resource that is currently being used by an API gateway. To delete the API Gateway certificate resource, you must first remove it from any API gateway that is using it.
- You can only specify one API Gateway certificate resource for an API gateway.
- You cannot update an API Gateway certificate resource after you have created it.
- You can change the API Gateway certificate resource for an existing API gateway if you originally specified one when you first created the API gateway.

**Important:**
For public or production systems, Oracle recommends using custom TLS certificates. Oracle recommends only using TLS certificates obtained by the API Gateway service for private or non-production systems (for example, for development and testing).

**Setting up a Custom Domain Name and TLS Certificate for an API Gateway**

To set up a custom domain name and TLS certificate for an API gateway:

**Step 1: Obtain a TLS Certificate from your Chosen Certificate Authority**

The precise steps to obtain a TLS certificate will be different, according to the Certificate Authority you choose to use. At a high level, the steps will probably be somewhat similar to the following, but always refer to the Certificate Authority documentation for more detailed information:

1. Create a certificate signing request for your chosen Certificate Authority.
   Typically, you'll include information like the organization name, locality, and country in the certificate signing request.
   You'll also include a common name in the certificate signing request as the fully qualified domain name of the site you want to secure. The common name usually connects the TLS certificate with a particular domain. This domain name is used as the custom domain name for API gateways.
   When you create a certificate signing request, a public key is added to the request, and a corresponding private key is also generated and stored in a local file. You'll use this private key when you set up an API Gateway certificate resource, so make a note of its location. The private key you use to obtain a TLS certificate:
   - must be an RSA key
   - must be in PEM-encoded X.509 format
   - must start with -----BEGIN RSA PRIVATE KEY-----
   - must end with -----END RSA PRIVATE KEY-----
   - must not be protected by a passphrase
   - must have a minimum length of 2048 bits and must not exceed 4096 bits

2. Submit the certificate signing request to the Certificate Authority.
   The Certificate Authority returns:
   - a file containing the custom TLS certificate for the API gateway itself (known as the 'leaf certificate' or 'end-entity certificate')
   - typically one or more files containing intermediate certificates that form a certificate chain from the leaf certificate back to the Certificate Authority

You can now use these certificate files to create an API Gateway certificate resource.

**Step 2: Create an API Gateway Certificate Resource**

An API Gateway certificate resource is a named definition of a TLS certificate that you can use when creating or updating an API gateway using the API Gateway service.
An API Gateway certificate resource comprises:

- a name of your choice for the certificate resource itself
- the custom TLS certificate for the API gateway (the 'leaf certificate' or 'end-entity certificate') returned by the Certificate Authority
- any intermediate certificates forming a certificate chain from the leaf certificate back to the Certificate Authority
- the private key paired with the public key that was included in the original certificate signing request

Note that you cannot update an API Gateway certificate resource after you have created it.

You can create an API Gateway certificate resource using the Console or the CLI.

**Using the Console**

To create an API Gateway certificate resource using the Console:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **API Gateway**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Certificates** page, click **Add Certificate** and specify:
   - **Name**: The name of the new API Gateway certificate resource. Avoid entering confidential information.
   - **Certificate**: The custom TLS certificate returned by the Certificate Authority (the 'leaf certificate' or 'end-entity certificate'). Drag and drop, select, or paste a valid TLS certificate. Note that the TLS certificate you specify:
     - must be in PEM-encoded X.509 format
     - must start with `-----BEGIN CERTIFICATE-----`
     - must end with `-----END CERTIFICATE-----`
     - must not exceed 4096 bits in length
   - **Intermediate Certificates**: (Optional) If there is one or more intermediate certificates forming a certificate chain from the TLS certificate back to the Certificate Authority, include the contents of the intermediate certificate files in the correct order. The correct order begins with the certificate directly signed by the Trusted Root Certificate Authority at the bottom, with any additional certificate directly above the Certificate Authority that signed it. For example:

```
-----BEGIN CERTIFICATE-----
<PEM_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<PEM_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<PEM_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<PEM_encoded_certificate>
```

If you have concatenated the contents of intermediate certificate files into a single certificate chain file in the correct order, drag and drop that file, or select that file, or paste that file's content.

If you don't have a concatenated certificate chain file, paste the contents of the individual certificate files, in the correct order.

The combined length of any intermediate certificates you specify must not exceed 10240 bits.

- **Private Key:** The private key used to obtain the TLS certificate from the Certificate Authority. Drag and drop, select, or paste a valid private key in this field. Note that the key you specify:
  - must be an RSA key
  - must be in PEM-encoded X.509 format
  - must start with `-----BEGIN RSA PRIVATE KEY-----`
  - must end with `-----END RSA PRIVATE KEY-----`
  - must not be protected by a passphrase
  - must have a minimum length of 2048 bits and must not exceed 4096 bits

4. Click **Create** to create the API Gateway certificate resource.

**Using the CLI**

To create an API Gateway certificate resource using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).

2. Open a command prompt and run `oci api-gateway certificate create` to create the API Gateway certificate resource:

   ```bash
   oci api-gateway certificate create --display-name "<certificate-name>" --compartment-id <compartment-ocid> --certificate-file <certificate-file-path> --intermediate-certificates-file <intermediate-certificates-file-path> --private-key-file <private-key-file-path>
   ```

   where:
   - `<certificate-name>` is the name of the new API Gateway certificate resource. Avoid entering confidential information.
   - `<compartment-ocid>` is the OCID of the compartment to which the new API Gateway certificate resource will belong.
   - `<certificate-file-path>` is the path and name of the file containing the leaf certificate returned by the Certificate Authority. For example, `~/.certs/cert.pem`. Note that the leaf certificate in the file you specify:
     - must be in PEM-encoded X.509 format
     - must start with `-----BEGIN CERTIFICATE-----`
     - must end with `-----END CERTIFICATE-----`
     - must not exceed 4096 bits in length
   - `<intermediate-certificates-file-path>` is optionally the path and name of a file containing one or more intermediate certificates forming a certificate chain from the leaf certificate back to the Certificate Authority. For example, `~/.certs/int_cert.pem`. If the file contains multiple intermediate certificates, the intermediate certificates must be in the correct order. The correct order ends with the certificate directly signed by the Trusted Root Certificate Authority, with any additional certificate directly preceding the Certificate Authority that signed it. For example:

     ```
     -----BEGIN CERTIFICATE-----
     <PEM_encoded_certificate>-----
     END CERTIFICATE-------------BEGIN CERTIFICATE-----
     <PEM_encoded_certificate>-----END CERTIFICATE-------------BEGIN
     ```
The combined length of any intermediate certificates you specify must not exceed 10240 bits.

- `<private-key-file-path>` is the path and name of the file containing the private key used to obtain the TLS certificate from the Certificate Authority. For example, `~/.certs/key.pem`. Note that the private key in the file you specify:
  - must be an RSA key
  - must be in PEM-encoded X.509 format
  - must start with `-----BEGIN RSA PRIVATE KEY-----`
  - must end with `-----END RSA PRIVATE KEY-----`
  - must not be protected by a passphrase
  - must have a minimum length of 2048 bits and must not exceed 4096 bits

For example:

```bash
oci api-gateway certificate create --display-name "Acme gateway certificate" --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --certificate-file ~/.certs/cert.pem --private-key-file ~/.certs/key.pem
```

The response to the command includes:

- The OCID of the new API Gateway certificate resource.
- The lifecycle state (for example, ACTIVE, FAILED).
- The id of the work request to create the API Gateway certificate resource (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API Gateway certificate resource is active (or the request has failed), include either or both of the following parameters:

- `--wait-for-state ACTIVE`
- `--wait-for-state FAILED`

For example:

```bash
oci api-gateway certificate create --display-name "Acme gateway certificate" --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --certificate-file ~/.certs/cert.pem --private-key-file ~/.certs/key.pem --wait-for-state ACTIVE
```

For more information about using the CLI, see [Command Line Interface (CLI)](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/iaas-index.htm). For a complete list of flags and options available for CLI commands, see [Command Line Reference](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/iaas-index.htm).

**Step 3: Specify the API Gateway certificate resource when creating an API gateway**

To specify the API Gateway certificate resource when creating an API gateway:

1. Follow the instructions in [Creating an API Gateway](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/iaas-index.htm#Create) on page 355 to create an API gateway using either the Console or the CLI.
2. Specify the API Gateway certificate resource as described in the instructions:
   - If using the Console: Use the **Certificate** field.
   - If using the CLI: Set the `--certificate-id <certificate-ocid>` property.

   The API Gateway service creates the new API gateway, and installs the custom TLS certificate and private key.
3. Obtain the public IP address of the API gateway.
Step 4: Record the Mapping Between the API Gateway's Custom Domain Name and Public IP Address With Your Chosen DNS Provider

The precise steps to record the mapping between an API gateway's custom domain name and its public IP address depend on the DNS provider you choose to use. Typically, you will create a new record (specifically a new A record) in the DNS provider's configuration. The record associates the domain name you configured when requesting the TLS certificate from your chosen Certificate Authority with the public IP address that the API Gateway service assigns to the new API gateway. Refer to your chosen DNS provider's documentation for more detailed information.

Renewing Custom TLS Certificates Used by API Gateways

TLS certificates are valid for a limited period of time (typically one or two years) before they expire. If the TLS certificate used by an API gateway expires, calls to an API deployed on the API gateway return warning messages. To avoid warning messages, you have to renew TLS certificates before they expire (sometime referred to as 'rotating' certificates)

If the API Gateway service obtained the original TLS certificate for you, the API Gateway service automatically renews the TLS certificate with the Oracle-designated Certificate Authority before it expires. However, if you obtained a custom TLS certificate yourself, you are responsible for renewing the custom TLS certificate with your chosen Certificate Authority before it expires (although the Console does show a warning if the TLS certificate is due to expire shortly).

When you request the renewal of a TLS certificate, the Certificate Authority returns a completely new TLS certificate. You cannot simply update the existing API Gateway certificate resource with the new TLS certificate. Instead, you create a new API Gateway certificate resource, add the new TLS certificate to the new certificate resource, and then update any API gateways that used the previous certificate resource to use the new certificate resource.

To renew the custom TLS certificate used by an API gateway:

1. Submit a TLS certificate renewal request to the Certificate Authority from which you originally obtained the TLS certificate. The exact steps to renew a TLS certificate depend on the Certificate Authority you use, so always refer to the Certificate Authority documentation for more detailed information.

When you create the certificate renewal request, a public key is added to the request, and a corresponding private key is also generated and stored in a local file. You'll use this private key when you set up the new API Gateway certificate resource, so make a note of its location.

The Certificate Authority returns a file containing the new custom TLS certificate, and typically one or more files containing intermediate certificates forming a certificate chain from the TLS certificate back to the Certificate Authority.

2. Create a new API Gateway certificate resource and add to it the new TLS certificate, any intermediate certificates, and the new private key (see Step 2: Create an API Gateway Certificate Resource on page 372).

3. Update all the existing API gateways that used the original API Gateway certificate resource to use the new API Gateway certificate resource (see Updating API Gateways and API Deployments on page 387).

4. When there are no API gateways still using the original API Gateway certificate resource, delete the original certificate resource:
   - If using the Console: On the Certificates page, click the Actions icon (three dots) beside the original API Gateway certificate resource you want to delete, and then click Delete.
   - If using the CLI: Use the following command to delete the original API Gateway certificate resource:

   ```sql
   oci api-gateway certificate delete --certificate-id <certificate-ocid>
   ```

   Note that you cannot delete an API Gateway certificate resource if there are API gateways still using it.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use the:

- **CreateCertificate** operation to create a new API Gateway certificate resource
- **DeleteCertificate** operation to delete an existing API Gateway certificate resource
- **UpdateCertificate** operation to change the details of an existing API Gateway certificate resource
- **GetCertificate** operation to see details of an existing API Gateway certificate resource
- **ListCertificates** operation to list all the certificates in a compartment
- **ChangeCertificateCompartment** operation to change the compartment to which an existing API Gateway certificate resource belongs

### Adding Path Parameters and Wildcards to Route Paths

You might want different API requests routed to the same backend, even when the request URLs vary to a greater or lesser extent from the route path definition in the API deployment specification.

When defining a route path in an API deployment specification, you can include a path parameter to exactly replace an individual segment of the path. If necessary, you can include multiple path parameters in the route path. You can also append the asterisk (*) wildcard to a path parameter in the route path to provide even more flexibility when identifying requests to send to the same backend.

The examples in this topic assume you are adding route paths to an API deployment specification in a JSON file. Note the examples also apply when you're defining an API deployment specification using dialogs in the Console.

#### Example: Adding Path Parameters to Match Similar URLs

You might have a requirement to route requests with similar URLs to the same backend. For example:

- `https://<gateway-hostname>/marketing/hello/apac/index.html`
- `https://<gateway-hostname>/marketing/hello/emea/index.html`

To enable calls to these similar URLs to resolve to the same backend, add a path parameter name enclosed within curly brackets as the segment of the route path that will vary between API calls. For example, `{region}` as shown below:

```json
{
  "routes": [
    {
      "path": "/hello/{region}/index.html",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaabb_xmq"
      }
    }
  ]
}
```

Note that path parameter names:

- Can include alphanumeric uppercase and lowercase characters.
- Can include the underscore `_` special character.
- Cannot include other special characters. In particular, note that you cannot include spaces, forward slashes, and curly brackets in path parameter names.

#### Example: Adding Path Parameters with a Wildcard to Match Dissimilar URLs

You might have a requirement to route requests to the same backend, even though the request URLs are significantly different. For example:

```json
{
  "routes": [
    {
      "path": "/hello/*index.html",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaabb_xmq"
      }
    }
  ]
}
```
To enable calls to these significantly different URLs to resolve to the same backend:

- add a path parameter name enclosed within curly brackets as the first segment of the route path that will differ between the various API calls
- add the asterisk (*) wildcard to the end of the path parameter name

For example, \{generic_welcome\*\} as shown below:

```json
{
   "routes": [
      {
         "path": "/hello/{generic_welcome*}",
         "methods": ["GET"],
         "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
      }
   ]
}
```

Note that a path parameter name with an asterisk wildcard will match:

- no path segment
- a single path segment
- multiple path segments

### Adding Context Variables to Policies and HTTP Back End Definitions

Calls to APIs deployed on an API gateway typically include parameters that you’ll want to use when defining the following in API deployment specifications:

- request policies and response policies
- HTTP and HTTPS back ends

To enable you to use parameters included in API calls, the API Gateway service saves the values of the following types of parameter in temporary ‘context tables’:

- Path parameters you define in the API deployment specification (see Adding Path Parameters and Wildcards to Route Paths on page 377) are saved in records in the request.path table.
- Query parameters included in the call to the API are saved in records in the request.query table.
- Header parameters included in the call to the API are saved in records in the request.headers table.
- Authentication parameters returned by an authorizer function or contained in a JSON Web Token (JWT) are saved in records in the request.auth table (see Using Authorizer Functions to Add Authentication and Authorization to API Deployments on page 431 and Using JSON Web Tokens (JWTs) to Add Authentication and Authorization to API Deployments on page 440 respectively).

Each record in a context table is identified by a unique key.

When defining request and response policies, and HTTP and HTTPS back ends, you can reference the value of a parameter in a context table using a ‘context variable’. A context variable has the format `<context-table-name>[<key>]` where:

- `<context-table-name>` is one of request.path, request.query, request.headers, or request.auth
• `<key>` is one of:
  • a path parameter name defined in the API deployment specification
  • a query parameter name included in the request to the API
  • a header name included in the request to the API
  • an authentication parameter name returned by an authorizer function or contained in a JWT token

If you want to include the context variable within a string in the API deployment specification (for example, in the `url` property of an HTTP back end definition), use the format `${<context-table-name>[<key>]}`.

For example, the `request.path[region]` context variable in the example below returns the value of the record identified by the `region` key in the `request.path` context table.

```
{
  "routes": [
    {
      "path": "/weather/{region}"
      "methods": ["GET"],
      "backend": {
        "type": "HTTP_BACKEND",
        "url": "https://api.weather.gov/${request.path[region]}"
      }
    }
  ]
}
```

Note the following:

• A single record is created in the context table for each discrete parameter in an HTTP request. If the HTTP request includes two (or more) parameters of the same type and with the same name, the value of each parameter with that name is saved in the same record in the context table and identified by the same key. However, only the first value in the context table record can be substituted in place of a context variable. When adding a context variable for which multiple values can exist in the context table record and you want the first value in the context table record to be substituted in place of the context variable, add the context variable to the API deployment specification in the format `${<context-table-name>[<key>]}`

• If a parameter value includes special characters that have been encoded, the encoding is preserved when the value is saved in the context table. When the value is substituted for a context variable, the encoded value is substituted in place of the context variable. For example, if San José is included in a query parameter as `San+José`, the encoded version is what will be substituted in place of the context variable for that query parameter.

• If a context variable key does not exist in the specified context table, an empty string is substituted in place of the context variable.

• If a context variable key contains a dot, the dot is treated as any other character. It is not treated as an indicator of a parent-child relationship between the strings either side of it.

• If a path parameter includes a wildcard (for example, `generic_welcome*`), the path parameter without the wildcard is used as the key.

• You can include a context variable as a path segment in the `url` property of an HTTP back end definition, but not as a query parameter. For example:
  
  • You can use the `request.query[state]` context variable as a path segment in the `url` property, as shown in the following valid HTTP back end definition:

```
{
  "path": "/weather/{region}"
  "methods": ["GET"],
  "backend": {
    "type": "HTTP_BACKEND",
    "url": "https://api.weather.gov/${request.path[region]}/
    ${request.query[state]}"
  }
}
```
You cannot use the `request.query[state]` context variable as a query parameter in the URL property, as shown in the following invalid HTTP back end definition:

```
{
  "path": "/weather/{region}",
  "methods": ["GET"],
  "backend": {
    "type": "HTTP_BACKEND",
    "url": "https://api.weather.gov/${request.path[region]}?state=${request.query[state]}"
  }
}
```

**Examples**

The examples in this section assume the following API deployment definition and basic API deployment specification in a JSON file:

```
{
  "displayName": "Marketing Deployment",
  "gatewayId": "ocid1.apigateway.oc1..aaaaaaaab______hga",
  "compartmentId": "ocid1.compartment.oc1..aaaaaaa7______ysq",
  "pathPrefix": "/marketing",
  "specification": {
    "routes": [
      {
        "path": "/weather",
        "methods": ["GET"],
        "backend": {
          "type": "HTTP_BACKEND",
          "url": "https://api.weather.gov"
        }
      }
    ],
    "freeformTags": {},
    "definedTags": {}
  }
}
```

Note the examples also apply when you're defining an API deployment specification using dialogs in the Console.

**Example 1: Query path parameter in a definition**

You can define a path parameter in the API deployment specification, and then use it elsewhere in the API deployment specification as a context variable.

This example creates a path parameter, `region`, and uses it in a context variable `request.path[region]` in the HTTP back end definition.

```
{
  "path": "/weather/{region}",
  "methods": ["GET"],
  "backend": {
    "type": "HTTP_BACKEND",
    "url": "https://api.weather.gov/${request.path[region]}"
  }
}
```
In this example, a request like \texttt{https://<gateway-hostname>/marketing/weather/west} resolves to \texttt{https://api.weather.gov/west}.

**Example 2: Different types of context variable in the same definition**

You can include different types of context variable in the same definition in the API deployment specification.

This example uses the following in the HTTP back end definition:

- a path parameter context variable, \texttt{request.path[region]}
- a query parameter context variable, \texttt{request.query[state]}

```json
{
  "path": "/weather/{region}",
  "methods": ["GET"],
  "backend": {
    "type": "HTTP_BACKEND",
    "url": "https://api.weather.gov/${request.path[region]}/
             ${request.query[state]}"
  }
}
```

In this example, a request like \texttt{https://<gateway-hostname>/marketing/weather/west?state=california} resolves to \texttt{https://api.weather.gov/west/california}.

**Example 3: Multiple context variables of the same type in the same definition**

You can include the same type of context variable multiple times in the same definition.

This example uses the following in the HTTP back end definition:

- a path parameter context variable, \texttt{request.path[region]}
- two query parameter context variables, \texttt{request.query[state]} and \texttt{request.query[city]}

```json
{
  "path": "/weather/{region}",
  "methods": ["GET"],
  "backend": {
    "type": "HTTP_BACKEND",
    "url": "https://api.weather.gov/${request.path[region]}/
             ${request.query[state]}/${request.query[city]}"
  }
}
```

In this example, a request like \texttt{https://<gateway-hostname>/marketing/weather/west?state=california&city=fremont} resolves to \texttt{https://api.weather.gov/west/california/fremont}.

**Example 4: Multiple values for the same parameter**

It is often valid for an HTTP request to include the same query parameter multiple times. The API Gateway service saves the value of each parameter with the same name to the same record in the context table. However, in the API deployment specification, it’s typically the case that only a single value can be substituted for a context variable. In these situations, you can indicate that only the first value recorded in the context table for a key is substituted in place of a context variable by enclosing the context variable within \texttt{{...}}.

For example, a valid request like \texttt{https://<gateway-hostname>/marketing/weather/west?state=california&city=fremont&city=belmont} has two occurrences of the \texttt{city} query parameter. On receipt of the HTTP request, the API Gateway service writes both values of the \texttt{city} query parameter \texttt{(fremont and belmont)} to the same record in the \texttt{request.query} table. When the definition of an HTTP back
end includes \${request.query[city]}, only the first value in the record is substituted in place of the context variable.

This example uses the following in the HTTP back end definition:

- a path parameter context variable, request.path[region]
- two query parameter context variables, request.query[state] and request.query[city]

```json
{
    "path": "/weather/{region}",
    "methods": ["GET"],
    "backend": {
        "type": "HTTP_BACKEND",
        "url": "https://api.weather.gov/${request.path[region]}/\${request.query[state]}/${request.query[city]}"
    }
}
```

In this example, a request like https://<gateway-hostname>/marketing/weather/west?state=california&city=fremont&city=belmont resolves to https://api.weather.gov/west/california/fremont. Note that only fremont (as the first value in the request.query context table record identified by the city key) is substituted for the request.query[city] context variable.

**Example 5: Parameter value includes encoded special characters**

If an HTTP request includes special characters (for example, the character é, the space character) that have been encoded, the value is stored in the context table in its encoded form. When the value from the context table is substituted for a context variable, the encoding is preserved.

This example uses the following in the HTTP back end definition:

- a path parameter context variable, request.path[region]
- a query parameter context variable, request.query[city]

```json
{
    "path": "/weather/{region}",
    "methods": ["GET"],
    "backend": {
        "type": "HTTP_BACKEND",
        "url": "https://api.weather.gov/${request.path[region]}/\${request.query[state]}/${request.query[city]}"
    }
}
```

In this example, a request like https://<gateway-hostname>/marketing/weather/west?city=San+José resolves to https://api.weather.gov/west/california/San+José.

**Example 6: Header parameters in a definition**

You can include values passed in the headers of a request as context variables in a definition. If the request includes a header, the value of the header is stored in the request.headers table, and the name of the header is used as the key.

This example uses the following in the HTTP back end definition:

- a path parameter context variable, request.path[region]
- a header parameter context variable, request.headers[X-Api-Key]

```json
{
    "path": "/weather/{region}",
    "methods": ["GET"],
    "backend": {
```
In this example, a request like `https://<gateway-hostname>/marketing/weather/west` included an `X-Api-Key` header with the value `abc123def456fhi789`. The request resolves to `https://api.weather.gov/west/abc123def456fhi789`.

**Example 7: Authentication parameters in a definition**

You can include values returned from an authorizer function or contained in a JWT token as context variables in a definition:

- An authorizer function validates the token passed by an API client when calling the API Gateway service. The authorizer function returns a response that includes information such as the validity of the authorization, information about the end user, access scope, and a number of claims in key-value pairs. Depending on the authorization token, the information might be contained within the token, or the authorizer function might invoke end-points provided by the authorization server to validate the token and to retrieve information about the end user. When the API Gateway service receives a key-value pair from the authorizer function, it saves the key-value pair in the `request.auth` table as an authentication parameter.

- A JWT token can optionally include a custom claim named `scope`, comprising a key-value pair. When the JWT token has been validated, the API Gateway service saves the key-value pair in the `request.auth` table as an authentication parameter.

This example uses the key-value pair returned by an authorizer function as the authentication parameter context variable `request.auth[region]` in the HTTP back end definition.

Assume an authorizer function `ocid1.fnfunc.oc1.phx.aaaaaaaaac2______kg6fq` validates the token passed by an API client in a call to the API Gateway service. The authorizer function returns a response to the API Gateway service that includes the region associated with the end user as a key-value pair, and also the authenticated end user's access scope. When the API Gateway service receives the key-value pair, it saves the key-value pair in the `request.auth` table as an authentication parameter.
In this example, a request like https://<gateway-hostname>/marketing/weather is made by an end user jdoe using an API client. The authorizer function validates the token passed by the API client in the request, and also determines that jdoe has the "weatherwatcher" access scope. The authorizer function identifies that jdoe is associated with the west region. The authorizer function returns jdoe's access scope to the API Gateway service, along with the region associated with jdoe. The API Gateway service saves the region associated with jdoe as an authentication parameter. The HTTP back end definition specifies that end users with the "weatherwatcher" access scope are allowed to access the HTTP back end. The API Gateway service uses the value of the authentication parameter context variable `request.auth[region]` in the request. The request resolves to https://api.weather.gov/west.

**Calling an API Deployed on an API Gateway**

Having deployed an API on an API gateway, you can call the deployed API.

**Tip:**

When assembling the curl command described in this topic, you can quickly get the value of the `https://<gateway-hostname>/<deployment-path-prefix>` string as the API deployment's endpoint using:

- The Console, by going to the **Gateway Details** page and clicking **Copy** beside the endpoint of the API deployment.
- The API, by using the **GetDeployments** operation.
Using curl

To call an API deployed on an API gateway:

1. Open a terminal window and type a cURL command similar to the following that is appropriate for the deployed API:

```
curl -k -X <method> https://<gateway-hostname>/<deployment-path-prefix>/<api-route-path>
```

where:

- `<method>` is a valid method for the deployed API (for example, GET, PUT).
- `<gateway-hostname>` is an automatically generated domain name in the format `<gateway-identifier>.apigateway.<region-identifier>.oci.customer-oci.com`, where:
  - `<gateway-identifier>` is the string of characters that identifies the API gateway. For example, lak...sjd (abbreviated for readability).
  - `<region-identifier>` is the identifier of the region in which the API gateway has been created. See Availability by Region on page 338.

For example, lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com.

Use the Console or the API to find out the domain name to use as the value of `<gateway-hostname>`.

- `<deployment-path-prefix>` is the prefix added to the path of every route in the API deployment. Note that the deployment path prefix in the request:
  - can contain multiple forward slashes (provided they are not adjacent)
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - cannot include parameters and wildcards
  - must match exactly the deployment path prefix defined for the API deployment (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)

Use the Console or the API to find out the path prefix to use as the value of `<deployment-path-prefix>`.

- `<api-route-path>` is the path to a particular route defined in the API deployment specification. Note that the route path in the request:
  - is relative to the deployment path prefix
  - can be a single forward slash
  - can include multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - need not match exactly the route path defined in the API deployment specification, provided the route path in the API deployment specification includes a path parameter with or without a wildcard (see Adding Path Parameters and Wildcards to Route Paths on page 377)

Use the Console or the API to find out the path to use as the value of `<api-route-path>`.

For example:

```
curl -k -X GET https://lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com/marketing/hello/
```

If the API gateway back end is a serverless function that accepts parameters, include those parameters in the call to the API. For example:

```
curl -k -X POST https://lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com/marketing/hello/ -d "name=John"
```
Listing API Gateways and API Deployments

Having created API gateways, and deployed APIs on API gateways by creating API deployments, you might need to list the existing API gateways or API deployments. For example, you might want to see whether there are any API gateways that are no longer required, quickly locate an API gateway by its OCID, or obtain the OCID of an API deployment.

Using the Console

To list API gateways or API deployments using the Console:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Choose a Compartment you have permission to work in.
3. To see a list of all existing API gateways in the current region and compartment (including their OCIDs), use the Gateways page.
4. To see more detail about an individual API gateway, click the name of the API gateway on the Gateways page to show the Gateway Details page.
5. To see a list of API deployments on an API gateway (including their endpoint, state, and OCID), click the name of the API gateway on the Gateways page and select Deployments from the Resources list.

Using the CLI

To list the API gateways and API deployments in a compartment using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. To list all the API gateways in a compartment, open a command prompt and run oci api-gateway gateway list to list the API gateways:

   `oci api-gateway gateway list --compartment-id <compartment-ocid>

where:

- `<compartment-ocid>` is the OCID of the compartment containing the API gateway.

For example:

   `oci api-gateway gateway list --compartment-id ocid1.compartment.oc1..aaaaaaaa7_____ysq`

If you want to list just those API gateways with a status of Active, include the --lifecycle-state ACTIVE parameter in the request. For example:

   `oci api-gateway gateway list --compartment-id ocid1.compartment.oc1..aaaaaaaa7_____ysq --lifecycle-state ACTIVE`
To list all the API deployments in a compartment, open a command prompt and run `oci api-gateway deployment list` to list the API deployments:

```
oci api-gateway deployment list --compartment-id <compartment-ocid>
```

where:

- `<compartment-ocid>` is the OCID of the compartment containing the API deployments.

For example:

```
oci api-gateway deployment list --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq
```

If you want to list just those API deployments with a status of Active, include the `--lifecycle-state ACTIVE` parameter in the request. For example:

```
oci api-gateway deployment list --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --lifecycle-state ACTIVE
```

If you want to list all the API deployments on a particular API gateway in a compartment, include the `--gateway-id` parameter in the request and specify the API gateway's OCID. For example:

```
oci api-gateway deployment list --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --gateway-id ocid1.apigateway.oc1..aaaaaaaab______hga
```

For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the:

- `ListGateways` operation to list API gateways
- `ListDeployments` operation to list API deployments

**Updating API Gateways and API Deployments**

Having created an API gateway, and deployed an API on the API gateway by creating an API deployment, you might decide to change either or both. For example, to change the API gateway's name or the tags applied to it, or to change an API deployment specification to add additional back ends to the API deployment.

Note that there are some properties of API gateways and API deployments for which you cannot change the original values.

You can update API gateways and API deployments using the Console, the CLI, and the API.

You can update an API deployment specification by:

- using dialogs in the Console
- editing a JSON file

**Using the Console**

To update an existing API gateway or an API deployment using the Console:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Choose a **Compartment** you have permission to work in.

3. On the **Gateways** page, click the name of the API gateway that you want to update (or that contains the API deployment you want to update) to show the **Gateway Details** page.

4. To update an API gateway:
   - Click **Edit** to change the API gateway's name. If you have set up a custom TLS certificate (and associated custom domain name), you can also change the API Gateway certificate resource used by the API gateway (see Setting Up Custom Domains and TLS Certificates on page 371). Avoid entering confidential information.
   - Click **Move Resource** to move the API gateway to a different compartment.
   - Click **Add Tag(s)** and **View Tag(s)** to change and view the tags applied to the API gateway.

5. To update an API deployment, on the **Gateway Details** page, select **Deployments** from the **Resources** list and click the Actions icon (three dots) beside the API deployment you want to update:
   - Click **Edit** to change the API deployment's name, or to replace the original API deployment specification. You can change the original API deployment specification by selecting one of two options:
     - **From Scratch**: Select to change API deployment specification properties using dialogs in the Console.
     - **Upload an existing API**: Select to change API deployment specification properties by uploading a replacement JSON file.
   - Click **Move Resource** to move the API deployment to a different compartment.
   - Click **Add Tag(s)** and **View Tag(s)** to change and view the tags applied to the API deployment.

**Using the CLI**

To update existing API gateways and API deployments using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).

2. To update an existing API gateway:
   - Open a command prompt and run `oci api-gateway gateway update` to update the API gateway:
     ```
     oci api-gateway gateway update --gateway-id <gateway-ocid> --<property-to-update> <property-value>
     ```
     where:
     - `<gateway-ocid>` is the OCID of the API gateway to update. To find out the API gateway's OCID, see Listing API Gateways and API Deployments on page 386.
     - `<property-to-update>` is the property to update. Note that you can only change the values for **display-name**, **freeform-tags** and **defined-tags** (and **certificate-id** if this was
originally set for the API gateway). All other values must be identical to values in the original gateway definition.

- `<property-value>` is the new value of the property you want to change.

For example:

```bash
oci api-gateway gateway update --gateway-id ocid1.apigateway.oc1..aaaaaaab______hga --display-name "Hello World Gateway - version 2"
```

The response to the command includes:

- The lifecycle state (for example, ACTIVE, FAILED).
- The id of the work request to update the API gateway (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API gateway is active (or the request has failed), include either or both the following parameters:

- `--wait-for-state ACTIVE`
- `--wait-for-state FAILED`

For example:

```bash
oci api-gateway gateway update --gateway-id ocid1.apigateway.oc1..aaaaaaab______hga --display-name "Hello World Gateway - version 2" --wait-for-state ACTIVE
```

b. (Optional) To see the status of the work request that is updating the API gateway, enter:

```bash
oci api-gateway work-request get --work-request-id <work-request-ocid>
```

c. (Optional) To view the logs of the work request that is updating the API gateway, enter:

```bash
oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

d. (Optional) If the work request that is updating the API gateway fails and you want to review the error logs, enter:

```bash
oci api-gateway work-request-error --work-request-id <work-request-ocid>
```

e. (Optional) To verify that the API gateway has been updated, enter the following command and confirm that the API gateway's properties are as you expect:

```bash
oci api-gateway gateway get --gateway-id <gateway-ocid>
```

3. To update an existing API deployment:

a. Open a command prompt and run `oci api-gateway deployment update` to update the API deployment:

```bash
oci api-gateway deployment update --deployment-id <deployment-ocid> --specification file:///<filename>
```

where:

- `<deployment-ocid>` is the OCID of the API deployment to update. To find out the API deployment's OCID, see Listing API Gateways and API Deployments on page 386.
- `<filename>` is the relative location and filename of the JSON file containing the replacement API deployment specification. For example, `replacement-specification.json`. For more
information about defining API deployment specifications, see Creating an API Deployment Specification on page 361.

For example:

```mermaid
circle: oci api-gateway deployment update --deployment-id ocid1.apideployment.oc1..aaaaaaaaab______pwa --specification file:///Users/jdoe/work/replacement-specification.json
```

The response to the command includes:

- The lifecycle state (for example, ACTIVE, FAILED).
- The id of the work request to update the API deployment (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API deployment is active (or the request has failed), include either or both the following parameters:

- `--wait-for-state ACTIVE`
- `--wait-for-state FAILED`

For example:

```mermaid
circle: oci api-gateway deployment update --deployment-id ocid1.apideployment.oc1..aaaaaaaaab______pwa --specification file:///Users/jdoe/work/replacement-specification.json --wait-for-state ACTIVE
```

b. (Optional) To see the status of the work request that is updating the API deployment, enter:

```mermaid
circle: oci api-gateway work-request get --work-request-id <work-request-ocid>
```

c. (Optional) To view the logs of the work request that is updating the API deployment, enter:

```mermaid
circle: oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

d. (Optional) If the work request that is updating the API deployment fails and you want to review the error logs, enter:

```mermaid
circle: oci api-gateway work-request-error --work-request-id <work-request-ocid>
```

e. (Optional) To verify that the API deployment has been updated, enter the following command and confirm that the API deployment's properties are as you expect:

```mermaid
circle: oci api-gateway deployment get --deployment-id <deployment-ocid>
```

For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the:

- `UpdateGateway` operation to update an API gateway
- `UpdateDeployment` operation to update an API deployment
Moving API Gateways and API Deployments Between Compartments

Having created an API gateway, and deployed an API on the API gateway by creating an API deployment, you might decide to move either or both from one compartment to another. An API gateway and the individual API deployments deployed on it can be in different compartments.

Note that calls to an API deployment will be disrupted while the API deployment (or the API gateway on which it is deployed) is being moved to a different compartment. Do not call the API deployment until the move operation is complete.

Using the Console

To move an API gateway or an API deployment to a different compartment using the Console:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Choose a Compartment you have permission to work in.
3. On the Gateways page, click the name of the API gateway that you want to move (or that contains the API deployment you want to move) to show the Gateway Details page.
4. On the Gateway Details page:
   - To move the API gateway, click Move Resource, select the compartment to which you want to move the API gateway, and click Move Resource to start the process of moving the API gateway. Note that API deployments on the API gateway are not moved to the new compartment.
   - To move an API deployment, select Deployments from the Resources list, click Move Resource, select the compartment to which you want to move the API deployment, and click Move Resource to start the process of moving the API deployment.

Do not call an API deployment while the API deployment (or the API gateway on which it is deployed) is in the process of being moved to the new compartment.

5. On the Gateway Details page, select Work Requests from the Resources list and confirm the move operation is complete.

   When the move operation is complete, resume calls to the API deployment.

Using the CLI

To move API gateways and API deployments to a different compartment using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. To move an API gateway to a different compartment:
   a. Open a command prompt and run `oci api-gateway gateway change-compartment` to move the API gateway:

   ```
   oci api-gateway gateway change-compartment --gateway-id <gateway-ocid>
   --compartment-id <compartment-ocid>
   ```

   where:
   - `<gateway-ocid>` is the OCID of the API gateway to move. To find out the API gateway's OCID, see [Listing API Gateways and API Deployments](page 386) on page 386.
   - `<compartment-ocid>` is the OCID of the compartment to which to move the API gateway.

   For example:

   ```
   oci api-gateway gateway change-compartment --gateway-id ocid1.apigateway.oc1..aaaaaaaab______hga
   --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq
   ```

   Note that API deployments on the API gateway are not moved.

   The response to the command includes:
   - The lifecycle state (for example, ACTIVE, FAILED).
   - The id of the work request to move the API gateway (details of work requests are available for seven days after completion, cancellation, or failure).

   If you want the command to wait to return control until the API gateway is active (or the request has failed), include either or both the following parameters:
   - `--wait-for-state ACTIVE`
   - `--wait-for-state FAILED`

   For example:

   ```
   oci api-gateway gateway change-compartment --gateway-id
   ocid1.apigateway.oc1..aaaaaaaab______hga
   --compartment-id
   ocid1.compartment.oc1..aaaaaaaa7______ysq
   --wait-for-state ACTIVE
   ```

   b. (Optional) To see the status of the work request that is moving the API gateway, enter:

   ```
   oci api-gateway work-request get --work-request-id <work-request-ocid>
   ```

c. (Optional) To view the logs of the work request that is moving the API gateway, enter:

   ```
   oci api-gateway work-request-log list --work-request-id <work-request-ocid>
   ```

d. (Optional) If the work request that is moving the API gateway fails and you want to review the error logs, enter:

   ```
   oci api-gateway work-request-error --work-request-id <work-request-ocid>
   ```

e. (Optional) To verify that the API gateway has been moved, enter the following command and confirm that the API gateway's new compartment OCID is as you expect:

   ```
   oci api-gateway gateway get --gateway-id <gateway-ocid>
   ```
3. To move an API deployment to a different compartment:
   
   a. Open a command prompt and run `oci api-gateway deployment change-compartment` to move the API deployment:

   ```
   oci api-gateway deployment change-compartment --deployment-id <deployment-ocid> --compartment-id <compartment-ocid>
   ```

   where:
   
   - `<deployment-ocid>` is the OCID of the API deployment to move. To find out the API deployment's OCID, see Listing API Gateways and API Deployments on page 386.
   - `<compartment-ocid>` is the OCID of the compartment to which to move the API deployment.

   For example:

   ```
   oci api-gateway deployment change-compartment --deployment-id ocid1.apideployment.oc1..aaaaaaaaab_____pwa --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq
   ```

   The response to the command includes:

   - The lifecycle state (for example, ACTIVE, FAILED).
   - The id of the work request to move the API deployment (details of work requests are available for seven days after completion, cancellation, or failure).

   If you want the command to wait to return control until the API deployment is active (or the request has failed), include either or both the following parameters:

   - `--wait-for-state ACTIVE`
   - `--wait-for-state FAILED`

   For example:

   ```
   oci api-gateway deployment change-compartment --deployment-id ocid1.apideployment.oc1..aaaaaaaaab_____pwa --compartment-id ocid1.compartment.oc1..aaaaaaaa7______ysq --wait-for-state ACTIVE
   ```

   b. (Optional) To see the status of the work request that is moving the API deployment, enter:

   ```
   oci api-gateway work-request get --work-request-id <work-request-ocid>
   ```

   c. (Optional) To view the logs of the work request that is moving the API deployment, enter:

   ```
   oci api-gateway work-request-log list --work-request-id <work-request-ocid>
   ```

   d. (Optional) If the work request that is moving the API deployment fails and you want to review the error logs, enter:

   ```
   oci api-gateway work-request-error --work-request-id <work-request-ocid>
   ```

   e. (Optional) To verify that the API deployment has been moved, enter the following command and confirm that the API deployment's new compartment OCID is as you expect:

   ```
   oci api-gateway deployment get --deployment-id <deployment-ocid>
   ```

   For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the:

• ChangeGatewayCompartment operation to move an API gateway to a different compartment.
• ChangeDeploymentCompartment operation to move an API deployment to a different compartment.

Deleting API Gateways and API Deployments

Having created an API gateway, and deployed an API on the API gateway by creating an API deployment, you might decide that either or both are no longer required.

You can delete an API gateway from the API Gateway service, provided there are no API deployments on it.

You can delete individual API deployments on an API gateway, one at a time. Note that when you delete an API deployment, its API deployment specification is permanently removed.

Note that deleted API gateways and API deployments continue to be shown in the Console for 90 days, with a status of Deleted. After 90 days, deleted API gateways and API deployments are no longer shown.

Using the Console

To delete an API gateway or an API deployment using the Console:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Choose a Compartment you have permission to work in.
3. On the Gateways page, click the name of the API gateway that you want to delete (or that contains the API deployment you want to delete) to show the Gateway Details page.
4. On the Gateway Details page:
   • To delete the API gateway, click Delete below the API gateway's name. The API gateway is permanently removed. Note that you cannot delete an API gateway if it still has API deployments on it. You must delete the API deployments first.
   • To delete an API deployment, select Deployments from the Resources list, click the Actions icon (three dots) beside the API deployment you want to delete, and select Delete. The API deployment and its API deployment specification are permanently removed.

Using the CLI

To delete API gateways and API deployments using the CLI:

1. Configure your client environment to use the CLI (Configuring Your Client Environment to use the CLI for API Gateway Development on page 355).
2. To delete an existing API gateway:
   a. Open a command prompt and run `oci api-gateway gateway delete` to delete the API gateway:

   ```bash
   oci api-gateway gateway delete --gateway-id <gateway-ocid>
   ```

   where:
   - `<gateway-ocid>` is the OCID of the API gateway to delete. To find out the API gateway's OCID, see `Listing API Gateways and API Deployments` on page 386.

   For example:

   ```bash
   oci api-gateway gateway delete --gateway-id ocid1.apigateway.oc1..aaaaaaab______hga
   ```

   Note that you cannot delete an API gateway if it still has API deployments on it (including API deployments that are in different compartments to the API gateway itself). You must delete the API deployments first.

   The response to the command includes:
   - The lifecycle state (for example, DELETED, FAILED).
   - The id of the work request to delete the API gateway (details of work requests are available for seven days after completion, cancellation, or failure).

   If you want the command to wait to return control until the API gateway has been deleted (or the request has failed), include either or both the following parameters:
   - `--wait-for-state DELETED`
   - `--wait-for-state FAILED`

   For example:

   ```bash
   oci api-gateway gateway delete --gateway-id ocid1.apigateway.oc1..aaaaaaab______hga --wait-for-state DELETED
   ```

   b. (Optional) To see the status of the work request that is deleting the API gateway, enter:

   ```bash
   oci api-gateway work-request get --work-request-id <work-request-ocid>
   ```

c. (Optional) To view the logs of the work request that is deleting the API gateway, enter:

   ```bash
   oci api-gateway work-request-log list --work-request-id <work-request-ocid>
   ```

d. (Optional) If the work request that is deleting the API gateway fails and you want to review the error logs, enter:

   ```bash
   oci api-gateway work-request-error --work-request-id <work-request-ocid>
   ```

e. (Optional) To verify that the API gateway has been deleted, enter the following command and confirm that the API gateway's lifecycle state is DELETED:

   ```bash
   oci api-gateway gateway get --gateway-id <gateway-ocid>
   ```
3. To delete an existing API deployment:

a. Open a command prompt and run `oci api-gateway deployment delete` to delete the API deployment:

```
oci api-gateway deployment delete --deployment-id <deployment-ocid>
```

where:

- `<deployment-ocid>` is the OCID of the API deployment to delete. To find out the API deployment's OCID, see Listing API Gateways and API Deployments on page 386.

For example:

```
oci api-gateway deployment delete --deployment-id ocid1.apideployment.oc1..aaaaaaaaab______pwa
```

The response to the command includes:

- The lifecycle state (for example, ACTIVE, DELETED).
- The id of the work request to delete the API deployment (details of work requests are available for seven days after completion, cancellation, or failure).

If you want the command to wait to return control until the API deployment is active (or the request has failed), include either or both of the following parameters:

- `--wait-for-state DELETED`
- `--wait-for-state FAILED`

For example:

```
oci api-gateway deployment delete --deployment-id ocid1.apideployment.oc1..aaaaaaaaab______pwa --wait-for-state DELETED
```

b. (Optional) To see the status of the work request that is deleting the API deployment, enter:

```
oci api-gateway work-request get --work-request-id <work-request-ocid>
```

c. (Optional) To view the logs of the work request that is deleting the API deployment, enter:

```
oci api-gateway work-request-log list --work-request-id <work-request-ocid>
```

d. (Optional) If the work request that is deleting the API deployment fails and you want to review the error logs, enter:

```
oci api-gateway work-request-error --work-request-id <work-request-ocid>
```

e. (Optional) To verify that the API deployment has been deleted, enter the following command and confirm that the API deployment’s lifecycle state is DELETED:

```
oci api-gateway deployment get --deployment-id <deployment-ocid>
```

For more information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use the:
Adding Logging to API Deployments

Having created an API gateway and deployed one or more APIs on it, there will likely be occasions when you'll need to see more detail about the flow of traffic into and out of the API gateway. For example, you might want to review responses returned to API clients, or to troubleshoot errors. You can specify that the API Gateway service stores information about requests and responses going through an API gateway, and information about processing within an API gateway, as logs in the Oracle Cloud Infrastructure Logging service.

You can define and store two kinds of logs for API deployments in the Oracle Cloud Infrastructure Logging service:

- Access logs, that record a summary of every request and response that goes through the API gateway to and from an API deployment. For more information about access log content, see API Deployment Access Log on page 2597.
- Execution logs, that record information about processing within the API gateway for an API deployment. For more information about execution log content, see API Deployment Execution Log on page 2598. You can specify a log level for execution logs as one of the following:
  - Information, to record a summary of every processing stage.
  - Warning, to record only transient errors that occur during processing. For example, a connection reset.
  - Error, to record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

You can set an execution log level for an API deployment, and also set different execution log levels for individual routes to override the execution log level inherited from the API deployment.

Note:

In earlier API Gateway releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could direct API Gateway to store access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage. This functionality is still available for any API deployments you created in earlier releases where you previously specified a logging policy.

You can set up a logging policy in the API deployment specification for all routes in the API deployment specification, and optionally also set up different logging policies for individual routes to override the policy set at the API deployment level. Each log object contains the log messages output in a ten minute logging window. Log objects are available in Object Storage approximately ten minutes after the end of the logging window.

However, note the following:

- If you set up Oracle Cloud Infrastructure Logging to store logs for an API deployment, you are no longer able to store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage for that API deployment.
- The ability to store access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage will be deprecated in a future release.
- To store access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage, you have to define the logging policy in a JSON file. You cannot use the Console to store access logs and execution logs in Oracle Cloud Infrastructure Object Storage.

You can add logging to an API deployment specification by:

- using the Console
using a JSON file

Using the Console to Add Logging

Using the Console to Configure and Enable Logs in Oracle Cloud Infrastructure Logging

To configure and enable API deployment logs using the Console to store logs in Oracle Cloud Infrastructure Logging:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. In the API Logging Policies section of the Basic Information page, specify one of the following options as the Execution Log Level to record information about processing within the API gateway:

   • Information: Record a summary of every processing stage. This is the default option.
   • Warning: Record only transient errors that occur during processing. For example, a connection reset.
   • Error: Record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

3. Click Next to enter details for individual routes in the API deployment on the Routes page and click Show Route Logging Policies.

4. Specify one of the following options as the Execution Log Level Override that applies to an individual route (to override the execution log level inherited from the API deployment):

   • Information: Record a summary of every processing stage.
   • Warning: Record only transient errors that occur during processing. For example, a connection reset.
   • Error: Record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

5. Click Next to review the details you entered for the API deployment.

6. Click Create or Save Changes to create or update the API deployment.

   The API deployment is shown on the API Deployment Details page.

7. Under Resources, click Logs, and then click the Enable Logging slider to create and enable a new API deployment log in the Oracle Cloud Infrastructure Logging service in the Create Log entry panel:

   • Compartment: By default, the current compartment.
   • Log Group: By default, the first log group in the compartment.
   • Log Category: Select either Execution or Access.
   • Log Name: By default, <deployment-name>_execution or <deployment-name>_access, depending on which category you select.

   For more information, see Enabling Logging for a Resource on page 2591.

8. Click Enable Log to create the new log and enable it.

Editing a JSON File to Add Logging

Editing a JSON File to Set Execution Log Level for Logs Stored in Oracle Cloud Infrastructure Logging

To edit the API deployment specification in a JSON file to set the log level for execution logs stored in Oracle Cloud Infrastructure Logging:
1. Using your preferred JSON editor, edit the existing API deployment specification in which you want to set the log level for execution logs stored in Oracle Cloud Infrastructure Logging, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

At a minimum, the API deployment specification will include a `routes` section containing:

- A path. For example, `/hello`
- One or more methods. For example, `GET`
- A definition of a back end. For example, a URL, or the OCID of a function in Oracle Functions.

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

2. (Optional) To set the log level for execution logs that applies globally to all routes in the API deployment specification:

   a. Insert a `loggingPolicies` section before the `routes` section. For example:

   ```json
   {
       "loggingPolicies": {},
       "routes": [
           {
               "path": "/hello",
               "methods": ["GET"],
               "backend": {
                   "type": "ORACLE_FUNCTIONS_BACKEND",
                   "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
               }
           }
       ]
   }
   ```

   b. Specify the level of detail to record about processing within the API gateway for all routes by including the `executionLog` policy in the `loggingPolicies` section, and setting the `logLevel` property to one of the following:

   - `INFO` to record a summary of every processing stage.
   - `WARN` to record only transient errors that occur during processing. For example, a connection reset.
   - `ERROR` to record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

   For example:

   ```json
   {
       "loggingPolicies": {
           "executionLog": {
               "logLevel": "INFO"
           }
       }
   }
   ```
3. (Optional) To set the log level for execution logs for a particular route (overriding the global execution log level inherited from the API deployment):

a. Insert a `loggingPolicies` section after the route's `backend` section. For example:

```json
{
  "loggingPolicies": {
    "executionLog": {
      "logLevel": "INFO"
    }
  },
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "loggingPolicies": {}
    }
  ]
}
```

b. Specify the level of detail to record about processing within the API gateway for the route by including the `executionLog` policy in the `loggingPolicies` section, and setting the `logLevel` property to one of the following:

- `INFO` to record a summary of every processing stage.
- `WARN` to record only transient errors that occur during processing. For example, a connection reset.
- `ERROR` to record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

For example:

```json
{
  "loggingPolicies": {
    "executionLog": {
      "logLevel": "INFO"
    }
  },
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "loggingPolicies": {}
    }
  ]
}
```
4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the **Upload an existing API** option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see [Deploying an API on an API Gateway by Creating an API Deployment](#) on page 363.

6. Having set the log level for execution logs, follow the instructions in [Enabling Logging for a Resource](#) on page 2591 to create and enable a new API deployment log in the Oracle Cloud Infrastructure Logging service.

### Editing a JSON File to Set Up Logging Policies to Store Logs in Object Storage

In earlier API Gateway releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could direct API Gateway to store and view access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage. This functionality is still available for any API deployments you created in earlier releases where you previously specified a logging policy, as described below. However, note the following:

- If you set up Oracle Cloud Infrastructure Logging to store logs for an API deployment, you are no longer able to store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage for that API deployment.
- The ability to store access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage will be deprecated in a future release.

To edit the API deployment specification in a JSON file to store logs in Object Storage:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add a logging policy, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

   At a minimum, the API deployment specification will include a **routes** section containing:

   - A path. For example, `/hello`
   - One or more methods. For example, GET
   - A definition of a back end. For example, a URL, or the OCID of a function in Oracle Functions.

   For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

   ```json
   {
     "routes": [
       {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
           "type": "ORACLE_FUNCTIONS_BACKEND",
           "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
       }
     ]
   }
   ```
2. (Optional) To add a logging policy to the API deployment specification that applies globally to all routes in the API deployment specification:

   a. Insert a `loggingPolicies` section before the `routes` section. For example:

   ```json
   {
     "loggingPolicies": {},
     "routes": [
       {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
           "type": "ORACLE_FUNCTIONS_BACKEND",
           "functionId": "ocid1.fnfunc.ocl.phxaaaaaaaaab______xmq"
         }
       }
     ]
   }
   
   b. (Optional) Record a summary of every request and response that goes through the gateway by including the `accessLog` policy in the `loggingPolicies` section, and setting the `isEnabled` property to `true`. For example:

   ```json
   {
     "loggingPolicies": {
       "accessLog": {
         "isEnabled": true
       },
       "routes": [
         {
           "path": "/hello",
           "methods": ["GET"],
           "backend": {
             "type": "ORACLE_FUNCTIONS_BACKEND",
             "functionId": "ocid1.fnfunc.ocl.phxaaaaaaaaab______xmq"
           }
         }
       ]
     }
   }
   
   c. (Optional) Record information about processing within the API gateway by including the `executionLog` policy in the `loggingPolicies` section, setting the `isEnabled` property to `true`, and setting the `logLevel` property to one of the following:

   - `INFO` to record a summary of every processing stage.
   - `WARN` to record only transient errors that occur during processing. For example, a connection reset.
   - `ERROR` to record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

   For example:

   ```json
   {
     "loggingPolicies": {
       "accessLog": {
         "isEnabled": true
       },
       "executionLog": {
         "isEnabled": true,
         "logLevel": "INFO"
       }
     }
   }
   ```
3. (Optional) To add a logging policy to the API deployment specification that applies to a particular route (overriding the global logging policy):

a. Insert a `loggingPolicies` section after the route's `backend` section. For example:

```json
    
    "loggingPolicies": { 
    
    "accessLog": { 
    
    "isEnabled": true 
    
    },
    "executionLog": { 
    
    "isEnabled": true, 
    
    "logLevel": "INFO"
    
    }
    
    }
    
    "routes": [ 
    
    { 
    
    "path": "/hello",
    "methods": ["GET"],
    "backend": { 
    
    "type": "ORACLE_FUNCTIONS_BACKEND",
    "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
    
    }
    
    }
    
    
    }  
    
    "loggingPolicies": {}  
    
    }
```

b. (Optional) Record a summary of every request and response that goes through the gateway to the route by including the `accessLog` policy in the `loggingPolicies` section, and setting the `isEnabled` property to `true`.

For example:

```json
    
    "loggingPolicies": { 
    
    "accessLog": { 
    
    "isEnabled": true 
    
    },
    "executionLog": { 
    
    "isEnabled": true, 
    
    "logLevel": "INFO"
    
    }
    
    }
    
    "routes": [ 
    
    { 
    
    "path": "/hello",
    "methods": ["GET"],
    "backend": { 
    
    "type": "ORACLE_FUNCTIONS_BACKEND",
    "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
    
    }
    
    }
    
    
    }  
    
    "loggingPolicies": {}  
    
    }
```
c. (Optional) Record information about processing within the API gateway for the route by including the executionLog policy in the loggingPolicies section, setting the isEnabled property to true, and setting the logLevel property to one of the following:

- **INFO** to record a summary of every processing stage.
- **WARN** to record only transient errors that occur during processing. For example, a connection reset.
- **ERROR** to record only persistent errors that occur during processing. For example, an internal error, or a call to a function that returns a 404 message.

For example:

```json
{
    "loggingPolicies": {
        "accessLog": {
            "isEnabled": true
        },
        "executionLog": {
            "isEnabled": true,
            "logLevel": "INFO"
        }
    },
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "loggingPolicies": {
                "accessLog": {
                    "isEnabled": true
                },
                "executionLog": {
                    "isEnabled": true,
                    "logLevel": "ERROR"
                }
            }
        }
    ]
}
```

4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:

- by specifying the JSON file in the Console when you select the **Upload an existing API** option
- by specifying the JSON file in a request to the API Gateway REST API

For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363.
Viewing Logs

Having added logging to an API deployment specification and deployed the API on an API gateway, the API Gateway service writes logs accordingly.

Viewing Logs in Oracle Cloud Infrastructure Logging

You can view the content of an API deployment log in Oracle Cloud Infrastructure Logging from the API Deployment Details page. Under Resources, click Logs, and then click the name of the log you want to view.

Alternatively, you can view the content of an API deployment log from the Oracle Cloud Infrastructure Logging Log Search page. See To view the contents of logs on page 2581.

For more information about the content of access and execution logs, see:

- API Deployment Access Log on page 2597
- API Deployment Execution Log on page 2598

Viewing Logs in Oracle Cloud Infrastructure Object Storage

In earlier API Gateway releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could direct API Gateway to store and view access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage. This functionality is still available for any API deployments you created in earlier releases where you previously specified a logging policy, as described below. However, note the following:

- If you set up Oracle Cloud Infrastructure Logging to store logs for an API deployment, you are no longer able to store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage for that API deployment.
- The ability to store access logs and execution logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage will be deprecated in a future release.

To view logs that have been stored in a storage bucket in Oracle Cloud Infrastructure Object Storage:

1. In the Console, under Core Infrastructure, click Object Storage.
2. Choose the Compartment that owns API Gateway-related resources. If the API gateway and the API deployment are in different compartments, choose the compartment that owns the API gateway.

   The Object Storage page shows the storage buckets in the compartment.

3. On the Object Storage page, click the storage bucket name that includes the OCID of the compartment that owns the API Gateway-related resources.
4. Click Objects under Resources to see a list of log objects in the storage bucket, each with a name in the format:

   `api_gateway_deployment_access_log/<deployment-ocid>/<datetimestamp>.log.gz`

   where:

   - `<deployment-ocid>` is the OCID of the API deployment.
   - `<datetimestamp>` is the date and time at the start of the logging window.

5. Click the Actions icon (three dots) beside the log you want to view, and then click Download and save the log as a file in a convenient location.
6. Open the log file in a text editor to view the log messages.

   Each log message contains:
   • the number of bytes sent in the message
   • the compartment OCID
   • the API deployment OCID
   • the API gateway OCID
   • the user agent
   • the request and the endpoint
   • the client IP address
   • the request duration (in seconds)
   • the message number
   • the timestamp

For example:

```
{"bodybytesSent":292,"compartmentId":"ocid1.compartment.oc1..aaaaaa7______ysq","deploymentId":"ocid1.apideployment.oc1.p.../marketing/hello
"remoteAddr":"123.45.678.90","remoteUser":"","requestDuration":0.167","re...
```

Adding an HTTP or HTTPS URL as an API Gateway Back End

A common requirement is to build an API with the HTTP or HTTPS URL of a back-end service, and an API gateway providing front-end access to the back-end URL.

Having used the API Gateway service to create an API gateway, you can create an API deployment to access HTTP and HTTPS URLs.

The HTTP or HTTPS URL that you specify for the back-end service can be:

• The URL of a service that is publicly available on the internet.
• The URL of an Oracle Cloud Infrastructure service (for example, Oracle Functions).
• The URL of a service on your own private or internal network (for example, connected to the VCN by FastConnect).

The URL you provide in the API deployment specification to identify the HTTP or HTTPS back-end service can include the host name or the host IP address. If you provide the host name, use the DHCP Options property of the API gateway's subnet to control how host names included in the API deployment specification are resolved to IP addresses at runtime:

• If the host name for a back-end service is publicly published on the internet, or if the host name belongs to an instance in the same VCN, select a DHCP options set for the API gateway's subnet that has the Oracle-provided Internet and VCN Resolver as the DNS Type. This is the default if you do not explicitly select a DHCP options set.
• If the host name is for a back-end service on your own private or internal network, select a DHCP options set for the API gateway's subnet that has Custom Resolver as the DNS Type, and has the URL of a suitable DNS server that can resolve the host name to an IP address.

Note that you can change the DNS server details in the DHCP options set specified for an API gateway's subnet. The API gateway will be reconfigured to use the updated DNS server details within two hours. For more information about resolving host names to IP addresses, see DNS in Your Virtual Cloud Network on page 2910 and DHCP Options on page 2917.

You can add HTTP and HTTPS back ends to an API deployment specification by:

• using the Console
• editing a JSON file
Using the Console to Add HTTP or HTTPS Back Ends to an API Deployment Specification

To add an HTTP or HTTPS back end to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. On the Routes page, create a new route and specify:
   - **Path**: A path for API calls using the listed methods to the back-end service. Note that the route path you specify:
     - is relative to the deployment path prefix (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)
     - must be preceded by a forward slash (/), and can be just that single forward slash
     - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
     - can include alphanumeric uppercase and lowercase characters
     - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
     - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)
   - **Methods**: One or more methods accepted by the back-end service. For example, GET, PUT.
   - **Type**: The type of the back-end service as HTTP.
   - **URL**: The URL you want to use as the back-end service, in the format `<protocol>://<host>[:<port>]/<path>` where:
     - `<protocol>` is either http or https.
     - `<host>` is the host name or the host IP address of the back-end service. For example, api.weather.gov. If you provide a host name, use the DHCP Options property of the API gateway's subnet to control how host names are resolved to IP addresses at runtime.
     - `<port>` is optionally a port number.
     - `<path>` is optionally a subdirectory or file at the host where the back-end service is located.

   Note that `<path>` must not contain parameters directly, but can contain context variables. For more information and examples showing how to use context variables to substitute path, query, and header parameters into the path, see Adding Context Variables to Policies and HTTP Back End Definitions on page 378.

   For example, "url": "https://api.weather.gov".

   - **Connection establishment timeout in seconds**: Optionally, a floating point value indicating how long (in seconds) to allow when establishing a connection with the back-end service. The minimum is 1.0, the maximum is 75.0. If not specified, the default of 60.0 seconds is used.
   - **Request transmit timeout in seconds**: Optionally, a floating point value indicating how long (in seconds) to allow when transmitting a request to the back-end service. The minimum is 1.0, the maximum is 300.0. If not specified, the default of 10.0 seconds is used.
   - **Reading response timeout in seconds**: Optionally, a floating point value indicating how long (in seconds) to allow when reading a response from the back-end service. The minimum is 1.0, the maximum is 300.0. If not specified, the default of 10.0 seconds is used.
   - **Disable SSL verification**: Whether to disable SSL verification when communicating with the back-end service. By default, this option is not selected.

In this example, the route defines a weather service as an HTTP back end.

<table>
<thead>
<tr>
<th>Field</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path</td>
<td>/weather</td>
</tr>
<tr>
<td>Field</td>
<td>Enter:</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>Methods:</td>
<td>GET</td>
</tr>
<tr>
<td>Type:</td>
<td>HTTP</td>
</tr>
<tr>
<td>URL:</td>
<td><a href="https://api.weather.gov">https://api.weather.gov</a></td>
</tr>
<tr>
<td>Connection establishment timeout in seconds:</td>
<td>45</td>
</tr>
<tr>
<td>Request transmit timeout in seconds:</td>
<td>15</td>
</tr>
<tr>
<td>Reading response timeout in seconds:</td>
<td>15</td>
</tr>
<tr>
<td>Disable SSL verification:</td>
<td>(Not selected)</td>
</tr>
</tbody>
</table>

3. (Optional) Click **Another Route** to enter details of additional routes.
4. Click **Next** to review the details you entered for the API deployment.
5. Click **Create** or **Save Changes** to create or update the API deployment.
6. (Optional) Confirm the API has been deployed successfully by calling it (see **Calling an API Deployed on an API Gateway** on page 384).

### Editing a JSON File to Add HTTP or HTTPS Back Ends to an API Deployment Specification

To add an HTTP or HTTPS back end to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, create a new API deployment specification (see **Creating an API Deployment Specification** on page 361) in the format:

   ```json
   {
       "requestPolicies": {},
       "routes": [
           {
               "path": "<api-route-path>",
               "methods": ["<method-list>"],
               "backend": {
                   "type": "HTTP_BACKEND",
                   "url": "<identifier>",
                   "connectTimeoutInSeconds": <seconds>,
                   "readTimeoutInSeconds": <seconds>,
                   "sendTimeoutInSeconds": <seconds>,
                   "isSSLVerifyDisabled": <true|false>
               },
               "requestPolicies": {}
           }
       ]
   }
   ```

   where:

   - "requestPolicies" specifies optional policies to control the behavior of an API deployment. If you want to apply policies to all routes in an API deployment specification, place the policies outside the `routes` section. If you want to apply the policies just to a particular route, place the policies inside the `routes` section.
• `<api-route-path>` specifies a path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  • is relative to the deployment path prefix (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)
  • must be preceded by a forward slash (/), and can be just that single forward slash
  • can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  • can include alphanumeric uppercase and lowercase characters
  • can include the special characters $ – _ . + ! * ' ( ) , % ; : @ & =
  • can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)
• `<method-list>` specifies one or more methods accepted by the back-end service, separated by commas. For example, "GET, PUT".
• "type": "HTTP_BACKEND" specifies the API gateway back end is an HTTP or HTTPS URL.
• "url": "<identifier>" specifies the URL you want to use as the back-end service, in the format <protocol>://<host>:<port>/<path> where:
  • <protocol> is either http or https.
  • <host> is the host name or the host IP address of the back-end service. For example, api.weather.gov. If you provide a host name, use the DHCP Options property of the API gateway's subnet to control how host names are resolved to IP addresses at runtime.
  • <port> is optionally a port number.
  • <path> is optionally a subdirectory or file at the host where the back-end service is located.
    Note that <path> must not contain parameters directly, but can contain context variables. For more information and examples showing how to use context variables to substitute path, query, and header parameters into the path, see Adding Context Variables to Policies and HTTP Back End Definitions on page 378.
For example, "url": "https://api.weather.gov".
• "connectTimeoutInSeconds": <seconds> is an optional floating point value indicating how long (in seconds) to allow when establishing a connection with the back-end service. The minimum is 0.0, the maximum is 75.0. If not specified, the default of 60.0 seconds is used.
• "readTimeoutInSeconds": <seconds> is an optional floating point value indicating how long (in seconds) to allow when reading a response from the back-end service. The minimum is 0.0, the maximum is 300.0. If not specified, the default of 10.0 seconds is used.
• "sendTimeoutInSeconds": <seconds> is an optional floating point value indicating how long (in seconds) to allow when transmitting a request to the back-end service. The minimum is 0.0, the maximum is 300.0. If not specified, the default of 10.0 seconds is used.
• "isSSLVerifyDisabled": <true|false> is an optional boolean value (either true or false) indicating whether to disable SSL verification when communicating with the back-end service. If not specified, the default of false is used.
For example, the following basic API deployment specification defines a weather service as an HTTP back end:

```json
{
    "routes": [
        {
            "path": "/weather",
            "methods": ["GET"],
            "backend": {
                "type": "HTTP_BACKEND",
                "url": "https://api.weather.gov",
                "connectTimeoutInSeconds": 45,
                "readTimeoutInSeconds": 15,
                "sendTimeoutInSeconds": 15,
            }]
    }
}
```
2. Save the JSON file containing the API deployment specification.
3. Use the API deployment specification when you create or update an API deployment in the following ways:
   • by specifying the JSON file in the Console when you select the Upload an existing API option
   • by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363.

4. (Optional) Confirm the API has been deployed by calling it (see Calling an API Deployed on an API Gateway on page 384).

Adding a Function in Oracle Functions as an API Gateway Back End

A common requirement is to build an API with serverless functions as a back end, and an API gateway providing front-end access to those functions.

Oracle Functions enables you to create serverless functions that are built as Docker images and pushed to a specified Docker registry. A definition of each function is stored as metadata in the Oracle Functions server. When a function is invoked for the first time, Oracle Functions pulls the function’s Docker image from the specified Docker registry, runs it as a Docker container, and executes the function. If there are subsequent requests to the same function, Oracle Functions directs those requests to the same running container. After a period being idle, the Docker container is stopped.

Having used the API Gateway service to create an API gateway, you can create an API deployment that invokes serverless functions defined in Oracle Functions.

Before you can use serverless functions in Oracle Functions as the back end for an API:

• Serverless functions referenced in the API deployment specification must have already been created and deployed in Oracle Functions. The functions must be routable from the VCN specified for the API gateway, either through an internet gateway (in the case of a public API gateway) or through a service gateway (in the case of a private API gateway). See Creating and Deploying Functions on page 2063. For a related Developer Tutorial, see Functions: Call a Function using API Gateway.
• Appropriate policies must already exist that give access to serverless functions defined in Oracle Functions to:
  • a group to which your user account belongs (see Create a Policy to Give API Gateway Users Access to Functions on page 344)
  • API gateways (see Create a Policy to Give API Gateways Access to Functions on page 345)

You can add serverless function back ends to an API deployment specification by:

• using the Console
• editing a JSON file

Creating and Deploying a Serverless Function in Oracle Functions for Use as an API Gateway Back End

To create a serverless function in Oracle Functions that can be invoked from an API gateway, follow the instructions in the Oracle Functions documentation to:

• Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions on page 2038.
• Create and deploy the function in a compartment to which API gateways have been granted access, as described in Creating and Deploying Functions on page 2063.
Using the Console to Add Serverless Function Back Ends to an API Deployment Specification

To add an Oracle Functions function back end to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the **From Scratch** option, and enter details on the **Basic Information** page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. On the **Routes** page, create a new route and specify:
   - **Path:** A path for API calls using the listed methods to the back-end service. Note that the route path you specify:
     - is relative to the deployment path prefix (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)
     - must be preceded by a forward slash (/), and can be just that single forward slash
     - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
     - can include alphanumeric uppercase and lowercase characters
     - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
     - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)
   - **Methods:** One or more methods accepted by the back-end service. For example, GET, PUT.
   - **Type:** The type of the back-end service as Oracle Functions.
   - **Application in <compartment-name>:** The name of the application in Oracle Functions that contains the function. You can select an application from a different compartment.
   - **Function Name:** The name of the function in Oracle Functions.

   In this example, the route defines a simple Hello World serverless function in Oracle Functions as a single back end.

<table>
<thead>
<tr>
<th>Field</th>
<th>Enter:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path:</td>
<td>/hello</td>
</tr>
<tr>
<td>Methods:</td>
<td>GET</td>
</tr>
<tr>
<td>Type:</td>
<td>Oracle Functions</td>
</tr>
<tr>
<td>Application in &lt;compartment-name&gt;:</td>
<td>acmeapp</td>
</tr>
<tr>
<td>Function Name:</td>
<td>acme-func</td>
</tr>
</tbody>
</table>

3. (Optional) Click **Another Route** to enter details of additional routes.

4. Click **Next** to review the details you entered for the API deployment.

5. Click **Create** or **Save Changes** to create or update the API deployment.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

   If the serverless function accepts parameters, include those in the call to the API. For example:

   ```bash
curl -k -X GET https://lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com/marketing/hello/ -d "name=John"
```

Editing a JSON File to Add Serverless Function Back Ends to an API Deployment Specification

To add an Oracle Functions function back end to an API deployment specification in a JSON file:
1. Using your preferred JSON editor, create the API deployment specification in a JSON file in the format:

```json
{
    "requestPolicies": {},
    "routes": [
        {
            "path": "<api-route-path>",
            "methods": ["<method-list>"]
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "<identifier>
            },
            "requestPolicies": {}
        }
    ]
}
```

where:

- "requestPolicies" specifies optional policies to control the behavior of an API deployment. If you want to apply policies to all routes in an API deployment specification, place the policies outside the `routes` section. If you want to apply the policies just to a particular route, place the policies inside the `routes` section. See [Adding Request Policies and Response Policies to API Deployment Specifications](#) on page 417.

- `<api-route-path>` specifies a path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  - is relative to the deployment path prefix (see [Deploying an API on an API Gateway by Creating an API Deployment](#) on page 363)
  - must be preceded by a forward slash (/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see [Adding Path Parameters and Wildcards to Route Paths](#) on page 377)

- `<method-list>` specifies one or more methods accepted by the back-end service, separated by commas. For example, "GET, PUT".

- `<identifier>` specifies the OCID of the function you want to use as the back-end service. For example, "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq".

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

2. Save the JSON file containing the API deployment specification.
3. Use the API deployment specification when you create or update an API deployment in the following ways:
   • by specifying the JSON file in the Console when you select the **Upload an existing API** option
   • by specifying the JSON file in a request to the API Gateway REST API

   For more information, see **Deploying an API on an API Gateway by Creating an API Deployment** on page 363.

4. (Optional) Confirm the API has been deployed and that the serverless function in Oracle Functions can be invoked successfully by calling the API (see **Calling an API Deployed on an API Gateway** on page 384). If the serverless function accepts parameters, include those in the call to the API. For example:

   curl -k -X GET https://lak...sjd.apigateway.us-phoenix-1.oci.customer-oci.com/marketing/hello/ -d "name=john"

### Adding Stock Responses as an API Gateway Back End

You'll often want to verify that an API has been successfully deployed on an API gateway without having to set up an actual back-end service. One approach is to define a route in the API deployment specification that has a path to a 'dummy' back end. On receiving a request to that path, the API gateway itself acts as the back end and returns a stock response you've specified.

Equally, there are some situations in a production deployment where you'll want a particular path for a route to consistently return the same stock response without sending a request to a back end. For example, when you want a call to a path to always return a specific HTTP status code in the response.

Using the API Gateway service, you can define a path to a stock response back end that always returns the same:

- HTTP status code
- HTTP header fields (name-value pairs)
- content in the body of the response

Note the following restrictions when defining stock responses and stock response back ends:

- each header name must not exceed 1KB in length
- each header value must not exceed 4KB in length
- each body response must not exceed 5KB in length (including any encoding)
- a stock response back end definition must not include more than 50 header fields

You can add stock response back ends to an API deployment specification by:

- using the Console
- editing a JSON file

### Using the Console to Add Stock Responses to an API Deployment Specification

To add stock responses to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the **From Scratch** option, and enter details on the **Basic Information** page.

   For more information, see **Deploying an API on an API Gateway by Creating an API Deployment** on page 363 and **Updating API Gateways and API Deployments** on page 387.
2. On the **Routes** page, create a new route and specify:

- **Path:** A path for API calls using the listed methods to the back-end service. Note that the route path you specify:
  - is relative to the deployment path prefix (see *Deploying an API on an API Gateway by Creating an API Deployment* on page 363)
  - must be preceded by a forward slash (/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see *Adding Path Parameters and Wildcards to Route Paths* on page 377)

- **Methods:** One or more methods accepted by the back-end service. For example, **GET,** **PUT**.

- **Type:** The type of the back-end service as **Stock Response**.

- **Status Code:** Any valid HTTP response code. For example, **200**

- **Body:** Optionally specifies the content of the response body, in an appropriate format. For example:
  - If you specify a **Header Name** and **Header Value** of **Content-Type** and **text/plain** respectively, the response body might be "Hello world.".
  - If you specify a **Header Name** and **Header Value** of **Content-Type** and **application/json** respectively, the response body might be ("username": "john.doe").

Note that the response body must not exceed 5KB in length (including any encoding).

- **Header Name** and **Header Value:** Optionally, you can specify the name of an HTTP response header and its value. For example, a name of **Content-Type** and a value of **application/json**. You can specify multiple header name and value pairs (up to a maximum of 50). Note that in each case:
  - the header name must not exceed 1KB in length
  - the header value must not exceed 4KB in length

In this example, a request to the **/test** path returns a 200 status code and a JSON payload in the body of the response.

<table>
<thead>
<tr>
<th>Field</th>
<th>Enter:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path:</td>
<td>/test</td>
</tr>
<tr>
<td>Methods:</td>
<td>GET</td>
</tr>
<tr>
<td>Type:</td>
<td>Stock Response</td>
</tr>
<tr>
<td>Status Code:</td>
<td>200</td>
</tr>
<tr>
<td>Body:</td>
<td>(&quot;username&quot;: &quot;john.doe&quot;)</td>
</tr>
<tr>
<td>Header Name:</td>
<td>Content-Type</td>
</tr>
<tr>
<td>Header Value:</td>
<td>application/json</td>
</tr>
</tbody>
</table>

In this example, a request to the **/test-redirect** path returns a 302 status code and a temporary url in the **Location** header of the response.

<table>
<thead>
<tr>
<th>Field</th>
<th>Enter:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path:</td>
<td>/test-redirect</td>
</tr>
<tr>
<td>Methods:</td>
<td>GET</td>
</tr>
<tr>
<td>Type:</td>
<td>Stock Response</td>
</tr>
<tr>
<td>Status Code:</td>
<td>302</td>
</tr>
</tbody>
</table>
3. (Optional) Click **Another Route** to enter details of additional routes.
4. Click **Next** to review the details you entered for the API deployment.
5. Click **Create** or **Save Changes** to create or update the API deployment.
6. (Optional) Confirm the API has been deployed successfully by calling it (see [Calling an API Deployed on an API Gateway](#) on page 384).

## Editing a JSON File to Add Stock Responses to an API Deployment Specification

To add stock responses to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add a stock response back end, or create a new API deployment specification (see [Creating an API Deployment Specification](#) on page 361).

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
    "routes": [  
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

2. In the `routes` section, include a new `path` section for a stock response back end:

```json
{
    "routes": [  
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        },
        {
            "path": "<api-route-path>",
            "methods": ["<method-list>"],
            "backend": {
                "type": "STOCK_RESPONSE_BACKEND",
                "status": <http-response-code>,
                "headers": [{
                    "name": "<header-name>",
                    "value": "<header-value>
                }],
                "body": "<body-content>"
            }
        }
    ]
}
```
where:

- `<api-route-path>` specifies a path for API calls using the listed methods to the stock response back end. Note that the route path you specify:
  - is relative to the deployment path prefix (see Deploying an API on an API Gateway by Creating an API Deployment on page 363)
  - must be preceded by a forward slash (/), and can be just that single forward slash
  - can contain multiple forward slashes (provided they are not adjacent), and can end with a forward slash
  - can include alphanumeric uppercase and lowercase characters
  - can include the special characters $ - _ . + ! * ' ( ) , % ; : @ & =
  - can include parameters and wildcards (see Adding Path Parameters and Wildcards to Route Paths on page 377)
- `<method-list>` specifies one or more methods accepted by the stock response back end, separated by commas. For example, "GET, PUT".
- "type": "STOCK_RESPONSE_BACKEND" indicates that the API gateway itself will act as the back end and return the stock response you define (the status code, the header fields and the body content).
- `<http-response-code>` is any valid HTTP response code. For example, 200
- "name": "<header-name>", "value": "<header-value>" optionally specifies the name of an HTTP response header and its value. For example, "name": "Content-Type", "value": "application/json". You can specify multiple "name": "<header-name>", "value": "<header-value>" pairs in the headers: section (up to a maximum of 50). Note that in each case:
  - `<header-name>` must not exceed 1KB in length
  - `<header-value>` must not exceed 4KB in length
- "body": "<body-content>" optionally specifies the content of the response body, in an appropriate format. For example:
  - If the Content-Type header is text/plain, the response body might be "body": "Hello world".
  - If the Content-Type header is application/json, the response body might be "body": 
    "\"username\": \"john.doe\"\". In the case of a JSON response, note that quotation marks in the response have to be escaped with a backslash (\) character.

Note that `<body-content>` must not exceed 5KB in length (including any encoding).

In this example, a request to the /test path returns a 200 status code and a JSON payload in the body of the response.

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      }
    },
    {
      "path": "/test",
      "methods": ["GET"],
      "backend": {
        "type": "STOCK_RESPONSE_BACKEND",
        "status": 200,
        "headers": [
```
In this example, a request to the /test-redirect path returns a 302 status code and a temporary url in the Location header of the response. This example also demonstrates that you can create an API deployment specification with just one route to a back end of type STOCK_RESPONSE_BACKEND.

```
{
  "routes": [
    {
      "path": "/test-redirect",
      "methods": ["GET"],
      "backend": {
        "type": "STOCK_RESPONSE_BACKEND",
        "status": 302,
        "headers": [{
          "name": "Location",
          "value": "http://www.example.com"
        }]
      }
    }
  ]
}
```

3. Save the JSON file containing the API deployment specification.
4. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.
5. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

### Adding Request Policies and Response Policies to API Deployment Specifications

You can control the behavior of an API deployment you create on an API gateway by adding request and response policies to the API deployment specification:

- a request policy describes actions to be performed on an incoming request from an API client before it is sent to a back end
- a response policy describes actions to be performed on a response returned from a back end before it is sent to an API client

You can use request policies and/or response policies to:

- limit the number of requests sent to back-end services
- enable CORS (Cross-Origin Resource Sharing) support
- provide authentication and authorization
- modify incoming requests and outgoing responses

You can add policies to an API deployment specification that apply globally to all routes in the API deployment specification, as well as policies that apply only to particular routes.
Note that API Gateway request policies and response policies are different to IAM policies, which control access to Oracle Cloud Infrastructure resources.

You can add request and response policies to an API deployment specification by:

• using the Console
• editing a JSON file

**Using the Console to Add Request Policies and Response Policies**

To add request policies and response policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the **From Scratch** option, and enter details on the **Basic Information** page.
   
   For more information, see [Deploying an API on an API Gateway by Creating an API Deployment](#) on page 363 and [Updating API Gateways and API Deployments](#) on page 387.

2. In the **API Request Policies** section of the **Basic Information** page, specify request policies that apply globally to all routes in the API deployment specification:
   
   • **Authentication**: A policy to control access to APIs you deploy to API gateways based on the end user sending a request, and define what it is that they are allowed to do. Having specified a global authentication policy first, you can then specify authorization policies that apply to individual routes in the API deployment specification. See [Adding Authentication and Authorization to API Deployments](#) on page 431.
   
   • **CORS**: A policy to enable CORS support in the APIs you deploy to API gateways. You can also specify CORS policies that apply to individual routes in the API deployment specification (you don't need to have entered a global CORS policy first). See [Adding CORS support to API Deployments](#) on page 424.
   
   • **Rate Limiting**: A policy to limit the rate at which API clients can make requests to back-end services. You can only apply a rate-limiting policy globally to all routes in the API deployment specification (not to individual routes). See [Limiting the Number of Requests to API Gateway Back Ends](#) on page 421.

3. Click **Next** to enter details for individual routes in the API deployment on the **Routes** page.

4. To specify request policies that apply to an individual route, click **Show Route Request Policies** and specify:
   
   • **Authorization**: A policy to specify the operations an end user is allowed to perform, based on the end user's access scopes. Note that you must have already specified a global authentication policy before you can specify an authorization policy on an individual route. See [Adding Authentication and Authorization to API Deployments](#) on page 431.
   
   • **CORS**: A policy to enable CORS support for individual routes in the API deployment specification (you don't need to have entered a global CORS policy first). See [Adding CORS support to API Deployments](#) on page 424.
   
   • **Header Transformations**: A policy to add, remove, and modify headers in requests. See [Using the Console to Add Header Transformation Request Policies](#) on page 453.
   
   • **Query Transformations**: A policy to add, remove, and modify query parameters in requests. See [Using the Console to Add Query Parameter Transformation Request Policies](#) on page 459.

5. To specify response policies that apply to an individual route, click **Show Route Response Policies** and specify:
   
   • **Header Transformations**: A policy to add, remove, and modify headers in responses. See [Using the Console to Add Header Transformation Response Policies](#) on page 465.

6. Click **Next** to review the details you entered for the API deployment.

7. Click **Create** or **Save Changes** to create or update the API deployment.

8. (Optional) Confirm the API has been deployed successfully by calling it (see [Calling an API Deployed on an API Gateway](#) on page 384).

**Editing a JSON File to Add Request Policies and Response Policies**

To add request policies and response policies to an API deployment specification in a JSON file:
1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add a request policy or response policy, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

At a minimum, the API deployment specification will include a routes section containing:

- A path. For example, /hello
- One or more methods. For example, GET
- A definition of a back end. For example, a URL, or the OCID of a function in Oracle Functions.

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
   "routes": [
      {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
      }
   ]
}
```

2. To add a request policy that applies globally to all routes in the API deployment specification:
   a. Insert a requestPolicies section before the routes section. For example:

```json
{
   "requestPolicies": {},
   "routes": [
      {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
      }
   ]
}
```
   b. Include a request policy in the requestPolicies section.

For example, to limit the number of requests sent to all routes in an API deployment specification, you'd include the rateLimiting policy in the requestPolicies section as follows:

```json
{
   "requestPolicies": {
      "rateLimiting": {
         "rateKey": "CLIENT_IP",
         "rateInRequestsPerSecond": 10
      }
   },
   "routes": [
      {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
      }
   ]
}
```
For more information about the rateLimiting request policy, see Limiting the Number of Requests to API Gateway Back Ends on page 421.

3. To add a request policy that applies to an individual route in the API deployment specification:

   a. Insert a requestPolicies section after the route's backend section. For example:

   ```json
   { "routes": [ { "path": "/hello", "methods": ["GET"], "backend": { "type": "ORACLE_FUNCTIONS_BACKEND", "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq" }, "requestPolicies": {} ] } }
   ```

   b. Include a request policy in the requestPolicies section.

      For example, to enable CORS support in an API deployment for a particular route, you'd include the cors policy in the requestPolicies section as follows:

      ```json
      { "routes": [ { "path": "/hello", "methods": ["GET"], "backend": { "type": "ORACLE_FUNCTIONS_BACKEND", "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq" }, "requestPolicies": { "cors": { "allowedOrigins": ["*", "https://oracle.com"], "allowedMethods": ["*", "GET"], "allowedHeaders": [], "exposedHeaders": [], "isAllowCredentialsEnabled": false, "maxAgeInSeconds": 3000 } } ] } }
      ```

      For more information about the cors request policy, see Adding CORS support to API Deployments on page 424.

4. To add a response policy that applies to an individual route in the API deployment specification:

   a. Insert a responsePolicies section after the route's backend section. For example:

   ```json
   { "routes": [ { "path": "/hello", }
   ```
b. Include a response policy in the `responsePolicies` section.

For example, to rename any `X-Username` header to `X-User-ID` in the response from a particular route, you'd include the `headerTransformations` policy in the `responsePolicies` section as follows:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "responsePolicies": {
        "headerTransformations": {
          "renameHeaders": {
            "items": [
              {
                "from": "X-Username",
                "to": "X-User-ID"
              }
            ]
          }
        }
      }
    }
  ]
}
```

For more information about the `headerTransformations` response policy, see Editing a JSON File to Add Header Transformation Response Policies on page 466.

5. Save the JSON file containing the API deployment specification.

6. Use the API deployment specification when you create or update an API deployment in the following ways:

   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363.

### Limiting the Number of Requests to API Gateway Back Ends

Having created an API gateway and deployed one or more APIs on it, you'll typically want to limit the rate at which API clients can make requests to back-end services. For example, to:

- maintain high availability and fair use of resources by protecting back ends from being overwhelmed by too many requests
- prevent denial-of-service attacks
- constrain costs of resource consumption
- restrict usage of APIs by your customers' users in order to monetize APIs

You apply a rate limit globally to all routes in an API deployment specification.
If a request is denied because the rate limit has been exceeded, the response header specifies when the request can be retried.

You use a request policy to limit the number of requests (see Adding Request Policies and Response Policies to API Deployment Specifications on page 417).

You can add a rate-limiting request policy to an API deployment specification by:

- using the Console
- editing a JSON file

**Using the Console to Add Rate-Limiting Request Policies**

To add a rate-limiting request policy to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the **From Scratch** option, and enter details on the **Basic Information** page.
   
   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. In the **API Request Policies** section of the **Basic Information** page, click the **Add** button beside **Rate Limiting** and specify:
   
   - **Number of Requests per Second**: The maximum number of requests per second to send to any one route.
   - **Type of Rate Limit**: How the maximum number of requests per second threshold is applied. You can specify that the maximum applies either to the number of requests sent from any one API client (identified by its IP address), or to the total number of requests sent from all API clients.

3. Click **Save Changes**, and then click **Next** to enter details for individual routes in the API deployment on the **Routes** page. Note that you cannot apply rate-limiting policies to individual routes in the API deployment specification.

4. Click **Next** to review the details you entered for the API deployment.

5. Click **Create** or **Save Changes** to create or update the API deployment.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

**Editing a JSON File to Add Rate-Limiting Request Policies**

To add a rate-limiting request policy to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add a request limit, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

   For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

   ```json
   {
   "routes": [
   {
   "path": "/hello",
   "methods": ["GET"],
   "backend": {
   "type": "ORACLE_FUNCTIONS_BACKEND",
   "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
   }
   }
   }
   ```

2. Insert a requestPolicies section before the routes section, if one doesn't exist already. For example:

   ```json
   {
   "requestPolicies": {
   }
   ```
API Gateway

```
"requestPolicies": {},
"routes": [ 
    
    
],

3. Add the following rateLimiting policy to the new requestPolicies section to apply to all routes defined in the specification:

```

```
{ "requestPolicies": { 
    "rateLimiting": { 
        "rateKey": "<ratekey-value>",
        "rateInRequestsPerSecond": <requests-per-second>
    }

},

"routes": [ 
    
    
],
```

where:

- `<ratekey-value>` specifies whether the maximum number of requests threshold applies to the number of requests from individual API clients (each identified by their IP address) or to the total number of requests sent to the back-end service. Valid values are CLIENT_IP and TOTAL.
- `<requests-per-second>` is the maximum number of requests per second to send to any route.

For example:

```

```

```
{ "requestPolicies": { 
    "rateLimiting": { 
        "rateKey": "CLIENT_IP",
        "rateInRequestsPerSecond": 10
    }

},

"routes": [ 
    
    
],
```

Oracle Cloud Infrastructure User Guide 423
4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

Adding CORS support to API Deployments

Web browsers typically implement a "same-origin policy" to prevent code from making requests against a different origin to the one from which the code was served. The intention of the same-origin policy is to provide protection from malicious web sites. However, the same-origin policy can also prevent legitimate interactions between a server and clients of a known and trusted origin.

Cross-Origin Resource Sharing (CORS) is a cross-origin sharing standard to relax the same-origin policy by allowing code on a web page to consume a REST API served from a different origin. The CORS standard uses additional HTTP request headers and response headers to specify the origins that can be accessed.

The CORS standard also requires that for certain HTTP request methods, the request must be "pre-flighted". Before sending the actual request, the web browser sends a pre-flight request to the server to determine whether the methods in the actual request are supported. The server responds with the methods it will allow in an actual request. The web browser only sends the actual request if the response from the server indicates that the methods in the actual request are allowed. The CORS standard also enables servers to notify clients whether requests can include credentials (cookies, authorization headers, or TLS client certificates).

For more information about CORS, see resources available online including those from W3C and Mozilla.

Using the API Gateway service, you can enable CORS support in the APIs you deploy to API gateways. When you enable CORS support in an API deployment, HTTP pre-flight requests and actual requests to the API deployment return one or more CORS response headers to the API client. You set the CORS response header values in the API deployment specification.

You use request policies to add CORS support to APIs (see Adding Request Policies and Response Policies to API Deployment Specifications on page 417). You can apply a CORS request policy globally to all routes in an API deployment specification, or just to particular routes.

You can add a CORS request policy to an API deployment specification by:
   - using the Console
   - editing a JSON file

Using the Console to Add CORS Request Policies

To add a CORS request policy to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.
2. In the API Request Policies section of the Basic Information page, click the Add button beside CORS and specify:
   - **Allowed Origins**: An origin that is allowed to access the API deployment. For example, https://oracle.com. Click + Another Origin to enter second and subsequent origins.
   - **Allowed Methods**: One or more methods that are allowed in the actual request to the API deployment. For example, GET, PUT.
   - **Allowed Headers**: Optionally, an HTTP header that is allowed in the actual request to the API deployment. For example, opc-request-id or If-Match. Click + Another Header to enter second and subsequent headers.
   - **Exposed Headers**: Optionally, an HTTP header that API clients can access in the API deployment's response to an actual request. For example, ETag or opc-request-id. Click + Another Header to enter second and subsequent headers.
   - **Max age in seconds**: Optionally, an integer value indicating how long (in delta-seconds) the results of a preflight request can be cached by a browser. If you don't specify a value, the default is 0.
   - **Enable Allow Credentials**: Whether the actual request to the API deployment can be made using credentials (cookies, authorization headers, or TLS client certificates). By default, this option is not selected.

To find out how the different fields in the CORS request policy map onto different CORS response headers, see How a CORS Request Policy Maps to a CORS Response on page 429.

3. Click Save Changes, and then click Next to enter details for individual routes in the API deployment on the Routes page. To specify CORS request policies that apply to an individual route, click Show Route Request Policies, click the Add button beside CORS, and specify:
   - **Allowed Origins**: An origin that is allowed to access the route. For example, https://oracle.com. Click + Another Origin to enter second and subsequent origins.
   - **Allowed Methods**: One or more methods that are allowed in the actual request to the route. For example, GET, PUT.
   - **Allowed Headers**: Optionally, an HTTP header that is allowed in the actual request to the route. For example, opc-request-id or If-Match. Click + Another Header to enter second and subsequent headers.
   - **Exposed Headers**: Optionally, an HTTP header that API clients can access in the API deployment's response to an actual request. For example, ETag or opc-request-id. Click + Another Header to enter second and subsequent headers.
   - **Max age in seconds**: Optionally, an integer value indicating how long (in delta-seconds) the results of a preflight request can be cached by a browser. If you don't specify a value, the default is 0.
   - **Enable Allow Credentials**: Whether the actual request to the route can be made using credentials (cookies, authorization headers, or TLS client certificates). By default, this option is not selected.

To find out how the different fields in the CORS request policy map onto different CORS response headers, see How a CORS Request Policy Maps to a CORS Response on page 429.

4. Click Save Changes, and then click Next to review the details you entered for the API deployment and for individual routes.

5. Click Create or Save Changes to create or update the API deployment.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

**Editing a JSON File to Add CORS Request Policies**

To add a CORS request policy to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add CORS support, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

   For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:
2. To specify a CORS request policy that applies globally to all the routes in an API deployment:
   
a. Insert a requestPolicies section before the routes section, if one doesn't exist already. For example:

```json
{  
  "requestPolicies": {},  
  "routes": [  
    {  
      "path": "/hello",  
      "methods": ["GET"],  
      "backend": {  
        "type": "ORACLE_FUNCTIONS_BACKEND",  
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"  
      }  
    }  
  ]
}
```

b. Add the following cors policy to the new requestPolicies section to apply globally to all the routes in an API deployment:

```json
{  
  "requestPolicies": {  
    "cors":{  
      "allowedOrigins": [<list-of-origins>],  
      "allowedMethods": [<list-of-methods>],  
      "allowedHeaders": [<list-of-implicit-headers>],  
      "exposedHeaders": [<list-of-exposed-headers>],  
      "isAllowCredentialsEnabled": <true|false>,  
      "maxAgeInSeconds": <seconds>
    }  
  },  
  "routes": [  
    {  
      "path": "/hello",  
      "methods": ["GET"],  
      "backend": {  
        "type": "ORACLE_FUNCTIONS_BACKEND",  
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"  
      }  
    }  
  ]
}
```
where:

- "allowedOrigins": [<list-of-origins>] is a required comma-separated list of origins that are allowed to access the API deployment. For example, "allowedOrigins": ["*", "https://oracle.com"]
- "allowedMethods": [<list-of-methods>] is an optional comma-separated list of HTTP methods that are allowed in the actual request to the API deployment. For example, "allowedMethods": ["*", "GET"]
- "allowedHeaders": [<list-of-implicit-headers>] is an optional comma-separated list of HTTP headers that are allowed in the actual request to the API deployment. For example, "allowedHeaders": ["opc-request-id", "If-Match"]
- "exposedHeaders": [<list-of-exposed-headers>] is an optional comma-separated list of HTTP headers that API clients can access in the API deployment's response to an actual request. For example, "exposedHeaders": ["ETag", "opc-request-id"]
- "isAllowCredentialsEnabled": <true|false> is either true or false, indicating whether the actual request to the API deployment can be made using credentials (cookies, authorization headers, or TLS client certificates). If not specified, the default is false.
- "maxAgeInSeconds": <seconds> is an integer value, indicating how long (in delta-seconds) the results of a preflight request can be cached by a browser. If not specified, the default is 0.

For example:

```json
{
    "requestPolicies": {
        "cors": {
            "allowedOrigins": ["*", "https://oracle.com"],
            "allowedMethods": ["*", "GET"],
            "allowedHeaders": [],
            "exposedHeaders": [],
            "isAllowCredentialsEnabled": false,
            "maxAgeInSeconds": 3000
        }
    },
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

To find out how the different fields in the CORS request policy map onto different CORS response headers, see How a CORS Request Policy Maps to a CORS Response on page 429.

3. To specify a CORS request policy that applies to an individual route:

   **a.** Insert a requestPolicies section after the backend section for the route to which you want the policy to apply. For example:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
```
b. Add the following cors policy to the new requestPolicies section to apply to just this particular route:

```
  "requestPolicies": {
    "cors": {
      "allowedOrigins": [<list-of-origins>],
      "allowedMethods": [<list-of-methods>],
      "allowedHeaders": [<list-of-implicit-headers>],
      "exposedHeaders": [<list-of-exposed-headers>],
      "isAllowCredentialsEnabled": <true|false>,
      "maxAgeInSeconds": <seconds>
    }
  }
}
```

where:

- **"allowedOrigins": [<list-of-origins>]** is a required comma-separated list of origins that are allowed to access the API deployment. For example, "allowedOrigins": ["*", "https://oracle.com"]
- **"allowedMethods": [<list-of-methods>]** is an optional comma-separated list of HTTP methods that are allowed in the actual request to the API deployment. For example, "allowedMethods": ["*", "GET"]
- **"allowedHeaders": [<list-of-implicit-headers>]** is an optional comma-separated list of HTTP headers that are allowed in the actual request to the API deployment. For example, "allowedHeaders": ["opc-request-id", "If-Match"]
- **"exposedHeaders": [<list-of-exposed-headers>]** is an optional comma-separated list of HTTP headers that API clients can access in the API deployment's response to an actual request. For example, "exposedHeaders": ["ETag", "opc-request-id"]
- **"isAllowCredentialsEnabled": <true|false>** is either true or false, indicating whether the actual request to the API deployment can be made using credentials (cookies, authorization headers, or TLS client certificates). If not specified, the default is false.
- **"maxAgeInSeconds": <seconds>** is an integer value, indicating how long (in delta-seconds) the results of a preflight request can be cached by a browser. If not specified, the default is 0.

For example:

```
  "requestPolicies": {
    "cors": {
      "allowedOrigins": ["https://example.com", "https://another.com"],
      "allowedMethods": ["GET", "POST"],
      "allowedHeaders": [
        "Content-Type",
        "Authorization",
        "Accept-Language"
      ],
      "exposedHeaders": [
        "ETag",
        "Location",
        "Vary"
      ],
      "isAllowCredentialsEnabled": true,
      "maxAgeInSeconds": 3600
    }
  }
```

To find out how the different fields in the CORS request policy map onto different CORS response headers, see How a CORS Request Policy Maps to a CORS Response on page 429.

4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the **Upload an existing API** option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

### How a CORS Request Policy Maps to a CORS Response

The different fields in a CORS request policy map onto different CORS response headers as shown in the table:

<table>
<thead>
<tr>
<th>Field</th>
<th>In pre-flight response</th>
<th>In actual request</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowed Origins</td>
<td>Required?: Yes</td>
<td>Datatype: string[]</td>
<td>n/a</td>
</tr>
<tr>
<td></td>
<td>Default: n/a</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Used to return a comma-separated list of origins that are allowed to access the API deployment. Only one origin is allowed by the CORS specification, so in the case of multiple origins the client origin needs to be dynamically checked against the list of allowed values. Values &quot;*&quot; and &quot;null&quot; are allowed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Required?</td>
<td>Datatype</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>cors.host</td>
<td>No</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>cors.methods</td>
<td>No</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>cors.headers</td>
<td>No</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>cors.exposed.headers</td>
<td>No</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>cors.credentials</td>
<td>No</td>
<td>boolean</td>
<td>false</td>
</tr>
<tr>
<td>cors.maxage</td>
<td>No</td>
<td>integer</td>
<td>0</td>
</tr>
</tbody>
</table>

**Notes**

- **allowed Methods**
  - **Access-Control-Allow-Methods**: Used to return a comma-separated list of HTTP methods that are allowed in the actual request to the API deployment. The default of Access-Control-Allow-Methods is to allow through all simple methods, even on preflight requests.

- **allowed Headers**
  - **Access-Control-Allow-Headers**: Used to return a comma-separated list of HTTP headers that are allowed in the actual request to the API deployment.

- **exposed Headers**
  - **Access-Control-Expose-Headers**: Used to return a comma-separated list of HTTP headers that clients can access in the API deployment's response to an actual request. This list of HTTP headers is in addition to the CORS-safelisted response headers.

- **isAllow Credentials Enabled**
  - **Access-Control-Allow-Credentials**: Used to return true or false, indicating whether the actual request to the API deployment can be made using credentials (cookies, authorization headers, or TLS client certificates).

  To allow requests to be made with credentials, set isAllowCredentialsEnabled to true.

- **maxAge InSeconds**
  - **Access-Control-Max-Age**: Used to indicate how long (in delta-seconds) the results of a preflight request can be cached by a browser. Ignored if set to 0.
Adding Authentication and Authorization to API Deployments

You can control access to APIs you deploy to API gateways based on the end user sending a request, and define what it is that they are allowed to do. For the APIs you deploy, you'll typically provide:

- Authentication functionality to determine the end user's identity. Is the end user really who they claim to be?
- Authorization functionality to determine appropriate access for an end user, and grant the necessary permissions. What is the end user allowed to do?

You can add authentication and authorization functionality to API gateways to support:

- HTTP Basic Authentication
- API Key Authentication
- OAuth Authentication and Authorization
- Oracle Identity Cloud Service (IDCS) Authentication

You can add authentication and authorization functionality to an API gateway as follows:

- You can have the API gateway pass an access token included in a request to an authorizer function deployed on Oracle Functions to perform validation (see Using Authorizer Functions to Add Authentication and Authorization to API Deployments on page 431).
- You can have the API gateway itself validate a JSON Web Token (JWT) included in the request with an identity provider (see Using JSON Web Tokens (JWTs) to Add Authentication and Authorization to API Deployments on page 440).

Using Authorizer Functions to Add Authentication and Authorization to API Deployments

You can control access to APIs you deploy to API gateways using an 'authorizer function' (as described in this topic), or using JWTs (as described in Using JSON Web Tokens (JWTs) to Add Authentication and Authorization to API Deployments on page 440).

You can add authentication and authorization functionality to API gateways by writing an 'authorizer function' that:

- Processes request attributes to verify the identity of an end user with an identity provider.
- Determines the operations that the end user is allowed to perform.
- Returns the operations the end user is allowed to perform as a list of 'access scopes' (an 'access scope' is an arbitrary string used to determine access).
- Optionally returns a key-value pair for use by the API deployment. For example, as a context variable for use in an HTTP back end definition (see Adding Context Variables to Policies and HTTP Back End Definitions on page 378).

You then deploy the authorizer function to Oracle Functions. See Creating an Authorizer Function on page 432. For a related Developer Tutorial containing an example authorizer function, see Functions: Validate an API Key with API Gateway.

Having deployed the authorizer function, you enable authentication and authorization for an API deployment by including two different kinds of request policy in the API deployment specification:

- An authentication request policy for the entire API deployment that specifies:
  - The OCID of the authorizer function that you deployed to Oracle Functions that will perform authentication and authorization.
  - The request attributes to pass to the authorizer function.
  - Whether unauthenticated end users can access routes in the API deployment.
- An authorization request policy for each route that specifies the operations an end user is allowed to perform, based on the end user's access scopes as returned by the authorizer function.

You can add authentication and authorization request policies to an API deployment specification by:

- Using the Console.
Prerequisites for Using Authorizer Functions

Before you can enable authentication and authorization for API deployments using authorizer functions:

- An identity provider (for example, Oracle Identity Cloud Service (IDCS), Auth0) must have already been set up, containing access scopes for users allowed to access the API deployment. See the identity provider documentation for more information (for example, the Oracle Identity Cloud Service (IDCS) documentation, the Auth0 documentation).
- An authorizer function must have been deployed to Oracle Functions already, and an appropriate policy must give API gateways access to Oracle Functions. For more information, see Creating an Authorizer Function on page 432.

If you use the Console to include an authentication request policy (rather than by editing a JSON file), you select the authorizer function and the application that contains it from a list.

Note that to use the Console (rather than a JSON file) to define an authentication request policy and specify an authorizer function, your user account must belong to a group that has been given access to the authorizer function by an IAM policy (see Create a Policy to Give API Gateway Users Access to Functions on page 344).

Creating an Authorizer Function

To create an authorizer function:

1. Write code to implement authentication and authorization:
   a. Write code in the authorizer function that accepts the following JSON input from API Gateway:

   ```json
   {
   "type": "TOKEN",
   "token": "<token-value>"
   }
   ```

   where:
   - "type": "TOKEN" indicates that the value being passed to the authorizer function is an auth token.
   - "token": "<token-value>" is the auth token being passed to the authorizer function.

   For example:

   ```json
   {
   "type": "TOKEN",
   "token": "eyJ0eXAiOiJKV1QiLCJhbGciOiJSUzI1nHyDtTwR3SEJ3z489..."
   }
   ```

   b. Write code in the authorizer function that returns the following JSON to API Gateway as an HTTP 200 response when the access token has been successfully verified:

   ```json
   { 
   "active": true,
   "principal": "<user-principal>",
   "scope": ["<scopes>"],
   "clientId": "<client-id>"
   }
   ```
where:

- "active": true indicates the access token originally passed to the authorizer function has been successfully verified.
- "principal": "<user-principal>" is the user or application obtained by the authorizer function from the identity provider.
- "scope": ["<scopes>"] is a comma-delimited list of strings that are the access scopes obtained by the authorizer function from the identity provider.
- "clientId": "<client-id>" is optionally the requestor's host (for example, the hostname or the client IP). Returning a clientId is not required.
- "expiresAt": "<date-time>" is a date-time string in ISO-8601 format indicating when the access token originally passed to the authorizer function will expire. This value is used when determining how long to cache results after calling the authorizer function.
- "context": {"<key>": "<value>", ... } is an optional comma-delimited list of key-value pairs in JSON format to return to API Gateway. The authorizer function can return any key-value pair for use by the API deployment (for example, the username or email address of the end user). For more information about using the value in the key-value pair returned by an authorizer function as a context variable in an HTTP back end definition, see Adding Context Variables to Policies and HTTP Back End Definitions on page 378.

For example:

```json
{
    "active": true,
    "principal": "https://example.com/users/jdoe",
    "scope": ["list:hello", "read:hello", "create:hello", "update:hello",
               "delete:hello", "someScope"],
    "clientId": "host123",
    "expiresAt": "2019-05-30T10:15:30+01:00",
    "context": {
        "email": "john.doe@example.com"
    }
}
```

c. Write code that returns the following JSON to API Gateway as an HTTP 5xx response if token verification is unsuccessful, or in the event of an error in the authorizer function or in Oracle Functions:

```json
{
    "active": false,
    "expiresAt": "<date-time>",
    "context": {
        "<key>": "<value>", ...
    },
    "wwwAuthenticate": "<directive>"
}
```

where:

- "active": false indicates the access token originally passed to the authorizer function has not been successfully verified.
- "expiresAt": "<date-time>" is a date-time string in ISO-8601 format indicating when the access token originally passed to the authorizer function will expire.
- "context": {"<key>": "<value>", ... } is an optional comma-delimited list of key-value pairs in JSON format to return to API Gateway. The authorizer function can return any key-value pair
(for example, the username or email address of the end user). Returning context key-value pairs is not required.

- "wwwAuthenticate": "<directive>" is the value of the WWW-Authenticate header to be returned by the authorizer function if verification fails, indicating the type of authentication that is required (such as Basic or Bearer). API Gateway returns the WWW-Authenticate header in the response to the API client, along with a 401 status code. For example, "wwwAuthenticate": "Bearer realm=\"example.com\"". For more information, see RFC 2617 HTTP Authentication: Basic and Digest Access Authentication.

For example:

```json
{
  "active": false,
  "expiresAt": "2019-05-30T10:15:30+01:00",
  "context": {
    "email": "james.doe@example.com"
  },
  "wwwAuthenticate": "Bearer realm=\"example.com\"
}
```

For a related Developer Tutorial containing an example authorizer function, see Functions: Validate an API Key with API Gateway.

2. Build a Docker image from the code, push the Docker image to a Docker registry, and create a new function in Oracle Functions based on the image. You can do this in different ways:

- You can use the Fn Project CLI command `fn deploy` to build a new Docker image, push the image to the Docker registry, and create a new function in Oracle Functions based on the image. See Creating and Deploying Functions on page 2063.

- You can use Docker commands to build the image and push it to the Docker registry, and then use the Fn Project CLI command `fn create function` (or the `CreateFunction` API operation) to create a new function in Oracle Functions based on the image. See Creating Functions from Existing Docker Images on page 2066.

3. Make a note of the OCID of the function you create in Oracle Functions. For example, `ocid1.fnfunc.oc1.phx.aaaaaaaaac2______kg6fq`

4. If one doesn't exist already, create an Oracle Cloud Infrastructure policy and specify a policy statement to give API gateways access to function-related resources. The policy enables API deployments on those API gateways to invoke the authorizer function. For more information, see Create a Policy to Give API Gateways Access to Functions on page 345

**Using the Console to Add Authentication and Authorization Request Policies**

To add authentication and authorization request policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the **From Scratch** option, and enter details on the **Basic Information** page.

For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.
2. In the API Request Policies section of the Basic Information page, click the Add button beside Authentication and specify:

- **Authentication Type**: Select Custom.
- **Application in <compartment-name>**: The name of the application in Oracle Functions that contains the authorizer function. You can select an application from a different compartment.
- **Function Name**: The name of the authorizer function in Oracle Functions.
- **Authentication Token**: Whether the access token is contained in a request header or a query parameter.
- **Authentication Token Value**: Depending on whether the access token is contained in a request header or a query parameter, specify:
  - **Header Name**: If the access token is contained in a request header, enter the name of the header.
  - **Parameter Name**: If the access token is contained in a query parameter, enter the name of the query parameter.
- **Enable Anonymous Access**: Whether unauthenticated (that is, anonymous) end users can access routes in the API deployment. By default, this option is not selected. If you never want anonymous users to be able to access routes, don't select this option. Note that if you do select this option, you also have to explicitly specify every route to which anonymous access is allowed by selecting Anonymous as the Authorization Type in each route's authorization policy.

3. Click Save Changes, and then click Next to enter details for individual routes in the API deployment on the Routes page. To specify an authorization policy that applies to an individual route, click Show Route Request Policies, click the Add button beside Authorization, and specify:

- **Authorization Type**: How to grant access to the route. Specify:
  - **Any**: Only grant access to end users that have been successfully authenticated, provided the authorizer function has also returned one of the access scopes you specify in the Allowed Scope field. In this case, the authentication policy's Enable Anonymous Access option has no effect.
  - **Anonymous**: Grant access to all end users, even if they have not been successfully authenticated by the authorizer function. In this case, you must have selected the authentication policy's Enable Anonymous Access option.
  - **Authentication only**: Only grant access to end users that have been successfully authenticated by the authorizer function. In this case, the authentication policy's Enable Anonymous Access option has no effect.

- **Allowed Scope**: If you selected Any as the Authorization Type, enter a comma-delimited list of one or more strings that correspond to access scopes returned by the authorizer function. Access will only be granted to end users that have been successfully authenticated if the authorizer function returns one of the access scopes you specify. For example, read:hello

---

**Note:**

If you don't include an authorization policy for a particular route, access is granted as if such a policy does exist and Authorization Type is set to Authentication only. In other words, regardless of the setting of the authentication policy's Enable Anonymous Access option:

- only authenticated end users can access the route
- all authenticated end users can access the route regardless of access scopes returned by the authorizer function
- anonymous end users cannot access the route

4. Click Save Changes, and then click Next to review the details you entered for the API deployment.
5. Click Create or Save Changes to create or update the API deployment.
6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

**Editing a JSON File to Add Authentication and Authorization Request Policies**

To add authentication and authorization request policies to an API deployment specification in a JSON file:
1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add authentication and authorization functionality, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

At a minimum, the API deployment specification will include a routes section containing:

- A path. For example, /hello
- One or more methods. For example, GET
- A definition of a back end. For example, a URL, or the OCID of a function in Oracle Functions.

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      }
    }
  ]
}
```

2. Add an authentication request policy that applies to all routes in the API deployment specification:

   a. Insert a requestPolicies section before the routes section, if one doesn't exist already. For example:

   ```json
   {
     "requestPolicies": {},
     "routes": [
       {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
           "type": "ORACLE_FUNCTIONS_BACKEND",
           "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
       }
     ]
   }
   ```

   b. Add the following authentication policy to the new requestPolicies section.

   ```json
   {
     "requestPolicies": {
       "authentication": {
         "type": "<type-value>",
         "isAnonymousAccessAllowed": <true|false>,
         "functionId": "<function-ocid>",
         "<tokenHeader>|"tokenQueryParam": <"<token-header-name>|"<token-query-param-name>">"
       }
     },
     "routes": [
       {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
           "type": "ORACLE_FUNCTIONS_BACKEND",
           "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         }
       }
     ]
   }
   ```
where:

- `<type-value>` is the authentication type. To use an authorizer function for authentication, specify `CUSTOM_AUTHENTICATION`.
- "isAnonymousAccessAllowed": `<true|false>` optionally indicates whether unauthenticated (that is, anonymous) end users can access routes in the API deployment specification. If you never want anonymous end users to be able to access routes, set this property to `false`. If you don’t include this property in the authentication policy, the default of `false` is used. Note that if you do include this property and set it to `true`, you also have to explicitly specify every route to which anonymous access is allowed by setting the `type` property to "ANONYMOUS" in each route’s authorization policy.
- `<function-ocid>` is the OCID of the authorizer function deployed to Oracle Functions.
- `<"tokenHeader"|"tokenQueryParam">: `<"token-header-name"|"token-query-param-name">` indicates whether it is a request header that contains the access token (and if so, the name of the header), or a query parameter that contains the access token (and if so, the name of the query parameter). Note that you can specify either "tokenHeader": "<token-header-name>" or "tokenQueryParam": "<token-query-param-name>", but not both.

For example, the following authentication policy specifies an OCI function that will validate the access token in the Authorization request header:

```json
{
    "requestPolicies": {
        "authentication": {
            "type": "CUSTOM_AUTHENTICATION",
            "isAnonymousAccessAllowed": false,
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaac2_____kg6fq",
            "tokenHeader": "Authorization"
        }
    },
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

3. Add an authorization request policy for each route in the API deployment specification:

   a. Insert a `requestPolicies` section after the first route’s `backend` section, if one doesn't exist already. For example:

```json
{
    "requestPolicies": {
        "authentication": {
            "type": "CUSTOM_AUTHENTICATION",
            "isAnonymousAccessAllowed": false,
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaac2_____kg6fq",
            "tokenHeader": "Authorization"
        }
    },
    "routes": [
```
b. Add the following authorization policy to the requestPolicies section:

```json
{
    "requestPolicies": {
        "authentication": {
            "type": "CUSTOM_AUTHENTICATION",
            "isAnonymousAccessAllowed": false,
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaac2______kg6fq",
            "tokenHeader": "Authorization"
        }
    },
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "requestPolicies": {
                "authorization": {
                    "type": <"AUTHENTICATION_ONLY"|"ANY_OF"|"ANONYMOUS">,
                    "allowedScope": [ "<scope>" ]
                }
            }
        }
    ]
}
```

where:

- "type": <"AUTHENTICATION_ONLY"|"ANY_OF"|"ANONYMOUS"> indicates how to grant access to the route:
  - "AUTHENTICATION_ONLY": Only grant access to end users that have been successfully authenticated. In this case, the "isAnonymousAccessAllowed" property in the API deployment specification's authentication policy has no effect.
  - "ANY_OF": Only grant access to end users that have been successfully authenticated, provided the authorizer function has also returned one of the access scopes you specify in the allowedScope property. In this case, the "isAnonymousAccessAllowed" property in the API deployment specification's authentication policy has no effect.
  - "ANONYMOUS": Grant access to all end users, even if they have not been successfully authenticated. In this case, you must explicitly set the "isAnonymousAccessAllowed" property to true in the API deployment specification's authentication policy.
  - "allowedScope": [ "<scope>" ] is a comma-delimited list of one or more strings that correspond to access scopes returned by the authorizer function. In this case, you must set the type property to "ANY_OF" (the "allowedScope" property is ignored if the type property is set to...
"AUTHENTICATION_ONLY" or "ANONYMOUS"). Also note that if you specify more than one scope, access to the route is granted if any of the scopes you specify is returned by the authorizer function.

For example, the following request policy defines a /hello route that only allows authenticated end users with the read:hello scope to access it:

```json
{
   "requestPolicies": {
      "authentication": {
         "type": "CUSTOM_AUTHENTICATION",
         "isAnonymousAccessAllowed": false,
         "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaac2______kg6fq",
         "tokenHeader": "Authorization"
      }
   },
   "routes": [
      {
         "path": "/hello",
         "methods": ["GET"],
         "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
         },
         "requestPolicies": {
            "authorization": {
               "type": "ANY_OF",
               "allowedScope": [ "read:hello" ]
            }
         }
      }
   ]
}
```

c. Add an authorization request policy for all remaining routes in the API deployment specification.

**Note:**

If you don't include an authorization policy for a particular route, access is granted as if such a policy does exist and the type property is set to "AUTHENTICATION_ONLY". In other words, regardless of the setting of the isAnonymousAccessAllowed property in the API deployment specification's authentication policy:

- only authenticated end users can access the route
- all authenticated end users can access the route regardless of access scopes returned by the authorizer function
- anonymous end users cannot access the route

4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:

   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).
Using JSON Web Tokens (JWTs) to Add Authentication and Authorization to API Deployments

You can control access to APIs you deploy to API gateways using JSON Web Tokens (JWTs) as described in this topic, or using an 'authorizer function' (as described in Using Authorizer Functions to Add Authentication and Authorization to API Deployments on page 431).

A JWT is a JSON-based access token sent in an HTTP request from an API client to a resource. JWTs are issued by identity providers (for example, Oracle Identity Cloud Service (IDCS), Auth0, Okta). When an API client attempts to access a protected resource, it must include a JWT. The resource validates the JWT with an authorization server using a corresponding public verification key, either by invoking a validation end-point on the authorization server or by using a local verification key provided by the authorization server.

A JWT comprises:

- A header, which identifies the type of token and the cryptographic algorithm used to generate the signature.
- A payload, containing claims about the end user's identity, and the properties of the JWT itself. A claim is a key value pair, where the key is the name of the claim. A payload is recommended (although not required) to contain certain reserved claims with particular names, such as expiration time (exp), audience (aud), issuer (iss), and not before (nbf). A payload can also contain custom claims with user-defined names.
- A signature, to validate the authenticity of the JWT (derived by base64 encoding the header and the payload).

You enable an API deployment to use JWTs for authentication and authorization by including two different kinds of request policy in the API deployment specification:

- An authentication request policy for the entire API deployment that specifies the use of JWTs, including how to validate them and whether unauthenticated end users can access routes in the API deployment.
- An authorization request policy for each route that specifies the operations an end user is allowed to perform, optionally based on values specified for the scope claim in the JWT.

Before an end user can access an API deployment that uses JWTs for authentication and authorization, they must obtain a JWT from an identity provider.

When calling an API deployed on an API gateway, the API client provides the JWT as a query parameter or in the header of the request. The API gateway validates the JWT using a corresponding public verification key provided by the issuing identity provider. Using the API deployment's authentication request policy, you can configure how the API gateway validates JWTs:

- You can configure the API gateway to retrieve public verification keys from the identity provider at runtime. In this case, the identity provider acts as the authorization server.
- You can configure the API gateway in advance with public verification keys already issued by an identity provider (referred to as 'static keys'), enabling the API gateway to verify JWTs locally at runtime without having to contact the identity provider. The result is faster token validation.

As well as using the public verification key from the issuing identity provider to verify the authenticity of a JWT, you can specify that reserved claims in the JWT's payload must have particular values before the API gateway considers the JWT to be valid. By default, API gateways validate JWTs using the expiration (exp), audience (aud), and issuer (iss) claims, along with the not before (nbf) claim if present. You can also specify acceptable values for custom claims. See Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.

When the JWT has been validated, the API gateway extracts claims from the JWT's payload as key value pairs and saves them as records in the request.auth context table for use by the API deployment. For example, as context variables for use in an HTTP back end definition (see Adding Context Variables to Policies and HTTP Back End Definitions on page 378). If the JWT's payload contains the scope claim, you can use the claim's values in authorization request policies for individual routes to specify the operations an end user is allowed to perform.

You can add authentication and authorization request policies to an API deployment specification by:

- Using the Console.
- Editing a JSON file.
Prerequisites for using JWTs

Before you can enable authentication and authorization for API deployments using JWTs:

- An identity provider (for example, Oracle Identity Cloud Service (IDCS), Auth0) must have already been set up to issue JWTs for users allowed to access the API deployment.
- If you want to use custom claims in authorization policies, the identity provider must be set up to add the custom claims to the JWTs it issues.

See the identity provider documentation for more information (for example, the Oracle Identity Cloud Service (IDCS) documentation, the Auth0 documentation).

Also note that to validate the JWT using a corresponding public verification key provided by the issuing identity provider:

- the signing algorithm used to generate the JWT's signature must be one of RS256, RS384, or RS512
- the public verification key must have a minimum length of 2048 bits and must not exceed 4096 bits

Using the Console to Add Authentication and Authorization Request Policies

To add authentication and authorization request policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.
   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. In the API Request Policies section of the Basic Information page, click the Add button beside Authentication and specify:

   - **Authentication Type**: Select JWT.
   - **Authentication Token**: Whether the JWT is contained in a request header or a query parameter.
   - **Authentication Token Value**: Depending on whether the JWT is contained in a request header or a query parameter, specify:
     - **Header Name** and **Authentication Scheme**: If the JWT is contained in a request header, enter the name of the header (for example Authorization), and the HTTP authentication scheme (only Bearer is currently supported).
     - **Parameter Name**: If the JWT is contained in a query parameter, enter the name of the query parameter.
   - **Enable Anonymous Access**: Whether unauthenticated (that is, anonymous) end users can access routes in the API deployment. By default, this option is not selected. If you never want anonymous end users to be able to access routes, don't select this option. Note that if you do select this option, you also have to explicitly specify every route to which anonymous access is allowed by selecting Anonymous as the Authorization Type in each route's authorization policy.

3. In the Issuers section, specify values that are allowed in the issuer (iss) claim of a JWT being used to access the API deployment:

   - **Allowed Issuers**: Specify the URL (or a text string) for an identity provider that is allowed in the issuer (iss) claim of a JWT to be used to access the API deployment. For example, to enable a JWT issued by the Oracle Identity Cloud Service (IDCS) to be used to access the API deployment, enter https://identity.oraclecloud.com/. See Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.
   - **Another Issuer**: Click to add additional identity providers (up to a maximum of five).

4. In the Audiences section, specify values that are allowed in the audience (aud) claim of a JWT being used to access the API deployment:

   - **Allowed Audiences**: Specify a value that is allowed in the audience (aud) claim of a JWT to identify the intended recipient of the token. For example, the audience could be, but need not be, the API gateway's hostname. See Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.
   - **Another Audience**: Click to add additional audiences (up to a maximum of five).
5. In the **Public Keys** section of the Authentication Policy window, specify how you want the API gateway to validate JWTs using public verification keys:

   - To configure the API gateway to validate JWTs by retrieving public verification keys from the identity provider at runtime, select **Remote JWKS** from the **Type** list and specify:

     - **URI**: The URI from which to retrieve the JSON Web Key Set (JWKS) to use to verify the signature on JWTs. For example, https://www.somejwksprovider.com/oauth2/v3/certs. For more information about the URI to specify, see **Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI** on page 451.

   Note the following:

     - The URI must be routable from the subnet containing the API gateway on which the API is deployed.
     - URIs that require authentication or authorization to return the JWKS are not supported.
     - If the API gateway fails to retrieve the JWKS, all requests to the API deployment will return an HTTP 500 response code. Refer to the API gateway's execution log for more information about the error (see **Adding Logging to API Deployments** on page 397).
     - Certain key parameters must be present in the JWKS to verify the JWT's signature (see **Key Parameters Required to Verify JWT Signatures** on page 452).

     - **Cache Duration in Hours**: The number of hours (between 1 and 24) the API gateway is to cache the JWKS set after retrieving it.

     - **Disable SSL Verification**: Whether to disable SSL verification when communicating with the identity provider. By default, this option is not selected. Oracle recommends not selecting this option because it can compromise JWT validation. API Gateway trusts certificates from multiple Certificate Authorities issued for Oracle Identity Cloud Service (IDCS), Auth0, Okta.

   - To configure the API gateway to validate JWTs with public verification keys already issued by an identity provider (enabling the API gateway to verify JWTs locally without having to contact the identity provider), select **Static Keys** from the **Type** list and specify:

     - **Key ID**: The identifier of the static key used to sign the JWT. The value must match the `kid` claim in the JWT header. For example, `master_key`.

     - **Format**: The format of the static key, as either a JSON Web Key or a PEM-encoded Public Key.

       - **JSON Web Key**: If the static key is a JSON Web Key, paste the key into this field. For example:

         ```
         {
           "kty": "RSA",
           "n": "0vx7agoebGc...KnqDKgw",
           "e": "AQAB",
           "alg": "RS256",
           "use": "sig"
         }
         ```

         Note that certain parameters must be present in the static key to verify the JWT's signature (see **Key Parameters Required to Verify JWT Signatures** on page 452). Also note that RSA is currently the only supported key type (`kty`).

       - **PEM-Encoded Public Key**: If the static key is a PEM-encoded public key, paste the key into this field. For example:

         ```
         -----BEGIN PUBLIC KEY-----
         XsE1CeYgglwW/KAhSSNRVdD60q1XYMWHOxZsFDZCLWxXxKMXCIyurVnrZ8x3oSmxwL5/8qVudomoP+yycJ2gWPIqgsZcQRheJWxVC5ep0MeEHlvLnEvC19utpAnjrsZCQ7plfZVFX7ORvezwqQhBw7wA2
         ```
6. (Optional) Click Show Advanced Options to specify a time difference to take into account when validating JWTs, and to specify additional claims in JWTs to process:

- **Maximum Clock Skew in Seconds:** (Optional) The maximum time difference between the system clocks of the identity provider that issued a JWT and the API gateway. The value you enter here is taken into account when the API gateway validates the JWT to determine whether it is still valid, using the not before (nbf) claim (if present) and the expiration (exp) claim in the JWT. The minimum (and default) is 0, the maximum is 120.

- **Verify Claims:** (Optional) In addition to the values for the audience `aud` and issuer `iss` claims that you already specified, you can specify names and values for one or more additional claims to validate in a JWT. Note that any key names and values you enter are simply handled as strings, and must match exactly with names and values in the JWT. Pattern matching and other datatypes are not supported. Also note that you can specify a claim can or must appear in the JWT without specifying a value for the claim by entering the claim's name in the **Claim Key** field, leaving the **Claim Values** field blank, and selecting **Required**:

  - **Claim Key:** (Optional) Specify the name of a claim that can be, or must be, included in a JWT. If the claim must be included in the JWT, select **Required**. The claim name you specify can be a reserved claim name such as the subject (`sub`) claim, or a custom claim name issued by a particular identity provider.

  - **Claim Values:** (Optional) Specify an acceptable value for the claim in the **Claim Key** field. Click the plus sign (+) to enter another acceptable value. If you specify one or more acceptable values for the claim, the API gateway validates that the claim has one of the values you specify.

  - **Required:** Select if the claim in the **Claim Key** field must be included in the JWT.

- **Another Claim:** Click to add additional claims (up to a maximum of ten).

7. Click **Save Changes**, and then click **Next** to enter details for individual routes in the API deployment on the **Routes** page. To specify an authorization policy that applies to an individual route, click **Show Route Request Policies**, click the **Add** button beside **Authorization**, and specify:

- **Authorization Type:** How to grant access to the route. Specify:
  
  - **Any:** Only grant access to end users that have been successfully authenticated, provided the JWT has a `scope` claim that includes at least one of the access scopes you specify in the **Allowed Scope** field. In this case, the authentication policy's **Enable Anonymous Access** option has no effect.
  
  - **Anonymous:** Grant access to all end users, even if they have not been successfully authenticated using the JWT. In this case, you must have selected the authentication policy's **Enable Anonymous Access** option.

- **Authentication only:** Only grant access to end users that have been successfully authenticated using the JWT. In this case, the authentication policy's **Enable Anonymous Access** option has no effect.

- **Allowed Scope:** If you selected **Any** as the **Authorization Type**, enter a comma-delimited list of one or more strings that correspond to access scopes in the JWT. Access will only be granted to end users that have been successfully authenticated if the JWT has a `scope` claim that includes one of the access scopes you specify. For example, `read:hello`

8. Click **Save Changes**, and then click **Next** to review the details you entered for the API deployment.
9. Click **Create** or **Save Changes** to create or update the API deployment.

10. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

### Editing a JSON File to Add Authentication and Authorization Request Policies

To add authentication and authorization request policies to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add authentication and authorization functionality, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

At a minimum, the API deployment specification will include a `routes` section containing:

- A path. For example, `/hello`
- One or more methods. For example, `GET`
- A definition of a back end. For example, a URL, or the OCID of a function in Oracle Functions.

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            }
        }
    ]
}
```

2. Add an **authentication** request policy that applies to all routes in the API deployment specification:

   a. Insert a `requestPolicies` section before the `routes` section, if one doesn’t exist already. For example:

   ```json
   {
       "requestPolicies": {},
       "routes": [
           {
               "path": "/hello",
               "methods": ["GET"],
               "backend": {
                   "type": "ORACLE_FUNCTIONS_BACKEND",
                   "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
               }
           }
       ]
   }
   ```

   b. Add the following **authentication** policy to the new `requestPolicies` section.

   ```json
   {
       "requestPolicies": {
           "authentication": {
               "type": "<type-value>",
               "isAnonymousAccessAllowed": <true|false>,
               "issuers": ["<issuer-url>", "<issuer-url>"],
               "<tokenHeader>"|"<tokenQueryParam>": "<token-header-name>"|"<token-query-param-name>",
               "tokenAuthScheme": "<authentication-scheme>",
               ...
           }
       }
   }
   ```
"audiences": ["<intended-audience>"],
"publicKeys": {
  "type": "<REMOTE_JWKS" | "STATIC_KEYS">,
  <public-key-config>
},
"verifyClaims": [ 
  {"key": "<claim-name>",&
  "values": ["<acceptable-value>"],
  "isRequired": <true|false>
  }
],
"maxClockSkewInSeconds": <seconds-difference>
}
},
"routes": [ 
  {"path": "/hello",
  "methods": ["GET"],
  "backend": { 
    "type": "ORACLE_FUNCTIONS_BACKEND",
    "functionId": "ocidl.fnfunc.ocl.phx.aaaaaaaaab______xmq"
  }
  }
]
}

where:

- `<type-value>` is the authentication type. To use JWTs for authentication, specify JWT_AUTHENTICATION.
- "isAnonymousAccessAllowed": <true|false> optionally indicates whether unauthenticated (that is, anonymous) end users can access routes in the API deployment specification. If you never want anonymous end users to be able to access routes, set this property to false. If you don’t include this property in the authentication policy, the default of false is used. Note that if you do include this property and set it to true, you also have to explicitly specify every route to which anonymous access is allowed by setting the type property to "ANONYMOUS" in each route's authorization policy.
- `<issuer-url>` is the URL (or a text string) for an identity provider that is allowed in the issuer (iss) claim of a JWT to be used to access the API deployment. For example, to enable a JWT issued by the Oracle Identity Cloud Service (IDCS) to be used to access the API deployment, enter https://identity.oraclecloud.com/. You can specify one or multiple identity providers (up to a maximum of five). See Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.
- "<"tokenHeader"|"tokenQueryParam">: <"token-header-name">|"<token-query-param-name>" indicates whether it is a request header that contains the JWT (and if so, the name of the header), or a query parameter that contains the access token (and if so, the name of the query parameter). Note that you can specify either "tokenHeader": "<token-header-name>" or "tokenQueryParam": "<token-query-param-name">", but not both.
- <tokenAuthScheme> is the name of the authentication scheme to use if the JWT is contained in a request header. For example, "Bearer".
- `<intended-audience>` is a value that is allowed in the audience (aud) claim of a JWT to identify the intended recipient of the token. For example, the audience could be, but need not be, the API gateway's hostname. You can specify one audience or multiple audiences (up to a maximum of five). See Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.
- "type": "<REMOTE_JWKS" | "STATIC_KEYS" indicates how you want the API gateway to validate JWTs using public verification keys. Specify REMOTE_JWKS to configure the API gateway to retrieve public verification keys from the identity provider at runtime. Specify STATIC_KEYS to
configure the API gateway with public verification keys already issued by an identity provider (enabling
the API gateway to verify JWTs locally without having to contact the identity provider).

- `<public-key-config>` provides the details of JWT validation, according to whether you specified
  "REMOTE_JWKS" or "STATIC_KEYS" as the value of "type": as follows:

  - If you specified "type": "REMOTE_JWKS" to configure the API gateway to validate JWTs by
    retrieving public verification keys from the identity provider at runtime, provide details as follows:

```
"publicKeys": {
  "type": "REMOTE_JWKS",
  "uri": "<uri-for-jwks>",
  "maxCacheDurationInHours": <cache-time>,
  "isSslVerifyDisabled": <true|false>
}
```

  where:

  - "uri": "<uri-for-jwks>" specifies the URI from which to retrieve the JSON Web Key
    Set (JWKS) to use to verify the signature on JWTs. For more information about the URI to specify,
    see Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI on page 451.
    Note the following:
    - The URI must be routable from the subnet containing the API gateway on which the API is
      deployed.
    - URIs that require authentication or authorization to return the JWKS are not supported.
    - If the API gateway fails to retrieve the JWKS, all requests to the API deployment will return an
      HTTP 500 response code. Refer to the API gateway's execution log for more information about
      the error (see Adding Logging to API Deployments on page 397).
    - Certain key parameters must be present in the JWKS to verify the JWT's signature (see Key
      Parameters Required to Verify JWT Signatures on page 452).
    - "maxCacheDurationInHours": <cache-time> specifies the number of hours (between 1
      and 24) the API gateway is to cache the JWKS set after retrieving it.
    - "isSslVerifyDisabled": <true|false> indicates whether to disable SSL verification
      when communicating with the identity provider. Oracle recommends not setting this option to
      true because it can compromise JWT validation. API Gateway trusts certificates from multiple
      Certificate Authorities issued for Oracle Identity Cloud Service (IDCS), Auth0, and Okta.

    For example:

```
"publicKeys": {
  "type": "REMOTE_JWKS",
  "uri": "https://www.somejwksprovider.com/oauth2/v3/certs",
  "maxCacheDurationInHours": 3,
  "isSslVerifyDisabled": false
}
```

- If you specified "type": "STATIC_KEYS", the details to provide depend on the format of the key
  already issued by the identity provider:

  - If the static key is a JSON Web Key, specify "format": "JSON_WEB_KEY", specify the
    identifier of the static key used to sign the JWT as the value of the "kid" parameter, and provide
    values for other parameters to verify the JWT's signature.

    For example:

```
"publicKeys": {
  "type": "STATIC_KEYS",
  "keys": [ 
  { "format": "JSON_WEB_KEY",
```

Oracle Cloud Infrastructure User Guide 446
"kid": "master_key",
"kty": "RSA",
"n": "0vx7agoebGc...KnqDKgw",
"e": "AQAB",
"alg": "RS256",
"use": "sig"
}
]

Note that certain parameters must be present in the static key to verify the JWT's signature (see Key Parameters Required to Verify JWT Signatures on page 452). Also note that RSA is currently the only supported key type (kty).

- If the static key is a PEM-encoded public key, specify "format": "PEM", specify the identifier of the static key used to sign the JWT as the value of "kid", and provide the key as the value of "key".

For example:

```json
"publicKeys": {
  "type": "STATIC_KEYS",
  "keys": [
    {
      "format": "PEM",
      "kid": "master_key"
      "key": "-----BEGIN PUBLIC KEY-----XsEiCeYgg1wW/KAhSSNRVd60QlXWzGh0hXzSFD2ClfdWxXKmZC1MvVr5rB1zmFEXnFmcsO2mxw1L5/8qQudomoP+yycJ2gWPiggs2cQRheJWxVC5ep0MeEHlvLnEvCi9utpAnjrsZCQ7p1fZVFJ7XORvezwqQhBfYzwEND PUBLIC KEY-----
    }
  ]
}
```

Note that the -----BEGIN PUBLIC KEY----- and -----END PUBLIC KEY----- markers are required.

- **verifyClaims** optionally specifies additional claim names and values for one or more additional claims to validate in a JWT (up to a maximum of ten).
  - "key": "<claim-name>" is the name of a claim that can be, or must be, included in a JWT. The claim name you specify can be a reserved claim name such as the subject (sub) claim, or a custom claim name issued by a particular identity provider.
  - "values": ["<acceptable-value>", "<acceptable-value>"], (optionally) indicates one or more acceptable values for the claim.
  - "isRequired": <true|false> indicates whether the claim must be included in the JWT.

Note that any key names and values you enter are simply handled as strings, and must match exactly with names and values in the JWT. Pattern matching and other datatypes are not supported.

- **maxClockSkewInSeconds**: <seconds-difference> optionally specifies the maximum time difference between the system clocks of the identity provider that issued a JWT and the API gateway. The value you specify is taken into account when the API gateway validates the JWT to determine whether it is still valid, using the not before (nbf) claim (if present) and the expiration (exp) claim in the JWT. The minimum (and default) is 0, the maximum is 120.

For example, the following authentication policy specifies an OCI function that will validate the access token in the Authorization request header:

```json
{
  "requestPolicies": {
    "authentication": {
      "type": "JWT_AUTHENTICATION",
      "isAnonymousAccessAllowed": false,
      "issuers": ["https://identity.oraclecloud.com/"],
      "verifyClaims": {
        "key": "custom-claim",
        "values": ["accepted-value-1", "accepted-value-2"],
        "isRequired": true
      }
    }
  }
}
```
3. Add an authorization request policy for each route in the API deployment specification:

   a. Insert a requestPolicies section after the first route's backend section, if one doesn't exist already. For example:

```json
"requestPolicies": {
  "authentication": {
    "type": "JWT_AUTHENTICATION",
    "isAnonymousAccessAllowed": false,
    "issuers": ["https://identity.oraclecloud.com/"],
    "tokenHeader": "Authorization",
    "tokenAuthScheme": "Bearer",
    "audiences": ["api.dev.io"],
    "publicKeys": {
      "type": "STATIC_KEYS",
      "keys": [
        {
          "format": "JSON_WEB_KEY",
          "kid": "master_key",
          "kty": "RSA",
          "n": "0vx7agoebGc...KnqDKgw",
          "e": "AQAB",
          "alg": "RS256",
          "use": "sig"
        }
      ]
    },
    "verifyClaims": {
      "key": "is_admin",
      "values": ["service:app", "read:hello"],
      "isRequired": true
    }
  },
  "maxClockSkewInSeconds": 10
}
```

b. Add the following authorization policy to the requestPolicies section:

```
{
  "requestPolicies": {
    "authentication": {
      "type": "JWT_AUTHENTICATION",
      "isAnonymousAccessAllowed": false,
      "issuers": ["https://identity.oraclecloud.com/"]
    },
    "verifyClaims": [
      {
        "key": "is_admin",
        "values": ["service:app", "read:hello"],
        "isRequired": true
      }
    ],
    "maxClockSkewInSeconds": 10
  },
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {}
    }
  ]
}
```
API Gateway

"methods": ["GET"],
"backend": {
  "type": "ORACLE_FUNCTIONS_BACKEND",
  "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaab________xmq"
},
"requestPolicies": {
  "authorization": {
    "type": "<"AUTHENTICATION_ONLY"|"ANY_OF"|"ANONYMOUS">,
    "allowedScope": [ "<scope>" ]
  }
}
}

where:

- "type": "<"AUTHENTICATION ONLY"|"ANY_OF"|"ANONYMOUS""> indicates how to grant access to the route:
  - "AUTHENTICATION ONLY": Only grant access to end users that have been successfully authenticated. In this case, the "isAnonymousAccessAllowed" property in the API deployment specification's authentication policy has no effect.
  - "ANY_OF": Only grant access to end users that have been successfully authenticated, provided the JWT's scope claim includes one of the access scopes you specify in the allowedScope property. In this case, the "isAnonymousAccessAllowed" property in the API deployment specification's authentication policy has no effect.
  - "ANONYMOUS": Grant access to all end users, even if they have not been successfully authenticated. In this case, you must explicitly set the "isAnonymousAccessAllowed" property to true in the API deployment specification's authentication policy.

- "allowedScope": [ "<scope>" ] is a comma-delimited list of one or more strings that correspond to access scopes included in the JWT's scope claim. In this case, you must set the type property to "ANY_OF" (the "allowedScope" property is ignored if the type property is set to "AUTHENTICATION ONLY" or "ANONYMOUS"). Also note that if you specify more than one scope, access to the route is granted if any of the scopes you specify is included in the JWT's scope claim.

For example, the following request policy defines a /hello route that only allows authenticated end users with the read:hello scope to access it:

```json
{
  "requestPolicies": {
    "authentication": {
      "type": "JWT_AUTHENTICATION",
      "isAnonymousAccessAllowed": false,
      "issuers": ["https://identity.oraclecloud.com/"],
      "tokenHeader": "Authorization",
      "tokenAuthScheme": "Bearer",
      "audiences": ["api.dev.io"],
      "publicKeys": {
        "type": "STATIC_KEYS",
        "keys": [
          { "format": "JSON_WEB_KEY",
            "kid": "master_key",
            "kty": "RSA",
            "n": "0vx7agoebGc...KnqDKgw",
            "e": "AQAB",
            "alg": "RS256",
            "use": "sig"
          }
        ]
      }
    }
  }
}
```
API Gateway

```
},

"verifyClaims": [

  {
    "key": "is_admin",
    "values": ["service:app", "read:hello"],
    "isRequired": true
  }
],

"maxClockSkewInSeconds": 10
}
]

"routes": [

  {
    "path": "/hello",
    "methods": ["GET"],
    "backend": {
      "type": "ORACLE_FUNCTIONS_BACKEND",
      "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
    },
    "requestPolicies": {
      "authorization": {
        "type": "ANY_OF",
        "allowedScope": ["read:hello"]
      }
    }
  }
]
}
```

c. Add an authorization request policy for all remaining routes in the API deployment specification.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you don't include an authorization policy for a particular route, access is granted as if such a policy does exist and the type property is set to &quot;AUTHENTICATION_ONLY&quot;. In other words, regardless of the setting of the isAnonymousAccessAllowed property in the API deployment specification's authentication policy:</td>
</tr>
<tr>
<td>• only authenticated end users can access the route</td>
</tr>
<tr>
<td>• all authenticated end users can access the route regardless of access scopes in the JWT's scope claim</td>
</tr>
<tr>
<td>• anonymous end users cannot access the route</td>
</tr>
</tbody>
</table>

4. Save the JSON file containing the API deployment specification.

5. Use the API deployment specification when you create or update an API deployment in the following ways:

   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

6. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

Identity Provider Details to Use for iss and aud Claims, and for the JWKS URI

The identity provider that issued the JWT determines the allowed values you have to specify for the issuer (iss) and the audience (aud) claims in the JWT. Which identity provider issued the JWT also determines the URI from which to retrieve the JSON Web Key Set (JWKS) to verify the signature on the JWT. Note that URIs that require authentication or authorization to return the JWKS are not supported.

Use the following table to find out what to specify for JWTs issued by the Oracle Identity Cloud Service (IDCS), Okta, and Auth0 identity providers.
<table>
<thead>
<tr>
<th>Identity Provider</th>
<th>Issuer (iss) claim</th>
<th>Audience (aud) claim</th>
<th>Format of URI from which to retrieve the JWKS</th>
</tr>
</thead>
</table>
To obtain the JWKS without logging in to Oracle Identity Cloud Service, see Change Default Settings in the Oracle Identity Cloud Service documentation. |
See the Okta documentation. |
| Auth0             | https://<your-account-name>.auth0.com/ | Customer-specific.  
See Audience in the Auth0 documentation. | https://<your-account-name>.auth0.com/.well-known/jwks.json |

**Key Parameters Required to Verify JWT Signatures**

To verify the signature on a JWT, API gateways require the following key parameters are present in either the JWKS returned from a URI or the static JSON Web Key you specify.

<table>
<thead>
<tr>
<th>Key Parameter</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>kid</td>
<td>The identifier of the key used to sign the JWT. The value must match the <code>kid</code> claim in the JWT header. For example, <code>master_key</code>.</td>
</tr>
<tr>
<td>kty</td>
<td>The type of the key used to sign the JWT. Note that RSA is currently the only supported key type.</td>
</tr>
<tr>
<td>use or key_ops</td>
<td>If the <code>use</code> parameter is present, then it must be set to <code>sig</code>. If the <code>key-ops</code> parameter is present, then <code>verify</code> must be one of the valid values.</td>
</tr>
<tr>
<td>n</td>
<td>The public key modulus.</td>
</tr>
<tr>
<td>e</td>
<td>The public key exponent.</td>
</tr>
<tr>
<td>alg</td>
<td>The signing algorithm (if present) must be set to one of RS256, RS384 or RS512.</td>
</tr>
</tbody>
</table>
Transforming Incoming Requests and Outgoing Responses

There are often situations when you'll want an API gateway to modify incoming requests before sending them to back-end services. Similarly, you might want the API gateway to modify responses returned by back-end services. For example:

- Back-end services might require requests to include a particular set of HTTP headers (for example, Accept-Language and Accept-Encoding). To hide this implementation detail from API consumers and API clients, you can use your API gateway to add the required headers.
- Web servers often include full version information in response headers. For security reasons, you might want to prevent API consumers and API clients knowing about the underlying technology stack. You can use your API gateway to remove server headers from responses.
- Back-end services might include sensitive information in a response. You can use your API gateway to remove such information.

Using an API gateway, you can:

- Add, remove, and modify headers in requests and responses.
- Add, remove, and modify query parameters in requests.
- Rewrite request URLs from a public format to an internal format, perhaps to support legacy applications and migrations.

You use request and response policies to transform the headers and query parameters of incoming requests, and the headers of outgoing responses (see Adding Request Policies and Response Policies to API Deployment Specifications on page 417).

You can include context variables in header and query parameter transformation request and response policies. Including context variables enables you to modify headers and query parameters with the values of other headers, query parameters, path parameters, and authentication parameters. Note that values of context variable values are extracted from the original request or response, and are not subsequently updated as an API gateway uses a transformation policy to evaluate a request or response. For more information about context variables, see Adding Context Variables to Policies and HTTP Back End Definitions on page 378.

If a header or query parameter transformation request or response policy will result in an invalid header or query parameter, the transformation policy is ignored.

You can add header and query parameter transformation request and response policies to an API deployment specification by:

- using the Console
- editing a JSON file

Adding Header Transformation Request Policies

You can add header transformation request policies to API deployment specifications using the Console or by editing a JSON file.

Using the Console to Add Header Transformation Request Policies

To add header transformation request policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. Click Save Changes, and then click Next to enter details for individual routes in the API deployment on the Routes page.

3. On the Routes page, select the route for which you want to specify header transformation request policies.

4. Click Show Route Request Policies.
5. Click the Add button beside **Header Transformations** to update the headers included in a request to the API gateway for the current route.

6. To limit the headers included in a request, specify:
   - **Action**: Filter.
   - **Type**: Either Block to remove from the request the headers you explicitly list, or Allow to only allow in the request the headers you explicitly list (any other headers are removed from the request).
   - **Header Names**: The list of headers to remove from the request or allow in the request (depending on the setting of **Type**). The names you specify are not case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, User-Agent.

7. To change the name of a header included in a request (whilst keeping its original value), specify:
   - **Action**: Rename.
   - **From**: The original name of the header that you are renaming. The name you specify is not case-sensitive, and must not be included in any other transformation request policies for the route. For example, X-Username.
   - **To**: The new name of the header you are renaming. The name you specify is not case-sensitive (capitalization might be ignored), and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, X-User-ID.

8. To add a new header to a request (or to change or retain the values of an existing header already included in a request), specify:
   - **Action**: Set.
   - **Behavior**: If the header already exists, specify what to do with the header's existing value:
     - **Overwrite**, to replace the header's existing value with the value you specify.
     - **Append**, to append the value you specify to the header's existing value.
     - **Skip**, to keep the header's existing value.
   - **Name**: The name of the header to add to the request (or to change the value of). The name you specify is not case-sensitive (capitalization might be ignored), and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, X-Api-Key.
   - **Values**: The value of the new header (or the value to replace or append to an existing header's value, depending on the setting of **Behavior**). The value you specify can be a simple string, or can include context variables enclosed within ${...} delimiters. For example, "value": "zyx987wvu654tsu321", "value": "${request.path[region]}", "value": "${request.headers[opc-request-id]}". You can specify multiple values.

9. Click **Save Changes**, and then click **Next** to review the details you entered for individual routes.

10. Click **Create** or **Save Changes** to create or update the API deployment.

11. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

### Editing a JSON File to Add Header Transformation Request Policies

To add header transformation request policies to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add header transformation request policies, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
```
2. Insert a `requestPolicies` section after the `backend` section for the route to which you want the header transformation request policy to apply. For example:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {}
    }
  ]
}
```

3. Add a `headerTransformations` section to the `requestPolicies` section.

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "headerTransformations":{}
      }
    }
  ]
}
```

4. To limit the headers included in a request, specify a `filterHeaders` header transformation request policy:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "headerTransformations": {
          "filterHeaders": {
            "type": "<BLOCK|ALLOW>",
            "items": [  
              "name": "<header-name>"
            ]
          }
        }
      }
    }
  ]
}
```
where:

- "type": "<BLOCK|ALLOW>" indicates what to do with the headers specified by "items": 
  
  ```
  [{ "name": "<header-name>" }]:
  ```

  - Use BLOCK to remove from the request the headers you explicitly list.
  - Use ALLOW to only allow in the request the headers you explicitly list (any other headers are removed from the request).

- "name": "<header-name>" is a header to remove from the request or allow in the request (depending on the setting of "type": "<BLOCK|ALLOW>".

  The name you specify is not case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists).

  For example, User-Agent.

You can remove and allow up to 50 headers in a `filterHeaders` header transformation request policy.

For example:

```json
{
 "routes": [
  {
   "path": "/hello",
   "methods": ["GET"],
   "backend": {
     "type": "ORACLE_FUNCTIONS_BACKEND",
     "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
   },
   "requestPolicies": {
     "headerTransformations": {
       "filterHeaders": {
         "type": "BLOCK",
         "items": [
           {
             "name": "User-Agent"
           }
         ]
       }
     }
   }
  }
]
}
```

In this example, the API gateway removes the User-Agent header from all incoming requests.

5. To change the name of a header included in a request (whilst keeping its original value), specify a `renameHeaders` header transformation request policy:

```json
{
 "routes": [
  {
   "path": "/hello",
   "methods": ["GET"],
   "backend": {
     "type": "ORACLE_FUNCTIONS_BACKEND",
     "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
   },
   "requestPolicies": {
     "renameHeaders": {
       "items": [
         {
          "oldName": "User-Agent",
          "newName": "New-Agent"
         }
       ]
     }
   }
  }
]
}
```
API Gateway

```
"headerTransformations": {
  "renameHeaders": {
    "items": [
      {
        "from": "<original-name>",
        "to": "<new-name>"
      }
    ]
  }
}
```

where:

- "from": "<original-name>" is the original name of the header that you are renaming. The name you specify is not case-sensitive, and must not be included in any other transformation request policies for the route. For example, X-Username.
- "to": "<new-name>" is the new name of the header you are renaming. The name you specify is not case-sensitive (capitalization might be ignored), and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists). For example, X-User-ID.

You can rename up to 20 headers in a `renameHeaders` header transformation request policy.

For example:

```
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "headerTransformations": {
          "renameHeaders": {
            "items": [
              {
                "from": "X-Username",
                "to": "X-User-ID"
              }
            ]
          }
        }
      }
    }
  ]
}
```

In this example, the API gateway renames any X-Username header to X-User-ID, whilst keeping the header's original value.

6. To add a new header to a request (or to change or retain the values of an existing header already included in a request), specify a `setHeaders` header transformation request policy:

```
{
  "routes": [
    {
      "path": "/hello",
```
"methods": ["GET"],
"backend": {
"type": "ORACLE_FUNCTIONS_BACKEND",
"functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
},
"requestPolicies": {
"headerTransformations": {
"setHeaders": {
"items": [
{
"name": "<header-name>",
"values": ["<header-value>"],
"ifExists": "<OVERWRITE|APPEND|SKIP>"
}
]
}
}
}
}

where:

- "name": "<header-name>" is the name of the header to add to the request (or to change the value of). The name you specify is not case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists). For example, X-Api-Key.
- "values": ["<header-value>"] is the value of the new header (or the value to replace or append to an existing header's value, depending on the setting of "ifExists": "<OVERWRITE|APPEND|SKIP>"). The value you specify can be a simple string, or can include context variables enclosed within ${...} delimiters. For example, "values": "zyx987wvu654tsu321", "values": "${request.path[region]}", "values": "${request.headers[opc-request-id]}".

You can specify up to 10 values. If you specify multiple values, the API gateway adds a header for each value.
- "ifExists": "<OVERWRITE|APPEND|SKIP>" indicates what to do with the header's existing value if the header specified by "<header-name>" already exists:
  - Use OVERWRITE to replace the header's existing value with the value you specify.
  - Use APPEND to append the value you specify to the header's existing value.
  - Use SKIP to keep the header's existing value.

If not specified, the default is OVERWRITE.

You can add (or change the values of) up to 20 headers in a setHeaders header transformation request policy.

For example:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "headerTransformations": {
          "setHeaders": {
            "items": [
              {
                "name": "X-Api-Key",
                "values": ["zyx987wvu654tsu321"],
```

```text*Oracle Cloud Infrastructure User Guide 458*`
In this example, the API gateway adds the X-Api-Key: zyx987wvu654tsu321 header to all incoming requests. If an incoming request already has an X-Api-Key header set to a different value, the API gateway replaces the existing value with zyx987wvu654tsu321.

7. Save the JSON file containing the API deployment specification.
8. Use the API deployment specification when you create or update an API deployment in the following ways:

   • by specifying the JSON file in the Console when you select the Upload an existing API option
   • by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

9. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

Adding Query Parameter Transformation Request Policies

You can add query parameter transformation request policies to API deployment specifications using the Console or by editing a JSON file.

Using the Console to Add Query Parameter Transformation Request Policies

To add query parameter transformation request policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. Click Save Changes, and then click Next to enter details for individual routes in the API deployment on the Routes page.

3. On the Routes page, select the route for which you want to specify query parameter transformation request policies.

4. Click Show Route Request Policies.

5. Click the Add button beside Query Parameter Transformations to update the query parameters included in a request to the API gateway for the current route.

6. To limit the query parameters included in a request, specify:

   • Action: Filter.
   • Type: Either Block to remove from the request the query parameters you explicitly list, or Allow to only allow in the request the query parameters you explicitly list (any other query parameters are removed from the request).
   • Query Parameter Names: The list of query parameters to remove from the request or allow in the request (depending on the setting of Type). The names you specify are case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, User-Agent.
7. To change the name of a query parameter included in a request (whilst keeping its original value), specify:
   - **Action**: Rename.
   - **From**: The original name of the query parameter that you are renaming. The name you specify is case-sensitive, and must not be included in any other transformation request policies for the route. For example, `X-Username`.
   - **To**: The new name of the query parameter you are renaming. The name you specify is case-sensitive (capitalization is respected), and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, `X-User-ID`.

8. To add a new query parameter to a request (or to change or retain the values of an existing query parameter already included in a request), specify:
   - **Action**: Set.
   - **Behavior**: If the query parameter already exists, specify what to do with the query parameter's existing value:
     - **Overwrite**, to replace the query parameter's existing value with the value you specify.
     - **Append**, to append the value you specify to the query parameter's existing value.
     - **Skip**, to keep the query parameter's existing value.
   - **Query Parameter Name**: The name of the query parameter to add to the request (or to change the value of). The name you specify is case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items you filter as allowed). For example, `X-Api-Key`.
   - **Values**: The value of the new query parameter (or the value to replace or append to an existing query parameter's value, depending on the setting of **Behavior**). The value you specify can be a simple string, or can include context variables enclosed within `_${...}_` delimiters. For example, "value": "zyx987wvu654tsu321", "value": "${request.path[region]}", "value": "${request.headers[opc-request-id]}". You can specify multiple values.

9. Click **Save Changes**, and then click **Next** to review the details you entered for individual routes.

10. Click **Create** or **Save Changes** to create or update the API deployment.

11. (Optional) Confirm the API has been deployed successfully by calling it (see **Calling an API Deployed on an API Gateway** on page 384).

**Editing a JSON File to Add Query Parameter Transformation Request Policies**

To add query parameter transformation request policies to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add query parameter transformation request policies, or create a new API deployment specification (see **Creating an API Deployment Specification** on page 361).

   For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

   ```json
   {
      "routes": [
        {
          "path": "/hello",
          "methods": ["GET"],
          "backend": {
            "type": "ORACLE_FUNCTIONS_BACKEND",
            "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
          }
        }
      ]
   }
   ```

   2. Insert a **requestPolicies** section after the **backend** section for the route to which you want the query parameter transformation request policy to apply. For example:

   ```json
   {
   }
3. Add a `queryParameterTransformations` section to the `requestPolicies` section.

```
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "queryParameterTransformations": {}
      }
    }
  ]
}
```

4. To limit the query parameters included in a request, specify a `filterQueryParameters` query parameters transformation request policy:

```
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "queryParameterTransformations": {
          "filterQueryParameters": {
            "type": "<BLOCK|ALLOW>",
            "items": [
              { "name": "<query-parameter-name>" }
            ]
          }
        }
      }
    }
  ]
}
```
where:

- "type": "<BLOCK|ALLOW>" indicates what to do with the query parameters specified by "items":
  - Use BLOCK to remove from the request the query parameters you explicitly list.
  - Use ALLOW to only allow in the request the query parameters you explicitly list (any other query parameters are removed from the request).
- "name": "<query-parameter-name>" is a query parameter to remove from the request or allow in the request (depending on the setting of "type": "<BLOCK|ALLOW>"). The name you specify is case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists). For example, User-Agent.

You can remove and allow up to 50 query parameters in a filterQueryParameters query parameter transformation request policy.

For example:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.ocl.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "queryParameterTransformations": {
          "filterQueryParameters": {
            "type": "BLOCK",
            "items": [
              {
                "name": "User-Agent"
              }
            ]
          }
        }
      }
    }
  ]
}
```

In this example, the API gateway removes the User-Agent query parameter from all incoming requests.

5. To change the name of a query parameter included in a request (whilst keeping its original value), specify a renameQueryParameters query parameter transformation request policy:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.ocl.phx.aaaaaaaaab______xmq"
      },
      "requestPolicies": {
        "queryParameterTransformations": {
          "renameQueryParameters": {
            "name": "User-Agent",
            "items": [
              {
                "name": "New-Parameter-Name"
              }
            ]
          }
        }
      }
    }
  ]
}
```

In this example, the API gateway changes the name of the User-Agent query parameter to New-Parameter-Name.
API Gateway

```
{
    "from": "<original-name>",
    "to": "<new-name>
}
```

where:

- "from": "<original-name>" is the original name of the query parameter that you are renaming. The name you specify is case-sensitive, and must not be included in any other transformation request policies for the route. For example, X-Username.
- "to": "<new-name>" is the new name of the query parameter you are renaming. The name you specify is case-sensitive (capitalization is respected), and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists). For example, X-User-ID.

You can rename up to 20 query parameters in a renameQueryParameters query parameter transformation request policy.

For example:

```
{
    "routes": [ 
    {
        "path": "/hello",
        "methods": ["GET"],
        "backend": { 
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______.xmq"
        },
        "requestPolicies": { 
        "queryParameterTransformations": { 
        "renameQueryParameters": { 
        "items": [ 
        {
            "from": "X-Username",
            "to": "X-User-ID"
        ]
        ]
        }
        }
        }
    } 
    ]
}
```

In this example, the API gateway renames any X-Username query parameter to X-User-ID, whilst keeping the query parameter's original value.

6. To add a new query parameter to a request (or to change or retain the values of an existing query parameter already included in a request), specify a setQueryParameters query parameter transformation request policy:

```
{
    "routes": [ 
    {
        "path": "/hello",
        "methods": ["GET"],
```

Oracle Cloud Infrastructure User Guide 463
"backend": {
    "type": "ORACLE_FUNCTIONS_BACKEND",
    "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
},
"requestPolicies": {
    "queryParameterTransformations": {
        "setQueryParameters": {
            "items": [
                {
                    "name": "<query-parameter-name>",
                    "values": ["<query-parameter-value>"]
                }
            ]
        }
    }
}

where:

- "name": "<query-parameter-name>" is the name of the query parameter to add to the request (or to change the value of). The name you specify is case-sensitive, and must not be included in any other transformation request policies for the route (with the exception of items in ALLOW lists). For example, X-API-Key.
- "values": ["<query-parameter-value>"] is the value of the new query parameter (or the value to replace or append to an existing query parameter's value, depending on the setting of "ifExists": "<OVERWRITE|APPEND|SKIP>"). The value you specify can be a simple string, or can include context variables enclosed within ${...} delimiters. For example, "values": "zyx987wvu654tsu321", "values": "${request.path[region]}", "values": "${request.headers[opc-request-id]}".

You can specify up to 10 values. If you specify multiple values, the API gateway adds a query parameter for each value.

- "ifExists": "<OVERWRITE|APPEND|SKIP>" indicates what to do with the query parameter's existing value if the query parameter specified by <query-parameter-name> already exists:
  - Use OVERWRITE to replace the query parameter's existing value with the value you specify.
  - Use APPEND to append the value you specify to the query parameter's existing value.
  - Use SKIP to keep the query parameter's existing value.

If not specified, the default is OVERWRITE.

You can add (or change the values of) up to 20 query parameters in a setQueryParameters query parameter transformation request policy.

For example:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "requestPolicies": {
                "queryParameterTransformations": {
                    "setQueryParameters": {
                        "items": []
                    }
                }
            }
        }
    ]
}
```
In this example, the API gateway adds the X-Api-Key:zyx987wvu654tsu321 query parameter to all incoming requests. If an incoming request already has an X-Api-Key query parameter set to a different value, the API gateway replaces the existing value with zyx987wvu654tsu321.

7. Save the JSON file containing the API deployment specification.
8. Use the API deployment specification when you create or update an API deployment in the following ways:
   - by specifying the JSON file in the Console when you select the Upload an existing API option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.
9. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

Adding Header Transformation Response Policies

You can add header transformation response policies to API deployment specifications using the Console or by editing a JSON file.

Using the Console to Add Header Transformation Response Policies

To add header transformation response policies to an API deployment specification using the Console:

1. Create or update an API deployment using the Console, select the From Scratch option, and enter details on the Basic Information page.

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

2. Click Save Changes, and then click Next to enter details for individual routes in the API deployment on the Routes page.

3. On the Routes page, select the route for which you want to specify header transformation response policies.

4. Click Show Route Response Policies.

5. Click the Add button beside Header Transformations to update the headers included in a response from the API gateway for the current route.

6. To limit the headers included in a response, specify:
   - Action: Filter.
   - Type: Either Block to remove from the response the headers you explicitly list, or Allow to only allow in the response the headers you explicitly list (any other headers are removed from the response).
   - Header Names: The list of headers to remove from the response or allow in the response (depending on the setting of Type). The names you specify are not case-sensitive, and must not be included in any other transformation response policies for the route (with the exception of items you filter as allowed). For example, User-Agent.
7. To change the name of a header included in a response (whilst keeping its original value), specify:
   
   • **Action**: Rename.
   • **From**: The original name of the header that you are renaming. The name you specify is not case-sensitive, and must not be included in any other transformation response policies for the route. For example, X-Username.
   • **To**: The new name of the header you are renaming. The name you specify is not case-sensitive (capitalization might be ignored), and must not be included in any other transformation response policies for the route (with the exception of items in ALLOW lists). For example, X-User-ID.

8. To add a new header to a response (or to change or retain the values of an existing header already included in a response), specify:
   
   • **Action**: Set.
   • **Behavior**: If the header already exists, specify what to do with the header's existing value:
     • **Overwrite**, to replace the header's existing value with the value you specify.
     • **Append**, to append the value you specify to the header's existing value.
     • **Skip**, to keep the header's existing value.
   • **Name**: The name of the header to add to the response (or to change the value of). The name you specify is not case-sensitive, and must not be included in any other transformation response policies for the route (with the exception of items you filter as allowed). For example, X-Api-Key.
   • **Values**: The value of the new header (or the value to replace or append to an existing header's value, depending on the setting of **Behavior**). The value you specify can be a simple string, or can include context variables enclosed within ${...} delimiters. For example, "value": "zyx987wvu654tsu321". You can specify multiple values.

9. Click **Save Changes**, and then click **Next** to review the details you entered for individual routes.

10. Click **Create** or **Save Changes** to create or update the API deployment.

11. (Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).

**Editing a JSON File to Add Header Transformation Response Policies**

To add header transformation response policies to an API deployment specification in a JSON file:

1. Using your preferred JSON editor, edit the existing API deployment specification to which you want to add header transformation response policies, or create a new API deployment specification (see Creating an API Deployment Specification on page 361).

For example, the following basic API deployment specification defines a simple Hello World serverless function in Oracle Functions as a single back end:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.ocl.phx.aaaaaaaaab______xmq"
      }
    }
  ]
}
```

2. Insert a `responsePolicies` section after the `backend` section for the route to which you want the header transformation response policy to apply. For example:

```json
{
  "routes": [
    {
      "path": "/hello",
      "responsePolicies": {
        "headers": [
          {
            "headers": [
              {
                "name": "X-Api-Key",
                "values": "abc123",
                "behavior": "overwrite"
              }
            ]
          }
        ]
      }
    }
  ]
}
```
3. Add a `headerTransformations` section to the `responsePolicies` section.

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "responsePolicies": {
                "headerTransformations": {};
            }
        }
    ]
}
```

4. To limit the headers included in a response, specify a `filterHeaders` header transformation response policy:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "responsePolicies": {
                "headerTransformations": {
                    "filterHeaders": {
                        "type": "<BLOCK|ALLOW>",
                        "items": [
                            {
                                "name": "<header-name>"
                            }
                        ]
                    }
                }
            }
        }
    ]
}
```
where:

- "type": "<BLOCK|ALLOW>" indicates what to do with the headers specified by "items":
  
  - Use BLOCK to remove from the response the headers you explicitly list.
  - Use ALLOW to only allow in the response the headers you explicitly list (any other headers are removed from the response).
- "name": "<header-name>" is a header to remove from the response or allow in the response (depending on the setting of "type": "<BLOCK|ALLOW>"). The name you specify is not case-sensitive, and must not be included in any other transformation response policies for the route (with the exception of items in ALLOW lists). For example, User-Agent.

You can remove and allow up to 20 headers in a filterHeaders header transformation response policy.

For example:

```
{
   "routes": [
   {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
         "type": "ORACLE_FUNCTIONS_BACKEND",
         "functionId": "ocid1.fnfunc.ocl.phx.aaaaaaaaab______xmq"
      },
      "responsePolicies": {
         "headerTransformations": {
            "filterHeaders": {
               "type": "BLOCK",
               "items": [
               {
                  "name": "User-Agent"
               }
               ]
            }
         }
      }
   }
   ]
}
```

In this example, the API gateway removes the User-Agent header from all outgoing responses.

5. To change the name of a header included in a response (whilst keeping its original value), specify a renameHeaders header transformation response policy:

```
{
   "routes": [
   {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
         "type": "ORACLE_FUNCTIONS_BACKEND",
         "functionId": "ocid1.fnfunc.ocl.phx.aaaaaaaaab______xmq"
      },
      "responsePolicies": {
         "headerTransformations": {
            "renameHeaders": {
               "items": [
               
```

Oracle Cloud Infrastructure User Guide
API Gateway

where:

- "from": "<original-name>" is the original name of the header that you are renaming. The name you specify is not case-sensitive, and must not be included in any other transformation response policies for the route. For example, X-Username.

- "to": "<new-name>" is the new name of the header you are renaming. The name you specify is not case-sensitive (capitalization might be ignored), and must not be included in any other transformation response policies for the route (with the exception of items in ALLOW lists). For example, X-User-ID.

You can rename up to 20 headers in a renameHeaders header transformation response policy.

For example:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "responsePolicies": {
        "headerTransformations": {
          "renameHeaders": {
            "items": [
              {
                "from": "X-Username",
                "to": "X-User-ID"
              }
            ]
          }
        }
      }
    }
  ]
}
```

In this example, the API gateway renames any X-Username header to X-User-ID, whilst keeping the header's original value.

6. To add a new header to a response (or to change or retain the values of an existing header already included in a response), specify a setHeaders header transformation response policy:

```json
{
  "routes": [
    {
      "path": "/hello",
      "methods": ["GET"],
      "backend": {
        "type": "ORACLE_FUNCTIONS_BACKEND",
        "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
      },
      "responsePolicies": {
        "headerTransformations": {
          "setHeaders": {
            "items": [
              {
                "name": "User-Id",
                "value": "123456"
              }
            ]
          }
        }
      }
    }
  ]
}
```
where:

- "name": "<header-name>" is the name of the header to add to the response (or to change the value of). The name you specify is not case-sensitive, and must not be included in any other transformation response policies for the route (with the exception of items in ALLOW lists). For example, X-API-Key.
- "values": ["<header-value>"] is the value of the new header (or the value to replace or append to an existing header's value, depending on the setting of "ifExists": "<OVERWRITE|APPEND|SKIP>"). The value you specify can be a simple string, or can include context variables enclosed within ${...} delimiters. For example, "values": "zyx987wvu654tsu321".

You can specify up to 10 values. If you specify multiple values, the API gateway adds a header for each value.
- "ifExists": "<OVERWRITE|APPEND|SKIP>" indicates what to do with the header's existing value if the header specified by <header-name> already exists:
  - Use OVERWRITE to replace the header's existing value with the value you specify.
  - Use APPEND to append the value you specify to the header's existing value.
  - Use SKIP to keep the header's existing value.

If not specified, the default is OVERWRITE.

You can add (or change the values of) up to 20 headers in a setHeaders header transformation response policy. For example:

```json
{
    "routes": [
        {
            "path": "/hello",
            "methods": ["GET"],
            "backend": {
                "type": "ORACLE_FUNCTIONS_BACKEND",
                "functionId": "ocid1.fnfunc.oc1.phx.aaaaaaaaab______xmq"
            },
            "responsePolicies": {
                "headerTransformations": {
                    "setHeaders": {
                        "items": [
                            {
                                "name": "X-API-Key",
                                "values": ["zyx987wvu654tsu321"],
                                "ifExists": "OVERWRITE"
                            }
                        ]
                    }
                }
            }
        }
    ]
}
```
In this example, the API gateway adds the `X-API-Key:zyx987wvu654tsu321` header to all outgoing responses. If an outgoing response already has an `X-API-Key` header set to a different value, the API gateway replaces the existing value with `zyx987wvu654tsu321`.

7. Save the JSON file containing the API deployment specification.

8. Use the API deployment specification when you create or update an API deployment in the following ways:

   - by specifying the JSON file in the Console when you select the **Upload an existing API** option
   - by specifying the JSON file in a request to the API Gateway REST API

   For more information, see Deploying an API on an API Gateway by Creating an API Deployment on page 363 and Updating API Gateways and API Deployments on page 387.

9. **(Optional) Confirm the API has been deployed successfully by calling it (see Calling an API Deployed on an API Gateway on page 384).**

### Examples

The examples in this section assume the following API deployment definition and basic API deployment specification in a JSON file:

```json
{
    "displayName": "Marketing Deployment",
    "gatewayId": "ocid1.apigateway.oc1..aaaaaaaab______hga",
    "compartmentId": "ocid1.compartment.oc1..aaaaaaaa7______ysq",
    "pathPrefix": "/marketing",
    "specification": {
        "routes": [
            {
                "path": "/weather",
                "methods": ["GET"],
                "backend": {
                    "type": "HTTP_BACKEND",
                    "url": "https://api.weather.gov"
                },
                "requestPolicies": {}
            }
        ],
        "freeformTags": {},
        "definedTags": {}
    }
}
```

Note the examples also apply when you're defining an API deployment specification using dialogs in the Console.

**Example 1: Transforming header parameters to query parameters**

In this example, assume an existing HTTP back end only handles requests containing query parameters, not header parameters. However, you want the HTTP back end to handle requests that include header parameters. To achieve this, you create an API deployment specification that includes a query parameter transformation request policy to pass the value obtained from a request header to the HTTP back end as a query parameter.

```json
"requestPolicies": {
    "queryParameterTransformations": {
        "setQueryParameters": {
            "items": [
                {
                    "name": "region",
                    "transform": "header/region",
                    "default": "default" // Optional default value
                }
            ]
        }
    }
}
```
In this example, a request like `curl -H "region: west" https://<gateway-hostname>/marketing/weather` resolves to `https://api.weather.gov?region=west`.

**Example 2: Transforming one header to a different header**

In this example, assume an existing HTTP back end only handles requests containing a particular header. However, you want the HTTP back end to handle requests that include a different header. To achieve this, you create an API deployment specification that includes a header transformation request policy to take the value obtained from one request header and pass it to the HTTP back end as a different request header.

```
"requestPolicies": { 
  "headerTransformations": { 
    "setHeaders": { 
      "items": [ 
        { 
          "name": "region",
          "values": ["${request.headers[locale]}"],
          "ifExists": "OVERWRITE"
        }
      ]
    }
  }
}
```

In this example, a request like `curl -H "locale: west" https://<gateway-hostname>/marketing/weather` resolves to the request `curl -H "region: west" https://api.weather.gov`.

**Example 3: Adding an authentication parameter obtained from a JWT as a request header**

In this example, assume an existing HTTP back end requires the value of the sub claim in a validated JSON Web Token (JWT) to be included in a request as a header with the name JWT_SUBJECT. The API Gateway service has saved the value of the sub claim included in the JWT as an authentication parameter in the request.auth table.

To include the value of sub in a header named JWT_SUBJECT, you create an API deployment specification that includes a header transformation request policy. The request policy obtains the sub value from the request.auth table and passes it to the HTTP back end as the value of the JWT_SUBJECT header.

```
"requestPolicies": { 
  "headerTransformations": { 
    "setHeaders": { 
      "items": [ 
        { 
          "name": "JWT_SUBJECT",
          "values": ["${request.auth[sub]}"],
          "ifExists": "OVERWRITE"
        }
      ]
    }
  }
}
```
In this example, when a request has been successfully validated, the JWT_SUBJECT header is added to the request passed to the HTTP back end.

**Example 4: Adding a key obtained from an authorizer function as a query parameter**

In this example, assume an existing HTTP back end requires requests to include a query parameter named access_key for authentication purposes. You want the access_key query parameter to have the value of a key named apiKey that has been returned by an authorizer function that has successfully validated the request. The API Gateway service has saved the apiKey value as an authentication parameter in the request.auth table.

To include the access_key query parameter in the request, you create an API deployment specification that includes a query parameter transformation request policy. The request policy obtains the apiKey value from the request.auth table and passes it to the HTTP back end as the value of the access_key query parameter.

```json
"requestPolicies": {
  "queryParameterTransformations": {
    "setQueryParameters": {
      "items": [
        {
          "name": "access_key",
          "values": ["${request.auth[apiKey]}"],
          "ifExists": "OVERWRITE"
        }
      ]
    }
  }
}
```

In this example, the access_key query parameter is added to the request passed to the HTTP back end, with the apiKey value from the request.auth table. A request like `https://<gateway-hostname>/marketing/weather` resolves to a request like `https://api.weather.gov?access_key=fw5n9abi0ep`

**Example 5: Adding a default value for an optional query parameter**

In this example, assume an existing HTTP back end requires requests to include a query parameter named country. However, the country query parameter is optional, and it’s not included by some of the API clients sending requests. If a request already includes a country query parameter and a value, you want both passed as-is to the HTTP back end. However, if a request doesn’t already include a country query parameter, you want the country query parameter and a default value added to the request.

To make sure every request includes a country query parameter, you create an API deployment specification that includes a query parameter transformation request policy. The request policy adds the country query parameter and a default value to any requests that do not already include the country query parameter.

```json
"requestPolicies": {
  "queryParameterTransformations": {
    "setQueryParameters": {
      "items": [
        {
          "name": "country",
          "values": ["usa"],
          "ifExists": "SKIP"
        }
      ]
    }
  }
}
```

Troubleshooting API Gateway

This topic covers common issues related to the API Gateway service and how you can address them.

Creating a new API gateway stalls with a state of Creating, or fails

It can take a few minutes to create a new API gateway. While it is being created, the API gateway is shown with a state of Creating on the Gateways page. When it has been created successfully, the new API gateway is shown with a state of Active.

If you have waited more than a few minutes for the API gateway to be shown with an Active state (or if the API gateway creation operation has failed):

1. Click the name of the API gateway, and click Work Requests to see an overview of the API gateway creation operation.
2. Click the Create Gateway operation to see more information about the operation (including error messages, log messages, and the status of associated resources) that will help to diagnose the cause of the problem.

Creating a new API deployment stalls with a state of Creating, or fails

It can take a few minutes to create a new API deployment. While it is being created, the API deployment is shown with a state of Creating on the Gateway Details page. When it has been created successfully, the new API deployment is shown with a state of Active.

If you have waited more than a few minutes for the API deployment to be shown with an Active state (or if the API deployment creation operation has failed):

1. Click the name of the API deployment, and click Work Requests to see an overview of the API deployment creation operation.
2. Click the Create Deployment operation to see more information about the operation (including error messages, log messages, and the status of associated resources) that will help to diagnose the cause of the problem.

Creating a new API gateway returns a "VNIC attachment failed due to the limit for number of private IP addresses for this subnet" message

When creating a new API gateway, you might see the following message:

```
VNIC attachment failed due to the limit for number of private IP addresses for this subnet
```

This message indicates that there are not enough private IP addresses available to create the API gateway in the specified subnet. An API gateway consumes three private IP addresses in the subnet.

To address this issue, use a subnet that has at least three available private IP addresses.

Creating a new API gateway returns a "The limit for number of private IP addresses for this subnet has been exceeded" message

When creating a new API gateway, you might see the following message:

```
The limit for number of private IP addresses for this subnet has been exceeded
```

This message indicates that there are not enough private IP addresses available to create the API gateway in the specified subnet. An API gateway consumes three private IP addresses in the subnet.
To address this issue, use a subnet that has at least three available private IP addresses.

**Creating a new public API gateway returns a "The limit for number of public IP addresses for this compartment has been exceeded" message**

When creating a new public API gateway, you might see the following message:

```
The limit for number of public IP addresses for this compartment has been exceeded
```

This message indicates that there are not enough public IP addresses available to create the public API gateway in the specified subnet's compartment. When creating a new public API gateway, an attempt is made to create a new public IP address in the subnet's compartment. The attempt to create the new public IP address fails if the quota for public IP addresses is exceeded in that compartment or tenancy. Note the public IP address is in addition to the three private IP addresses consumed by all API gateways.

To address this issue:

- If the compartment's quota is exceeded, contact your tenancy administrator to request additional public IP addresses for the compartment.
- If the tenancy's quota is exceeded, contact Oracle Support to request an increase to the tenancy's quota.

**Creating a new API gateway returns a "Work request was cancelled" message**

When creating a new API gateway, you might see the following message:

```
Work request was cancelled
```

This message indicates that you cancelled the work request to create the API gateway. The API gateway is shown with a status of Failed.

**Creating a new API gateway returns a "An unexpected error occurred. Contact Oracle Support for assistance" message**

When creating a new API gateway, you might see the following message:

```
An unexpected error occurred. Contact Oracle Support for assistance.
```

To address this issue, contact Oracle Support to request assistance.

**Creating a new API gateway returns an "Unknown resource <subnet-ocid>, make sure subnet exists,..." message and a 400 error**

When creating a new API gateway using the Console, API, SDK, or CLI, you might see the following error message and a 400 error code:

```
Unknown resource <subnet-ocid>, make sure subnet exists, the user can access the subnet and it is in the same region where the gateway will be created
```

This message indicates that the API Gateway service cannot access the subnet specified for the new API gateway.

To address this issue, double-check that:

- The subnet exists.
- You can access the subnet.
- The subnet is in the same region in which the API gateway will be created.
**API Gateway Internal Limits**

This topic describes various internal limits enforced by the API Gateway service, their default values, and whether you can change them.

**API Gateway Resource Limits**

This table describes internal limits enforced by the API Gateway service on API gateway resources.

<table>
<thead>
<tr>
<th>Limit</th>
<th>Description</th>
<th>Default Limit Value</th>
<th>Can you change it?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of API gateways</td>
<td>Maximum number of active API gateways per tenant.</td>
<td>10</td>
<td>Yes, contact us.</td>
</tr>
</tbody>
</table>

**API Deployment Resource Limits**

This table describes internal limits enforced by the API Gateway service on API deployment resources.

<table>
<thead>
<tr>
<th>Limit</th>
<th>Description</th>
<th>Default Limit Value</th>
<th>Can you change it?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of API deployments</td>
<td>Maximum number of active API deployments per gateway.</td>
<td>20</td>
<td>Yes, contact us.</td>
</tr>
<tr>
<td>Number of routes per API deployment</td>
<td>Maximum number of routes defined inside the API deployment specification.</td>
<td>50</td>
<td>Yes, contact us.</td>
</tr>
<tr>
<td>Path prefix length</td>
<td>Maximum length of path for API deployment.</td>
<td>2,000 characters</td>
<td>No</td>
</tr>
<tr>
<td>Route pattern length</td>
<td>Maximum length of path for a route in an API deployment.</td>
<td>2,000 characters</td>
<td>No</td>
</tr>
<tr>
<td>API deployment specification Size</td>
<td>Maximum length of json encoded API deployment specification in bytes.</td>
<td>1,000,000 bytes</td>
<td>No</td>
</tr>
<tr>
<td>Stock Response - header length</td>
<td>Maximum length of UTF-8 encoded json of stock response headers.</td>
<td>4096 bytes</td>
<td>No</td>
</tr>
<tr>
<td>Stock Response - header name length</td>
<td>Maximum length of a stock response header name.</td>
<td>1024 bytes</td>
<td>No</td>
</tr>
<tr>

</tr>
<tr>
<td>HTTP back end latency</td>
<td>Maximum duration of a full request to an HTTP back end.</td>
<td>300 seconds</td>
<td>No</td>
</tr>
</tbody>
</table>

API Gateway Metrics

You can monitor the health, capacity, and performance of API gateways and API deployments managed by the API Gateway service using metrics, alarms, and notifications.

This topic describes the metrics emitted by the API Gateway service in the oci_apigateway metric namespace.

Resources: gateways

Overview of the API Gateway Service Metrics

The API Gateway service metrics help you measure the connections to API gateways, and the quantity of data received and sent by API gateways. You can use metrics data to diagnose and troubleshoot API gateway and API deployment issues.

To view a default set of metrics charts in the Console, navigate to the API gateway you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
Available Metrics: oci_apigateway

The metrics listed in the following tables are automatically available for any API gateways you create. You do not need to enable monitoring on the resource to get these metrics.

API Gateway metrics include the following dimensions:

**RESOURCEID**

The *OCID* of the API gateway.

**DEPLOYMENTID**

The *OCID* of the API deployment.

**ROUTE**

The route path for API calls to the back-end service.

**HTTPMETHODTYPE**

The HTTP methods of incoming connections accepted by the back-end service (such as GET, HEAD, POST, PUT, DELETE).

**HTTPSTATUSCODE**

The HTTP response status code received from the API gateway (such as 200, 201, 502, 504).

**HTTPSTATUSCATEGORY**

The category of the HTTP response status code received from the API gateway (such as 2xx, 3xx, 4xx, 5xx).

**BACKENDTYPE**

The type of back end by which an API gateway routes requests to a back-end service (such as HTTP_BACKEND, ORACLE_FUNCTIONS_BACKEND, STOCK_RESPONSE_BACKEND).

**BACKENDHTTPSTATUSCODE**

The HTTP response status code received from the back end (such as 200, 201, 502, 504).

**BACKENDHTTPSTATUSCATEGORY**

The category of the HTTP response status code received from the back end (such as 2xx, 3xx, 4xx, 5xx).

<table>

<tr>
<td>--------------------</td>
<td>---------------------</td>
<td>--------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Latency</td>
<td>Gateway Latency</td>
<td>Seconds</td>
<td>Average time that it takes for a request to be processed and its response to be sent. This is calculated from the time the API gateway receives the first byte of an HTTP request to the time when the response send operation is completed.</td>
</tr>
<tr>
<td>IntegrationLatency</td>
<td>Backend Latency</td>
<td>Seconds</td>
<td>Time between the API gateway sending a request to the back-end service and receiving a response from the back-end service.</td>
</tr>
<tr>
<td>InternalLatency</td>
<td>Internal Latency</td>
<td>Seconds</td>
<td>Time spent internally in the API gateway to process the request.</td>
</tr>
</tbody>
</table>

**Using the Console**

To view default metric charts for a single API gateway

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click API Gateway.
2. Select the region you are using with API Gateway.
3. Select the compartment containing the API gateway for which you want to view metrics.
   
   The Gateways page shows all the API gateways in the compartment you selected.
4. Click the name of the API gateway for which you want to view metrics.
5. Under Resources, click Metrics.
   
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for API Gateway. For more information about the emitted metrics, see Available Metrics: oci_apigateway on page 479.

   For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.
**Not seeing the API gateway metrics data you expect?**

If you don't see the metrics data for an API gateway that you expect, see the following possible causes and resolutions.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>I called an API deployed on an API gateway but the HTTP Requests chart doesn't show the API call.</td>
<td>You might have called the API outside the time period covered by the HTTP Requests chart.</td>
<td>Confirm the Start Time and End Time cover the period when you called the API.</td>
<td>Adjust the Start Time and End Time as necessary.</td>
</tr>
<tr>
<td>I called an API deployed on an API gateway but the HTTP Requests chart doesn't show the API call, even</td>
<td>Although you called the API between the Start Time and End Time, the x-axis (window of data display)</td>
<td>Confirm the x-axis (window of data display) covers the period when the API was called.</td>
<td>Adjust the x-axis (window of data display) as necessary.</td>
</tr>
<tr>
<td>though I called the API between the Start Time and End Time.</td>
<td>might be excluding the API call.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>This is expected behavior. If there is no metrics data to show in the selected interval, the data line is discontinuous.</td>
<td>Increase the Interval (for example, from 1 minute to 5 minutes, or from 1 minute to 1 hour).</td>
<td>Adjust the Interval as necessary.</td>
</tr>
</tbody>
</table>

**To view default metric charts for all the API gateways in a compartment**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Select the region you are using with API Gateway
3. Select the compartment containing the API gateways for which you want to view metrics.
4. For Metric Namespace, select oci_apigateway.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace. For more information about the emitted metrics, see Available Metrics: oci_apigateway on page 479.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 7

Archive Storage

This chapter explains how to upload, manage, and access data using Archive Storage.

Overview of Archive Storage

The Archive Storage service is ideal for storing data that is seldom accessed, but requires long retention periods. Archive Storage is more cost effective than Object Storage for preserving cold data. Unlike Object Storage, Archive Storage data retrieval is not instantaneous.

Oracle Cloud Infrastructure supports multiple storage tiers that offer cost and performance flexibility. Archive is the default storage tier for Archive Storage buckets.

Archive Storage is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

Using Archive Storage

Important:

You interact with the data stored in the Archive Storage using the same resources and management interfaces that you use for data stored in Object Storage. All Object Storage features are also supported in Archive Storage.

Use the following Object Storage resources to store and manage Archive Storage data.

Buckets

Buckets are logical containers for storing objects. A bucket is associated with a single compartment that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

When you initially create the bucket container for your data, you decide which default storage tier (Archive or Standard) is appropriate for your data. The default tier is automatically selected when you upload objects to the bucket, but you can instead select a different tier. Also, if objects meet the criteria of an object lifecycle policy rule, Object Storage can automatically move objects to Archive, while remaining in the Standard tier bucket.

Once set, you cannot change the default storage tier property for a bucket:

• An existing Standard tier bucket cannot be changed to an Archive tier bucket.
• An existing Archive tier bucket cannot be changed to a Standard tier bucket.

In addition to the inability to change the default storage tier designation of a bucket, there are other reasons why storage tier selection for buckets requires careful consideration:

• The minimum storage retention period for the Archive tier is 90 days. If you delete or overwrite objects from the Archive tier before the minimum retention requirements are met, you are charged the prorated cost of storing the data for the full 90 days.
• When you restore objects, you are returning those objects to the Standard tier for access. You are billed for the Standard class tier while the restored objects reside in that tier.
You can use object lifecycle policy rules to automatically delete objects in an Archive Storage bucket based on the age of the object. You cannot, however, use object lifecycle policy rules to automatically restore archived objects to the Standard tier. See Restoring and Downloading Objects for information on restoring objects.

See Managing Buckets on page 3398 for detailed instructions on creating an Archive Storage bucket.

## Objects

Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

You upload objects to an Archive Storage bucket the same way you upload objects to a standard Object Storage bucket. The difference is that when you upload an object to an Archive Storage bucket, the object is immediately archived. You must first restore the object before you can download it.

Archived objects are displayed in the object listing of a bucket. You can also display the details of each object. See Managing Objects on page 3419 for detailed instructions on uploading objects to an Archive Storage bucket.

## Restoring and Downloading Objects

To download an object from Archive Storage, you must first restore the object. Restoration takes at most an hour from the time an Archive Storage restore request is made, to the time the first byte of data is retrieved. The retrieval time metric is measured as Time To First Byte (TTFB). How long the full restoration takes, depends on the size of the object. You can determine the status of the restoration by looking at the object Details. Once the status shows as Restored, you can then download the object.

After an object is restored, you have a window of time to download the object. By default, you have 24 hours to download an object, but you can alternatively specify a time from 1 to 240 hours. You can find out how much of the download time is remaining by looking at Available for Download in object Details. After the allotted download time expires, the object returns to Archive Storage. You can always access the metadata for an object, regardless of whether the object is in an archived or restored state.

See Managing Objects on page 3419 for detailed instructions on restoring, checking status of, and downloading Archive Storage objects.

## Ways to Access Archive Storage

Archive Storage and Object Storage use the same management interfaces:

- The Console is an easy-to-use, browser-based interface. To access Archive Storage in the console, do the following:
  - Sign in to the Console.
  - Open the navigation menu. Under Core Infrastructure, click Object Storage. A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
  - Click the name of the Archive Storage tier bucket you want to manage.
- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Command Line Interface (CLI) on page 4192.
- The REST API provides the most functionality, but requires programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs on page 4368. Object Storage is accessible with the following APIs:
  - Object Storage Service
  - Amazon S3 Compatibility API
  - Swift API (for use with Oracle RMAN)
• Oracle Cloud Infrastructure provides SDKs that interact with Archive Storage and Object Storage without you having to create a framework. For general information about using the SDKs, see Software Development Kits and Command Line Interface on page 4225.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API). IAM also manages user credentials for things like API signing keys, auth tokens, and customer secret keys for Amazon S3 Compatibility API. See User Credentials on page 2360 for details.

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control things like who can create users, create and manage the cloud network, launch instances, create buckets, and download objects. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see the Policy Reference on page 2167. For specific details about writing policies for Archive Storage, see Details for Object Storage, Archive Storage, and Data Transfer on page 2324.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators:

• The policy Let Object Storage admins manage buckets and objects on page 2149 lets the specified group do everything with buckets and objects.
• Users that need to restore archived objects require the OBJECT_RESTORE permission.

WORM Compliance

Use retention rules to achieve WORM compliance with Archive Storage so that after the data is written, the data cannot be overwitten. Retention rules are configured at the bucket level and are applied to all individual objects in the bucket. You cannot update, overwrite, or delete objects or object metadata until the retention rule is deleted (indefinite rule) or for the duration specified (time-bound rules). You can, however, always restore an object from Archive Storage.

For more information, see Using Retention Rules to Preserve Data on page 3458.

Limits on Archive Storage Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

• Number of namespaces per root compartment: 1
• Maximum object size: 10 TiB
• Maximum object part size in a multipart upload: 50 GiB
• Maximum number of parts in a multipart upload: 10,000
• Maximum object size allowed by PutObject API: 50 GiB
• Maximum size of object metadata: 2 K
Chapter 8

Audit

This chapter explains how to work with audit logs.

Overview of Audit

The Oracle Cloud Infrastructure Audit service automatically records calls to all supported Oracle Cloud Infrastructure public application programming interface (API) endpoints as log events. Currently, all services support logging by Audit. Object Storage service supports logging for bucket-related events, but not for object-related events. Log events recorded by the Audit service include API calls made by the Oracle Cloud Infrastructure Console, Command Line Interface (CLI), Software Development Kits (SDK), your own custom clients, or other Oracle Cloud Infrastructure services. Information in the logs includes the following:

• Time the API activity occurred
• Source of the activity
• Target of the activity
• Type of action
• Type of response

Each log event includes a header ID, target resources, timestamp of the recorded event, request parameters, and response parameters. You can view events logged by the Audit service by using the Console, API, or the SDK for Java. Data from events can be used to perform diagnostics, track resource usage, monitor compliance, and collect security-related events.

Version 2 Audit Log Schema

On October 8, 2019, Oracle introduced the Audit version 2 schema, which provides the following benefits:

• Captures state changes of resources
• Better tracking of long running APIs
• Provides troubleshooting information in logs

The new schema is being implemented over time. Oracle continues to provide Audit logs in the version 1 format, but you cannot access version 1 format logs from the Console. The Console displays only the version 2 format logs. However, not all resources are emitting logs using the version 2 schema. For those services that are not emitting in the version 2 format, Oracle converts version 1 logs to version 2 logs, leaving fields blank if information for the version 2 schema cannot be determined.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:
Audit

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For an example of policy that gives groups access to audit logs, see Required IAM Policy on page 494. To modify the Audit log retention period, you must be a member of the Administrators group. See The Administrators Group and Policy on page 2125.

Contents of an Audit Log Event

The following explains the contents of an Audit log event. Every audit log event includes two main parts:

- Envelopes that act as a container for all event messages
- Payloads that contain data from the resource emitting the event message

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloudEventsVersion</td>
<td>The version of the CloudEvents specification.</td>
</tr>
<tr>
<td>contentType</td>
<td>Set to application/json. The content type of the data contained in the data attribute.</td>
</tr>
<tr>
<td>data</td>
<td>The payload of the event. Information within data comes from the resource emitting the event.</td>
</tr>
<tr>
<td>eventID</td>
<td>The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.</td>
</tr>
</tbody>
</table>
### Audit

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>eventTime</strong></td>
<td>The time of the event, expressed in RFC 3339 timestamp format.</td>
</tr>
<tr>
<td><strong>eventType</strong></td>
<td>The type of event that happened.</td>
</tr>
<tr>
<td><strong>eventTypeVersion</strong></td>
<td>The version of the event type. This version applies to the payload of the event, not the envelope. Use cloudEventsVersion to determine the version of the envelope.</td>
</tr>
<tr>
<td><strong>source</strong></td>
<td>The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.</td>
</tr>
</tbody>
</table>

#### Payload

The data in these fields depends on which service produced the event log and the event type it defines.

#### Data

The data object contains the following attributes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.additionalDetails</td>
<td>A container object for attributes unique to the resource emitting the event.</td>
</tr>
<tr>
<td>data.availabilityDomain</td>
<td>The availability domain where the resource resides.</td>
</tr>
<tr>
<td>data.compartmentId</td>
<td>The OCID of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>data.compartmentName</td>
<td>The name of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>data.definedTags</td>
<td>Defined tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>data.eventGroupingId</td>
<td>This value links multiple audit events that are part of the same API operation. For example, a long running API operation that emits an event at the start and the end of the operation.</td>
</tr>
<tr>
<td>data.eventName</td>
<td>Name of the API operation that generated this event. Example: LaunchInstance</td>
</tr>
<tr>
<td>data.freeformTags</td>
<td>Free-form tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>data.identity</td>
<td>A container object for identity attributes. See Identity.</td>
</tr>
</tbody>
</table>
### Audit

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.request</td>
<td>A container object for request attributes. See Request.</td>
</tr>
<tr>
<td>data.resourceId</td>
<td>An OCID or an ID for the resource emitting the event.</td>
</tr>
<tr>
<td>data.resourceName</td>
<td>The name of the resource emitting the event.</td>
</tr>
<tr>
<td>data.response</td>
<td>A container object for response attributes. See Response.</td>
</tr>
<tr>
<td>data.stateChange</td>
<td>A container object for state change attributes. See State Change.</td>
</tr>
</tbody>
</table>

### Identity

The identity object contains the following attributes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.identity.authType</td>
<td>The type of authentication used.</td>
</tr>
<tr>
<td>data.identity.callerId</td>
<td>The OCID of the caller. The caller that made a request on behalf of the principal.</td>
</tr>
<tr>
<td>data.identity.callerName</td>
<td>The name of the user or service issuing the request. This value is the friendly name associated with callerId.</td>
</tr>
<tr>
<td>data.identity.consoleSessionId</td>
<td>This value identifies any Console session associated with this request.</td>
</tr>
<tr>
<td>data.identity.credentials</td>
<td>The credential ID of the user.</td>
</tr>
<tr>
<td>data.identity.ipAddress</td>
<td>The IP address of the source of the request.</td>
</tr>
<tr>
<td>data.identity.principalId</td>
<td>The OCID of the principal.</td>
</tr>
<tr>
<td>data.identity.principalName</td>
<td>The name of the user or service. This value is the friendly name associated with principalId.</td>
</tr>
<tr>
<td>data.identity.tenantId</td>
<td>The OCID of the tenant.</td>
</tr>
<tr>
<td>data.identity.userAgent</td>
<td>The user agent of the client that made the request.</td>
</tr>
</tbody>
</table>

### Request

The request object contains the following attributes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.request.action</td>
<td>The HTTP method of the request.</td>
</tr>
<tr>
<td></td>
<td>Example: GET</td>
</tr>
<tr>
<td>data.request.headers</td>
<td>The HTTP header fields and values in the request.</td>
</tr>
<tr>
<td>data.request.id</td>
<td>The unique identifier of a request.</td>
</tr>
<tr>
<td>data.request.parameters</td>
<td>All the parameters supplied by the caller during this operation.</td>
</tr>
<tr>
<td>data.request.path</td>
<td>The full path of the API request.</td>
</tr>
<tr>
<td></td>
<td>Example: /20160918/instances/ocid1.instance.ocl.phx.&lt;unique_ID&gt;</td>
</tr>
</tbody>
</table>
Response

The response object contains the following attributes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.response.headers</td>
<td>The headers of the response.</td>
</tr>
<tr>
<td>data.response.message</td>
<td>A friendly description of what happened during the operation.</td>
</tr>
<tr>
<td>data.response.payload</td>
<td>This value is included for backward compatibility with the Audit version 1 schema, where it contained metadata of interest from the response payload.</td>
</tr>
<tr>
<td>data.response.responseTime</td>
<td>The time of the response to the audited request, expressed in RFC 3339 timestamp format.</td>
</tr>
<tr>
<td>data.response.status</td>
<td>The status code of the response.</td>
</tr>
</tbody>
</table>

State Change

The state change object contains the following attributes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.stateChange.current</td>
<td>Provides the current state of fields that may have changed during an operation. To determine how the current operation changed a resource, compare the information in this attribute to data.stateChange.previous.</td>
</tr>
<tr>

An Example Audit Log

The following is an example an event recorded by the Audit service.

```json
{
    "eventType": "com.oraclecloud.ComputeApi.GetInstance",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventId": "<unique_ID>",
    "eventTime": "2019-09-18T00:10:59.252Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": null,
        "eventName": "GetInstance",
        "compartmentId": "ocid1.tenancy.oc1..<unique_ID>",
        "compartmentName": "compartmentA",
        "resourceName": "my_instance",
        "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeformTags": null,
        "definedTags": null,
        "identity": {
            "principalName": "ExampleName",
            "principalId": "ocid1.user.oc1..<unique_ID>",
            "authType": "natv",
            "callerName": null,
```
Viewing Audit Log Events

Audit provides records of API operations performed against supported services as a list of log events. The service logs events at both the tenant and compartment level.

When viewing events logged by Audit, you might be interested in specific activities that happened in the tenancy or compartment and who was responsible for the activity. You will need to know that the approximate time and date something happened and the compartment in which it happened to display a list of log events that includes the activity in question. List log events by specifying a time range on the 24-hour clock in Greenwich Mean Time (GMT), calculating the offset for your local time zone, as appropriate. New activity is appended to the existing list, usually within 15 minutes of the API call, though processing time can vary.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.
Audit

For administrators: The following policy statement gives the specified group (Auditors) the ability to view all the Audit event logs in the tenancy:

Allow group Auditors to read audit-events in tenancy

To give the group access to the Audit event logs in a specific compartment only (ProjectA), write a policy like the following:

Allow group Auditors to read audit-events in compartment ProjectA

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more details about policies for the Audit, see Details for the Audit Service on page 2177.

Searching and Filtering in the Console

When you navigate to Audit in the Console, a list of results is generated for the current compartment. Audit logs are organized by compartment, so if you are looking for a particular event, you must know which compartment the event occurred in. You can filter the list in all the following ways:

- Date and time
- Request Action Types (operations)
- Keywords

For example, users begin to report that their attempts to log in are failing. You want to use Audit to research the problem. Adjust the date and time to search for corresponding failures during a window of time that starts a little before the events were reported. Look for corresponding failures and similar operations preceding the failures to correlate a reason for the failures.

Note:
The service logs events at the time they are processed. There can be a delay between the time an operation occurs and when it is processed.

You can filter results by request actions to zero in on only the events with operations that interest you. For example, say that you only want to know about instances that were deleted during a specific time frame. Select a delete request action filter to see only the events with delete operations.

You can also filter by keywords. Keyword filters are powerful when combined with the values from audit event fields. For example, say that you know the user name of an account and want a list of all activity by that account in a particular time frame. Do a search using the user name as a keyword filter.

Every audit event contains the same fields, so search for values from those fields. To get a better understanding of what values are available, see Contents of an Audit Log Event on page 489.

Using the Console

To search log events

1. Open the navigation menu. Under Governance and Administration, go to Governance and click Audit.
   The list of events that occurred in the current compartment is displayed.

2. Click one of the compartments under Compartment.
   Audit organizes logs by compartment, so if you are looking for a particular event, you must know which compartment the event occurred in.

3. Click in the Start Date box to choose the start date and time for the range of results you want to see. You can click the arrows on either side of the month to go backward or forward.
4. (Optional) Specify a time by doing one of the following:
   a. Click Time and specify an exact start time in thirty-minute increments.
   b. Type an exact time in the Start Date box.

      The service uses a 24-hour clock, so you must provide a number between 0 and 23 for the hour. Also remember to calculate the offset between Greenwich Mean Time (GMT) and your local time.

5. Repeat step 3 and 4 to choose an end date and time.

6. (Optional) In Request Action Types, specify one or more operations with which to filter results.
   - GET
   - POST
   - PUT
   - PATCH
   - DELETE

7. (Optional) In the Keywords box, type the text you want to find and click Search.

   Tip: If you want to find log events with a specific status code, include quotes (") around the code to avoid results that have those numbers embedded in a longer string.

The results are updated to include only log events that were processed within the time range and filters you specified.

If an event occurred in the recent past, you might have to wait to see it in the list. The service typically requires up to 15 minutes for processing.

If there are more than 100 results for the specified time range, you can click the right arrow next to the page number at the bottom of the page to advance to the next page of log events.

Tip:

If you get fewer than 100 results on the last page of a results list, you might still have more results, which you can access by clicking the right arrow. If there are more results, Audit prompts you.

If you want to view all the key-value pairs in a log event, see To view the details of a log event on page 496.

To view the details of a log event

View the details of your event:
   - To see only the top-level details, click the down arrow to the right of an event.
   - To see lower-level details, click {...} to the right of the collapsed parameter.

To copy the details of a log event

The following assumes that you have expanded a row in your results.
   - To copy an entire event, click the clipboard icon to the right of the event parameter.
   - To copy a portion of an event, click the clipboard icon to the right of the nested parameter or value you want to copy.

The log event is copied to your clipboard. The Audit service logs events in JSON format. You can paste the log event details into a text editor to save and review later or to use with standard log analysis tools.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operation to list audit log events:
   - ListEvents
Audit

Note:
This API is not intended for bulk-export operations. For bulk export, see Bulk Export of Audit Log Events on page 497.

Bulk Export of Audit Log Events

You can request a bulk export of audit logs, and within 5-10 business days Oracle support will begin making copies of the logs and adding them to buckets in your tenancy. The export includes logs for the specified regions, beginning after you make the request and continuing into the future.

Highlights

• Administrators have full control of the buckets and can provide access to others with IAM policy statements.
• Exported logs remain available indefinitely.

Tip:
You can automatically manage archiving and deleting logs using Object Storage. See Using Object Lifecycle Management on page 3466.

• Specify all the regions you want exported in your request. If you only request some regions, then decide later you want to add other regions, you must make another request.
• To disable your bulk export, contact Oracle support. New logs will stop being added to the bucket, and audit logs will only be available through the Console, based on the retention period you have defined.

Required IAM Policy

To access the bucket where Oracle exports the audit logs, you must be a member of the Administrators group. See The Administrators Group and Policy on page 2125.

Requesting an Export of Audit Logs

A member of the Administrators group for your tenancy must create a ticket at My Oracle Support and provide the following information:

• Ticket name: Export Audit Logs - <your_company_name>
• Tenancy OCID
• Regions

For example:

• Ticket name: Export Audit Logs - ACME
• Tenancy OCID: ocid1.tenancy.oc1.<unique_ID>
• Regions: US East (Ashburn), region identifier= us-ashburn-1; (US West (Phoenix)), region identifier = us-phoenix-1

Note:
It can take 5-10 business days before your My Oracle Support ticket is complete and the logs are available to you.

Bucket and Object Details

This section specifies the naming conventions of the bucket and objects you receive.

Bucket Name Format

Oracle support creates buckets for audit log exports using the following naming format:

oci-logs.audit.<compartment_OCID>
• **oci-logs** identifies that Oracle created this bucket.
• **_audit** identifies that the bucket contains audit events.
• **<compartment_OCID>** identifies the compartment where the audit events were generated.

For example:

```plaintext
oci-logs._audit.ocid1compartment.oc1..<unique_ID>
```

**Important:**

If the OCID of the compartment that generated the audit log contains a colon, your bucket name will not match the OCID. To create a bucket, Oracle must substitute colon characters (:) from the OCID with dot characters (.) in the bucket name.

**Object Name Format**

Objects use the following naming format:

```plaintext
<region>/<ad>/<YYYY-MM-DDTHH:MMZ>[_<seqNum>].log.gz
```

- **<region>** identifies the region where the audit events were generated.
- **<ad>** identifies the availability domain where the audit events were generated.
- **<YYYY-MM-DDTHH:MMZ>** identifies the start time of the earliest audit event listed in the object.
- **[_<seqNum>]** identifies a conditional sequence number. If present, this number means that either an event came in late or the object became too large to write. Sequence numbers start at two. Apply multiple sequence numbers to the original object in the order listed.

For example:

```plaintext
us-phoenix-1/ad1/2019-03-21T00:00Z.log.gz
us-phoenix-1/ad1/2019-03-21T00:00Z_2.log.gz
```

**File Format**

Files list a single audit event per line. For more information, see [Contents of an Audit Log Event](#) on page 489.

**Note:**

Audit introduced a version 2 schema of Audit logs but bulk export is currently only available for version 1 schema logs.
Chapter 9

Block Volume

This chapter explains how to create storage volumes and attach them to instances.

Overview of Block Volume

The Oracle Cloud Infrastructure Block Volume service lets you dynamically provision and manage block storage volumes. You can create, attach, connect, and move volumes, as well as change volume performance, as needed, to meet your storage, performance, and application requirements. After you attach and connect a volume to an instance, you can use the volume like a regular hard drive. You can also disconnect a volume and attach it to another instance without the loss of data.

These components are required to create a volume and attach it to an instance:

- **Instance**: A bare metal or virtual machine (VM) host running in the cloud.
- **Volume attachment**: There are two types of volume attachments:
  - **iSCSI** on page 501: A TCP/IP-based standard used for communication between a volume and attached instance.
  - **Paravirtualized** on page 501: A virtualized attachment available for VMs.
- **Volume**: There are two types of volumes:
  - **Block volume**: A detachable block storage device that allows you to dynamically expand the storage capacity of an instance.
  - **Boot volume**: A detachable boot volume device that contains the image used to boot a Compute instance. See Boot Volumes on page 609 for more information.

For additional Oracle Cloud Infrastructure terms, see the Glossary.

Block Volume is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

Typical Block Volume Scenarios

**Scenario A: Expanding an Instance's Storage**

A common usage of Block Volume is adding storage capacity to an Oracle Cloud Infrastructure instance. After you have launched an instance and set up your cloud network, you can create a block storage volume through the Console or API. Then, you attach the volume to an instance using a volume attachment. After the volume is attached, you connect to the volume from your instance's guest OS using iSCSI. The volume can then be mounted and used by your instance.

**Scenario B: Persistent and Durable Storage**

A Block Volume volume can be detached from an instance and moved to a different instance without the loss of data. This data persistence enables you to migrate data between instances and ensures that your data is safely stored, even when it is not connected to an instance. Any data remains intact until you reformat or delete the volume.
To move your volume to another instance, unmount the drive from the initial instance, terminate the iSCSI connection, and attach the volume to the second instance. From there, you connect and mount the drive from that instance's guest OS to have access to all of your data.

Additionally, Block Volume volumes offer a high level of data durability compared to standard, attached drives. All volumes are automatically replicated for you, helping to protect against data loss, see Block Volume Durability on page 505.

**Scenario C: Instance Scaling**

When you terminate an instance, you can keep the associated boot volume and use it to launch a new instance with a different instance type or shape. This allows you to easily switch from a bare metal instance to a VM instance and vice versa, or scale up or scale down the number of cores for an instance. See Creating an Instance on page 695 for steps to launch an instance based on a boot volume.

**Volume Attachment Types**

When you attach a block volume to a VM instance, you have two options for attachment type, iSCSI or paravirtualized. Paravirtualized attachments simplify the process of configuring your block storage by removing the extra commands that are required before connecting to an iSCSI-attached volume. The trade-off is that IOPS performance for iSCSI attachments is greater than that for paravirtualized attachments. You should consider your requirements when selecting a volume's attachment type.

### Important:

Connecting to Volumes on Linux Instances

When connecting to volumes on Linux instances, if you want to automatically mount these volumes on instance boot, you need to use some specific options in the `/etc/fstab` file, or the instance may fail to launch. See Traditional fstab Options on page 528 and fstab Options for Block Volumes Using Consistent Device Paths on page 527 for more information.

**iSCSI**

iSCSI attachments are the only option when connecting a block volume to any of the following types of instances:

- Bare metal instances
- VM instances based on Windows images that were published before February 2018
- VM instances based on Linux images that were published before December 2017

After the volume is attached, you need to log in to the instance and use the `iscsiadm` command-line tool to configure the iSCSI connection. For more information about the additional configuration steps required for iSCSI attachments, see iSCSI Commands and Information on page 505, Connecting to a Volume on page 524, and Disconnecting From a Volume on page 562.

IOPS performance is better with iSCSI attachments compared to paravirtualized attachments. For more information about iSCSI-attached volume performance, see Block Volume Performance on page 567.

**Paravirtualized**

Paravirtualized attachments are an option when attaching volumes to the following types of VM instances:

- For VM instances launched from Oracle-provided images, you can select this option for Linux-based images published in December 2017 or later, and Windows images published in February 2018 or later.
- For VM instances launched from custom images, the volume attachment type is based on the volume attachment type from the VM the custom image was created from.
After you attach a volume using the paravirtualized attachment type, it is ready to use, and you do not need to run any additional commands. However, because of the overhead of virtualization, this reduces the maximum IOPS performance for larger block volumes.

**Volume Access Types**

When you attach a block volume, you can specify one of the following options for access type:

- **Read/write**: This is the default option for volume attachments. With this option, an instance can read and write data to the volume.
- **Read/write, shareable**: With this option, you can attach a volume to more than one instance at a time and those instances can read and write data to the volume. To prevent data corruption from uncontrolled read/write operations with multiple instance volume attachments you must install and configure a cluster-aware solution for system before you can use the volume, see Configuring Multiple Instance Volume Attachments with Read/Write Access on page 521 for more information.
- **Read-only**: With this option, an instance can only read data on the volume. It cannot update data on the volume. Specify this option to safeguard data against accidental or malicious modifications.

To change the access type for a block volume, you need to detach the volume and specify the new access type when you reattach the volume. For more information, see Detaching a Volume on page 563 and Attaching a Volume on page 517.

The access type for boot volumes is always read/write. If you want to change the access type, you need to stop the instance and detach the boot volume. You can then reattach it to another instance as a block volume, with read-only specified as the access type. For more information, see Detaching a Boot Volume on page 623 and Attaching a Volume on page 517.

**Device Paths**

When you attach a block volume to a compatible Linux-based instance, you can select a device path that remains consistent between instance reboots. This enables you to refer to the volume using a consistent device path. For example, you can use the device path when you set options in the /etc/fstab file to automatically mount the volume on instance boot.

Consistent device paths are supported on instances when all of the following things are true:

- The instance was created using an Oracle-provided image.
- The image is a Linux-based image.
- The image was released in November 2018 or later. For specific version numbers, see Oracle-Provided Image Release Notes.
- The instance was launched after January 11, 2019.

For instances launched using the image OCID or an existing boot volume, if the source image supports consistent device paths, the instance supports device paths.

Consistent device paths are not supported on Linux-based partner images or custom images that are created from other sources. This feature does not apply to Windows-based images.

**Important:**

You must select a device path when you attach a volume using the Console, it is required. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

For more information about consistent device paths, see Connecting to Volumes With Consistent Device Paths on page 518.

**Regions and Availability Domains**

Volumes are only accessible to instances in the same availability domain. You cannot move a volume between availability domains or regions, they are only accessible within the region or availability domain they were created in.
However volume backups are not limited to the availability domain of the source volume, you can restore them to any availability domain within that region, see Restoring a Backup to a New Volume on page 557. You can also copy a volume backup to a new region and restore the backup to a volume in any availability domain in the new region, for more information see Copying a Volume Backup Between Regions on page 558.

For more information, see Regions and Availability Domains on page 180.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

**Moving Resources**

You can move Block Volume resources such as block volumes, boot volumes, volume backups, volume groups, and volume group backups from one compartment to another. For more information, see Move Block Volume Resources Between Compartments on page 564.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.
Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

The following Block Volume resources emit events:

- Block volumes and block volume backups
- Boot volumes and boot volume backups
- Volume groups and volume group backups

Note:
For troubleshooting, see Known Issues - Block Volume for a list of known issues related to Block Volume events.

Block Volume Encryption

The Oracle Cloud Infrastructure Block Volume service always encrypts all block volumes, boot volumes, and volume backups at rest by using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption. By default all volumes and their backups are encrypted using the Oracle-provided encryption keys. Each time a volume is cloned or restored from a backup the volume is assigned a new unique encryption key.

You have the option to encrypt all of your volumes and their backups using the keys that you own and manage using the Vault service, for more information see Overview of Vault on page 3952. If you do not configure a volume to use the Vault service or you later unassign a key from the volume, the Block Volume service uses the Oracle-provided encryption key instead. This applies to both encryption at-rest and in-transit encryption.

For how to use your own key for new volumes, see Creating a Volume on page 515. See To assign a key to an existing Block Volume on page 3972 for how to assign or change the key for an existing volume.

All the data moving between the instance and the block volume is transferred over an internal and highly secure network. If you have specific compliance requirements related to the encryption of the data while it is moving between the instance and the block volume, the Block Volume service provides the option to enable in-transit encryption for paravirtualized volume attachments on virtual machine (VM) instances.

Important:
In-transit encryption for boot and block volumes is only available for virtual machine (VM) instances launched from Oracle-provided images, it is not supported on bare metal instances. It is also not supported in most cases for instances launched from custom images imported for "bring your own image" (BYOI) scenarios. To confirm support for certain Linux-based custom images and for more information contact Oracle support, see Getting Help and Contacting Support on page 125.

Block Volume Data Eradication

The Oracle Cloud Infrastructure Block Volume service uses eventual-overwrite data eradication, which guarantees that block volumes you delete cannot be accessed by anyone else and that the deleted data is eventually overwritten. When you terminate a volume, its associated data is overwritten in the storage infrastructure before any future volume allocations.

Block Volume Performance

Block Volume performance varies with volume size, see Block Volume Performance on page 567 for more information.

The Block Volume service's elastic performance feature enables you to dynamically change the volume performance. You can select one of the following volume performance options for your block volumes:

- Balanced
• Higher Performance
• Lower Cost

For more information about this feature and the performance options, see Block Volume Elastic Performance on page 581 and Changing the Performance of a Volume on page 582

**Block Volume Durability**

The Oracle Cloud Infrastructure Block Volume service offers a high level of data durability compared to standard, attached drives. All volumes are automatically replicated for you, helping to protect against data loss. Multiple copies of data are stored redundantly across multiple storage servers with built-in repair mechanisms. For service level objective, the Block Volume service is designed to provide 99.99 percent annual durability for block volumes and boot volumes. However, we recommend that you make regular backups to protect against the failure of an availability domain.

**Block Volume Capabilities and Limits**

Block Volume volumes can be created in sizes ranging from **50 GB** to **32 TB** in **1 GB** increments. By default, Block Volume volumes are **1 TB**.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Additional limits include:

• **Attached block volumes per instance**: 32
• **Attached boot volumes per instance**: 1

**Note:**

Boot volumes attached to an instance as a data volume and not as the instance’s boot volume count towards the limit for attached block volumes.

• **Number of backups**
  • Monthly universal credits: 100,000
  • Pay-as-you-go: 100,000

**iSCSI Commands and Information**

Block volumes attached with the iSCSI on page 501 attachment type use the iSCSI protocol to connect a volume to an instance. See Volume Attachment Types on page 501 for more information about volume attachment options.

Once the volume is attached, you need to log on to the instance and use the iscsiadm command-line tool to configure the iSCSI connection. After you configure the volume, you can mount it and use it like a normal hard drive.

To enhance security, Oracle enforces an iSCSI security protocol called CHAP that provides authentication between the instance and volume.

**Accessing a Volume’s iSCSI Information**

When you successfully attach a volume to an instance, Block Volume provides a list of iSCSI information. You need the following information from the list when you connect the instance to the volume.

• IP address
• Port
• CHAP user name and password (if enabled)
• IQN
The CHAP credentials are auto-generated by the system and cannot be changed. They are also unique to their assigned volume/instance pair and cannot be used to authenticate another volume/instance pair.

The Console provides this information on the details page of the volume’s attached instance. Click the Actions icon (three dots) on your volume’s row, and then click **iSCSI Information**. The system also returns this information when the **AttachVolume** API operation completes successfully. You can re-run the operation with the same parameter values to review the information.

See **Attaching a Volume** on page 517 and **Connecting to a Volume** on page 524 for step-by-step instructions.

### Recommended iSCSI Initiator Parameters for Linux-based Images

iSCSI attached volumes for Linux-based images are managed by the Linux iSCSI initiator service, `iscsid`. Oracle Cloud Infrastructure images use iSCSI default settings for the `iscsid` service’s parameters, with the exception of the following parameters:

- `node.startup = automatic`
- `node.session.timeo.replacement_timeout = 6000`
- `node.conn[0].timeo.noop_out_interval = 0`
- `node.conn[0].timeo.noop_out_timeout = 0`
- `node.conn[0].iscsi.HeaderDigest = None`

If you are using custom images, you should update the `iscsid` service configuration by modifying the `/etc/iscsi/iscsid.conf` file.

### Additional Reading

There is a wealth of information on the internet about iSCSI and CHAP. If you need more information on these topics, try the following pages:

- [Oracle Linux 8 Managing Storage Devices - Working with iSCSI Devices](#)
- [Oracle Linux Administrator's Guide for Release 7 - About iSCSI Storage](#)
- [Oracle Linux Administrator's Guide for Release 6 - About iSCSI Storage](#)
- [Troubleshooting iSCSI Configuration Problems](#)

### Volume Groups

The Oracle Cloud Infrastructure Block Volume service provides you with the capability to group together multiple volumes in a volume group. A volume group can include both types of volumes, boot volumes, which are the system disks for your Compute instances, and block volumes for your data storage. You can use volume groups to create volume group backups and clones that are point-in-time and crash-consistent.

This simplifies the process to create time-consistent backups of running enterprise applications that span multiple storage volumes across multiple instances. You can then restore an entire group of volumes from a volume group backup.

Similarly, you can also clone an entire volume group in a time-consistent and crash-consistent manner. A deep disk-to-disk and fully isolated clone of a volume group, with all the volumes associated in it, becomes available for use within a matter of seconds. This speeds up the process of creating new environments for development, quality assurance, user acceptance testing, and troubleshooting.

For more information about Block Volume-backed system disks, see **Boot Volumes** on page 609. For more information about Block Volume backups see **Overview of Block Volume Backups** on page 540. See **Cloning a Volume** on page 560 for more information about Block Volume clones.

This capability is available using the Console, command line interface (CLI), SDKs, or REST APIs.
Volume groups and volume group backups are high-level constructs that allow you to group together multiple volumes. When working with volume groups and volume group backups, keep the following in mind:

- You can only add a volume to a volume group when the volume status is available.
- You can add up to 32 volumes in a volume group, up to a maximum size limit of 128 TB. For example, if you wanted to add 32 volumes of equal size to a volume group, the maximum size for each volume would be 4 TB. Or you could add volumes that vary in size, however the overall combined size of all the block and boot volumes in the volume group must be 128 TB or less. Make sure you account for the size of any boot volumes in your volume group when considering volume group size limits.

- Each volume may only be in one volume group.
- When you clone a volume group, a new group with new volumes are created. For example, if you clone a volume group containing three volumes, once this operation is complete, you will now have two separate volume groups and six different volumes with nothing shared between the volume groups.
- When you update a volume group using the CLI, SDKs, or REST APIs you need to specify all the volumes to include in the volume group each time you use the update operation. If you do not include a volume ID in the update call, that volume will be removed from the volume group.
- When you delete a volume group the individual volumes in the group are not deleted, only the volume group is deleted.
- When you delete a volume that is part of a volume group you must first remove it from the volume group before you can delete it.
- When you delete a volume group backup, all the volume backups in the volume group backup are deleted.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes, backups, and volume groups.

See the following policy examples for working with volume groups:

- Let users create a volume group on page 2147 lets the specified group create a volume group from a set of volumes.
- Let users clone a volume group on page 2148 lets the specified group clone a volume group from an existing volume group.
- Let users create a volume group backup on page 2148 lets the specified group create a volume group backup.
- Let users restore a volume group backup on page 2148 lets the specified group create a volume group by restoring a volume group backup.

**Tip:**

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.
Managing Volume Groups

This section covers how to perform tasks related to managing your volume groups using the Console, command line interface (CLI), and REST APIs.

Using the Console

To create a volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. Click Create Volume Group.
3. Fill in the required volume information:
   - **Name**: A user-friendly name or description. Avoid entering confidential information.
   - **Compartment**: The compartment for the volume group.
   - **Availability Domain**: The availability domain for the volume group.
   - **Backup Policy**: The backup policy to use for scheduled backups. For more information, see Policy-Based Volume Group Backups on page 514.
   - **Volumes**: For each volume you want to add, select the compartment containing the volume and then the volume to add. Click + Volume to add additional volumes.
4. Click Create Volume Group.

To view the volumes in a volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. In the Volume Groups list, click the volume group you want to view the volumes for.
3. To view the block volumes for the volume group, in Resources, click Block Volumes.
4. To view the boot volumes for the volume group, in Resources, click Boot Volumes.

To add block volumes to an existing volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. In the Volume Groups list, click the volume group you want to add the volume to.
3. In Resources, click Block Volumes.
4. Click Add Block Volumes.
5. For each block volume you want to add, select the compartment containing the volume and then select the volume to add. Click + Volume to add additional volumes.
6. Once you have selected all the block volumes to add to the volume group, click Add.

To remove block volumes from an existing volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. In the Volume Groups list, click the volume group you want to add the volume to.
3. In Resources, click Block Volumes.
4. In Actions menu for the block volume you want to remove, click Remove.
5. In the Confirm dialog, click Remove.

**Note:**

You cannot add a volume with an existing backup policy assignment to a volume group with a backup policy assignment. You must first remove the backup policy assignment from the volume before you can add it to the volume group.

To add boot volumes to an existing volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.
3. In **Resources**, click **Boot Volumes**.
4. Click **Add Boot Volumes**.

   **Note:**
   You cannot add a volume with an existing backup policy assignment to a volume group with a backup policy assignment. You must first remove the backup policy assignment from the volume before you can add it to the volume group.

5. For each boot volume you want to add, select the compartment containing the volume and then select the volume to add. Click + **Volume** to add additional volumes.
6. Once you have selected all the boot volumes to add to the volume group, click **Add**.

**To remove boot volumes from an existing volume group**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.
3. In **Resources**, click **Boot Volumes**.
4. In the **Actions** menu for the boot volume you want to remove, click **Remove**.
5. In the **Confirm** dialog, click **Remove**.

**To create a clone of the volume group**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click **Create Volume Group Clone** in the **Actions** menu for the volume group you want to clone.

**To delete the volume group**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to delete.
3. On the **Volume Group Details** page, click **Terminate**.
4. On the **Terminate Volume Group** dialog, click **Terminate**.

   **Note:**
   When you delete a volume group the individual volumes in the group are not deleted, only the volume group is deleted.

**Using the CLI**

For information about using the CLI, see [Command Line Interface (CLI)](#) on page 4192.

**To retrieve information about the supported operations**

Open a command prompt and run the one of the following commands to retrieve the information.

- To retrieve the supported operations for volume groups:

  `oci bv volume-group --help`

- To retrieve the supported operations for volume group backups:

  `oci bv volume-group-backup --help`

- To retrieve help for a specific volume group operation:

  `oci bv volume-group <operation_name> --help`
• To retrieve help for a specific volume group backup operation:

```
oci bv volume-group-backup <operation_name> --help
```

**To list the volume groups in a specified compartment**

Open a command prompt and run:

```
oci bv volume-group list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-group list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

**To create a volume group from existing volumes**

Open a command prompt and run:

```
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --source-details <Source_details_JSON>
```

Volume status must be available to add it to a volume group.

For example:

```
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain ABbv:PHX-AD-1 --source-details '{"type": "volumeIds", "volumeIds": ["ocid1.volume.oc1.phx.<unique_ID_1>", "ocid1.volume.oc1.phx.<unique_ID_2>" ]}'
```

**To clone a volume group from another volume group**

Open a command prompt and run:

```
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --source-details <Source_details_JSON>
```

For example:

```
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain ABbv:PHX-AD-1 --source-details '{"type": "volumeGroupId", "volumeGroupId": "ocid1.volumegroup.oc1.phx.<unique_ID>" }'
```

**To retrieve a volume group**

Open a command prompt and run:

```
oci bv volume-group get --volume-group-id <volume-group-ID>
```

For example:

```
oci bv volume-group get --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```
To update display name or add/remove volumes from a volume group

Open a command prompt and run:

```
oci bv volume-group update --volume-group-id <volume-group_ID> --volume-ids <volume_ID_JSON>
```

You can update the volume group display name along with adding or removing volumes from the volume group. The volume group is updated to include only the volumes specified in the update operation. This means that you need to specify the volume IDs for all of the volumes in the volume group each time you update the volume group.

The following example changes the volume group's display name for a volume group with two volumes:

```
oci bv volume-group update --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID> --volume-ids '["ocid1.volume.oc1.phx.<unique_ID_1>","ocid1.volume.oc1.phx.<unique_ID_2>"]' --display-name "new display name"
```

If you specify volumes in the command that are not part of the volume group they are added to the group. Any volumes not specified in the command are removed from the volume group.

To delete a volume group

Open a command prompt and run:

```
oci bv volume-group delete --volume-group-id <volume-group_ID>
```

When you delete a volume group, the individual volumes in the group are not deleted, only the volume group is deleted.

For example:

```
oci bv volume-group delete --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations for working with volume groups:

- ListVolumeGroups
- CreateVolumeGroup
- DeleteVolumeGroup
- GetVolumeGroup
- UpdateVolumeGroup

Volume Group Backups

A volume group backup provides coordinated point-in-time-consistent backups of all the volumes in a volume group automatically. You can perform most of the same backup operations and tasks with volume groups that you can perform with individual block volumes and boot volumes. You can restore a volume group backup to a volume group, or you can restore individual volumes in the volume group from volume backups. With volume group backups, you can manage the backup settings for several volumes in one place, consistently. This simplifies the process to create time-consistent backups of running enterprise applications that span multiple storage volumes across multiple instances.

For a general overview of the Block Volume's service backup functionality, see Overview of Block Volume Backups on page 540.
**Source Region**

Volume group backups include a **Source Region** field. This specifies the region for the volume group that the backup was created from. For volume group backups copied from another region, this field will show the region the volume group backup was copied from.

**Manual Volume Group Backups**

Manual backups are on-demand one-off backups that you can launch immediately for volume groups by following the steps outlined in the procedures in this section. For general information about the manual backups feature for the Block Volume service, see **Manual Backups** on page 540.

*Using the Console*

To create a backup of the volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click **Create Volume Group Backup** in the **Actions** menu for the volume group you want to create a backup for.

To restore a volume group from a volume group backup

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Group Backups**.
2. In the **Volume Group Backups** list, click the volume group backup you want to restore.
3. Click **Create Volume Group**.
4. Fill in the required volume information:
   - **Name**: A user-friendly name or description. Avoid entering confidential information.
   - **Compartment**: The compartment for the volume group.
   - **Availability Domain**: The availability domain for the volume group.
5. Click **Create Volume Group**.

*Using the CLI*

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192.

To list volume backup groups

Open a command prompt and run:

```
oci bv volume-group-backup list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-group-backup list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

To create a volume group backup

Open a command prompt and run:

```
oci bv volume-group-backup create --volume-group-id <volume-group_ID>
```

For example:

```
oci bv volume-group-backup create --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```

To retrieve a volume group backup
Open a command prompt and run:

```bash
oci bv volume-group-backup get --volume-group-backup-id <volume-group-backup_ID>
```

For example:

```bash
oci bv volume-group-backup get --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID>
```

To update display name for a volume group backup

Open a command prompt and run:

```bash
oci bv volume-group-backup update --volume-group-backup-id <volume-group-backup_ID> --display-name <new_display_name>
```

You can only update the display name for the volume group backup.

For example:

```bash
oci bv volume-group-backup update --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID> --display-name "new display name"
```

To restore a volume group from a volume group backup

Open a command prompt and run:

```bash
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --source-details <Source_details_JSON>
```

For example:

```bash
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain ABby:PHX-AD-1 --source-details '{"type": "volumeGroupBackupId", "volumeGroupBackupId": "ocid1.volumegroup.oc1.sea.<unique_ID>"}'
```

To delete a volume group backup

Open a command prompt and run:

```bash
oci bv volume-group-backup delete --volume-group-backup-id <volume-group-backup_ID>
```

When you delete a volume group backup, all volume backups in the group are deleted.

For example:

```bash
oci bv volume-group-backup delete --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID>
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations for working with volume group backups:

- ListVolumeGroupBackups
- CreateVolumeGroupBackup
• DeleteVolumeGroupBackup
• GetVolumeGroupBackup
• UpdateVolumeGroupBackup

Policy-Based Volume Group Backups

These are automated scheduled backups as defined by the backup policy assigned to the volume group. Policy-based backups for volume groups are essentially the same as policy-based backups for block volumes, the main difference is that the backup policy is applied to all the volumes in the volume group instead of a single volume. For general information about policy-based backups, see Policy-Based Backups on page 547. The process to create and configure user defined backup policies are the same for volume groups as they are for volumes, see Creating and Configuring User Defined Backup Policies on page 552 for these procedures.

Note:
Oracle defined backup policies are not supported for scheduled volume group backups.

Caution:
Vault encryption keys for volumes are not copied to the destination region for scheduled volume and volume group backups enabled for cross region copy. For more information, see Vault encryption keys not copied to destination region for scheduled cross region backup copies.

Managing Backup Policy Assignments to Volume Groups

The backup policy assigned to a volume group defines the frequency and schedule for volume group backups. This section covers how to perform tasks related to managing the backup policy assignments for your volume groups using the Console, command line interface (CLI), and REST APIs.

If a volume group has an assigned backup policy, you must remove any backup policy assignments from volumes before you can add them to the volume group.

Before you can assign a backup policy to an existing volume group containing one or more volumes with assigned backup policies, you must remove those policy assignments from the individual volumes before you can assign the policy to the volume group.

Using the Console

To assign a backup policy to a volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. Click the volume group for which you want to assign a backup policy to.
3. On the Volume Group Details page click Edit.
4. In the BACKUP POLICIES section, select the compartment containing the backup policies.
5. Select the appropriate backup policy for your requirements.
6. Click Save Changes.

To change a backup policy assigned to a volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. Click the volume group for which you want to change the backup policy for.
3. On the Volume Group Details page click Edit.
4. In the BACKUP POLICIES section, select the compartment containing the backup policy.
5. Select the backup policy you want to switch to.
6. Click Save Changes.

To remove a backup policy assigned to a volume group

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Volumes Groups.
2. Click the volume group for which you want to remove the backup policy for.
3. On the Volume Group Details page click Edit.
4. In the **BACKUP POLICIES** section, select **None** from the list, and then click **Save Changes**.

**Using the CLI**

For information about using the CLI, see [Command Line Interface (CLI)] on page 4192.

**To assign a backup policy to a volume group**

Open a command prompt and run:

```bash
oci bv volume-backup-policy-assignment create --asset-id <volume_group_ID> --policy-id <policy_ID>
```

For example:

```bash
oci bv volume-backup-policy-assignment create --asset-id ocid1.volumegroup.oc1..<unique_ID> --policy-id ocid1.volumebackuppolicy.oc1..<unique_ID>
```

**To get the backup policy assigned to a volume group**

Open a command prompt and run:

```bash
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id <volume_group_ID>
```

For example:

```bash
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id ocid1.volumegroup.oc1..<unique_ID>
```

**To retrieve a specific backup policy assignment**

Open a command prompt and run:

```bash
oci bv volume-backup-policy-assignment get --policy-assignment-id <backup-policy-ID>
```

For example:

```bash
oci bv volume-backup-policy-assignment get --policy-assignment-id ocid1.volumebackuppolicyassignment.oc1.phx.<unique_ID>
```

**Using the API**

Use the following operations to manage backup policy assignments to volume groups:

- CreateVolumeBackupPolicyAssignment
- DeleteVolumeBackupPolicyAssignment
- GetVolumeBackupPolicyAssetAssignment
- GetVolumeBackupPolicyAssignment

For information about using the API and signing requests, see [REST APIs] on page 4368 and [Security Credentials] on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface] on page 4225.

**Creating a Volume**

You can create a volume using Block Volume.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: The policy in *Let volume admins manage block volumes, backups, and volume groups* on page 2146 lets the specified group do everything with block volumes and backups.

If you’re new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see *Details for the Core Services* on page 2181.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see *Monitoring Overview* on page 2660 and *Notifications Overview* on page 3350.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see *Resource Tags* on page 211.

**Using the Console**

1. Open the navigation menu. Under *Core Infrastructure*, go to *Block Storage* and click *Block Volumes*.
2. Click *Create Block Volume*.
3. Fill in the required volume information:
   - **Name**: A user-friendly name or description. Avoid entering confidential information.
   - **Domain**: Must be in the same *availability domain* as the instance.
   - **Size**: Must be between 50 GB and 32 TB. You can choose in 1 GB increments within this range. The default is 1024 GB. If you choose a size outside of your service limit, you may be prompted to request an increase. For more information, see *Service Limits* on page 215.
   - **Backup Policy**: Optionally, you can select the appropriate backup policy for your requirements. See *Policy-Based Backups* on page 547 for more information about backup policies.
   - **Volume Performance**: Optionally, you can select the appropriate performance setting for your requirements. See *Block Volume Elastic Performance* on page 581 for more information about volume performance options. The default option is *Balanced*.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see *Resource Tags* on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
   - **Encryption**: Optionally, you can encrypt the data in this volume using your own Vault encryption key. To use Vault for your encryption needs, select the *Encrypt using customer-managed keys* radio button. Then, select the *Vault compartment* and *Vault* that contain the master encryption key you want to use. Also select the *Master encryption key compartment* and *Master encryption key*. For more information about encryption, see *Overview of Vault* on page 3952.
4. Click *Create Block Volume*.

   The volume will be ready to attach once its icon no longer lists it as *PROVISIONING* in the volume list. For more information, see *Attaching a Volume* on page 517.
Using the API

To create a volume, use the following operation:

- CreateVolume

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Attaching a Volume

You can attach a volume to an instance in order to expand the available storage on the instance. If you specify iSCSI on page 501 as the volume attachment type, you must also connect and mount the volume from the instance for the volume to be usable. For more information, see Volume Attachment Types on page 501 and Connecting to a Volume on page 524.

You can attach volumes to more than one instance at a time, see Attaching a Volume to Multiple Instances on page 520. To prevent data corruption from uncontrolled read/write operations with multiple instance volume attachments you must install and configure a clustered file system before you can use the volume, see Configuring Multiple Instance Volume Attachments with Read/Write Access on page 521 for more information.

Note:
You should only attach Linux volumes to Linux instances and Windows volumes to Windows instances.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to attach block volumes to Compute instances.

- All block volumes attached to a Compute instance in a security zone must themselves be in a security zone.
- Block volumes in a security zone cannot be attached to a Compute instance that is not in a security zone.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the Instances list, click the instance that you want to attach a volume to.
3. In the Resources section, click Attached Block Volumes.
4. Click Attach Block Volume.
5. Select the volume attachment type, iSCSI, Paravirtualized, or Let Oracle Cloud Infrastructure choose the best attachment type.

For more information, see Volume Attachment Types on page 501.
6. In the **Block Volume Compartment** drop-down list, select the compartment.
7. Specify the volume you want to attach to. To use the volume name, choose **SELECT VOLUME** and then select the volume from the **Block Volume** drop-down list. To specify the volume OCID, choose **ENTER VOLUME OCID** and then enter the OCID into the **Block Volume OCID** field.
8. If the instance supports consistent device paths, and the volume you are attaching is not a boot volume, select a path from the **Device Path** drop-down list when attaching. This is required and enables you to specify a device path for the volume attachment that remains consistent between instance reboots.

   For more information about this feature and the instances that support it, see **Connecting to Volumes With Consistent Device Paths** on page 518

   Tip:
   
   You must select a device path when you attach a volume from the Console, it is not optional. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

9. Select the access type, **Read/Write** or **Read-only**.

   For more information, see **Volume Access Types** on page 502.

10. For paravirtualized volume attachments on virtual machine (VM) instances, you can optionally encrypt data that is transferred between the instance and the Block Volume service storage servers. To do this, select the **Use in-transit encryption** check box. If you configured the volume to use an encryption key that you manage using the Vault service, this key is used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used. See **Block Volume Encryption** on page 504 for more information.

11. Click **Attach**.

    When the volume's icon no longer lists it as **Attaching**, if the attachment type is **Paravirtualized** on page 501, you can use the volume. If the attachment type is **iSCSI** on page 501, you need to connect to the volume first. For more information, see **Connecting to a Volume** on page 524.

    On Linux-based instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the **/etc/fstab** file, or the instance may fail to launch. This applies to both iSCSI and paravirtualized attachment types. For volumes using consistent device paths, see **fstab Options for Block Volumes Using Consistent Device Paths** on page 527. For all other volumes, see **Traditional fstab Options** on page 528.

**Using the API**

To attach a volume to an instance, use the following operation:

- **AttachVolume**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

**Connecting to Volumes With Consistent Device Paths**

Oracle Cloud Infrastructure supports consistent device paths for block volumes that are attached to compatible Linux-based instances. When you attach a block volume to an instance, you must select a device path that remains consistent between instance reboots. This enables you to use a consistent device path when you refer to the volume to perform tasks such as:

- Creating partitions.
- Creating file systems.
- Mounting file systems.
- Specifying options in the **/etc/fstab** file to ensure that volumes are mounted properly when automatically mounting volumes on instance boot. For more information, see **fstab Options for Block Volumes Using Consistent Device Paths** on page 527.
When you use consistent device paths on compatible Linux-based instances, the boot volume’s device path is:

```
/dev/oracleoci/oraclevda
```

**Note:**
Device paths are not available when you attach a boot volume as a data volume to a second instance.

**Images that Support Consistent Device Paths**

Consistent device paths are supported on instances when all of the following things are true:

- The instance was created using an Oracle-provided image.
- The image is a Linux-based image.
- The image was released in November 2018 or later. For specific version numbers, see Oracle-Provided Image Release Notes.
- The instance was launched after January 11, 2019.

For instances launched using the image OCID or an existing boot volume, if the source image supports consistent device paths, the instance supports device paths.

Consistent device paths are not supported on Linux-based partner images or custom images that are created from other sources. This feature does not apply to Windows-based images.

**Important:**
You must select a device path when you attach a volume using the Console, it is required. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

**Device Paths in the Console**

You select a device path when you attach a block volume to an instance.

If you specify a device path, the path appears in the Attached Block Volumes list for an instance, in the Device Path field. An example is shown in the following screenshot.

**Device Paths on the Instance**

Use the following sample commands to perform various configuration tasks on the attached volume. Commands are provided for volumes that use consistent device paths and for volumes that don’t.

**Creating a partition with fdisk**

- No device path specified:
  ```
  fdisk /dev/sdb
  ```

- Device path specified:
  ```
  fdisk /dev/oracleoci/oraclevdb
  ```

**Creating an ext3 file system**

- No device path specified:
  ```
  /sbin/mkfs.ext3 /dev/sdb1
  ```
• Device path specified:
  
  
  ```bash
/sbin/mkfs.ext3 /dev/oracleoci/oraclevdb1
  ```

**Updating the /etc/fstab file**

• No device path specified:
  
  ```bash
UUID=84dc162c-43dc-429c-9ac1-b511f3f0e23c /oradiskvdb1 xfs
defaults,_netdev,noatime 0 2
  ```

• Device path specified:
  
  ```bash
/dev/oracleoci/oraclevdb1 /oradiskvdb1 xfs
defaults,_netdev,noatime 0 2
  ```

**Mounting the file system**

• No device path specified:
  
  ```bash
mount /dev/sdb1 /oradiskvdb1
  ```

• Device path specified:
  
  ```bash
mount /dev/oracleoci/oraclevdb1 /oradiskvdb1
  ```

### Attaching a Volume to Multiple Instances

The Oracle Cloud Infrastructure Block Volume service provides the capability to attach a block volume to multiple Compute instances. With this feature, you can share block volumes across instances in read/write or read-only mode. Attaching block volumes as read/write and shareable enables you to deploy and manage your cluster-aware solutions.

This topic describes how to attach block volumes as shareable, along with the limits and considerations for this feature.

See [Volume Access Types](#) on page 502 for more information about the available access type options. For attaching volumes to single instances, see [Attaching a Volume](#) on page 517.

### Limits and Considerations

• The Block Volume service does not provide coordination for concurrent write operations to block volumes attached to multiple instances, so if you configure the block volume as read/write and shareable you must deploy a cluster aware system or solution on top of the shared storage, see [Configuring Multiple Instance Volume Attachments with Read/Write Access](#) on page 521.

• Once you attach a block volume to an instance as read-only, it can only be attached to other instances as read-only. If you want to attach the block volume to an instance as read/write, you need to detach the block volume from all instances and then you can reattach the block volume to instances as read/write.

• If the block volume is already attached to an instance as read/write non-shareable you can't attach it to another instance until you detach it from the first instance. You can then reattach it to both the first and second instances as read/write shareable.

• You can't delete a block volume until it has been detached from all instances it was attached to. When viewing the instances attached to the block volume from the Resources section of the Volume Details page, you should note that only instances in the selected compartment will be displayed. You may need to change the compartment to list additional instances that are attached to the volume.

• You can attach a block volume as read/write shareable or read-only shareable up to a maximum of eight instances.

• Block volumes attached as read-only are configured as shareable by default.

• Performance characteristics described in [Block Volume Performance](#) on page 567 are per volume, so when a block volume is attached to multiple instances the performance is shared across all the attached instances.
Configuring Multiple Instance Volume Attachments with Read/Write Access

The Block Volume service does not provide coordination for concurrent write operations to volumes attached to multiple instances. To prevent data corruption from uncontrolled read/write operations you must install and configure a cluster aware system or solution such as Oracle Cluster File System version 2 (OCFS2) on top of the shared storage before you can use the volume.

You can see an sample walkthrough of scenario using OCFS2 described in Using the Multiple-Instance Attach Block Volume Feature to Create a Shared File System on Oracle Cloud Infrastructure. The summary of the required steps for this scenario are:

1. Attach the block volume to an instance as Read/Write-Shareable using the Console, CLI, or API.
2. Set up your OCFS2/O2CB cluster nodes.
3. Create your OCFS2 file system and mount point.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

To attach a volume to multiple instances from the Instance details page

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the Instances list, click the instance that you want to attach a volume to.
3. In the Resources section, click Attached Block Volumes.
4. Click Attach Block Volume.
5. Select the volume attachment type, iSCSI or Paravirtualized.
   For more information, see Volume Attachment Types on page 501.
6. Select the volume access type. Select Read/Write-Shareable if you want to enable read/write attachments to multiple instances or Read-only-Shareable for read-only attachments to multiple instances.
   For more information, see Volume Access Types on page 502.
7. In the Block Volume Compartment drop-down list, select the compartment.
8. Specify the volume you want to attach to. To use the volume name, choose SELECT VOLUME and then select the volume from the Block Volume drop-down list. To specify the volume OCID, choose ENTER VOLUME OCID and then enter the OCID into the Block Volume OCID field.
9. If the instance supports consistent device paths select a path from the Device Path drop-down list when attaching. This is required and enables you to specify a device path for the volume attachment that remains consistent between instance reboots.
   For more information about this feature and the instances that support it, see Connecting to Volumes With Consistent Device Paths on page 518

Tip:

You must select a device path when you attach a volume from the Console, it is not optional. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.
For paravirtualized volume attachments on virtual machine (VM) instances, you can optionally encrypt data that is transferred between the instance and the Block Volume service storage servers. To do this, select the Use in-transit encryption check box. If you configured the volume to use an encryption key that you manage using the Vault service, this key is used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used. See Block Volume Encryption on page 504 for more information.

Click Attach.

When the volume's icon no longer lists it as Attaching, if the attachment type is Paravirtualized on page 501, you can use the volume. If the attachment type is iSCSI on page 501, you need to connect to the volume first. For more information, see Connecting to a Volume on page 524.

On Linux-based instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the /etc/fstab file, or the instance may fail to launch. This applies to both iSCSI and paravirtualized attachment types. For volumes using consistent device paths, see fstab Options for Block Volumes Using Consistent Device Paths on page 527. For all other volumes, see Traditional fstab Options on page 528.

To attach a volume to multiple instances from the Block Volume details page

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. In the Block Volumes list, click the block volume that you want to attach to an instance.
3. In the Resources section, click Attached Instances.
4. Click Attach to Instance.
5. Select the volume attachment type, iSCSI or Paravirtualized.
6. Select the volume access type. Select Read/Write-Shareable if you want to enable read/write attachments to multiple instances or Read-only-Shareable for read-only attachments to multiple instances.
7. In the Choose Instance drop-down list, select the instance. Click Change Compartment if the instance is in a different compartment than the default one listed. If you want to specify the instance using the OCID, select the ENTER INSTANCE OCID option and then copy the OCID in the textbox.
8. If the instance supports consistent device paths select a path from the Device Path drop-down list when attaching. This is required and enables you to specify a device path for the volume attachment that remains consistent between instance reboots.

For more information about this feature and the instances that support it, see Connecting to Volumes With Consistent Device Paths on page 518

Tip:
You must select a device path when you attach a volume from the Console, it is not optional. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

9. For paravirtualized volume attachments on virtual machine (VM) instances, you can optionally encrypt data that is transferred between the instance and the Block Volume service storage servers. To do this, select the Use in-transit encryption check box. If you configured the volume to use an encryption key that you manage using the Vault service, this key is used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used. See Block Volume Encryption on page 504 for more information.

10. Click Attach.

When the volume's icon no longer lists it as Attaching, if the attachment type is Paravirtualized on page 501, you can use the volume. If the attachment type is iSCSI on page 501, you need to connect to the volume first. For more information, see Connecting to a Volume on page 524.

On Linux-based instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the /etc/fstab file, or the instance may fail to launch. This applies to both iSCSI and paravirtualized attachment types. For volumes using consistent device paths, see fstab Options for Block Volumes Using Consistent Device Paths.
Using Consistent Device Paths on page 527. For all other volumes, see Traditional fstab Options on page 528.

To view the instances attached to a volume from the Volume details page

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. In the Block Volumes list, click the block volume that you want to view the attached instances for.
3. In the Resources section, click Attached Instances.

All the attached instances in the selected compartment will be displayed in the list. To view attached instances in other compartments, change the compartment in the COMPARTMENT drop down list.

To view the volumes attached to an instance from the Instance details page

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the Instances list, click the instance that you want to view the attached volumes for.
3. In the Resources section, click Attached Block Volumes.

All the block volumes attached to the instance will be displayed in the list, regardless of the compartment the block volumes are in.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 4192.

To attach a volume to an instance as shareable, read/write

Open a command prompt and run:

```
oci compute volume-attachment attach --instance-id <instance_ID> --type <attachment_type> --volume-id <volume_ID> --read-only true/false --is-shareable true
```

For example:

```
oci compute volume-attachment attach --instance-id ocid1.instance.oc1..<unique_ID> --type iscsi --volume-id ocid1.volume.oc1..<unique_ID> --read-only false --is-shareable true
```

To list all the instances attached to a volume

Open a command prompt and run:

```
oci compute volume-attachment list --compartment-id <compartment_ID> --volume-id <volume_ID>
```

For example:

```
oci compute volume-attachment attach --compartment-id ocid1.compartment.oc1..<unique_ID> --volume-id ocid1.volume.oc1..<unique_ID>
```

Note:

This operation will only return the attached instances that are in the specified compartment. You need to run this operation for every compartment that may contain instances that are attached to the specified volume.

Using the API

Use the following APIs to attach volumes and work with volume attachments to instances:
Block Volume

- **AttachVolume**
  
  Set the `isShareable` attribute of `AttachVolumeDetails` to `true`.

- **GetVolumeAttachment**

- **ListVolumeAttachments**

  The `ListVolumeAttachments` operation will only return the attached instances that are in compartment you specify. You need to run this operation for every compartment that may contain instances that are attached to the specified volume.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

**Additional Resources**

See the following links for example deployments of shared file systems on Oracle Cloud Infrastructure.

- GitHub project for automated terraform deployment of BeeGFS: `oci-beegfs`
- GitHub project for automated terraform deployment of Lustre: `oci-lustre`
- GitHub project for automated terraform deployments of IBM Spectrum Scale (GPFS) distributed parallel file system on Oracle Cloud Infrastructure: `oci-ibm-spectrum-scale`
- Refer to page 8 of Deploying Microsoft SQL Server Always On Availability Groups for an example of setting up shared access.

**Connecting to a Volume**

For volumes attached with Paravirtualized on page 501 as the volume attachment type, you do not need to perform any additional steps after Attaching a Volume on page 517, the volumes are connected automatically. However, for Linux-based images, if you want to mount these volumes on instance boot, you need to perform additional configuration steps. If you specified a device path when you attached the volume, see Fstab Options for Block Volumes Using Consistent Device Paths on page 527. If you did not specify a device path or if your instance was created from an image that does not support device paths, see Traditional Fstab Options on page 528.

For volumes attached with iSCSI on page 501 as the volume attachment type, you need to connect and mount the volume from the instance for the volume to be usable. For more information about attachment type options, see Volume Attachment Types on page 501. In order to connect the volume, you must first `attach` the volume to the instance, see Attaching a Volume on page 517.

**Connecting to iSCSI-Attached Volumes**

**Required IAM Policy**

Connecting a volume to an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

**Prerequisites**

You must attach the volume to the instance before you can connect the volume to the instance's guest OS. For details, see Attaching a Volume.

To connect the volume, you need the following information:

- iSCSI IP Address
- iSCSI Port numbers
- `CHAP` credentials (if you enabled CHAP)
- IQN

The Console provides the commands required to configure, authenticate, and log on to iSCSI.
Connecting to a Volume on a Linux Instance

1. Use the Console to obtain the iSCSI data you need to connect the volume:
   a. Log on to Oracle Cloud Infrastructure.
   b. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
   c. Click the name of the instance to display the instance details.
   d. In the Resources section on the Instance Details page, click Attached Block Volumes to view the attached block volume.
   e. Click the Actions icon (three dots) next to the volume you’re interested in, and then click iSCSI Commands and Information.
   
   The iSCSI Commands and Information dialog box displays specific identifying information about your volume and the iSCSI commands you’ll need. The commands are ready to use with the appropriate information included. You can copy and paste the commands into your instance session window for each of the following steps.

2. Log on to your instance’s guest OS.
3. Register the volume with the iscsiadm tool.

   ```
   iscsiadm -m node -o new -T <volume IQN> -p <iSCSI IP address>:<iSCSI port>
   ```

   A successful registration response resembles the following:

   ```
   New iSCSI node [tcp:[hw=,ip=,net_if=,iscsi_if=default] 169.254.0.2,3260,-1
   ign.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418] added
   ```

4. Configure iSCSI to automatically connect to the authenticated block storage volumes after a reboot:

   ```
   iscsiadm -m node -T <volume IQN> -o update -n node.startup -v automatic
   ```

   **Note:** All command arguments are essential. Success returns no response.

5. Skip this step if CHAP is not enabled. If you enabled CHAP when you attached the volume, authenticate the iSCSI connection by providing the volume's CHAP credentials as follows:

   ```
   iscsiadm -m node -T <volume IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n node.session.auth.authmethod -v CHAP
   ```

   ```
   iscsiadm -m node -T <volume IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n node.session.auth.username -v <CHAP user name>
   ```

   ```
   iscsiadm -m node -T <volume's IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n node.session.auth.password -v <CHAP password>
   ```

   Success returns no response.

6. Log in to iSCSI:

   ```
   iscsiadm -m node -T <volume's IQN> -p <iSCSI IP Address>:<iSCSI port> -l
   ```

   A successful login response resembles the following:

   ```
   Logging in to [iface: default, target:
   ign.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418, portal:
   169.254.0.2,3260] (multiple)
   ```

7. You can now format (if needed) and mount the volume. To get a list of mountable iSCSI devices on the instance, run the following command:

```
fdisk -l
```

The connected volume listing resembles the following:

```
Disk /dev/sdb: 274.9 GB, 274877906944 bytes, 536870912 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
```

Tip:

If you have multiple volumes that do not have CHAP enabled, you can log in to them all at once by using the following commands:

```
iscsiadm -m discovery -t sendtargets -p <iSCSI IP address>:<iSCSI port>
iscsiadm -m node -l
iscsiadm -m node -l
```

Connecting to a Volume on a Windows Instance

Caution:

When connecting to a Windows boot volume as a data volume from a second instance, you need to append -IsMultipathEnabled $True to the Connect-IscsiTarget command. See Attaching a Windows boot volume as a data volume to another instance fails for more information.

1. Use the Console to obtain the iSCSI data you need to connect the volume:
   a. Log on to Oracle Cloud Infrastructure.
   b. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
   c. Click your instance's name to display the instance details.
   d. In the Resources section on the Instance Details page, click Attached Block Volumes to view the attached block volume.
   e. Click the Actions icon (three dots) next to the volume you're interested in, and then click iSCSI Commands and Information.

   The iSCSI Commands and Information dialog box displays your volume’s IP address and port, which you’ll need to know later in this procedure.

2. Log in to your instance using a Remote Desktop client.
3. On your Windows instance, open the iSCSI Initiator. The steps to open the iSCSI Initiator may vary depending on the version of Windows.

   For example: Open Server Manager, click Tools, and then select iSCSI Initiator.
4. In the iSCSI Initiator Properties dialog box, click the Discovery tab, and then click Discover Portal.
5. Enter the block volume IP Address and Port, and then click OK.
6. Click the Targets tab.
7. Under Discovered targets, select the volume IQN.
8. Click Connect.
9. Make sure that the Add this connection to the list of favorite targets check box is selected, and then click OK.
You can now format (if needed) and mount the volume. To view a list of mountable iSCSI devices on your instance, in Server Manager, click File and Storage Services, and then click Disks.

The disk is displayed in the list.

**fstab Options for Block Volumes Using Consistent Device Paths**

On Linux instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the /etc/fstab file, or the instance may fail to launch.

**Note:**

These steps are for block volumes that are attached with consistent device paths enabled. If the block volume does not have consistent device paths enabled, use the legacy etc/fstab options instead.

**Prerequisites**

Before using a consistent device path, you should confirm that the instance supports consistent device paths and is correctly configured.

To verify that the volume is attached to a supported instance, connect to the instance and run the following command:

```
ll /dev/oracleoci/oraclevd*
```

The output will look similar to the following:

```
lrwxrwxrwx. 1 root root 6 Feb  7 21:02 /dev/oracleoci/oraclevda -> ../sda
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda1 -> ../sda1
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda2 -> ../sda2
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda3 -> ../sda3
```

If you don't see this output and instead see the following error message:

```
cannot access /dev/oracleoci/oraclevd*: No such file or directory
```

there may be a problem with the instance configuration for device paths. For assistance with this, contact Support.

**Use the _netdev and nofail Options**

By default, the /etc/fstab file is processed before the initiator starts. To configure the mount process to initiate before the volumes are mounted, specify the _netdev option on each line of the /etc/fstab file.

When you create a custom image of an instance where the volumes, excluding the root volume, are listed in the /etc/fstab file, instances will fail to launch from the custom image. To prevent this issue, specify the nofail option in the /etc/fstab file.

In the example scenario with three volumes, the /etc/fstab file entries for the volumes with the _netdev and nofail options are as follows:

```
/dev/oracleoci/oraclevdb /mnt/vol1 xfs defaults,_netdev,nofail 0 2
/dev/oracleoci/oraclevdc /mnt/vol2 xfs defaults,_netdev,nofail 0 2
/dev/oracleoci/oraclevdd /mnt/vol3 xfs defaults,_netdev,nofail 0 2
```

After you have updated the /etc/fstab file, use the following command to mount the volumes:

```
bash-4.2$ sudo mount -a
```

Reboot the instance to confirm that the volumes are mounted properly on reboot with the following command:

```
bash-4.2$ sudo reboot
```
**Troubleshooting Issues with the /etc/fstab File**

If the instance fails to reboot after you update the /etc/fstab file, you may need to undo the changes to the /etc/fstab file. To update the file, first connect to the serial console for the instance. When you have access to the instance using the serial console connection, you can remove, comment out, or fix the changes that you made to the /etc/fstab file.

**Traditional fstab Options**

On Linux instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the /etc/fstab file, or the instance may fail to launch.

**Note:**

These steps are for block volumes that do not have **consistent device paths** enabled. If consistent device paths are enabled for the block volume, use the /etc/fstab options for block volumes using consistent device paths instead.

**Volume UUIDs**

On Linux operating systems, the order in which volumes are attached is non-deterministic, so it can change with each reboot. If you refer to a volume using the device name, such as /dev/sdb, and you have more than one non-root volume, you can't guarantee that the volume you intend to mount for a specific device name will be the volume mounted.

To prevent this issue, specify the volume UUID in the /etc/fstab file instead of the device name. When you use the UUID, the mount process matches the UUID in the superblock with the mount point specified in the /etc/fstab file. This process guarantees that the same volume is always mounted to the same mount point.

**Determining the UUID for a Volume**

1. Follow the steps to attach a volume and connect to the volume.
2. After the volumes are connected, create the file system of your choice on each volume using standard Linux tools.
   
   The remaining steps assume that three volumes were connected, and that an XFS file system was created on each volume.
3. Run the following command to use the blkid utility to get the UUIDs for the volumes:

```
sudo blkid
```

The output will look similar to the following:

```
{{ /dev/sda3: UUID="1701c7e0-7527-4338-ae9f-672fd8d24ec7" TYPE="xfs" PARTUUID="82d2ba4e-4d6e-4a33-9c4d-ba52db57ea61"}}
{{ /dev/sdal: UUID="5750-10A1" TYPE="vfat" PARTLABEL="EFI System Partition" PARTUUID="082c26fd-85f5-4db2-9f4e-9288a3f3e784"}}
{{ /dev/sda2: UUID="1aad7aca-689d-4f4f-afff-e0d46fc1b89f" TYPE="swap" PARTUUID="94ee5675-a805-49b2-aaf5-2fa15aade8d5"}}
{{ /dev/sdb: UUID="699a776a-3d8e-4c88-8f46-209101f318b6" TYPE="xfs"}}
{{ /dev/sdd: UUID="85566369-7148-4ff0-bf97-50954caee7854" TYPE="xfs"}}
{{ /dev/sdc: UUID="ba0ac1d3-58cf-4ff0-bd28-f2df532f7de9" TYPE="xfs"}}
```

The root volume in this output is /dev/sda*. The additional remote volumes are:

- /dev/sdb
- /dev/sdc
- /dev/sdd

4. To automatically attach the volumes at /mnt/vol1, /mnt/vol2, and /mnt/vol3 respectively, create the three directories using the following commands:

```
bash-4.2$ sudo mkdir /mnt/vol1
```
{% bash-4.2$ sudo mkdir /mnt/vol2 %}
{% bash-4.2$ sudo mkdir /mnt/vol3 %}

**Use the _netdev and nofail Options**

By default, the `/etc/fstab` file is processed before the initiator starts. To configure the mount process to initiate before the volumes are mounted, specify the `_netdev` option on each line of the `/etc/fstab` file.

When you create a custom image of an instance where the volumes, excluding the root volume, are listed in the `/etc/fstab` file, instances will fail to launch from the custom image. To prevent this issue, specify the `nofail` option in the `/etc/fstab` file.

In the example scenario with three volumes, the `/etc/fstab` file entries for the volumes with the `_netdev` and `nofail` options are as follows:

```
UUID=699a776a-3d8d-4c88-8f46-209101f318b6 /mnt/vol1 xfs defaults,_netdev,nofail 0 2
UUID=ba0ac1d3-58cf-4ff0-bd28-f2df532f7de9 /mnt/vol2 xfs defaults,_netdev,nofail 0 2
UUID=85566369-7148-4ffc-bf97-50954cae7854 /mnt/vol3 xfs defaults,_netdev,nofail 0 2
```

After you have updated the `/etc/fstab` file, use the following command to mount the volumes:

```
bash-4.2$ sudo mount -a
```

Reboot the instance to confirm that the volumes are mounted properly on reboot with the following command:

```
bash-4.2$ sudo reboot
```

**Troubleshooting Issues with the `/etc/fstab` File**

If the instance fails to reboot after you update the `/etc/fstab` file, you may need to undo the changes to the `/etc/fstab` file. To update the file, first connect to the serial console for the instance. When you have access to the instance using the serial console connection, you can remove, comment out, or fix the changes that you made to the `/etc/fstab` file.

**Listing Volumes**

You can list all Block Volume volumes in a specific compartment, as well as detailed information on a single volume.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a `policy` by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which `compartment` you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to list volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes. A detailed list of volumes in your current compartment is displayed.
• To view the volumes in a different compartment, change the compartment in the Compartment drop-down menu.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

List Volumes:
Get a list of volumes within a compartment.
• ListVolumes

Get a Single Volume:
Get detailed information on a single volume:
• GetVolume

Listing Volume Attachments

You can use the API to list all Block Volume volume attachments in a specific compartment, as well as detailed information on a single volume attachment.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to list volume attachments. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

List Attachments:
Get information on all volume attachments in a specific compartment.
• ListVolumeAttachments

Get a Single Attachment:
Get detailed information on a single attachment.
• GetVolumeAttachment

Renaming a Volume

You can use the API to change the display name of a Block Volume volume.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to rename block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the API

To update a volume's display name, use the following operation:

- UpdateVolume

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Editing a Volume's Settings

The Oracle Cloud Infrastructure Block Volume service enables you to edit the following settings for block volumes and boot volumes:

- Expand the volume size.
- Change the volume performance.
- Enable performance auto-tune.
- Assigning a volume backup policy.

You can edit these settings when volumes are online and attached to instances or while they’re detached from instances. See the applicable sections in this topic for links to tasks describing the steps to edit these settings, along with additional information about working with these settings.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Resizing Volumes

The Block Volume service's online resizing feature enables you to expand the size of an existing volume in place. After you resize an online volume, you need to rescan the disk and extend the partition. For more information, see:

- Resizing a Volume on page 532
- Rescanning the Disk for a Block Volume or Boot Volume on page 535
Changing the Volume Performance

The elastic performance feature of the Block Volume service allows you to dynamically change the volume performance, see Block Volume Elastic Performance on page 581 for more information. You can change volume performance for your block volumes and boot volumes while they are online, without any downtime, see Changing the Performance of a Volume on page 582. For specific information about this task in the Console, see Using the Console on page 582.

Enabling Performance Auto-tune for a Volume

With the performance auto-tune feature of the Block Volume service, you can configure your volumes to optimize cost with performance. When auto-tune is enabled, a volume’s performance it automatically adjusted to the lower cost option when the volume is detached from all instances. The performance is then automatically reset to the default performance option when you reattach the volume to an instance. For details, see Auto-tune Volume Performance on page 583.

Assigning a Backup Policy to a Volume

The Block Volume service provides you with the capability to perform volume backups automatically on a schedule and retain them based on the selected backup policy.

There are two kinds of backup policies:

- **User defined**: Custom backup policies that you create and configure schedules for. With user defined policies, you can also enable scheduled cross-region backups, so that scheduled volume backups are automatically copied to a second region, see Scheduling Volume Backup Copies Across Regions on page 548.
- **Oracle defined**: Predefined backup policies that have a set backup frequency and retention period. You cannot modify these policies.

For more information about scheduling volume backups, see Policy-Based Backups. For task-based procedures, see Managing Backup Policy Assignments to Volumes.

Resizing a Volume

The Oracle Cloud Infrastructure Block Volume service lets you expand the size of block volumes and boot volumes. You have several options to increase the size of your volumes:

- Expand an existing volume in place with online resizing. See Online Resizing of Block Volumes Using the Console on page 533 for the steps to do this.
- Restore from a volume backup to a larger volume. See Restoring a Backup to a New Volume on page 557 and Restoring a Boot Volume on page 618.
- Clone an existing volume to a new, larger volume. See Cloning a Volume on page 560 and Cloning a Boot Volume on page 621.
- Expand an existing volume in place with offline resizing. See Offline Resizing of Block Volumes Using the Console on page 534 for the steps to do this.

For more information about the Block Volume service, see the Block Volume FAQ.

You can only increase the size of the volume, you cannot decrease the size.

**Note:**

Resizing IDE type boot volumes is not supported. This applies to both offline and online resizing. To workaround this limitation, you can do one of the following:

- Terminate the VM instance, ensuring that you keep the boot volume when you terminate the instance. Resize the boot volume that you have kept,
and then launch a new VM instance, using the resized boot volume as the image source.
• Create a clone of the boot volume, resize the boot volume clone, and then launch a new VM instance using the resized boot volume clone as the image source.

Caution:
Before you resize a boot or block volume, you should create a backup of the volume.

Note:
After a volume has been resized, the first backup on the resized volume will be a full backup. See Volume Backup Types on page 541 for more information about full versus incremental volume backups.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Online Resizing of Block Volumes Using the Console
With online resizing, you can expand the volume size without detaching the volume from an instance.

To resize a block volume attached to a Linux-based instance
1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. In the Block Volumes list, click the block volume you want to resize.
3. Click Edit Size or Performance.
4. Specify the new size in VOLUME SIZE (IN GB). You must specify a larger value than the block volume's current size.
5. Click Save Changes. This opens a dialog that lists the commands to rescan the disk that you need to run after the volume is provisioned. You need to run these commands so that the operating system identifies the expanded volume size. Click the Copy link to copy the commands, and then click Close to close the dialog.
6. Log on to your instance's OS and then paste and run the rescan commands you copied in the previous step into your instance session window. The rescan commands are also provided in Rescanning the Disk for Volumes Attached to Linux-Based Instances on page 535.
7. Extend the partition, see Extending the Partition for a Block Volume on page 536.

To resize a block volume attached to a Windows instance
This procedure describes the process for online resizing for block volumes attached to Windows instances, or other instance types that are not Linux-based.
1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. In the Block Volumes list, click the block volume you want to resize.
3. Click Edit Size or Performance.
4. Specify the new size in **VOLUME SIZE (IN GB)**. You must specify a larger value than the block volume's current size.
5. Click **Save Changes**.
6. Rescan the disk, see **Rescanning the Disk for Volumes Attached to Windows Instances** on page 536.
7. Extend the partition, see **Extending the Partition for a Block Volume** on page 536.

**To resize a boot volume for a Linux-based Instance**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Boot Volumes** list, click the boot volume you want to resize.
3. Click **Edit Size or Performance**.
4. Specify the new size in **VOLUME SIZE (IN GB)**. You must specify a larger value than the boot volume's current size.
5. Click **Save Changes**. This opens a dialog that lists the commands to rescan the disk that you need to run after the volume is provisioned. You need to run these commands so that the operating system identifies the expanded volume size. Click the **Copy** link to copy the commands, and then click **Close** to close the dialog.
6. Log on to your instance's OS and then paste and run the rescan commands you copied in the previous step into your instance session window. The rescan commands are also provided in **Rescanning the Disk for Volumes Attached to Linux-Based Instances** on page 535.
7. Extend the partition and grow the file system using the **oci-growfs** command from **OCI Utilities** on page 642.

**Resizing a Boot Volume for a Windows Instance**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Boot Volumes** list, click the boot volume you want to resize.
3. Click **Resize**.
4. Click **Save Changes**.
5. Rescan the disk, see **Rescanning the Disk for Volumes Attached to Windows Instances** on page 536.
6. Extend the partition, see **Extending the System Partition on a Windows-Based Image** on page 612.

**Offline Resizing of Block Volumes Using the Console**
With offline resizing, you detach the volume from an instance before you expand the volume size. Once the volume is resized and reattached, you need to extend the partition, but you do not need to rescan the disk.

**Considerations When Resizing an Offline Volume**
Whenever you detach and reattach volumes, there are complexities and risks for both Linux-based and Windows-based instances. This applies to both paravirtualized and iSCSI attachment types. You should keep the following in mind when resizing volumes:

- When you reattach a volume to an instance after resizing, if you are not using consistent device paths, or the instance does not support consistent device paths, device order and path may change. If you are using a tool such as Logical Volume Manager (LVM), you may need to fix the device mappings. For more information about consistent device paths, see **Connecting to Volumes With Consistent Device Paths** on page 518.
- When you detach and then reattach an iSCSI-attached volume to an instance, the volume's IP address will increment.
- Before you resize a volume, you should create a full backup of the volume.

**To resize a block volume attached to a Linux-based instance**
1. Detach the block volume, see **Detaching a Volume** on page 563.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
3. In the **Block Volumes** list, click the block volume you want to resize.
4. Click **Edit Size or Performance**.
5. Specify the new size in **VOLUME SIZE (IN GB)**. You must specify a larger value than the block volume's current size.
6. Click **Save Changes**. This opens a dialog that lists the required steps to complete the volume resize. For offline resizing, you need to extend the partition after you reattach the volume. Click **Close** to close the dialog.
7. Reattach the volume, see **Attaching a Volume** on page 517.
8. Extend the partition, see **Extending the Partition for a Block Volume** on page 536.

### Resizing a Boot Volume for a Windows Instance

1. Stop the instance, see **Stopping and Starting an Instance** on page 779.
2. Detach the boot volume, see **Detaching a Boot Volume** on page 623.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
4. In the **Boot Volumes** list, click the boot volume you want to resize.
5. Click **Edit Size or Performance**.
6. Specify the new size in **VOLUME SIZE (IN GB)**. You must specify a larger value than the block volume's current size.
7. Reattach the boot volume, see **Attaching a Boot Volume** on page 613.
8. Restart the instance, see **Stopping and Starting an Instance** on page 779.
9. Extend the partition, see **Extending the System Partition on a Windows-Based Image** on page 612.

### Resizing a Boot Volume for a Linux Instance

1. Stop the instance, see **Stopping and Starting an Instance** on page 779.
2. Detach the boot volume, see **Detaching a Boot Volume** on page 623.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
4. In the **Boot Volumes** list, click the boot volume you want to resize.
5. Click **Edit Size or Performance**.
6. Specify the new size in **VOLUME SIZE (IN GB)**. You must specify a larger value than the block volume's current size.
7. Attach the boot volume to a second instance as a data volume. See **Attaching a Volume** on page 517 and **Connecting to a Volume** on page 524.
8. Extend the partition and grow the file system, see **Extending the Root Partition on a Linux-Based Image** on page 612.
9. Reattach the boot volume, see **Attaching a Boot Volume** on page 613.
10. Restart the instance, see **Stopping and Starting an Instance** on page 779.

### Rescanning the Disk for a Block Volume or Boot Volume

The Oracle Cloud Infrastructure Block Volume service lets you expand the size of block volumes and boot volumes while they are online and attached to instances, for more information, see **Online Resizing of Block Volumes Using the Console** on page 533. After the volume is provisioned, you need to run commands to rescan the disk, so that the operating system identifies the expanded volume size. You will need to run different rescan commands depending on the operating system of the attached instance. This topic describes some procedures you can use to rescan the disk.

#### Required IAM Policy

Rescanning the disk does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

### Rescanning the Disk for Volumes Attached to Linux-Based Instances

For volumes attached to Linux-based instances, run the following commands rescan the disk for a block volume:

```bash
sudo dd iflag=direct if=/dev/<device_name> of=/dev/null count=1
echo "1" | sudo tee /sys/class/block/<device_name>/device/rescan
```

These commands are also displayed in the dialog that opens after you click **Save Changes** in the **Edit Size or Performance** dialog, and you can copy them from that dialog.
Next Steps

After you've rescanned the disk, you need to extend the partition. See Extending the Partition for a Block Volume on a Linux-Based Image on page 537 for block volumes. For boot volumes, use the oci-growfs operation from OCI Utilities on page 642.

Rescanning the Disk for Volumes Attached to Windows Instances

Using Disk Management or diskpart

For volumes formatted as FAT32 or NTFS, you can rescan the disk using the Windows interface, in Disk Management, or you can use the diskpart utility's rescan command from the command line.

Rescanning the disk using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the diskpart utility:
   ```bash
diskpart
   ```
3. At the DISKPART prompt, run the following command:
   ```bash
   rescan
   ```

Rescanning the disk using the Windows interface

1. Open the Disk Management system utility on the instance.
2. Click Action, and then click Rescan Disks.

Update disk information.

Using Cygwin

For volumes formatted with a non-native Windows file system, such as volumes formatted using Oracle Automatic Storage Management (Oracle ASM), you can't use the Windows interface or the diskpart utility. Instead, you can use the dd process from a Cygwin terminal to rescan the disk. You can also use this for native Windows file systems. For more information, see Cygwin.

Next Steps

After you've rescanned the disk, you need to extend the partition. See Extending the Partition for a Block Volume on a Windows-Based Image on page 539 for block volumes, see Extending the System Partition on a Windows-Based Image on page 612 for boot volumes.

Extending the Partition for a Block Volume

The Oracle Cloud Infrastructure Block Volume service lets you expand the size of block volumes with offline volume resizing. For more information, see Resizing a Volume on page 532. In order to take advantage of the larger volume size, you need to extend the partition for the block volume. For boot volumes, see Extending the Partition for a Boot Volume on page 612.

Note:

After a volume has been resized, the first backup on the resized volume will be a full backup. See Volume Backup Types on page 541 for more information about full versus incremental volume backups.

Required IAM Policy

Extending a partition on an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.
Extending the Partition for a Block Volume on a Linux-Based Image

On Linux-based images, use the following steps to extend the partition for a block volume.

Prerequisites

After you have resized a volume, you need to attach it to an instance before you can extend the partition and grow the file system. See Attaching a Volume on page 517 and Connecting to a Volume on page 524 for more information.

Extending the Linux Partition

Extending a partition

1. To identify the volume that you want to extend the partition for, run the following command to list the attached block volumes:

   `lsblk`

2. Run the following command to edit the volume's partition table with `parted`:

   `parted <volume_id>`

   `<volume_id>` is the volume identifier, for example `/dev/sdc`.

3. When you run `parted`, you may encounter the following error message:

   Warning: Not all of the space available to `<volume_id>` appears to be used, you can fix the GPT to use all of the space (an extra `volume_size` blocks)
or continue with the current setting?

You are then prompted to fix the error or ignore the error and continue with the current setting. Specify the option to fix the error.

4. Run the following command to change the display units to sectors so that you can see the precise start position for the volume:

\[(parted)\ unit\ s\]

5. Run the following command to display the current partitions in the partition table:

\[(parted)\ print\]

Make note of the values in the **Number**, **Start**, and **File system** columns for the root partition.

6. Run the following command to remove the existing root partition:

\[(parted)\ rm\ <partition_number>\]

\(<partition_number>\) is the value from the **Number** column.

7. Run the following command to recreate the partition:

\[(parted)\ mkpart\]

At the **Start?** prompt, specify the value from the **Start** column. At the **File system type?** prompt, specify the value from the **File system** column. Specify 100% for the **End?** prompt.

8. Run the following command to exit parted:

\[(parted)\ quit\]

This command forces a rewrite of the partition table with the new partition settings that you specified.

9. To verify that the root partition was extended, run the following command to list the attached block volumes:

\[lsblk\]

After you extend the root partition you need to grow the file system. The steps in the following procedure apply only to xfs file systems.

**Growing the file system for a partition**

1. Before you grow the file system, repair any issues with the file system on the extended partition by running the following command:

\[xfs\_repair\ <partition\_id>\]

\(<partition\_id>\) is the partition identifier, for example /dev/sdc1. See Checking and Repairing an XFS File System for more information.

2. After you have confirmed that there are no more issues to repair, you need to create a mount point to run the xfs_growfs against. To do this, create a directory and mount the partition to that directory by running the following commands:

\[mkdir\ <directory\_name>\]

\[mount\ <device>\ <directory\_name>\]

\(<device>\) is the device path to the file system, for example /dev/sdc1.
3. After you have created the mount point run the following command to grow the file system:

```
mount <partition_id> <directory_name> -o nouuid
```

<partition_id> is the partition identifier, for example /dev/sdc1, and <directory_name> is the directory name, for example data.

4. To verify that the file system size is correct, run the following command to display the file system details:

```
xfs_growfs -d <directory_name>
```

<directory_name> is the name for the directory you created in the previous step, for example data.

---

**Extending the Partition for a Block Volume on a Windows-Based Image**

On Windows-based images, you can extend a partition using the Windows interface or from the command line using the DISKPART utility.

**Windows Server 2012 and Later Versions**

The steps to extend a partition for a block volume attached to an instance running Windows Server 2012, Windows Server 2016, or Windows Server 2019 are the same, and are described in the following procedures.

**Extending a partition using the Windows interface**

1. Open the Disk Management system utility on the instance.
2. Right-click the expanded block volume and select **Extend Volume**.
3. Follow the instructions in the **Extend Volume Wizard**:
   a. Select the disk that you want to extend, enter the size, and then click **Next**.
   b. Confirm that the disk and size settings are correct, and then click **Finish**.
4. Verify that the block volume's disk has been extended in Disk Management.

**Extending a partition using the command line with DISKPART**

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

```
diskpart
```

3. At the DISKPART prompt, run the following command to display the instance's volumes:

```
list volume
```

4. Run the following command to select the expanded block volume:

```
select volume <volume_number>
```

<volume_number> is the number associated with the block volume that you want to extend the partition for.

5. Run the following command to extend the partition:

```
extend size=<increased_size_in_MB>
```

<increased_size_in_MB> is the size in MB that you want to extend the partition to.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.</td>
</tr>
</tbody>
</table>

6. To confirm that the partition was extended, run the following command and verify that the block volume's partition has been extended:

```
list volume
```

---

**Overview of Block Volume Backups**

The backups feature of the Oracle Cloud Infrastructure Block Volume service lets you make a point-in-time snapshot of the data on a block volume. You can make a backup of a volume when it is attached to an instance or while it is detached. These backups can then be restored to new volumes either immediately after a backup or at a later time that you choose.

Backups are encrypted and stored in Oracle Cloud Infrastructure Object Storage, and can be restored as new volumes to any availability domain within the same region they are stored. This capability provides you with a spare copy of a volume and gives you the ability to successfully complete disaster recovery within the same region.

There are two ways you can initiate a backup, either by manually starting the backup, or by assigning a policy which defines a set backup schedule.

**Manual Backups**

These are on-demand one-off backups that you can launch immediately by following the steps described in Backing Up a Volume on page 546. When launching a manual backup, you can specify whether an incremental or a full backup should be performed. See Volume Backup Types for more information about backup types.

**Policy-Based Backups**

These are automated scheduled backups as defined by the backup policy assigned to the volume.

There are two kinds of backup policies:

- **Oracle defined**: Predefined backup policies that have a set backup frequency and retention period. You cannot modify these policies. For more information, see Oracle Defined Backup Policies on page 550.
- **User defined**: Custom backup policies that you create and configure schedules and retention periods for. You can also enable scheduled cross-region automated backups with user defined policies, see Scheduling Volume Backup Copies Across Regions on page 548. For more information, see User Defined Backup Policies on page 547.
Tags
When a volume backup is created, the source volume's tags are automatically included in the volume backup. This also includes volumes with custom backup policies applied to create backups on a schedule. Source volume tags are automatically assigned to all backups when they are created. You can also apply additional tags to volume backups as needed.

When a volume backup is copied to a new region, tags are also automatically copied with the volume backup. When the volume is restored from a backup, the volume is restored with the source volume's tags.

Volume Backup Types
There are two backup types available in the Block Volume service:

- **Incremental**: This backup type includes only the changes since the last backup.
- **Full**: This backup type includes all changes since the volume was created.

For data recovery purposes, there is no functional difference between an incremental backup and a full backup. You can restore a volume from any of your incremental or full volume backups. Both backup types enable you to restore the full volume contents to the point-in-time snapshot of the volume when the backup was taken. You don't need to keep the initial full backup or subsequent incremental backups in the backup chain and restore them in sequence, you only need to keep the backups taken for the times you care about.

Backup Details
For incremental backups, they are a record of all the changes since the last backup. If the first backup on a volume is created as incremental, it is effectively a full backup. For full backups, they are a record of all the changes since the volume was created.

For example, in a scenario where you create a 16 TB block volume, modify 40 GB on the volume, and then launch a full backup of the volume, upon completion, the volume backup size is 40 GB. If you then modify an additional 4 GB and create an incremental backup, the unique size of the incremental backup will be 4 GB. If the full backup is deleted, the incremental backup will retain the full 44 GB necessary to restore the volume contents. In this example, if there was a third incremental backup of non-overlapping blocks, with a size of 1 GB, created after the second incremental backup, and then the full backup is deleted, the third backup would stay at a 1 GB size, and the second incremental backup size would be updated to 44 GB. The blocks are accounted for in the earliest backup that references them.

**Note:**

After a volume has been resized, the first backup on the resized volume will be a full backup. See [Resizing a Volume](https://docs.oracle.com/en-us/iaas/Content/Block/Concepts/block-volumes.htm#resize) on page 532 for more information about volume resizing.

Planning Your Backup
The primary use of backups is to support business continuity, disaster recovery, and long-term archiving requirements. When determining a backup schedule, your backup plan and goals should consider the following:

- **Frequency**: How often you want to back up your data.
- **Recovery time**: How long you can wait for a backup to be restored and accessible to the applications that use it. The time for a backup to complete varies on several factors, but it will generally take a few minutes or longer, depending on the size of the data being backed up and the amount of data that has changed since your last backup.
- **Number of stored backups**: How many backups you need to keep available and the deletion schedule for those you no longer need. You can only create one backup at a time, so if a backup is underway, it will need to complete before you can create another one. For details about the number of backups you can store, see [Block Volume Capabilities and Limits](https://docs.oracle.com/en-us/iaas/Content/Block/Concepts/block-volumes.htm#lim) on page 505.
The common use cases for using backups are:

- Needing to create multiple copies of the same volume. Backups are highly useful in cases where you need to create many instances with many volumes that need to have the same data formation.
- Taking a snapshot of your work that you can restore to a new volume at a later time.
- Ensuring you have a spare copy of your volume in case something goes wrong with your primary copy.

**Volume Backup Size**

Volume backup size may be larger than the current volume usage. Some of the reasons for this could include the following:

- Any part of a volume that has been written to is considered initialized, so will always be part of a volume backup.
- Many operating systems write or zero out the content, which results in these blocks marked as used. The Block Volume service considers these blocks updated and includes them in the volume backup.
- Volume backups also include metadata, which can be up to 1 GB in additional data. For example, in a full backup of a 256 GB Windows boot disk, you may see a backup size of 257 GB, which includes an additional 1 GB of metadata.

**Copying Block Volume Backups Across Regions**

You can copy block volume backups between regions using the Console, command line interface (CLI), SDKs, or REST APIs. For steps, see Copying a Volume Backup Between Regions on page 558. This capability enhances the following scenarios:

- **Disaster recovery and business continuity:** By copying block volume backups to another region at regular intervals, it makes it easier for you to rebuild applications and data in the destination region if a region-wide disaster occurs in the source region.
- **Migration and expansion:** You can easily migrate and expand your applications to another region.

You can also enable scheduled cross-region automated backups with user defined policies, see Scheduling Volume Backup Copies Across Regions on page 548.

To copy volume backups between regions, you must have permission to read and copy volume backups in the source region, and permission to create volume backups in the destination region. For more information see Required IAM Policy on page 620.

Once you have copied the volume backup to the new region you can then restore from that backup by creating a new volume from the backup using the steps described in Restoring a Backup to a New Volume on page 557.

**Volume Backup Encryption**

The Oracle Cloud Infrastructure Block Volume service always encrypts all block volumes, boot volumes, and volume backups at rest by using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption.

The Oracle Cloud Infrastructure Vault service enables you to bring and manage your own keys to use for encrypting volumes and their backups. When you create a volume backup, the encryption key used for the volume is also used for the volume backup. When you restore the backup to create a new volume you configure a new key, see Restoring a Backup to a New Volume on page 557. See also Overview of Vault on page 3952.

If you do not configure a volume to use the Vault service, the Block Volume service uses the Oracle-provided encryption key instead. This applies to both encryption at-rest and in-transit encryption.

**Best Practices When Creating Block Volume Backups**

When creating and restoring from backups, keep in mind the following:

- Before creating a backup, you should ensure that the data is consistent: Sync the file system, unmount the file system if possible, and save your application data. Only the data on the disk will be backed up. When creating a backup, after the backup state changes from REQUEST_RECEIVED to CREATING, you can return to writing data to the volume. While a backup is in progress, the volume that is being backed up cannot be deleted.
• If you want to attach a restored volume that has the original volume attached, be aware that some operating systems do not allow you to restore identical volumes. To resolve this, you should change the partition IDs before restoring the volume. The steps to change an operating system's partition ID vary by operating system. For instructions, see your operating system's documentation.

• You should not delete the original volume until you have verified that the backup you created of it completed successfully.

See Backing Up a Volume on page 546 and Restoring a Backup to a New Volume on page 557 for more information.

**Differences Between Block Volume Backups and Clones**

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

<table>
<thead>
<tr>
<th></th>
<th>Volume Backup</th>
<th>Volume Clone</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.</td>
<td>Creates a single point-in-time copy of a volume without having to go through the backup and restore process.</td>
</tr>
<tr>
<td><strong>Use case</strong></td>
<td>Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.</td>
<td>Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.</td>
</tr>
<tr>
<td><strong>Speed</strong></td>
<td>Slower (minutes or hours)</td>
<td>Faster (seconds)</td>
</tr>
<tr>
<td><strong>Cost</strong></td>
<td>Lower cost</td>
<td>Higher cost</td>
</tr>
<tr>
<td><strong>Storage location</strong></td>
<td>Object Storage</td>
<td>Block Volume</td>
</tr>
<tr>
<td><strong>Retention policy</strong></td>
<td>Policy-based backups expire, manual backups do not expire</td>
<td>No expiration</td>
</tr>
<tr>
<td><strong>Volume groups</strong></td>
<td>Supported. You can back up a volume group.</td>
<td>Supported. You can clone a volume group.</td>
</tr>
</tbody>
</table>

For background information and steps to clone a block volume, see Cloning a Volume on page 560.

**Using the CLI or REST APIs to Customize and Manage the Lifecycle of Volume Backups**

You can use the CLI, REST APIs, or the SDKs to automate, script, and manage volume backups and their lifecycle.

**Using the CLI**

This section provides basic sample CLI commands that you can use in a script, such as a cron job run by the cron utility on Linux-based operating systems, to perform automatic backups at specific times. For information about using the CLI, see Command Line Interface (CLI) on page 4192.
To create a manual backup of the specified block volume

Open a command prompt and run:

```
oci bv backup create --volume-id <block_volume_OCID> --display-name <Name> --type <FULL|INCREMENTAL>
```

For example:

```
oci bv backup create --volume-id ocid1.volume.oc1..<unique_ID> --display-name "backup display name" --type FULL
```

To delete a block volume backup

Open a command prompt and run:

```
oci bv backup delete --volume-backup-id <volume_backup_OCID>
```

For example:

```
oci bv backup delete --volume-backup-id ocid1.volume.oc1..<unique_ID>
```

To create a manual backup of the specified boot volume

Open a command prompt and run:

```
oci bv boot-volume-backup create --volume-id <boot_volume_OCID> --display-name <Name> --type <FULL|INCREMENTAL>
```

For example:

```
oci bv boot-volume-backup create --volume-id ocid1.volume.oc1..<unique_ID> --display-name "backup display name" --type FULL
```

To delete a boot volume backup

Open a command prompt and run:

```
oci bv backup delete --boot-volume-backup-id <boot_volume_backup_OCID>
```

For example:

```
oci bv backup delete --boot-volume-backup-id ocid1.volume.oc1..<unique_ID>
```

To list the Oracle-defined backup policies

Open a command prompt and run:

```
oci bv volume-backup-policy list
```

To assign an Oracle-defined backup policy to a boot or block volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment create --asset-id <volume_OCID> --policy-id <policy_OCID>
```
For example:

```bash
oci bv volume-backup-policy-assignment create --asset-id ocid1.volume.oc1..<unique_ID> --policy-id ocid1.volumebackuppolicy.oc1..<unique_ID>
```

**To un-assign an Oracle-defined backup policy from a boot or block volume**

Open a command prompt and run:

```bash
oci bv volume-backup-policy-assignment delete --policy-assignment-id <policy_assignment_OCID>
```

For example:

```bash
oci bv volume-backup-policy-assignment delete --policy-assignment-id ocid1.volumebackuppolicyassign.oc1..<unique_ID>
```

**To retrieve the backup policy assignment ID for a boot or block volume**

Open a command prompt and run:

```bash
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id <volume_OCID>
```

For example:

```bash
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id ocid1.volume.oc1..<unique_ID>
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations for working with block volume backups, boot volume backups, and backup policies.

**Block Volume Backups**

- CreateVolumeBackup
- DeleteVolumeBackup
- GetVolumeBackup
- ListVolumeBackups
- UpdateVolumeBackup

**Boot Volume Backups**

- CreateBootVolumeBackup
- DeleteBootVolumeBackup
- GetBootVolumeBackup
- ListBootVolumeBackups
- UpdateBootVolumeBackup

**Volume Backup Policies and Policy Assignments**

- GetVolumeBackupPolicy
- ListVolumeBackupPolicies
- CreateVolumeBackupPolicyAssignment
- DeleteVolumeBackupPolicyAssignment
Block Volume

- GetVolumeBackupPolicyAssetAssignment
- GetVolumeBackupPolicyAssignment

**Backing Up a Volume**

You can create a backup of a volume using Block Volume. Volume backups are point-in-time snapshots of volume data. For more information about volume backups, see Overview of Block Volume Backups on page 540.

For information to help you decide whether to create a backup or a clone of a boot volume, see Differences Between Block Volume Backups and Clones on page 543.

**Note:**

Volume backup size may be larger than the current volume usage. See Volume Backup Size on page 542 for more information.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups. The policy in Let boot volume backup admins manage only backups on page 2147 further restricts access to just creating and managing backups.

**Tip:**

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. Click the block volume that you want to create a backup for.
3. Click Create Manual Backup.
4. Enter a name for the backup. Avoid entering confidential information.
5. Select the backup type, either incremental or full. See Volume Backup Types on page 541 for information about backup types.
6. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click Create Backup.

The backup will be completed once its icon no longer lists it as CREATING in the volume list.

**Using the API**

To back up a volume, use the following operation:

- CreateVolumeBackup

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
For more information about backups, see Overview of Block Volume Backups on page 540 and Restoring a Backup to a New Volume on page 557.

**Policy-Based Backups**

The Oracle Cloud Infrastructure Block Volume service provides you with the capability to perform volume backups and volume group backups automatically on a schedule and retain them based on the selected backup policy.

With user defined policies, you can also enable scheduled cross-region backups, so that scheduled volume backups are automatically copied to a second region, see Scheduling Volume Backup Copies Across Regions on page 548. These features allow you to adhere to your data compliance and regulatory requirements.

Caution:

Deleting Block Volumes with Policy-Based Backups

All policy-based backups will eventually expire, so if you want to keep a volume backup indefinitely, you need to create a manual backup.

Volume backups are point-in-time snapshots of volume data. For more information about volume backups, see Overview of Block Volume Backups on page 540.

There are two kinds of backup policies:

- **User defined**: Custom backup policies that you create and configure schedules for.
- **Oracle defined**: Predefined backup policies that have a set backup frequency and retention period. You cannot modify these policies.

Note:

Timing for Scheduled Backups

Scheduled volume backups are not guaranteed to start at the exact time specified by the backup schedule. You may see up to several hours of delay between the scheduled start time and the actual start time for the volume backup in scenarios where the system is overloaded. This applies to both user defined and Oracle defined backup policies.

Caution:

Full Backups and Oracle Defined Policies

Starting November 3, 2021, Oracle defined policies will no longer include full backups. See Full backups removed from Oracle defined backup policies.

**User Defined Backup Policies**

Oracle Cloud Infrastructure enables you to customize your backup schedules with user defined policies. These are backup policies that you define the backup frequency and retention period for. There are two parts to user defined backup policies, the backup policy itself, and then one or more schedules in the policy.

To get started with user defined backup policies, you need to first create the backup policy, see To create a user defined backup policy on page 552. After this step, you have an empty backup policy, so the next step is to define and add schedules to the policy.

**Schedules**

Schedules define the backup frequency and retention period for a user defined backup policy, just like Oracle defined backup policies. The difference is that you can customize the schedules associated with user defined policies. This gives you control over the backup frequency and retention period.

When defining a schedule for a user defined backup policy, the first thing you configure is the schedule type, this specifies the backup frequency. Oracle Cloud Infrastructure provides the following schedule types:
Block Volume

- **Daily**: Backups are generated daily. You specify the hour of the day for the backup.
- **Weekly**: Backups are generated weekly. You specify the day of the week, and the hour of that day for the backup.
- **Monthly**: Backups are generated monthly. You specify the day of the month, and the hour of that day for the backup.
- **Yearly**: Backups are generated yearly. You specify the month, the day of that month, and the hour of that day for the backup.

In addition to frequency, you also configure the following:

- **Retention time**: The amount of time to keep the backup, in days, weeks, months, or years. The time period is based on the schedule type.
- **Backup type** Options are full or incremental, see Volume Backup Types on page 541 for more information.
- **Timezone** The time zone to use for the backup schedule. Options are UTC or the regional data center time zone.

For more information, see To add a schedule to a user defined backup policy on page 552.

You can also edit or remove schedules for a user defined policy at any time, see To edit a schedule for a user defined backup policy on page 553 and To delete a schedule for a user defined backup policy on page 553.

**Duplicating Existing Backup Policies**

You can create a new backup policy by duplicating any of the existing backup policies.

If one of the Oracle defined policies is close to meeting your volume backup requirements, but with some changes, you can create a new backup policy by duplicating the Oracle defined policy. This creates a new user defined backup policy with schedules already assigned, enabling you to use the Oracle defined policy’s settings as a starting point to save time and simplify the process.

You can also duplicate an existing user defined policy. For more information, see To duplicate a backup policy on page 553. You can then add, edit, or delete schedules for the new backup policy.

**Scheduling Volume Backup Copies Across Regions**

The Block Volume service enables you to copy volume backups from one region to another for business continuity and disaster recovery scenarios, for more information, see Copying Block Volume Backups Across Regions on page 542. With user-defined policies, you can automate this process, so that volume backups are copied to another region on a schedule. Enabling the automatic copying of scheduled volume backups is only supported with user-defined policies, so if you need to use this feature for a volume currently configured with an Oracle defined policy, you need to duplicate the policy and then enable cross region copy. The volume backup copy in the target region has the same retention period as the volume backup in the source region.

**Caution:**

Vault encryption keys for volumes are not copied to the destination region for scheduled volume and volume group backups enabled for cross region copy.

For more information, see Vault encryption keys not copied to destination region for scheduled cross region backup copies.

**Note:**

It may take up to 24 hours for daily scheduled volume backups to be copied to the target region. You can verify that the volume backup was copied by switching to the target region and checking the list of volume backups for that region. If the volume backup has not been copied yet, you can perform a manual copy of that volume backup to the target region using the steps described in Copying a Volume Backup Between Regions on page 558.

**Cost**

Once this feature is enabled, your bill will include charges for storing volume backups in both the source region and the destination region. You may also see an increase in network costs. For pricing details, see Oracle Storage Cloud Pricing. The Object Storage price applies to backup storage. Outbound Data Transfer price will be applicable for network costs with cross-region backup copies.
Regions Pairs

When you enable cross region copy for a backup policy, the default target region is based on the source region for the backup.

**Note:**

You can change the default target region using the CLI, see Configuring a Custom Target Region on page 549. This capability is not available in the Console.

The following table lists the source and target region pairs for cross region copy. To copy a volume backup to a region not paired with the backup's source region, you must manually copy the volume backup, see Copying a Volume Backup Between Regions on page 558.

<table>
<thead>
<tr>
<th>Source Region</th>
<th>Target Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>US West (Phoenix)</td>
<td>US East (Ashburn)</td>
</tr>
<tr>
<td>US East (Ashburn)</td>
<td>US West (Phoenix)</td>
</tr>
<tr>
<td>US West (San Jose)</td>
<td>US West (Phoenix)</td>
</tr>
<tr>
<td>Brazil East (Sao Paulo)</td>
<td>US West (Phoenix)</td>
</tr>
<tr>
<td>Chile (Santiago)</td>
<td>Brazil East (Sao Paulo)</td>
</tr>
<tr>
<td>Canada Southeast (Toronto)</td>
<td>Canada Southeast (Montreal)</td>
</tr>
<tr>
<td>Canada Southeast (Montreal)</td>
<td>Canada Southeast (Toronto)</td>
</tr>
<tr>
<td>Japan Central (Osaka)</td>
<td>Japan East (Tokyo)</td>
</tr>
<tr>
<td>Japan East (Tokyo)</td>
<td>Japan Central (Osaka)</td>
</tr>
<tr>
<td>India South (Hyderabad)</td>
<td>India West (Mumbai)</td>
</tr>
<tr>
<td>India West (Mumbai)</td>
<td>India South (Hyderabad)</td>
</tr>
<tr>
<td>Germany Central (Frankfurt)</td>
<td>Switzerland North (Zurich)</td>
</tr>
<tr>
<td>UK South (London)</td>
<td>Germany Central (Frankfurt)</td>
</tr>
<tr>
<td>UK West (Newport)</td>
<td>UK South (London)</td>
</tr>
<tr>
<td>Australia East (Sydney)</td>
<td>Australia Southeast (Melbourne)</td>
</tr>
<tr>
<td>Australia Southeast (Melbourne)</td>
<td>Australia East (Sydney)</td>
</tr>
<tr>
<td>Netherlands Northwest (Amsterdam)</td>
<td>Germany Central (Frankfurt)</td>
</tr>
<tr>
<td>Saudi Arabia West (Jeddah)</td>
<td>Germany Central (Frankfurt)</td>
</tr>
<tr>
<td>South Korea Central (Seoul)</td>
<td>South Korea North (Chuncheon)</td>
</tr>
<tr>
<td>South Korea North (Chuncheon)</td>
<td>South Korea Central (Seoul)</td>
</tr>
</tbody>
</table>

Configuring a Custom Target Region

You can change the default target region for the scheduled cross region backup copy feature using the CLI. You can do this when you create a new backup policy or you can update the target region for an existing backup policy. When you create a new policy, specify the custom target region using the destination-region parameter. If you're updating an existing policy, you need to ensure that you include all the existing backup policy settings that you want to keep when you update the policy with the custom target region. To do this:

1. Use the get operation to retrieve the existing policy settings.
2. Save those settings.
3. Use the settings you saved from the previous step in the **update** operation, along with the custom target region specified in the **destination-region** parameter.

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192.

**Note:**
This capability is not available in the Console.

**To create a volume backup policy with a custom target region:**

Open a command prompt and run:

```bash
oci bv volume-backup-policy create --compartment-id <compartment_ID> --display-name <display_name> --destination-region <region_ID> --schedules file//<path>/<scheduleJSON>.json
```

For example:

```bash
oci bv volume-backup-policy create --compartment-id ocid1.compartment.oc1..<unique_ID> --display-name MyPolicyName --destination-region us-sanjose-1 --schedules file//~/input.json
```

When you update an existing policy, you need to specify all the policy's settings in the update operation, including the existing settings that you want to keep. To ensure that you include all the settings, you should first retrieve those settings using the **get** operation.

**To get the volume backup policy:**

Open a command prompt and run:

```bash
oci bv volume-backup-policy get --policy-id <backup_policy_ID>
```

For example:

```bash
oci bv volume-backup-policy get --policy-id ocid1.volumebackuppolicy.oc1..<unique_ID>
```

Save these settings and then use them when you call the **update** operation.

**To update the volume backup policy with a custom target region:**

Open a command prompt and run:

```bash
oci bv volume-backup-policy update --policy-id <backup_policy_ID> --display-name <display_name> --destination-region <region_ID> --schedules file//<path>/<scheduleJSON>.json
```

For example:

```bash
oci bv volume-backup-policy create --policy-id ocid1.volumebackuppolicy.oc1..<unique_ID> --display-name MyPolicyName --destination-region us-sanjose-1 --schedules file//~/input.json
```

**Oracle Defined Backup Policies**

There are three Oracle defined backup policies, Bronze, Silver, and Gold. Each backup policy is comprised of schedules with a set backup frequency and a retention period that you cannot modify. If the backup policy settings for Oracle defined policies don't meet your requirements, you should use **User Defined Backup Policies** on page 547 instead. With user defined backup policies you define and control the schedules. You can also enable the automatic copying of volume backups to a second region, which is not supported with Oracle defined policies.
Note:
Oracle defined backup policies are not supported for scheduled volume group backups.

Caution:
Full Backups and Oracle Defined Policies
Starting November 3, 2021, Oracle defined policies will no longer include full backups. See Full backups removed from Oracle defined backup policies.

Bronze Policy
The bronze policy includes monthly incremental backups, run on the first day of the month. These backups are retained for twelve months. This policy also includes a full backup, run yearly during the first part of January. This backup is retained for five years.

Silver Policy
The silver policy includes weekly incremental backups that run on Sunday. These backups are retained for four weeks. This policy also includes monthly incremental backups, run on the first day of the month and are retained for twelve months. Also includes a full backup, run yearly during the first part of January. This backup is retained for five years.

Gold Policy
The gold policy includes daily incremental backups, retained for seven days, along with weekly incremental backups, run on Sunday and retained for four weeks. Includes monthly incremental backups, run on the first day of the month, retained for twelve months. Also include a full backup, run yearly, during the first part of January. This backup is retained for five years.

Working with Backup Policies
There are two types of tasks when working with backup policies:

- Creating and Configuring User Defined Backup Policies on page 552
- Managing Backup Policy Assignments to Volumes on page 555

The linked sections listed above provide information for working with backup policies using the Console, CLI, and REST APIs.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

Important:
To view or work with backup policies, you need access to the root compartment, which is where the predefined backup policies are located.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups. The policy in Let volume backup admins manage only backups on page 2146 further restricts access to just creating and managing backups.
Tip:

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

Creating and Configuring User Defined Backup Policies

Using the Console

You can use the Console to create and update user defined backup policies.

To create a user defined backup policy

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Backup Policies.
2. Click Create Backup Policy.
3. Specify a name for the backup policy. Avoid entering confidential information.
4. Select the compartment to create the backup policy in.

   While you select a compartment for the backup policy, it is accessible across your tenancy.
5. Optionally, you can enable cross region copy to the specified region. This automates the copying of the volume backup to a second region after each backup is created. The target region specified for the backup copy is based on the region pair for the policy's source region and cannot be changed. For more information, see Regions Pairs on page 549.
6. Click Create Backup Policy to create the backup policy.

To add a schedule to a user defined backup policy

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Backup Policies.
2. Click the backup policy you want to add the schedule to.
3. Click Add Schedule.
4. Specify the backup frequency by selecting from the Schedule Type options: Daily, Weekly, Monthly, or Yearly, and then configure the additional schedule options. Depending on the schedule type, the additional schedule options will include one or more of the following:
   - Hour of the day
   - Day of the week
   - Day of the month
   - Month of the year
5. Specify the Retention Time, which will be in days, weeks, months, or years, depending on the schedule type you selected in the previous step.
6. Select Full or Incremental for Backup Type.
7. Select the Timezone to base the schedule settings on, either UTC or Regional Data Center Time.
8. Click Add Schedule.

To enable cross region copy for a user defined backup policy

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Backup Policies.
2. Click the backup policy that you want to enable cross region copy for.
3. On the details page, for Cross Region Copy Target, click Enable.
4. Click **Enable** in the confirmation dialog.

**To disable cross region copy for a user defined backup policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the backup policy that you want to disable cross region copy for.
3. On the details page, for **Cross Region Copy Target**, click **Disable**.
4. Click **Disable** in the confirmation dialog.

**To duplicate a backup policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the backup policy that you want to duplicate. Both Oracle defined and user defined backup policies can be duplicated.
3. Click **Duplicate**.
4. Specify a name for the policy. Avoid entering confidential information.
5. Select the compartment to create the backup policy in. It does not need to be the same compartment as the backup policy you are duplicating.
6. Optionally, you can enable cross region copy to the specified region. This automates the copying of the volume backup to a second region after each backup is created. The default target region specified for the backup copy is based on the region pair for the policy’s source region. For more information, see **Regions Pairs** on page 549.
7. Click **Duplicate Backup Policy**.

**To edit a schedule for a user defined backup policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the backup policy that you want to edit a schedule for.
3. In **Schedules**, for the schedule you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. After making your changes to the schedule, click **Update**.

**To delete a schedule for a user defined backup policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the user defined backup policy that you want to delete a schedule for.
3. In **Schedules**, for the schedule you want to delete, click the Actions icon (three dots), and then click **Delete**.
4. Click **Delete** in the confirmation dialog.

**To delete a user defined backup policy**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the user defined backup policy you want to delete.
3. Click **Delete**.
4. Enter the name of the backup policy and click **Delete**.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192.

Use the following operations to work with backup policies:

**To create a user defined backup policy**

Open a command prompt and run:

```
oci bv volume-backup-policy create --compartment-id <compartment_ID> --schedules file://<path>/<scheduleJSON>.json
```

For example:

```
oci bv volume-backup-policy create --compartment-id ocid1.compartment.oc1..<unique_ID> --schedules file://~/input.json
```
To list the backup policies in a specified compartment

Open a command prompt and run:

```
oci bv volume-backup-policy list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-backup-policy list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

To retrieve a specific backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy get --backup-policy-id <backup-policy-ID>
```

For example:

```
oci bv volume-backup-policy get --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID>
```

To update the display name for a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy update --backup-policy-id <backup-policy_ID> --display-name <backup-policy_name>
```

For example:

```
oci bv volume-backup-policy update --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID> --display-name "new display name"
```

To update the schedules for a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy update --backup-policy-id <backup-policy_ID> --schedules file//<path>/scheduleJSON.json
```

For example:

```
oci bv volume-backup-policy update --volume-group-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID> --schedules file//~/input.json
```

To delete a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy delete --backup-policy-id <backup-policy_ID>
```

You can only delete a user defined backup policy if it is not assigned to any volumes. You cannot delete Oracle defined backup policies.

For example:

```
oci bv volume-backup-policy delete --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID>
```
**Using the API**

Use the following operations to work with backup policies:

- `CreateVolumeBackupPolicy`
- `DeleteVolumeBackupPolicy`
- `UpdateVolumeBackupPolicy`
- `ListVolumeBackupPolicies`
- `GetVolumeBackupPolicy`

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For more information about backups, see Overview of Block Volume Backups on page 540 and Restoring a Backup to a New Volume on page 557.

**Managing Backup Policy Assignments to Volumes**

If a volume is part of a volume group with a backup policy assignment, the backup policy assignment is managed by the volume group. In this scenario, to update the backup policy assigned you must change the assignment for the volume group or remove the volume from the group.

**To assign a backup policy to a volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to assign a backup policy to.
3. On the **Block Volume Information** tab, in **Scheduled Backups**, check the **Managed By** field.

**Using the Console**

You can use the Console to assign, change, or remove both user defined and Oracle defined backup policies for existing volumes.

**To assign a backup policy to a volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to assign a backup policy to.
3. On the **Block Volume Information** tab click **Edit**.
4. In the **BACKUP POLICIES** section, select the compartment containing the backup policies.
5. Select the appropriate backup policy for your requirements.
6. Click **Save Changes**.

**To change a backup policy assigned to a volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to change the backup policy for.
3. On the **Block Volume Information** tab click **Edit**.
4. In the **BACKUP POLICIES** section, select the compartment containing the backup policy.
5. Select the backup policy you want to switch to.
6. Click **Save Changes**.

**To remove a backup policy assigned to a volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to remove the backup policy for.
3. On the **Block Volume Information** tab click **Edit**.
4. In the **BACKUP POLICIES** section, select **None** from the list, and then click **Save Changes**.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 4192.

Use the following operations to work with volume backup policy assignments to volumes:
To assign a backup policy to a volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment create --asset-id <volume_ID> --policy-id <policy_ID>
```

For example:

```
oci bv volume-backup-policy-assignment create --asset-id ocid1.volume.oc1..<unique_ID> --policy-id ocid1.volumebackuppolicy.oc1..<unique_ID>
```

To get the backup policy assigned to a volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id <volume_ID>
```

For example:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id ocid1.volume.oc1..<unique_ID>
```

To retrieve a specific backup policy assignment

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment get --policy-assignment-id <backup-policy-ID>
```

For example:

```
oci bv volume-backup-policy-assignment get --policy-assignment-id ocid1.volumebackuppolicyassignment.oc1.phx.<unique_ID>
```

To delete a backup policy assignment

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment delete --policy-assignment-id <backup-policy_ID>
```

You can only delete a user defined backup policy if it is not assigned to any volumes. You cannot delete Oracle defined backup policies.

For example:

```
oci bv volume-backup-policy-assignment delete --policy-assignment-id ocid1.volumebackuppolicyassignment.oc1.phx.<unique_ID>
```

Using the API

Use the following operations to manage backup policy assignments to volumes:

- CreateVolumeBackupPolicyAssignment
- DeleteVolumeBackupPolicyAssignment
- GetVolumeBackupPolicyAssetAssignment
- GetVolumeBackupPolicyAssignment
Restoring a Backup to a New Volume

You can restore a backup of a volume as a new volume using Block Volume.

You can restore a volume from any of your incremental or full volume backups. Both backup types enable you to restore the full volume contents to the point-in-time snapshot of the volume when the backup was taken. You don't need to keep the initial full backup or subsequent incremental backups in the backup chain and restore them in sequence, you only need to keep the backups taken for the times you care about. See Volume Backup Types on page 541 for information about full and incremental backup types.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups.

Tip:

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

1. Open the navigation menu. Under Block Storage, click Block Volume Backups.
   
   A list of the block volume backups in the compartment you're viewing is displayed. If you don’t see the one you're looking for, make sure you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the Actions icon (three dots) for the block volume backup you want to restore.
3. Click Create Block Volume.
4. Enter a name for the block volume and choose the availability domain in which you want to restore it. Avoid entering confidential information.
5. You can restore a block volume backup to a larger volume size. To do this, check Custom Block Volume Size (GB), and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you restore the block volume backup to a larger size volume, you need to extend the volume's partition, see Extending the Partition for a Block Volume on page 536 for more information.
6. Optionally, you can select the appropriate backup policy for your requirements. See Policy-Based Backups on page 547 for more information about backup policies.
7. Optionally, you can encrypt the data in this volume using your own Vault encryption key. To use Vault for your encryption needs, select the Encrypt using Vault check box. Then, select the Vault compartment and Vault that contain the master encryption key you want to use. Also select the Master encryption key compartment and Master encryption key. For more information about encryption, see Overview of Vault on page 3952.
8. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
9. Click Create. The volume will be ready to attach once its icon no longer lists it as **PROVISIONING** in the volume list. For more information, see **Attaching a Volume** on page 517.

**Caution:**

If you want to attach a restored volume that has the original volume attached, be aware that some operating systems do not allow you to restore identical volumes. To resolve this, you should change the partition IDs before restoring the volume. How to change an operating system's partition ID varies by operating system; for instructions, see your operating system's documentation.

**Using the API**

The API used to restore a backup is **CreateVolume**. The API has an optional volumeBackupId parameter that you can use to define the backup from which the data should be restored on the newly created volume. For details, see **CreateVolumeDetails Reference**.

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

For more information about backups, see **Overview of Block Volume Backups** on page 540 and **Backing Up a Volume** on page 546.

**Copying a Volume Backup Between Regions**

You can copy volume backups from one region to another region using the Oracle Cloud Infrastructure Block Volume service. For more information, see **Copying Block Volume Backups Across Regions** on page 542. You can also enable scheduled cross-region automated backups with user defined policies, see **Scheduling Volume Backup Copies Across Regions** on page 548.

**Note:**

When copying block volume backups across regions in your tenancy, you can copy up to five concurrent backups per tenancy at a time from a specific source region.

**Volume Backup Type Considerations**

When volume backups are copied to another region, the volume backup type in the destination region will always match the source **volume backup types**, except for certain scenarios for incremental backups.

Incremental backups will be copied as full volume backups in the following scenarios:

- When the volume backup being copied is the first volume backup taken after a volume has been resized. This applies to volume backups copied on a schedule and volume backups copied manually.
- Volume backups that were the result of a cross region copy, if they are then copied back to their source region. This applies to volume backups copied on a schedule and volume backups copied manually.
- When the volume backup is being copied to a destination region where the previous incremental backup copy is not in the **AVAILABLE** state. This applies to volume backups copied on a schedule and volume backups copied manually.
- When the volume backup is copied out of order. For example, in the scenario where you have incremental volume backups #1 through #5, and you copy volume backup #3 and then volume backup #1, the volume backups may be copied as full backups to the destination region. This only applies to volume backups that are copied manually. This does not apply to volume backups created and copied using backup policies, as scheduled volume backups are always copied in sequential order.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
For administrators: The first two statements listed in the Let volume admins manage block volumes, backups, and volume groups on page 2146 policy lets the specified group do everything with block volumes and backups with the exception of copying volume backups across regions. The aggregate resource type volume-family does not include the VOLUME_BACKUP_COPY permission, so to enable copying volume backups across regions you need to ensure that you include the third statement in that policy, which is:

```
Allow group VolumeAdmins to use volume-backups in tenancy where request.permission='VOLUME_BACKUP_COPY'
```

To restrict access to just creating and managing volume backups, including copying volume backups between regions, use the policy in Let boot volume backup admins manage only backups on page 2147. The individual resource type volume-backups includes the VOLUME_BACKUP_COPY permission, so you do not need to specify it explicitly in this policy.

If you are copying volume backups encrypted using Vault between regions or you want the copied volume backup to use Vault for encryption in the destination region, you need to use a policy that allows the Block Volume service to perform cryptographic operations with keys in the destination region. For a sample policy showing this, see Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools on page 2153.

### Restricting Access

The specific permissions needed to copy volume backups across regions are:

- **Source region**: VOLUME_BACKUP_READ, VOLUME_BACKUP_COPY
- **Destination region**: VOLUME_BACKUP_CREATE

### Sample Policies

#### To restrict a group to specific source and destination regions for copying volume backups

In this example, the group is restricted to copying volume backups from the UK South (London) region to the Germany Central (Frankfurt) region.

```
Allow group MyTestGroup to read volume-backups in tenancy where all 
{request.region='lhr'}
Allow group MyTestGroup to use volume-backups in tenancy where all 
{request.permission='VOLUME_BACKUP_COPY', request.region = 'lhr'},
Allow group MyTestGroup to manage volume-backups in tenancy where all 
{request.permission='VOLUME_BACKUP_CREATE', request.region = 'fra'}
```

#### To restrict some source regions to specific destination regions while enabling all destination regions for other source regions

In this example, the following is enabled for the group:

- Manage volume backups in all regions.
- Copy volume backups from the US West (Phoenix) and US East (Ashburn) regions to any destination regions.
- Copy volume backups from the Germany Central (Frankfurt) and UK South (London) regions only to the Germany Central (Frankfurt) or UK South (London) regions.

```
Allow group MyTestGroup to read volume-backups in tenancy where all 
{request.region='lhr'}
Allow group MyTestGroup to manage volume-backups in tenancy where any 
{request.permission!=VOLUME_BACKUP_COPY'}
Allow group MyTestGroup to use volume-backups in tenancy where all 
{request.permission='VOLUME_BACKUP_COPY', any {request.region='lhr', request.region='fra'}, any{target.region='fra', target.region='lhr'}}
```
If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

1. Open the navigation menu. Under Block Storage, click Block Volume Backups.

   A list of the block volume backups in the compartment you're viewing is displayed. If you don't see the one you're looking for, make sure you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the Actions icon (three dots) for the block volume backup you want to copy to another region.

3. Click Copy to Another Region.

4. Enter a name for the backup and choose the region to copy the backup to. Avoid entering confidential information.

5. In the Encryption section select whether you want the volume backup to use the Oracle-provided encryption key or your own Vault encryption key. If you select the option to use your own key, paste the OCID for encryption key from the destination region.

6. Click Copy Block Volume Backup.

7. Confirm that the source and destination region details are correct in the confirmation dialog and then click OK.

**Using the API**

To copy a volume backup to another region, use the following operation:

- CopyVolumeBackup

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

**Next Steps**

After copying the block volume backup, switch to the destination region in the Console and verify that the copied backup appears in the list of block volume backups for that region. You can then restore the backup by creating a new block volume from it using the steps in Restoring a Backup to a New Volume on page 557.

For more information about backups, see Overview of Block Volume Backups on page 540.

**Cloning a Volume**

You can create a clone from a volume using the Block Volume service. Cloning enables you to make a copy of an existing block volume without needing to go through the backup and restore process.

A cloned volume is a point-in-time direct disk-to-disk deep copy of the source volume, so all the data that is in the source volume when the clone is created is copied to the clone volume. Any subsequent changes to the data on the source volume are not copied to the clone. Since the clone is a copy of the source volume it will be the same size as the source volume unless you specify a larger volume size when you create the clone.

The clone operation occurs immediately, and you can attach and use the cloned volume as a regular volume as soon as the state changes to available. At this point, the volume data is being copied in the background, and can take up to thirty minutes depending on the size of the volume.

There is a single point-in-time reference for a source volume while it is being cloned, so if the source volume is attached when a clone is created, you need to wait for the first clone operation to complete from the source volume before creating additional clones. If the source volume is detached, you can create up to ten clones from the same source volume simultaneously.

You can only create a clone for a volume within the same region, availability domain and tenant. You can create a clone for a volume between compartments as long as you have the required access permissions for the operation.

For more information about the Block Volume service and cloned volumes, see the Block Volume FAQ.
### Differences Between Block Volume Clones and Backups

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

<table>
<thead>
<tr>
<th>Description</th>
<th>Volume Backup</th>
<th>Volume Clone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.</td>
<td>Creates a single point-in-time copy of a volume without having to go through the backup and restore process.</td>
<td></td>
</tr>
</tbody>
</table>

| Use case                                  | Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time. | Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment. |

<table>
<thead>
<tr>
<th>Speed</th>
<th>Slower (minutes or hours)</th>
<th>Faster (seconds)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cost</td>
<td>Lower cost</td>
<td>Higher cost</td>
</tr>
<tr>
<td>Storage location</td>
<td>Object Storage</td>
<td>Block Volume</td>
</tr>
<tr>
<td>Retention policy</td>
<td>Policy-based backups expire, manual backups do not expire</td>
<td>No expiration</td>
</tr>
<tr>
<td>Volume groups</td>
<td>Supported. You can back up a volume group.</td>
<td>Supported. You can clone a volume group.</td>
</tr>
</tbody>
</table>

For more information about block volume backups, see [Overview of Block Volume Backups](#) on page 540 and [Backing Up a Volume](#) on page 546.

### Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Block Volumes** list, click the volume that you want to clone.
3. In **Resources**, click **Clones**.
4. Click **Create Clone**.
5. Specify a name for the clone. Avoid entering confidential information.
6. If you want to clone the block volume to a larger size volume, check **Custom Block Volume Size (GB)** and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you clone the block volume to a larger size volume, you need to extend the volume's partition. See [Extending the Partition for a Block Volume](#) on page 536 for more information.
7. If you want to change the elastic performance setting when cloning the volume, check **Custom Block Volume Performance** and select the elastic performance setting you want the volume clone to use. See [Block Volume Elastic Performance](#) on page 581 for more information. You can also change the elastic performance setting after you have cloned the volume, see [Block Volume Elastic Performance](#) on page 581. If you leave **Custom Block Volume Performance** unchecked, the cloned volume will use the same elastic performance setting as the source volume.
8. Click **Create Clone**.
The volume is ready use when its icon lists it as **AVAILABLE** in the volume list. At this point, you can perform various actions on the volume such as creating a clone from the volume, attaching it to an instance, or deleting the volume.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

To create a clone from a volume, use the `CreateVolume` operation and specify `VolumeSourceFromVolumeDetails` for `CreateVolumeDetails`.

**Disconnecting From a Volume**

For volumes attached with **iSCSI** on page 501 as the volume attachment type you need to disconnect the volume from an instance before you detach the volume. For more information about attachment type options, see [Volume Attachment Types](#) on page 501.

**Required IAM Policy**

Disconnecting a volume from an instance does not require a specific IAM policy. Don't confuse this with detaching a volume (see [Detaching a Volume](#) on page 563).

**Disconnecting from a Volume on a Linux Instance**

Caution: We recommend that you unmount and disconnect the volume from the instance using `iscsiadm` before you detach the volume. Failure to do so may lead to loss of data.

1. Log on to your instance's guest OS and unmount the volume.
2. Run the following command to disconnect the instance from the volume:

   ```
   iscsiadm -m node -T <IQN> -p <Iscsi IP ADDRESS>:<Iscsi PORT> -u
   ```

   A successful logout response resembles the following:

   ```
   Logging out of session [sid: 2, target:
   iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418, portal:
   169.254.0.2,3260]
   Logout of [sid: 2, target:
   iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418, portal:
   169.254.0.2,3260] successful.
   ```

3. You can now detach the volume without the risk of losing data.

**Disconnecting from a Volume on a Windows Instance**

1. Use a Remote Desktop client to log on to your Windows instance, and then open Disk Management.
2. Right-click the volume you want to disconnect, and then click Offline.
3. Open iSCSI Initiator, select the target, and then click Disconnect.
4. Confirm the session termination. The status should show as Inactive.
5. In iSCSI Initiator, click the Favorite Targets tab, select the target you are disconnecting, and then click Remove.
6. Click the Volumes and Devices tab, select the volume from the Volume List, and then click Remove.
7. You can now detach the volume without the risk of losing data.
Detaching a Volume

When an instance no longer needs access to a volume, you can detach the volume from the instance without affecting the volume's data.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

Caution:

For volumes attached using iSCSI on page 501, we recommend that you unmount and disconnect the volume from the instance using iscsiadm before you detach the volume. Failure to do so may lead to loss of data. See Disconnecting From a Volume on page 562 for more information.

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the Instance list locate the instance. Click its name to display the instance details.
3. In the Resources section on the Instance Details page, click Attached Block Volumes
4. Click the Actions icon (three dots) next to the volume you want to detach, and then click Detach. Confirm when prompted.

Using the API

To delete an attachment, use the following operation:

- DetachVolume

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Deleting a Volume

You can delete a volume that is no longer needed.

Caution:

- You cannot undo this operation. Any data on a volume will be permanently deleted once the volume is deleted.
- All policy-based backups will eventually expire, so if you want to keep a volume backup indefinitely, you need to create a manual backup. See Overview of Block Volume Backups on page 540 for information about policy-based and manual backups.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and
which **compartment** you should work in.

For administrators: The policy in *Let volume admins manage block volumes, backups, and volume groups* on page
2146 lets the specified group do everything with block volumes and backups.

If you're new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142. For
reference material about writing policies for instances, cloud networks, or other Core Services API resources, see
*Details for the Core Services* on page 2181.

**Using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Block Volumes** list, find the volume you want to delete.
3. Click **Terminate** next to the volume you want to delete and confirm the selection when prompted.

**Using the API**

To delete a volume, use the following operation:

- **DeleteVolume**

For information about using the API and signing requests, see *REST APIs* on page 4368 and *Security Credentials* on
page 179. For information about SDKs, see *Software Development Kits and Command Line Interface* on page 4225.

**Move Block Volume Resources Between Compartments**

You can move Block Volume resources such as block volumes, boot volumes, volume backups, volume groups,
and volume group backups from one compartment to another. When you move a Block Volume resource to a
new compartment, associated resources are not moved. After you move the resource to the new compartment,
inherent policies apply immediately and affect access to the resource through the Console. For more information, see
*Managing Compartments* on page 2431.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When moving Block Volume resources between compartments you need to ensure that the resource users have sufficient access permissions on the compartment the resource is being moved to.</td>
</tr>
</tbody>
</table>

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access
is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and
which **compartment** you should work in.

For administrators: The following policies allow users to move Block Volume resources to a different compartment:

- **Allow group BlockCompartmentMovers to manage volume-family in tenancy**

If you're new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142.

**Security Zones**

**Security Zones** ensure that your cloud resources comply with Oracle security principles. If any operation on a
resource in a security zone compartment violates a **policy for that security zone**, then the operation is denied.

The following security zone policies affect your ability to move Block Volume resources from one compartment to
another:

- You can't move a block volume or boot volume from a security zone to a standard compartment.
• You can't move a block volume or boot volume from a standard compartment to a compartment that is in a security zone if the volume violates any security zone policies.

**Using the Console**

**To move a block volume to a new compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Scope** section, select a compartment.
3. Find the block volume in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To move a block volume backup to a new compartment**

1. Open the navigation menu. Under **Block Storage**, click **Block Volume Backups**.
2. In the **Scope** section, select a compartment.
3. Find the block volume backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To move a volume group to a new compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Scope** section, select a compartment.
3. Find the volume group in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To move a volume group backup to a new compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Group Backups**.
2. In the **Scope** section, select a compartment.
3. Find the volume group backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To move a boot volume to a new compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Scope** section, select a compartment.
3. Find the boot volume in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To move a boot volume backup to a new compartment**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volume Backups**.
2. In the **Scope** section, select a compartment.
3. Find the boot volume backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)** on page 4192.
To move a block volume to a new compartment
Open a command prompt and run:

```bash
oci bv volume change-volume-compartment --volume-id <volume OCID> --compartment-id <destination_compartment OCID>
```

To move a block volume backup to a new compartment
Open a command prompt and run:

```bash
oci bv volume-backup change-volume-backup-compartment --volume-backup-id <volume_backup OCID> --compartment-id <destination_compartment OCID>
```

To move a volume group to a new compartment
Open a command prompt and run:

```bash
oci bv volume-group change-volume-group-compartment --volume-group-id <volume_group OCID> --compartment-id <destination_compartment OCID>
```

To move a volume group backup to a new compartment
Open a command prompt and run:

```bash
oci bv volume-group-backup change-volume-group-backup-compartment --volume-group-backup-id <volume_group_backup OCID> --compartment-id <destination_compartment OCID>
```

To move a boot volume to a new compartment
Open a command prompt and run:

```bash
oci bv boot-volume change-boot-volume-compartment --boot-volume-id <boot_volume OCID> --compartment-id <destination_compartment OCID>
```

To move a boot volume backup to a new compartment
Open a command prompt and run:

```bash
oci bv boot-volume-backup change-boot-volume-backup-compartment --boot-volume-backup-id <boot_volume_backup OCID> --compartment-id <destination_compartment OCID>
```

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations for moving Block Volume resources between compartments:

- ChangeVolumeCompartment
- ChangeVolumeBackupCompartment
- ChangeVolumeGroupCompartment
- ChangeVolumeGroupBackupCompartment
- ChangeBootVolumeCompartment
- ChangeBootVolumeBackupCompartment
Block Volume Performance

The content in the sections below apply to **Category 7** and **Section 2.7.1.8.1** (Oracle Cloud Infrastructure - Block Volume subsection) of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

The Oracle Cloud Infrastructure Block Volume service lets you dynamically provision and manage block storage volumes. You can create, attach, connect and move volumes as needed to meet your storage and application requirements. The Block Volume service uses NVMe-based storage infrastructure, and is designed for consistency. You just need to provision the capacity needed and performance scales with the performance characteristics of the elastic performance option selected up to the service maximums. See Block Volume Elastic Performance on page 581 for specific details about the elastic performance options.

The Block Volume service supports creating volumes sized from 50 GB to a maximum size of 32 TB, in 1 GB increments. You can attach up to 32 block volumes to an instance, with a maximum of 1 PB of attached volumes per instance. The instance's boot volume does not count towards this limit.

Latency performance is independent of the instance shape or volume size, and is always sub-millisecond at the 95th percentile for the **Balanced** and **Higher Performance** elastic performance options. Per instance performance is up to 700,000 IOPS, see Host Maximum on page 573.

---

**Note:**

The throughput and IOPS performance results described in this topic are for unformatted iSCSI-attached data volumes, attached to bare metal Compute instances. Performance results may be lower for different scenarios, such as Windows-formatted data volumes, volumes using paravirtualized attachments, boot volumes, among other types of volume scenarios. For more information, see Performance Limitations and Considerations on page 569.

---

**Note:**

You should perform benchmark analysis during proof of concept testing to verify that your environment's configuration will have adequate performance for your application requirements, for more information, see Metrics and Performance Testing on page 569.

---

Higher Performance

The **Higher Performance** elastic performance option is recommended for workloads with the highest I/O requirements, requiring the best possible performance, such as large databases. This option provides the best linear performance scale with 75 IOPS/GB up to a maximum of 35,000 IOPS per volume. Throughput also scales at the highest rate at 600 KBPS/GB up to a maximum of 480 MBPS per volume.

The following table lists the Block Volume service’s throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Higher Performance** elastic performance option you can provision a minimum volume size using this table as a reference.

<table>
<thead>
<tr>

</table>
### Balanced Performance

The **Balanced** elastic performance option provides a good balance between performance and cost savings for most workloads, including those that perform random I/O such as boot volumes. This option provides linear performance scaling with 60 IOPS/GB up to 25,000 IOPS per volume. Throughput scales at 480 KBPS/GB up to a maximum of 480 MBPS per volume.

The following table lists the Block Volume service's throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Balanced** elastic performance option you can provision a minimum volume size using this table as a reference.

</tr>
</tbody>
</table>

### Lower Cost

The **Lower Cost** elastic performance option is recommended for throughput intensive workloads with large sequential I/O, such as streaming, log processing, and data warehouses. This option gives you linear scaling 2 IOPS/GB up to a maximum of 3000 IOPS per volume.

The following table lists the Block Volume service's throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Lower Cost** elastic performance option you can provision a minimum volume size using this table as a reference.

</table>
## Performance Limitations and Considerations

- Block Volume performance SLA for IOPS per volume and IOPS per instance applies to the **Balanced** and **Higher Performance** elastic performance settings only, not to the **Lower Cost** setting.

- The performance results described in this topic are for unformatted data volumes. Performance is lower for Windows-formatted data volumes. Linux-formatted data volume performance will be similar to performance for unformatted data volumes.

- The throughput performance results are for bare metal Compute instances. Throughput performance on virtual machine (VM) Compute instances is dependent on the network bandwidth that is available to the instance, and further limited by that bandwidth for the volume. For details about the network bandwidth available for VM shapes, see the **Network Bandwidth** column in the VM Shapes on page 658 table.

- IOPS performance is independent of the instance type or shape, so is applicable to all bare metal and VM shapes, for iSCSI attached volumes.

- Block Volume performance SLA for IOPS per volume and IOPS per instance applies to raw, unformatted volumes, with iSCSI volume attachments only, not to paravirtualized volume attachments, at the Block Volume service level.

Paravirtualized attachments simplify the process of configuring your block storage by removing the extra commands needed before accessing a volume. However, due to the overhead of virtualization, this reduces the maximum IOPS performance for larger block volumes. The performance of paravirtualized-attached volumes is 90% of the performance for iSCSI-attached volumes. If storage IOPS performance is of paramount importance for your workloads, you can continue to experience the guaranteed performance Oracle Cloud Infrastructure Block Volume offers by using iSCSI attachments.

Boot volumes are paravirtualized-attached volumes, so the volume performance will reflect this.

- For the **Lower Cost** option you may not see the same latency performance that you see with the **Balanced** or **Higher Performance** elastic performance options. You may also see a greater variance in latency with the **Lower Cost** option.

- Windows Defender Advanced Threat Protection (Windows Defender ATP) is enabled by default on all Oracle-provided Windows images. This tool has a significant negative impact on disk I/O performance. The IOPS performance characteristics described in this topic are valid for Windows bare metal instances with Windows Defender ATP disabled for disk I/O. Customers must carefully consider the security implications of disabling Windows Defender ATP. See Windows Defender Advanced Threat Protection.

- Block volume performance is per volume, so when a block volume is attached to multiple instances the performance is shared across all the attached instances. See Attaching a Volume to Multiple Instances on page 520.

## Metrics and Performance Testing

See Using Block Volumes Service Metrics to Calculate Block Volume Throughput and IOPS for a walkthrough of a performance testing scenario with FIO that shows how you can use Block Volume metrics to determine the performance characteristics of your block volume.

For more information about FIO command samples you can use for performance testing see Sample FIO Commands for Block Volume Performance Tests on Linux-based Instances on page 575.

Testing Methodology and Performance for Balanced Elastic Performance Option

Caution:

- Before running any tests, protect your data by making a backup of your data and operating system environment to prevent any data loss.
- Do not run FIO tests directly against a device that is already in use, such as /dev/sdX. If it is in use as a formatted disk and there is data on it, running FIO with a write workload (readwrite, randrw, write, trimwrite) will overwrite the data on the disk, and cause data corruption. Run FIO only on unformatted raw devices that are not in use.

This section describes the setup of the test environments, the methodology, and the observed performance for the Balanced elastic performance configuration option. Some of the sample volume sizes tested were:

- 50 GB volume - 3,000 IOPS @ 4K
- 1 TB volume - 25,000 IOPS @ 4K
- Host maximum, Ashburn (IAD) region, twenty 1 TB volumes - 400,000 IOPS @ 4K

These tests used a wide range of volume sizes and the most common read and write patterns and were generated with the Gartner Cloud Harmony test suite. To show the throughput performance limits, 256k or larger block sizes should be used. For most environments, 4K, 8K, or 16K blocks are common depending on the application workload, and these are used specifically for IOPS measurements.

In the observed performance images in this section, the X axis represents the volume size tested, ranging from 4KB to 1MB. The Y axis represents the IOPS delivered. The Z axis represents the read/write mix tested, ranging from 100% read to 100% write.

Note:

Performance Notes for Instance Types

- The throughput performance results are for bare metal instances. Throughput performance on VM instances is dependent on the network bandwidth that is available to the instance, and further limited by that bandwidth for the volume. For details about the network bandwidth available for VM shapes, see the Network Bandwidth column in the VM Shapes table.
- IOPS performance is independent of the instance type or shape, so is applicable to all bare metal and VM shapes, for iSCSI attached volumes.

1 TB Block Volume

A 1 TB volume was mounted to a bare metal instance running in the Phoenix region. The instance shape was dense, workload was direct I/O with 10GB working set. The following command was run for the Gartner Cloud Harmony test suite:

```
~/block-storage/run.sh --nopurge --noprecondition --fio_direct\=1 --fio_size=10g --target /dev/sdb --test iops --skip_blocksize 512b
```

The results showed that for 1 TB, the bandwidth limit for the larger block size test occurs at 320MBS.

The following images show the observed performance for 1 TB:

Plot A.3 - IOPS Steady State Measurement Window - RNDV4KIB
**50 GB Block Volume**

A 50 GB volume was mounted to a bare metal instance running in the Phoenix region. The instance shape was dense, workload was direct I/O with 10GB working set. The following command was run for the Gartner Cloud Harmony test suite:

```
~/block-storage/run.sh --nopurge --noprecondition --fio_direct=1 --fio_size=10g --target /dev/sdb --test iops --skip_blocksize 512b
```

The results showed that for the 50 GB volume, the bandwidth limit is confirmed as 24,000 KBPS for the larger block size tests (256 KB or larger block sizes), and the maximum of 3,000 IOPS at 4K block size is delivered. For small volumes, a 4K block size is common.

The following images show the observed performance for 50 GB:
 Depending on the instance shape, a single instance with multiple attached volumes can achieve performance of up to 700,000 IOPS when the elastic performance settings for the attached volumes are set to balanced or higher performance.

To test performance, run the following command for the Gartner Cloud Harmony test suite using thirty 800 GB higher performance volumes:

```
sudo ./run.sh --savefio --nopurge --noprecondition --nozerofill --nosecureerase --notrim -v --fio_direct=1 --fio_size=10g --target /dev/sdy, /dev/sdf, /dev/sda, /dev/sdaa, /dev/sdc, /dev/sda, /dev/sde, /dev/sdaa, /dev/sdc, /dev/sda, /dev/sde, /dev/sdaa, /dev/sdc, /dev/sda, /dev/sde, /dev/sdaa, /dev/sdc, --test iops --skip_blocksize 512b&
```

The following images show the observed performance:
Sample FIO Commands for Block Volume Performance Tests on Linux-based Instances

This topic describes sample FIO commands you can use to run performance tests for the Oracle Cloud Infrastructure Block Volume service on instances created from Linux-based images.

Installing FIO

To install and configure FIO on your instances with Linux-based operating systems, run the commands applicable to the operating system version for your instance.

**Oracle Linux and CentOS**

Run the following command to install and configure FIO for your Oracle Linux or CentOS systems.

- Oracle Linux 8:
  ```bash
  sudo dnf install fio -y
  ```
- Oracle Autonomous Linux 7.x, Oracle Linux 6.x, Oracle Linux 7.x, CentOS 7.x, and CentOS 8.x:
  ```bash
  sudo yum install fio -y
  ```

**Ubuntu**

Run the following commands to install and configure FIO for your Ubuntu systems:

```bash
sudo apt-get update & & sudo apt-get install fio -y
```

This applies to Ubuntu 16.04, 18.04, and Ubuntu Minimal 16.04, 18.04.
**FIO Commands**

**IOPS Performance Tests**

Use the following FIO example commands to test IOPS performance. You can run the commands directly or create a job file with the command and then run the job file.

**Test random reads**

Run the following command directly to test random reads:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=4k --
ioengine=libaio --iodepth=256 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=iops-test-job --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

   ```
   [global]
   bs=4K
   iodepth=256
   direct=1
   ioengine=libaio
   group_reporting
   time_based
   runtime=120
   numjobs=4
   name=raw-randread
   rw=randread
   
   [job1]
   filename=device name
   ```

2. Run the job using the following command:

   ```
fio randomread.fio
   ```

**Test file random read/writes**

Run the following command against the mount point to test file read/writes:

```
sudo fio --filename=/custom mount point/file --size=500GB --direct=1 --
rw=randrw --bs=4k --ioengine=libaio --iodepth=256 --runtime=120 --numjobs=4
--time_based --group_reporting --name=iops-test-job --eta-newline=1
```

Add both the read IOPS and the write IOPS returned.

**Test random read/writes**

**Caution:**

Do not run FIO tests with a write workload (readwrite, randrw, write, trimwrite) directly against a device that is in use.

Run the following command to test random read/writes:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=4k --
ioengine=libaio --iodepth=256 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=iops-test-job --eta-newline=1
```

Add both the read IOPS and the write IOPS returned.
In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomreadwrite.fio, with the following:

```
[globals]
bs=4K
iodepth=256
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-randomreadwrite
rw=randrw

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio randomreadwrite.fio
```

**Test sequential reads**

For workloads that enable you to take advantage of sequential access patterns, such as database workloads, you can confirm performance for this pattern by testing sequential reads.

Run the following command to test sequential reads:

```
sudo fio --filename=device name --direct=1 --rw=read --bs=4k --
ioengine=libaio --iodepth=256 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=iops-test-job --eta-newline=1 --readonly
```

In some cases you may see more consistent results if you use a job file instead of running the command directly. Use the following instructions for this approach:

1. Create a job file, fioread.fio, with the following:

```
[globals]
bs=4K
iodepth=256
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-read
rw=read

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio read.fio
```

**Throughput Performance Tests**

Use the following FIO example commands to test throughput performance.
**Test random reads**

Run the following command to test random reads:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=64k --
ioengine=libaio --iodepth=64 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=throughput-test-job --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

   ```
   [global]
   bs=64K
   iodepth=64
   direct=1
   ioengine=libaio
   group_reporting
   time_based
   runtime=120
   numjobs=4
   name=raw-randread
   rw=randread
   
   [job1]
   filename=device name
   ```

2. Run the job using the following command:

   ```
fio randomread.fio
   ```

**Test file random read/writes**

Run the following command against the mount point to test file read/writes:

```
sudo fio --filename=/custom mount point/file --size=500GB --direct=1 --
wtrandrw --bs=64k --ioengine=libaio --iodepth=64 --runtime=120 --numjobs=4
--time_based --group_reporting --name=throughput-test-job --eta-newline=1
```

Add both the read MBPs and the write MBPs returned.

**Test random read/writes**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not run FIO tests with a write workload (readwrite, randrw, write, trimwrite) directly against a device that is in use.</td>
</tr>
</tbody>
</table>

Run the following command to test random read/writes:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=64k --
ioengine=libaio --iodepth=64 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=throughput-test-job --eta-newline=1
```

Add both the read MBPs and the write MBPs returned.

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

   ```
   [global]
   bs=64K
   ```
iodepth=64
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-randreadwrite
rw=randrw

[job1]
filename=device name

2. Run the job using the following command:

fio randomreadwrite.fio

Test sequential reads

For workloads that enable you to take advantage of sequential access patterns, such as database workloads, you can confirm performance for this pattern by testing sequential reads.

Run the following command to test sequential reads:

```
sudo fio --filename=device name --direct=1 --rw=read --bs=64k --
ioengine=libaio --iodepth=64 --runtime=120 --numjobs=4 --time_based --
group_reporting --name=throughput-test-job --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fioread.fio, with the following:

```
[global]
bs=64K
iodepth=64
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-read
rw=read

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio read.fio
```

Latency Performance Tests

Use the following FIO example commands to test latency performance. You can run the commands directly or create a job file with the command and then run the job file.
**Test random reads for latency**

Run the following command directly to test random reads for latency:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=4k --
ioengine=libaio --iodepth=1 --numjobs=1 --time_based --group_reporting --
name=readlatency-test-job --runtime=120 --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomreadlatency.fio, with the following:

```
[global]
bs=4K
iodepth=1
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=1
name=readlatency-test-job
rw=randread

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio fiorandomreadlatency.fio
```

**Test random read/writes for latency**

```
Caution:
Do not run FIO tests with a write workload (readwrite, randrw, write, trimwrite) directly against a device that is in use.
```

Run the following command directly to test random read/writes for latency:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=4k --
ioengine=libaio --iodepth=1 --numjobs=1 --time_based --group_reporting --
name=rwlatency-test-job --runtime=120 --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomrwlatency.fio, with the following:

```
[global]
bs=4K
iodepth=1
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=1
name=rwlatency-test-job
rw=randrw

[job1]
```
2. Run the job using the following command:

```
filename=device name
```

```
fio fioradomrwlateny.fio
```

## Block Volume Elastic Performance

The elastic performance feature of the Oracle Cloud Infrastructure Block Volume service allows you to dynamically change the volume performance, along with enabling you to pay for the performance characteristics you require independently from the size of your block volumes and boot volumes.

This feature includes the concept of volume performance units (VPUs). You can purchase more VPUs to allocate more resources to a volume, increasing IOPS/GB and throughput per GB. You also have the flexibility to purchase fewer VPUs, which reduces the performance characteristics for a volume, however it can also provide cost savings. You can also choose not to purchase any VPUs which can provide significant cost savings for volumes that don’t require the increased performance characteristics.

For specific pricing details, see [Oracle Storage Cloud Pricing](#).

### Elastic Performance Configuration Options

There are three elastic performance configuration options, as described below.

- **Balanced**: This is the default setting for new and existing block and boot volumes. It provides a good balance between performance and cost savings for most workloads, including those that perform random I/O such as boot volumes. This option provides linear performance scaling with 60 IOPS/GB up to 25,000 IOPS per volume. Throughput scales at 480 KBPS/GB up to a maximum of 480 MBPS per volume. With this option you are purchasing 10 VPUs per GB/month.

- **Higher Performance**: Recommended for workloads with the highest I/O requirements, requiring the best possible performance, such as large databases. This option provides the best linear performance scale with 75 IOPS/GB up to a maximum of 35,000 IOPS per volume. Throughput also scales at the highest rate at 600 KBPS/GB up to a maximum of 480 MBPS per volume. With this option you are purchasing 20 VPUs per GB/month.

- **Lower Cost**: Recommended for throughput intensive workloads with large sequential I/O, such as streaming, log processing, and data warehouses. The cost is only the storage cost, there is no additional VPU cost. This option gives you linear scaling 2 IOPS/GB up to a maximum of 3000 IOPS per volume. This option is only available for block volumes, it is not available for boot volumes.

The following table lists the performance characteristics for each elastic performance level.

<table>
<thead>
<tr>
<th>Performance Level</th>
<th>IOPS/GB</th>
<th>Max IOPS/Volume</th>
<th>Throughput/GB (KB/s per GB)</th>
<th>Max Throughput/Volume (MB/s per volume)</th>
<th>VPUs/GB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower Cost</td>
<td>2</td>
<td>3000</td>
<td>240</td>
<td>Up to 480</td>
<td>0</td>
</tr>
<tr>
<td>Balanced</td>
<td>60</td>
<td>25,000</td>
<td>480</td>
<td>480</td>
<td>10</td>
</tr>
<tr>
<td>Higher Performance</td>
<td>75</td>
<td>35,000</td>
<td>600</td>
<td>480</td>
<td>20</td>
</tr>
</tbody>
</table>

See [Block Volume Performance](#) on page 567 for additional performance details for the Block Volume service.

VPUs refer to volume performance units, see [Oracle Storage Cloud Pricing](#) for specific pricing details.

### Configuring Volume Performance

You can configure the volume performance for a block volume when you create a volume, see [Creating a Volume](#) on page 515. You can also change the volume performance for an existing block volume, see [To change the volume performance for an existing block volume](#) on page 582.
When you create a Compute instance, the volume performance for the instance's boot volume is set to Balanced by default. You can change this setting after the instance has launched, see To change the volume performance for an existing boot volume on page 582.

### Changing the Performance of a Volume

The Block Volume service's elastic performance feature enables you to dynamically configure the volume performance for block volumes and boot volumes, for more information, see Block Volume Elastic Performance on page 581.

#### Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

#### Limitations

- You can only change the elastic performance configuration on three volumes concurrently per tenancy.
- When changing volume performance for boot volumes, you can only select the Balanced or Higher Performance options.

#### Using the Console

The default volume performance setting for existing block volumes or when you create a new block volume is Balanced. You can change the default setting when you create a new block volume, see Creating a Volume on page 515. You can also change the volume performance setting for an existing block volume using the steps in the following procedure.

To change the volume performance for an existing block volume

1. Open the navigation menu. Under Core Infrastructure, go to Block Storage and click Block Volumes.
2. Click the block volume that you want to change the performance for.
3. Click Edit Size or Performance.
4. Click the volume performance option you want to change to.
5. Click Save Changes.

When you create an instance, the volume performance setting for the instance's boot volume is set to Balanced. You can change this setting to Higher Performance after the instance has been launched.

To change the volume performance for an existing boot volume

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volumes.
2. Click the boot volume that you want to change the performance for.
3. Click Edit Size or Performance.
4. Click the volume performance option you want to change to.
5. Click Save Changes.

#### Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 4192.

Use the `volume update` operation or the `boot-volume update` operation with `vpus-per-gb` parameter to update a block volume's elastic performance setting. The `vpus-per-gb` parameter is where you specify the volume performance units (VPUs). VPUs represent the volume performance settings, with the following allowed values:
### Block Volume

- **0**: Represents **Lower Cost** setting, applies to block volumes only.
- **10**: Represents **Balanced** setting, applies to both block volumes and boot volumes.
- **20**: Represents **Higher Performance** setting, applies to both block volumes and boot volumes.

For example:

```bash
oci bv volume update --volume-id <volume_ID> --vpus-per-gb 20
```

### Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

### Block Volumes

To update a block volume's performance setting, use the following operation:

- **UpdateVolume**

  The volume performance setting is specified in the `vpusPerGB` attribute of `UpdateVolumeDetails`. Allowed values are 0, 10, and 20.

### Boot Volumes

To update a boot volume's performance setting, use the following operation:

- **UpdateBootVolume**

  The volume performance setting is specified in the `vpusPerGB` attribute of `UpdateBootVolumeDetails`. Allowed values are 10 and 20.

### Auto-tune Volume Performance

The Block Volume service has three elastic performance configuration options:

- **Balanced**
- **Higher Performance**
- **Lower Cost**

For more information about these settings, see [Block Volume Elastic Performance](#) on page 581. The auto-tune feature enables you to configure your block volumes and boot volumes to use the optimal performance setting based on whether the volume is attached or detached from an instance.

When you create a volume, the default volume performance setting is **Balanced**. You can change this default performance setting when you create the volume, see [Creating a Volume](#) on page 515. You can also change the default performance setting on an existing volume, see [Changing the Performance of a Volume](#) on page 582. When the performance auto-tune feature is disabled, your volume’s performance will always be the default performance setting. If performance auto-tune is enabled, when your block volume is attached to one or more instances, the volume’s performance will be the default performance setting. When the volume is detached, the Block Volume service will adjust the performance setting to **Lower Cost** for both block volumes and boot volumes. When the volume is reattached, the performance is adjusted back to the default performance setting.

When viewing the **Block Volume Details** or **Boot Volume Details** pages in the Console, the applicable fields are:

- **Current Performance**: This is the volume’s effective performance. If the auto-tune performance feature is disabled for the volume, **Current Performance** will always be what is specified in the **Default Performance**, regardless of whether the volume is attached or detached. If the auto-tune performance feature is enabled for the volume, **Current Performance** will be adjusted to **Lower Cost** when the volume is detached. Note that **Current Performance** won’t show the performance setting as **Lower Cost** until the performance adjustment is complete.
- **Default Performance**: This is the volume’s performance setting that you specify when you create the volume or when you change the performance setting for an existing volume. When the volume is attached, regardless of whether the auto-tune performance feature is enabled or not, this is the volume’s performance.
• **Auto-tune Performance**: This field indicates whether the auto-tune performance feature is enabled for the volume. When it is off, the volume’s effective performance is always the same as what is specified for **Default Performance**. When it is on, the volume performance is adjusted to **Lower Cost** when the volume is detached.

See **Timing Limits and Considerations** for details about when these settings take effect.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: The policy in **Let volume admins manage block volumes, backups, and volume groups** on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you’re new to policies, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see **Details for the Core Services** on page 2181.

**Timing Limits and Considerations**

The following list identifies some timing considerations you should be aware of when using the performance auto-tune feature.

• When you enable the auto-tune performance feature for a detached volume, the Block Volume service starts the performance adjustment to **Lower Cost** after 14 days.

• When you enable the auto-tune performance feature for an attached volume, the Block Volume service starts the performance adjustment to **Lower Cost** 14 days after you detach the volume.

• If you disable the auto-tune performance feature while a volume is detached, Block Volume service starts the performance adjustment to the **Default Performance** setting right away.

• Attaching a volume with the auto-tune performance feature enabled may take longer than attaching a volume with it off, as the Block Volume service adjusts the performance before the volume attachment completes.

• If you change the **Default Performance** for a detached volume with the auto-tune performance feature enabled, the **Current Performance** for the volume will remain **Lower Cost** until you reattach the volume.

• If you clone a detached volume with the auto-tune performance feature enabled, the Block Volume service starts the performance adjustment to **Lower Cost** after 14 days.

**Using the Console**

The following procedures describe how to enable the auto-tune performance feature in the Console.

**To enable the auto-tune performance feature for a block volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the block volume that you want to enable the auto-tune performance feature for.
3. Click **Edit**.
4. In the **Volume Size and Performance** section, click the **AUTO-TUNE PERFORMANCE** slider so that it changes from **Off** to **On**.
5. Click **Save Changes**.

**To enable the auto-tune performance feature for a boot volume**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Click the boot volume that you want to enable the auto-tune performance feature for.
3. Click **Edit**.
4. In the **Volume Size and Performance** section, click the **AUTO-TUNE PERFORMANCE** slider so that it changes from **Off** to **On**.
5. Click **Save Changes**.
Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Block Volumes
To enable or disable the auto-tune performance feature for a block volume, use the following operation:

• UpdateVolume

The auto-tune performance setting is specified in the isAutoTuneEnabled attribute of UpdateVolumeDetails.

Boot Volumes
To enable or disable the auto-tune performance feature for a boot volume, use the following operation:

• UpdateBootVolume

The auto-tune performance setting is specified in the isAutoTuneEnabled attribute of UpdateBootVolumeDetails.

Block Volume Metrics
You can monitor the health, capacity, and performance of your block volumes and boot volumes by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_blockstore (the Block Volume service) Resources: Block volumes and boot volumes

See Using Block Volumes Service Metrics to Calculate Block Volume Throughput and IOPS for a walkthrough of a performance testing scenario with FIO that shows how you can use these metrics to determine the performance characteristics of your block volume.

Overview of Metrics for an Instance and Its Storage Devices
If you're not already familiar with the different types of metrics available for an instance and its storage and network devices, see Compute Instance Metrics on page 788.

Available Metrics: oci_blockstore
The Block Volume service metrics help you measure volume operations and throughput related to Compute instances.

The metrics listed in the following table are automatically available for any block volume or boot volume, regardless of whether the attached instance has monitoring enabled. You do not need to enable monitoring on the volumes to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

ATTACHMENTID
The OCID of the volume attachment.

RESOURCEID
The OCID of the volume.
### Block Volume

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumeReadThroughput</td>
<td>Volume Read Throughput</td>
<td>bytes</td>
<td>Read throughput. Expressed as bytes read per interval.</td>
<td>attachmentId, resourceId</td>
</tr>
<tr>
<td>VolumeWriteThroughput</td>
<td>Volume Write Throughput</td>
<td>bytes</td>
<td>Write throughput. Expressed as bytes written per interval.</td>
<td></td>
</tr>
<tr>
<td>VolumeReadOps*</td>
<td>Volume Read Operations</td>
<td>reads</td>
<td>Activity level from I/O reads. Expressed as reads per interval.</td>
<td></td>
</tr>
<tr>
<td>VolumeWriteOps*</td>
<td>Volume Write Operations</td>
<td>writes</td>
<td>Activity level from I/O writes. Expressed as writes per interval.</td>
<td></td>
</tr>
</tbody>
</table>

* The Compute service separately reports network-related metrics as measured on the instance itself and aggregated across all the attached volumes. Those metrics are available in the `oci_computeagent` metric namespace. For more information, see Compute Instance Metrics on page 788.

### Using the Console

**To view default metric charts for a single volume**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance to view its details.
3. Under Resources, click either Attached Block Volumes or Boot Volume to view the volume you're interested in.
4. Click the volume to view its details.
5. Under Resources, click Metrics.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**To view default metric charts for multiple volumes**

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. For Compartment, select the compartment that contains the volumes you're interested in.
3. For Metric Namespace, select `oci_blockstore`.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 10

Compliance Documents

This chapter explains how to view and download compliance documents.

Overview of Compliance Documents

The Oracle Cloud Infrastructure Compliance Documents service lets you view and download compliance documents that you could previously access only by submitting a request to the Elevated Support Portal.

Note:
Compliance Documents is not available in Oracle Cloud Infrastructure Government Cloud realms.

Types of Compliance Documents

When viewing compliance documents, you can filter on the following types:

- **Audit**: A general audit report.
- **Bridge Letter (BridgeLetter)**: A bridge letter. Bridge letters provide compliance information for the period of time between the end date of an SOC report and the date of the release of a new SOC report.
- **Certificate**: A document indicating certification by a particular authority, with regard to certification requirements and examination results conforming to said requirements.
- **SOC3**: A Service Organization Controls 3 audit report that provides information relating to a service organization's internal controls for security, availability, confidentiality, and privacy.
- **Other**: A compliance document that doesn't fit into any of the preceding, more specific categories.

If you need to further narrow down what documents are displayed, you can combine the type filter with the environment filter.

Types of Environments

The environments, or business pillars or platforms, to which the documents belong include:

- **OCI**: Oracle Cloud Infrastructure is a set of complementary cloud infrastructure services that let you build and run applications and services in a highly available hosted environment.
- **PAAS**: Oracle Platform as a Service (PaaS) provides various platforms to build and deploy applications within the public, private, or hybrid cloud.

Regions and Availability Domains

You can use the Compliance Documents service in all regions. For a list of supported regions, see Regions and Availability Domains on page 180.
Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. However, you cannot specifically access Compliance Documents by using the API or Command Line Interface (CLI). Compliance Documents does not have public API, SDK, or CLI support at this time.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Viewing and Downloading Compliance Documents

This section describes how to view compliance documents. The Console displays documents available to your tenancy for the currently selected region.

To view a list of all compliance documents

1. Open the navigation menu. Under the Governance and Administration group, go to Governance and click Compliance Documents.
2. The Compliance Documents page displays all documents you have permission to view. From this page, you can do the following:
   - Filter. You can filter documents by environment or by type.
   - Sort. You can sort documents by name, type, or creation date.
   - Download. You can download documents to your local computer.

To download a compliance document

1. Open the navigation menu. Under the Governance and Administration group, go to Governance and click Compliance Documents.
2. The Compliance Documents page displays all documents you have permission to view.
3. Next to the name of the document, click Download.
4. Review the terms of use.
5. When you're ready, select the I have reviewed and accept these terms and conditions check box, and then click Download File.

To sort a list of compliance documents

1. Open the navigation menu. Under the Governance and Administration group, go to Governance and click Compliance Documents.
2. By default, the list displays documents according to the document name, in alphabetical order. To sort the list another way, do one of the following:
   - Click Name. The list sorts alphabetically, according to the summary of the announcement. If you begin by viewing the default sort order, the sort order will change to show documents in reverse alphabetical order by name.
   - Click Type. The list sorts according to the type of the document, in alphabetical order by type.
   - Click Created. The list sorts according to the date and time the document was created.
3. To sort the list again, repeat the previous step.
Chapter 11

Compute

This chapter explains how to launch, access, manage, and terminate compute instances.

Overview of the Compute Service

Oracle Cloud Infrastructure Compute lets you provision and manage compute hosts, known as instances. You can launch instances as needed to meet your compute and application requirements. After you launch an instance, you can access it securely from your computer, restart it, attach and detach volumes, and terminate it when you're done with it. Any changes made to the instance's local drives are lost when you terminate it. Any saved changes to volumes attached to the instance are retained.

Oracle Cloud Infrastructure offers both bare metal and virtual machine instances:

- **Bare Metal**: A bare metal compute instance gives you dedicated physical server access for highest performance and strong isolation.
- **Virtual Machine**: A virtual machine (VM) is an independent computing environment that runs on top of physical bare metal hardware. The virtualization makes it possible to run multiple VMs that are isolated from each other. VMs are ideal for running applications that do not require the performance and resources (CPU, memory, network bandwidth, storage) of an entire physical machine.

An Oracle Cloud Infrastructure VM compute instance runs on the same hardware as a bare metal instance, leveraging the same cloud-optimized hardware, firmware, software stack, and networking infrastructure.

Be sure to review Best Practices for Your Compute Instance on page 594 for important information about working with your Oracle Cloud Infrastructure Compute instance.

Oracle Cloud Infrastructure uses Oracle Ksplice to apply important security and other critical kernel updates to the hypervisor hosts without a reboot. Oracle Cloud Infrastructure can apply these patches transparently without the need to pause any VMs, and all hypervisor hosts support this capability. For more information, see Installing and Running Oracle Ksplice on page 664.

Compute is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 140.

Instance Types

When you create a Compute instance, you can select the most appropriate type of instance for your applications based on characteristics such as the number of CPUs, amount of memory, and network resources. Oracle Cloud Infrastructure offers a variety of shapes that are designed to meet a range of compute and application requirements:

- **Standard shapes**: Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel or AMD processors.
- **DenseIO shapes**: Designed for large databases, big data workloads, and applications that require high-performance local storage. DenseIO shapes include locally-attached NVMe-based SSDs.
- **GPU shapes**: Designed for hardware-accelerated workloads. GPU shapes include Intel or AMD CPUs and NVIDIA graphics processors.
• **High performance computing (HPC) shapes:** Designed for high-performance computing workloads that require high frequency processor cores and cluster networking for massively parallel HPC workloads. HPC shapes are available for bare metal instances only.

For more information about the available bare metal and VM shapes, see Compute Shapes on page 655, Bare Metal Instances, Virtual Machines, and Virtual Machines and Bare Metal (GPU).

**Flexible Shapes**

Flexible shapes let you customize the number of OCPUs and the amount of memory allocated to an instance. When you create a VM instance using the flexible shape, you select the number of OCPUs and the amount of memory that you need for the workloads that run on the instance. The network bandwidth and number of VNICS scale proportionately with the number of OCPUs. This flexibility enables you to build VMs that match your workload, allowing you to optimize performance and minimize cost. For more information, see Flexible Shapes on page 655.

Currently, flexible memory is available on VM.Standard.E3.Flex instances that run on AMD Rome processors. For this VM and processor combination, you can select from 1 to 64 OCPUs. The amount of memory allowed is based on the number of OCPUs selected. For each OCPU, you can select up to 64 GB of memory, with a maximum of 1024 GB total. The minimum amount of memory allowed is either 1 GB or a value matching the number of OCPUs, whichever is greater.

**Components for Launching Instances**

The components required to launch an instance are:

- **availability domain**
  The Oracle Cloud Infrastructure data center within your geographical region that hosts cloud resources, including your instances. You can place instances in the same or different availability domains, depending on your performance and redundancy requirements. For more information, see Regions and Availability Domains on page 180.

- **virtual cloud network**
  A virtual version of a traditional network—including subnets, route tables, and gateways—on which your instance runs. At least one cloud network has to be set up before you launch instances. For information about setting up cloud networks, see Networking Overview on page 2748.

- **key pair (for Linux instances)**
  A security mechanism required for Secure Shell (SSH) access to an instance. Before you launch an instance, you’ll need at least one key pair. For more information, see Managing Key Pairs on Linux Instances on page 693.

- **tags**
  You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

- **password (for Windows instances)**
  A security mechanism required to access an instance that uses an Oracle-provided Windows image. The first time you launch an instance using a Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

- **image**
  A template of a virtual hard drive that determines the operating system and other software for an instance. For details about Oracle Cloud Infrastructure platform images, see Oracle-Provided Images on page 629. You can also launch instances from:
Compute

- Trusted third-party images published by Oracle partners from the Partner Image catalog. For more information about partner images, see Overview of Marketplace on page 2650 and Working with Listings on page 2651.
- Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure
- Custom images, including bring your own image scenarios.
- Boot Volumes on page 609.

**shape**

A template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance. You choose the most appropriate shape when you launch an instance. See Compute Shapes on page 655 for a list of available bare metal and VM shapes.

You can optionally attach volumes to an instance. For more information, see Overview of Block Volume on page 500.

**Creating Automation with Events**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

The following Compute resources emit events:

- Autoscaling configurations and autoscaling policies
- Cluster networks
- Console histories
- Images
- Instances and instance attachments
- Instance configurations
- Instance console connections
- Instance pools

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

**Work Requests**

Compute is one of the Oracle Cloud Infrastructure services that is integrated with the Work Requests API. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests in the user guide, and the Work Requests API.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.
Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Storage for Compute Instances

You can expand the storage that's available for your Compute instances with the following services:

- **Block Volume**: Lets you dynamically provision and manage block volumes that you can attach to one or more Compute instances. See Overview of Block Volume on page 500 for more information. For steps to attach block volumes to Compute instances, see Attaching a Volume on page 517 and Attaching a Volume to Multiple Instances on page 520.
- **File Storage**: A durable, scalable, secure, enterprise-grade network file system that you can connect to from any Compute instance in your virtual cloud network (VCN). See Overview of File Storage on page 1920 for more information.
- **Object Storage**: An internet-scale, high-performance storage platform that lets you store an unlimited amount of unstructured data of any content type. This storage is regional and not tied to any specific Compute instance. See Overview of Object Storage on page 3392 for more information.
- **Archive Storage**: A storage platform that lets you store an unlimited amount of unstructured data of any content type that doesn't require instantaneous data retrieval. This storage is regional and not tied to any specific Compute instance. See Overview of Archive Storage on page 484 for more information.

Limits on Compute Resources

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Additional limits include:

- To attach a volume to an instance, both the instance and volume must be within the same availability domain.
- Many Compute operations are subject to throttling.

A service limit is different from host capacity. A service limit is the quota or allowance set on a resource. Host capacity is the physical infrastructure that resources such as Compute instances run on.

Metadata Key Limits

Custom metadata keys (any key you define that is not ssh_authorized_keys or user_data) have the following limits:

- Max number of metadata keys: 128
- Max size of key name: 255 characters
- Max size of key value: 255 characters

ssh_authorized_keys is a special key that does not have these limits, but its value is validated to conform to a public key in the OpenSSH format.

user_data has a maximum size of 16KB. For Linux instances with cloud-init configured, you can populate the user_data field with a Base64-encoded string of cloud-init user data. For more information on formats that cloud-init accepts, see cloud-init formats.
Best Practices for Your Compute Instance

Oracle Cloud Infrastructure Compute provides bare metal and virtual machine (VM) compute capacity that delivers performance, flexibility, and control without compromise. It's powered by Oracle’s next generation, internet-scale infrastructure, designed to help you develop and run your most demanding applications and workloads in the cloud.

You can provision compute capacity through an easy-to-use web console or the API, SDKs, or CLI. The compute instance, once provisioned, provides you with access to the host. This gives you complete control of your instance.

Though you have full management authority for your instance, we recommend a variety of best practices to ensure system availability and top performance.

IP Addresses Reserved for Use by Oracle

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

169.254.0.0/16

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.

Class D and Class E

All addresses from 224.0.0.0 to 239.255.255.255 (Class D) are prohibited for use in a VCN, they are reserved for multicast address assignments in the IP standards. See RFC 3171 for details.

All addresses from 240.0.0.0 to 255.255.255.255 (Class E) are prohibited for use in a VCN, they are reserved for future use in the IP standards. See RFC 1112, Section 4 for details.

Three IP Addresses in Each Subnet

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.

Essential Firewall Rules

All Oracle-provided images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance’s boot and block volumes.

- We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
- We recommend that you do not create custom images without these rules unless you understand the security risks.
• Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See Ubuntu instance fails to reboot after enabling Uncomplicated Firewall (UFW) for more information.

System Resilience
Follow industry-wide hardware failure best practices to ensure the resilience of your solution in the event of a hardware failure. Some best practices include:
• Design your system with redundant compute nodes in different availability domains to support failover capability.
• Create a custom image of your system drive each time you change the image.
• Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.

Uninterrupted Access to the Instance
Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

User Access
If you created your instance using an Oracle-provided Linux image, you can use SSH to access your instance from a remote host as the opc user. After logging in, you can add users on your instance.

If you do not want to share SSH keys, you can create additional SSH-enabled users.

If you created your instance using an Oracle-provided Windows image, you can access your instance using a Remote Desktop client as the opc user. After logging in, you can add users on your instance.

For more information about user access, see Adding Users on an Instance on page 737. For steps to log in to an instance, see Connecting to an Instance on page 733.

NTP Service
Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). We recommend that you configure your instances to use the Oracle Cloud Infrastructure NTP service. For information about how to configure instances to use this service, see Configuring the Oracle Cloud Infrastructure NTP Service for an Instance on page 596.

Fault Domains
A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. Each availability domain has three fault domains. By properly leveraging fault domains you can increase the availability of applications running on Oracle Cloud Infrastructure. See Fault Domains on page 182 for more information.

Your application's architecture will determine whether you should separate or group instances using fault domains.

Scenario 1: Highly Available Application Architecture
In this scenario you have a highly available application, for example you have two web servers and a clustered database. In this scenario you should group one web server and one database node in one fault domain and the other
half of each pair in another fault domain. This ensures that a failure of any one fault domain does not result in an outage for your application.

Scenario 2: Single Web Server and Database Instance Architecture

In this scenario your application architecture is not highly available, for example you have one web server and one database instance. In this scenario both the web server and the database instance must be placed in the same fault domain. This ensures that your application will only be impacted by the failure of that single fault domain.

Customer-Managed Virtual Machine (VM) Maintenance

When an underlying infrastructure component needs to undergo maintenance, you are notified before the impact to your VM instances. During an infrastructure maintenance event, where applicable, Oracle Cloud Infrastructure live migrates Standard VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. If a VM cannot be live migrated, there might be a short downtime while the instance is reboot migrated.

You can control how and when your applications experience maintenance downtime by proactively rebooting (or stopping and starting) the instances at any time before the scheduled maintenance event. A maintenance reboot is different from a normal reboot. When you reboot an instance for maintenance, the instance is stopped on the physical VM host that needs maintenance, and then restarted on a healthy VM host.

If you choose not to reboot before the scheduled time, then Oracle Cloud Infrastructure will migrate the instances before proceeding with the planned infrastructure maintenance. Optionally, you can configure the instances to remain stopped after they are reboot migrated. For more information, see Recovering a Virtual Machine (VM) During Planned Maintenance on page 780.

Configuring the Oracle Cloud Infrastructure NTP Service for an Instance

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). The Oracle Cloud Infrastructure NTP service uses redundant Stratum 1 devices in every availability domain. The Stratum 1 devices are synchronized to dedicated Stratum 2 devices that every host synchronizes against. The service is available in every region.

This topic describes how to configure your Compute instances to use this NTP service.

You can also choose to configure your instances to use a public NTP service or use FastConnect to leverage an on-premises NTP service.

Note:

Oracle-provided images for Oracle Autonomous Linux 7.x, Oracle Linux 8.x, Oracle Linux 7.x, CentOS 7.x, and CentOS 8.x released after February 2018 include the Chrony service by default. You do not need to configure the Oracle Cloud Infrastructure NTP service for these instances.

Oracle Linux 6.x

Use the following steps to configure your Oracle Linux 6.x instances to use the Oracle Cloud Infrastructure NTP service.

1. Configure IPtables to allow connections to the Oracle Cloud Infrastructure NTP service, using the following commands:

```
sudo iptables -I BareMetalInstanceServices 8 -d 169.254.169.254/32 -p udp -m udp --dport 123 -m comment --comment "Allow access to OCI local NTP service" -j ACCEPT
```

```
sudo service iptables save
```
2. Install the NTP service with the following command:

   ```
sudo yum install ntp
   ```

3. Set the date of your instance with the following command:

   ```
sudo ntpdate 169.254.169.254
   ```

4. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:
   
a. In the `server` section, comment out the lines specifying the RHEL servers:

   ```
   #server 0.rhel.pool.ntp.org iburst
   #server 1.rhel.pool.ntp.org iburst
   #server 2.rhel.pool.ntp.org iburst
   #server 3.rhel.pool.ntp.org iburst
   ```

   b. Add an entry for the Oracle Cloud Infrastructure NTP server:

   ```
   server 169.254.169.254 iburst
   ```

   The modified `server` section now contains the following:

   ```
   # Please consider joining the pool (http://www.pool.ntp.org/join.html).
   #server 0.rhel.pool.ntp.org iburst
   #server 1.rhel.pool.ntp.org iburst
   #server 2.rhel.pool.ntp.org iburst
   #server 3.rhel.pool.ntp.org iburst
   server 169.254.169.254 iburst
   ```

5. Set the NTP service to launch automatically when the instance boots with the following command:

   ```
sudo chkconfig ntpd on
   ```

6. Start the NTP service with the following command:

   ```
sudo /etc/init.d/ntpd start
   ```

7. Confirm that the NTP service is configured correctly with the following command:

   ```
ntpq -p
   ```

   The output will be similar to the following:

   ```
remote       refid   st  t when poll reach   delay  offset  jitter
==============================================================================
169.254.169.254 192.168.32.3     2 u    2   64    1    0.338    0.278
0.187
```
2. Install the NTP service with the following command:

```
yum -y install ntp
```

3. Change the firewall rules to allow inbound and outbound traffic with the Oracle Cloud Infrastructure NTP server, at 169.254.169.254, on UDP port 123 with the following command:

```
awk -v n=13 -v s=' <passthrough ipv="ipv4">-A OUTPUT -d 169.254.169.254/32 -p udp -m udp --dport 123 -m comment --comment "Allow access to OCI local NTP service" -j ACCEPT </passthrough>' 'NR == n {print s} {print}' /etc/firewalld/direct.xml > tmp && mv tmp /etc/firewalld/direct.xml
```

At the prompt `mv: overwrite '/etc/firewalld/direct.xml'?`, enter `y`.

4. Restart the firewall with the following command:

```
service firewalld restart
```

5. Set the date of your instance with the following command:

```
ntpdate 169.254.169.254
```

6. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:

   a. In the `server` section comment out the lines specifying the RHEL servers:

```
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
```

   b. Add an entry for the Oracle Cloud Infrastructure NTP service:

```
server 169.254.169.254 iburst
```

The modified `server` section should now contain the following:

```
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
server 169.254.169.254 iburst
```

7. Start and enable the NTP service with the following commands:

```
systemctl start ntpd
systemctl enable ntpd
```

You also need disable the chrony NTP client to ensure that the NTP service starts automatically after a reboot, using the following commands:

```
systemctl stop chronyd
systemctl disable chronyd
```
8. Confirm that the NTP service is configured correctly with the following command:

```
ntpq -p
```

The output will be similar to the following:

```
remote           refid      st t when poll reach delay  offset  jitter
jitter
==============================================================================
169.254.169.254 192.168.32.3     2 u    2   64    1    0.338    0.278 0.187
```

Windows Server 2012 R2 and later versions

You can configure your Windows Server instances to use the Oracle Cloud Infrastructure NTP service by running the following commands in Windows Powershell as Administrator.

```
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'Type' -Value NTP -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'AnnounceFlags' -Value 5 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer' -Name 'Enabled' -Value 1 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'NtpServer' -Value '169.254.169.254,0x9' -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient' -Name 'SpecialPollInterval' -Value 900 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'MaxPosPhaseCorrection' -Value 1800 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'MaxNegPhaseCorrection' -Value 1800 -Type DWord
```

Steps 1 - 7 below walk you though these registry changes, you can use these steps to manually edit the registry instead of using PowerShell. If you use the PowerShell commands, you can skip steps 1 - 7, and proceed with steps 8 and 9 to complete the process of configuring your Windows instance to use the Oracle Cloud Infrastructure NTP service.

1. Change the server type to NTP:
   a. From Registry Editor, navigate to:

   ```
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\Type
   ```
   
   b. Click Type.
   
   c. Change the value to NTP and click OK.

2. Configure the Windows Time service to enable the Timeserv_Announce_Yes and Reliable_Timeserv_Announce_Auto flags.
   To configure, set the AnnounceFlags parameter to 5:
   a. From Registry Editor, navigate to:

   ```
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\AnnounceFlags
   ```
   
   b. Click AnnounceFlags.
   
   c. Change the value to 5 and click OK.
3. Enable the NTP server:
   a. From Registry Editor, navigate to:
      ```
      HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\
      \TimeProviders\NtpServer\
      ```
   b. Click **Enabled**.
   c. Change the value to 1 and click **OK**.

4. Set the time sources:
   a. From Registry Editor, navigate to:
      ```
      HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\
      ```
   b. Click **NtpServer**.
   c. Change the value to 169.254.169.254,0x9 and click **OK**.

5. Set the poll interval:
   a. From Registry Editor, navigate to:
      ```
      HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\
      \TimeProviders\NtpClient\
      ```
   b. Click **SpecialPollInterval**.
   c. Set the value to the interval that you want the time service to synchronize on. The value is in seconds. To set it for 15 minutes, set the value to 900, and click **OK**.

6. Set the phase correction limit settings to restrict the time sample boundaries:
   a. From Registry Editor, navigate to:
      ```
      HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\
      ```
   b. Click **MaxPosPhaseCorrection**.
   c. Set the value to the maximum time offset in the future for time samples. The value is in seconds. To set it for 30 minutes, set the value to 1800 and click **OK**.
   d. Click **MaxNegPhaseCorrection**.
   e. Set the value to the maximum time offset in the past for time samples. The value is in seconds. To set it for 30 minutes, set the value to 1800 and click **OK**.

7. Restart the time service by running the following command from a command prompt:
   ```
   net stop w32time && net start w32time
   ```

8. Test the connection to the NTP service by running the following command from a command prompt:
   ```
   w32tm /query /peers
   ```
   The output will be similar to the following:
   ```
   #Peer: 1
   Peer: 169.254.169.254,0x9
   State: Active
   Time Remaining: 22.1901786s
   Mode: 3 (Client)
   Stratum: 0 (unspecified)
   PeerPoll Interval: 10 (1024s)
   HostPoll Interval: 10 (1024s)
   ```
   After the time specified in the poll interval has elapsed, **State** will change from **Pending** to **Active**.
Protecting Data on NVMe Devices

Some instance shapes in Oracle Cloud Infrastructure include locally attached NVMe devices. These devices provide extremely low latency, high performance block storage that is ideal for big data, OLTP, and any other workload that can benefit from high-performance block storage.

Note that these devices are not protected in any way; they are individual devices locally installed on your instance. Oracle Cloud Infrastructure does not take images, back up, or use RAID or any other methods to protect the data on NVMe devices. It is your responsibility to protect and manage the durability of the data on these devices.

Oracle Cloud Infrastructure offers high-performance remote block (iSCSI) LUNs that are redundant and can be backed up using an API call. See Overview of Block Volume on page 500 for more information.

See Compute Shapes on page 655 for information about which shapes support local NVMe storage.

Finding the NVMe devices on your instance

You can identify the NVMe devices by using the lsblk command. The response returns a list. NVMe devices begin with "nvme", as shown in the following example for a BM.DenseIO1.36 instance:

```
[root@somehost ~]# lsblk
NAME    MAJ:MIN  RM  SIZE     RO TYPE MOUNTPOINT
sda       8:0    0  46.6G    0 disk
##sda1    8:1    0  512M     0 part /boot/efi
##sda2    8:2    0   8G      0 part [SWAP]
##sda3    8:3    0   38G     0 part /
nvme0n1  259:6    0  2.9T    0 disk
nvme1n1  259:8    0  2.9T    0 disk
nvme2n1  259:0    0  2.9T    0 disk
nvme3n1  259:1    0  2.9T    0 disk
nvme4n1  259:7    0  2.9T    0 disk
nvme5n1  259:4    0  2.9T    0 disk
nvme6n1  259:5    0  2.9T    0 disk
nvme7n1  259:2    0  2.9T    0 disk
nvme8n1  259:3    0  2.9T    0 disk
```

Failure Modes and How to Protect Against Them

There are three primary failure modes you should plan for:

- Protecting Against the Failure of an NVMe Device on page 601
- Protecting Against the Loss of the Instance or Availability Domain on page 609
- Protecting Against Data Corruption or Loss from Application or User Error on page 609

Protecting Against the Failure of an NVMe Device

A protected RAID array is the most recommended way to protect against an NVMe device failure. There are three RAID levels that can be used for the majority of workloads:
- RAID 1: An exact copy (or mirror) of a set of data on two or more disks; a classic RAID 1 mirrored pair contains two disks, as shown:
- RAID 10: Stripes data across multiple mirrored pairs. As long as one disk in each mirrored pair is functional, data can be retrieved, as shown:

Blocks mirrored and striped
• RAID 6: Block-level striping with two parity blocks distributed across all member disks, as shown.

**RAID 6**

For more information about RAID and RAID levels, see [RAID](#).

Because the appropriate RAID level is a function of the number of available drives, the number of individual LUNs needed, the amount of space needed, and the performance requirements, there isn't one correct choice. You must understand your workload and design accordingly.

**Important:**

If you're partitioning or formatting your disk as part of this process and the drive is larger than 2 TB, you should create a GUID Partition Table (GPT).

If you want to create a GPT, use `parted` instead of the `fdisk` command.

For more information, see [About Disk Partitions](#) in the Oracle Linux Administrator's Guide.

---

**Options for Using a BM.DenseIO1.36 Shape**

There are several options for BM.DenseIO1.36 instances with nine NVMe devices.

For all options below, you can optionally increase the default RAID resync speed limit value. Increasing this value to more closely match the fast storage speed on the bare metal instances can decrease the amount of time required to set up RAID.

Use the following command to increase the speed limit value:

```
$ sysctl -w dev.raid.speed_limit_max=10000000
```

**Option 1: Create a single RAID 6 device across all nine devices**

This array is redundant, performs well, will survive the failure of any two devices, and will be exposed as a single LUN with about 23.8TB of usable space.
Use the following commands to create a single RAID 6 device across all nine devices:

$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=9 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1 /dev/nvme8n1

$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null

Option 2: Create a four device RAID 10 and a five device RAID 6 array

These arrays would be exposed as two different LUNs to your applications. This is a recommended choice when you need to isolate one type of I/O from another, such as log and data files. In this example, your RAID 10 array would have about 6.4TB of usable space and the RAID 6 array would have about 9.6TB of usable space.

Use the following commands to create a four-device RAID 10 and a five-device RAID 6 array:

$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1 /dev/nvme8n1

$ sudo mdadm --create /dev/md1 --raid-devices=5 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1

$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null

Option 3: Create an eight-device RAID 10 array

If you need the best possible performance and can sacrifice some of your available space, then an eight-device RAID 10 array is an option. Because RAID 10 requires an even number of devices, the ninth device is left out of the array and serves as a hot spare in case another device fails. This creates a single LUN with about 12.8 TB of usable space.

Use the following commands to create an eight-device RAID 10 array:

$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=8 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1

The following command adds /dev/nvme8n as a hot spare for the /dev/md0 array:

$ sudo mdadm /dev/md0 --add /dev/nvme8n1

$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null

Option 4: Create two four-device RAID 10 arrays

For the best possible performance and I/O isolation across LUNs, create two four-device RAID 10 arrays. Because RAID 10 requires an even number of devices, the ninth device is left out of the arrays and serves as a global hot spare in case another device in either array fails. This creates two LUNS, each with about 6.4 TB of usable space.
Compute

Use the following commands to create two four-device RAID 10 arrays with a global hot spare:

```bash
$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1

$ sudo mdadm --create /dev/md1 --raid-devices=4 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1
```

Creating a global hot spare requires the following two steps:

1. Add the spare to either array (it does not matter which one) by running these commands:

   ```bash
   $ sudo mdadm /dev/md0 --add /dev/nvme8n1
   $ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
   ```

2. Edit `/etc/mdadm` to put both arrays in the same spare-group. Add `spare-group=global` to the end of the line that starts with `ARRAY`, as follows:

   ```bash
   $ sudo vi /etc/mdadm.conf
   ```

   ```bash
   ARRAY /dev/md0 metadata=1.2 spares=1 name=mdadm.localdomain:0
   UUID=43f93ce6:4a19d07b:51762f1b:250e2327 spare-group=global

   ARRAY /dev/md1 metadata=1.2 name=mdadm.localdomain:1
   UUID=7521e51a:83999f00:99459a19:0c836693 spare-group=global
   ```

### Monitoring Your Array

It's important for you to be notified if a device in one of your arrays fails. Mdadm has built-in tools that can be utilized for monitoring, and there are two options you can use:

- Set the `MAILADDR` option in `/etc/mdadm.conf` and then run the `mdadm` monitor as a daemon
- Run an external script when `mdadm` detects a failure

#### Set the MAILADDR option in `/etc/mdadm.conf` and run the `mdadm` monitor as a daemon

The simplest method is to set the `MAILADDR` option in `/etc/mdadm.conf`, and then run the `mdadm` monitor as a daemon, as follows:

1. The `DEVICE partitions` line is required for `MAILADDR` to work; if it is missing, you must add it, as follows:

   ```bash
   $ sudo vi /etc/mdadm.conf
   ```

   ```bash
   DEVICE partitions
   ```

   ```bash
   ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eese14532
   ```

   ```bash
   MAILADDR <my.name@example.com>
   ```

2. Run the monitor using the following command:

   ```bash
   $ sudo nohup mdadm --monitor --scan --daemonize &
   ```
3. To verify that the monitor runs at startup, run the following commands:

```bash
$ sudo chmod +x /etc/rc.d/rc.local
$ sudo vi /etc/rc.local
```

Add the following line to the end of `/etc/rc.local`:

```
nohup mdadm --monitor --scan --daemonize &
```

4. To verify that the email and monitor are both working run the following command:

```bash
$ sudo mdadm --monitor --scan --test -1
```

Note that these emails will likely be marked as spam. The `PROGRAM` option, described later in this topic, allows for more sophisticated alerting and messaging.

**Run an external script when a failure is detected**

A more advanced option is to create an external script that would run if the `mdadm` monitor detects a failure. You would integrate this type of script with your existing monitoring solution. The following is an example of this type of script:

```bash
#!/bin/bash
event=$1
device=$2
if [ $event == "Fail" ]
    then
        <"do something">
    else
        if [ $event == "FailSpare" ]
            then
                <"do something else">
        else
            if [ $event == "DegradedArray" ]
                then
                    <"do something else else">
            else
                if [ $event == "TestMessage" ]
                    then
                        <"do something else else else">
                fi
        fi
    fi
$ sudo chmod +x /etc/mdadm.events
```

Next, add the `PROGRAM` option to `/etc/mdadm.conf`, as shown in the following example:
1. The DEVICE partitions line is required for MAILADDR to work; if it is missing, you must add it, as follows:

```
$ sudo vi /etc/mdadm.conf
```

```
DEVICE partitions
```

```
ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eese14532
MAILADDR <my.name@example.com>
```

```
PROGRAM /etc/mdadm.events
```

2. Run the monitor using the following command:

```
$ sudo nohup mdadm --monitor --scan --daemonize &
```

3. To verify that the monitor runs at startup, run the following commands:

```
$ sudo chmod +x /etc/rc.d/rc.local
$ sudo vi /etc/rc.local
```

Add the following line to the end of /etc/rc.local:

```
nohup mdadm --monitor --scan --daemonize &
```

4. To verify that the email and monitor are both working run the following command:

```
$ sudo mdadm --monitor --scan --test -1
```

Note that these emails will likely be marked as spam. The PROGRAM option, described later in this topic, allows for more sophisticated alerting and messaging.

**Simulate the failure of a device**

You can use mdadm to manually cause a failure of a device to see whether your RAID array can survive the failure, as well as test the alerts you have set up.

1. Mark a device in the array as failed by running the following command:

```
$ sudo mdadm /dev/md0 --fail /dev/nvme0n1
```

2. Recover the device or your array might not be protected. Use the following command:

```
$ sudo mdadm /dev/md0 --add /dev/nvme0n1
```

Your array will automatically rebuild in order to use the "new" device. Performance will be decreased during this process.

3. You can monitor the rebuild status by running the following command:

```
$ sudo mdadm --detail /dev/md0
```

**What To Do When an NVMe Device Fails**

Compute resources in the cloud are designed to be temporary and fungible. If an NVMe device fails while the instance is in service, you should start another instance with the same amount of storage or more, and then copy the data onto the new instance, replacing the old instance. There are multiple toolsets for copying large amounts of data, with rsync being the most popular. Since the connectivity between instances is a full 10 Gb/sec, copying data should
be quick. Remember that with a failed device, your array may no longer be protected, so you should copy the data off of the impacted instance as quickly as possible.

**Using the Linux Logical Volume Manager**

The Linux Logical Volume Manager (LVM) provides a rich set of features for managing volumes. If you need these features, we strongly recommend that you use `mdadm` as described in preceding sections of this topic to create the RAID arrays, and then use LVM's `pvcreate`, `vgcreate`, and `lvcreate` commands to create volumes on the `mdadm` LUNs. You should not use LVM directly against your NVMe devices.

**Protecting Against the Loss of the Instance or Availability Domain**

Once your data is protected against the loss of a NVMe device, you need to protect it against the loss of an instance or the loss of the availability domain. This type of protection is typically done by replicating your data to another availability domain or backing up your data to another location. The method you choose depends on your objectives. For details, see the disaster recovery concepts of Recovery Time Objective (RTO) and Recovery Point Objective (RPO).

**Replication**

Replicating your data from one instance in one availability domain to another has the lowest RTO and RPO at a significantly higher cost than backups; for every instance in one availability domain, you must have another instance in a different availability domain.

For Oracle database workloads, you should use the built-in Oracle Data Guard functionality to replicate your databases. Oracle Cloud Infrastructure availability domains are each close enough to each other to support high performance, synchronous replication. Asynchronous replication is also an option.

For general-purpose block replication, DRBD is the recommended option. You can configure DRBD to replicate, synchronously or asynchronously, every write in one availability domain to another availability domain.

**Backups**

Traditional backups are another way to protect data. All commercial backup products are fully supported on Oracle Cloud Infrastructure. If you use backups, the RTO and RPO are significantly higher than using replication because you must recreate the compute resources that failed and then restore the most recent backup. Costs are significantly lower because you don't need to maintain a second instance. Do not store your backups in the same availability domain as their original instance.

**Protecting Against Data Corruption or Loss from Application or User Error**

The two recommended ways of protecting against data corruption or loss from application or user error are regularly taking snapshots or creating backups.

**Snapshots**

The two easiest ways to maintain snapshots are to either use a file system that supports snapshots, such as ZFS, or use LVM to create and manage the snapshots. Because of the way LVM has implemented copy-on-write (COW), performance may significantly decrease when a snapshot is taken using LVM.

**Backups**

All commercial backup products are fully supported on Oracle Cloud Infrastructure. Make sure that your backups are stored in a different availability domain from the original instance.

**Boot Volumes**

When you launch a virtual machine (VM) or bare metal instance based on an Oracle-provided image or custom image, a new boot volume for the instance is created in the same compartment. That boot volume is associated with that instance until you terminate the instance. When you terminate the instance, you can preserve the boot volume and
Compute its data. For more information, see Terminating an Instance on page 783. This feature gives you more control and management options for your compute instance boot volumes, and enables:

- **Instance scaling**: When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. See Creating an Instance on page 695 for steps to launch an instance based on a boot volume. This allows you to switch easily from a bare metal instance to a VM instance and vice versa, or scale up or down the number of cores for an instance.

- **Troubleshooting and repair**: If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Boot volumes are encrypted by default, the same as other block storage volumes. For more information, see Block Volume Encryption on page 504.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>In-transit encryption for boot and block volumes is only available for virtual machine (VM) instances launched from Oracle-provided images, it is not supported on bare metal instances. It is also not supported in most cases for instances launched from custom images imported for &quot;bring your own image&quot; (BYOI) scenarios. To confirm support for certain Linux-based custom images and for more information contact Oracle support, see Getting Help and Contacting Support on page 125.</td>
</tr>
</tbody>
</table>

You can group boot volumes with block volumes into the same volume group, making it easy to create a group volume backup or a clone of your entire instance, including both the system disk and storage disks at the same time. See Volume Groups on page 506 for more information.

You can move Block Volume resources such as boot volumes and boot volume backups between compartments. For more information, see Move Block Volume Resources Between Compartments on page 564.

For more information about the Block Volume service and boot volumes, see the Block Volume FAQ.

**Custom Boot Volume Sizes**

When you launch an instance, you can choose whether to use the selected image's default boot volume size, or to specify a custom size up to 32 TB. This capability is available for the following image source options:

- Oracle-provided image
- Custom image
- Image OCID

See Creating an Instance on page 695 for more information.

For Linux-based images, the custom boot volume size must be larger than the image's default boot volume size or 50 GB, whichever is higher.

For Windows-based images, the custom boot volume size must be larger than the image's default boot volume size or 256 GB, whichever is higher. The minimum size requirement for Windows images is to ensure that there is enough space available for Windows patches and updates that can require a large amount of space, to improve performance, and to provide adequate space for setting a suitable page file (see this Microsoft known issue for page file settings on Windows Server 2012 R2).

After you launch an instance, you can't change the boot volume size.

If you specify a custom boot volume size, you need to extend the volume to take advantage of the larger size. For steps, see Extending the Partition for a Boot Volume on page 612.
**Boot Volume Performance**

Boot volume performance varies with volume size, see Block Volume Performance on page 567 for more information.

The Block Volume service's elastic performance feature enables you to dynamically change the volume performance for boot volumes. Once an instance has been created, you can change the volume performance of the boot volume to one of the following performance options:

- Balanced
- Higher Performance

For more information about this feature and the performance options, see Block Volume Elastic Performance on page 581 and Changing the Performance of a Volume on page 582

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to list boot volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes, boot volumes, and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

To access the Console, you must use a supported browser.

See the following tasks for managing boot volumes:

- Listing Boot Volumes on page 614
- Attaching a Boot Volume on page 613
- Detaching a Boot Volume on page 623
- Listing Boot Volume Attachments on page 615
- Deleting a Boot Volume on page 624

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage boot volumes:

- BootVolume
- ListBootVolumes
- GetBootVolume
- UpdateBootVolume
- DetachBootVolume
- DeleteVolume
- BootVolumeAttachment
- AttachBootVolume
- GetBootVolumeAttachment
- ListBootVolumeAttachments
Extending the Partition for a Boot Volume

When you create a new virtual machine (VM) instance or bare metal instance based on an Oracle-provided image or custom image, you have the option of specifying a custom boot volume size. You can also expand the size of the boot volume for an existing instance; see Resizing a Volume on page 532 for more information. In order to take advantage of the larger size, you need to extend the partition for the boot volume. For block volumes, see Extending the Partition for a Block Volume on page 536.

Note:

After a boot volume has been resized, the first backup on the resized boot volume will be a full backup. See Boot Volume Backup Types on page 615 for more information about full versus incremental boot volume backups.

Required IAM Policy

Extending a partition on an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

Extending the Root Partition on a Linux-Based Image

For instances running Linux-based images, you need to extend the root partition and then grow the file system using the `oci-growfs` operation from OCI Utilities on page 642.

Extending the System Partition on a Windows-Based Image

On Windows-based images, you can extend a partition using the Windows interface or from the command line using the DISKPART utility.

Windows Server 2012 and Later Versions

The steps for extending a system partition on instances running Windows Server 2012, Windows Server 2016, or Windows Server 2019 are the same, and are described in the following procedures.

Extending the system partition using the Windows interface

1. Open the Disk Management system utility on the instance.
2. Right-click the boot volume and select Extend Volume.
3. Follow the instructions in the Extend Volume Wizard:
   a. Select the disk that you want to extend, enter the size, and then click Next.
   b. Confirm that the disk and size settings are correct, and then click Finish.
4. Verify that the boot volume's system disk has been extended in Disk Management.

Extending the system partition using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

```
diskpart
```

3. At the DISKPART prompt, run the following command to display the instance's volumes:

```
list volume
```

4. Run the following command to select the boot volume:

```
select volume <volume_number>
```

<volume_number> is the number associated with the boot volume that you want to extend the partition for.

5. Run the following command to extend the partition:

```
extend size=<increased_size_in_MB>
```

<increased_size_in_MB> is the size in MB that you want to extend the partition to.

**Caution:**
When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.

6. To confirm that the partition was extended, run the following command and verify that the boot volume's partition has been extended:

```
list volume
```

### Attaching a Boot Volume

If a boot volume has been detached from the associated instance, you can reattach it to the instance. If you want to restart an instance with a detached boot volume, you must reattach the boot volume using the steps described in this topic.

If a boot volume has been detached from the associated instance, or if the instance is stopped or terminated, you can attach the boot volume to another instance as a data volume. For steps, see [Attaching a Volume](#) on page 517.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in [Let users launch compute instances](#) on page 2143 includes the ability to attach and detach existing block volumes. The policy in [Let volume admins manage block volumes, backups, and volume groups](#) on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see [Details for the Core Services](#) on page 2181.

### Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to attach block volumes to Compute instances:

- The boot volume for a Compute instance in a security zone must also be in a security zone.
- A Compute instance that isn't in a security zone can't be attached to a boot volume that is in a security zone.
Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you want to reattach the boot volume to.
4. Click the Actions icon (three dots), and then click Attach Boot Volume. Confirm when prompted.

   You can start the instance when the boot volume’s state is Attached.

Using the API

To attach a volume to an instance, use the following operation:

- AttachBootVolume

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Listing Boot Volumes

You can list all boot volumes in a specific compartment, or detailed information on a single boot volume.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to list volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volumes.
2. Choose your Compartment.

   A detailed list of volumes in the current compartment is displayed. To see detailed information for a specific volume, click the boot volume name.

   The instance associated with the boot volume is listed in the Attached Instance field. If the value for this field displays the message None in this Compartment, the boot volume has been detached from the associated instance, or the instance has been terminated while the boot volume was preserved.

   To view the volumes in a different compartment, change the compartment in the Compartment drop-down menu.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

List Boot Volumes:

Get a list of boot volumes within a compartment.

- ListBootVolumes

Get a Single Boot Volume:

Get detailed information on a single boot volume:
Listing Boot Volume Attachments

You can use the API to list all the boot volume attachments in a specific compartment. You can also use the API to retrieve detailed information on a single boot volume attachment.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to list volume attachments. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

List Boot Volume Attachments:

Get information on all boot volume attachments in a specific compartment.

- ListBootVolumeAttachments

Get a Single Boot Volume Attachment:

Get detailed information on a single boot volume attachment.

- GetBootVolumeAttachment

Overview of Boot Volume Backups

The backups feature of the Oracle Cloud Infrastructure Block Volume service lets you make a crash-consistent backup, which is a point in time snapshot of a boot volume without application interruption or downtime. You can make a backup of a boot volume while it is attached to a running instance, or you can make a backup of a boot volume while it is detached from the instance. Boot volume backup capabilities are the same as block volume backup capabilities. See Overview of Block Volume Backups on page 540 for more information.

There are two ways you can initiate a boot volume backup, the same as block volume backups. You can either manually start the backup, or assign a policy which defines a set backup schedule. See Manual Backups on page 540 and Policy-Based Backups on page 540 for more information.

Boot Volume Backup Types

The Block Volume service supports the same backups types for boot volumes as for block volumes:

- **Incremental**: This backup type includes only the changes since the last backup.
- **Full**: This backup type includes all changes since the volume was created.

You can restore a boot volume from any of your incremental or full boot volume backups. Both backup types enable you to restore the full boot volume contents to the point-in-time snapshot of the boot volume when the backup was taken. You don't need to keep the initial full backup or subsequent incremental backups in the backup chain and restore them in sequence, you only need to keep the backups taken for the times you care about.
Note:

After a boot volume has been resized, the first backup on the resized boot volume will be a full backup. See Resizing a Volume on page 532 for more information about volume resizing.

Tags

When a boot volume backup is created, the source boot volume’s tags are automatically included in the boot volume backup. This also includes boot volumes with custom backup policies applied to create backups on a schedule. Source boot volume tags are automatically assigned to all backups when they are created. You can also apply additional tags to volume backups as needed.

When you create an instance from the boot volume backup, the instance is created includes the source boot volume’s tags.

Backing Up a Boot Volume

You can create boot volume backups using the Console or the REST APIs/command line interface (CLI). See Backing Up a Boot Volume on page 617 and the BootVolumeBackup API for more information.

Boot Volume Backup Size

Boot volume backup size may be larger than the source boot volume size. Some of the reasons for this could include the following:

- Any part of the boot volume that has been written to is considered initialized, so will always be part of the boot volume backup.
- Many operating systems write or zero out the content, which results in these blocks marked as used. The Block Volume service considers these blocks updated and includes them in the volume backup.
- Boot volume backups also include metadata, which can be up to 1 GB in additional data. For example, in a full backup of a 256 GB Windows boot disk, you may see a backup size of 257 GB, which includes an additional 1 GB of metadata.

Restoring a Boot Volume

Before you can use a boot volume backup, you need to restore it. For steps, see Restoring a Boot Volume on page 618.

Making a boot volume backup while an instance is running creates a crash-consistent backup, meaning the data is in the identical state it was in at the time the backup was made. This is the same state it would be in the case of a loss of power or hard crash. In most cases, you can restore a boot volume backup and use it to create an instance. Alternatively, you can attach it to an instance as a data volume to repair it or recover data, see Attaching a Volume on page 517. To ensure a bootable image, you should create a custom image from your instance. For information about creating custom images, see Managing Custom Images on page 665.

Copying Boot Volume Backups Across Regions

You can copy boot volume backups between regions using the Console, command line interface (CLI), SDKs, or REST APIs. For steps, see Copying a Boot Volume Backup Between Regions on page 619. This capability enhances the following scenarios:

- **Disaster recovery and business continuity:** By copying boot volume backups to another region at regular intervals, it makes it easier for you to restore instances in the destination region if a region-wide disaster occurs in the source region.
- **Migration and expansion:** You can easily migrate and expand your instances to another region.

To copy boot volume backups between regions, you must have permission to read and copy boot volume backups in the source region, and permission to create boot volume backups in the destination region. For more information see Required IAM Policy on page 620.

Once you have copied the boot volume backup to the new region you can then restore from that backup by creating a new volume from the backup using the steps described in Restoring a Boot Volume on page 618.
Differences Between Boot Volume Backups and Clones

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

<table>
<thead>
<tr>
<th></th>
<th>Volume Backup</th>
<th>Volume Clone</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.</td>
<td>Creates a single point-in-time copy of a volume without having to go through the backup and restore process.</td>
</tr>
<tr>
<td><strong>Use case</strong></td>
<td>Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.</td>
<td>Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.</td>
</tr>
<tr>
<td><strong>Speed</strong></td>
<td>Slower (minutes or hours)</td>
<td>Faster (seconds)</td>
</tr>
<tr>
<td><strong>Cost</strong></td>
<td>Lower cost</td>
<td>Higher cost</td>
</tr>
<tr>
<td><strong>Storage location</strong></td>
<td>Object Storage</td>
<td>Block Volume</td>
</tr>
<tr>
<td><strong>Retention policy</strong></td>
<td>Policy-based backups expire, manual backups do not expire</td>
<td>No expiration</td>
</tr>
<tr>
<td><strong>Volume groups</strong></td>
<td>Supported. You can back up a volume group.</td>
<td>Supported. You can clone a volume group.</td>
</tr>
</tbody>
</table>

Backing Up a Boot Volume

You can create a backup of a boot volume using the Oracle Cloud Infrastructure Block Volume service. Boot volume backups are point-in-time snapshots of a boot volume. For more information about boot volume backups, see Overview of Boot Volume Backups on page 615. This topic describes how to create a manual boot volume backup.

You can also configure a backup policy that creates backups automatically based on a specified schedule and retention policy. This works the same as block volumes. See Policy-Based Backups on page 547 for more information.

For information to help you decide whether to create a backup or a clone of a boot volume, see Differences Between Boot Volume Backups and Clones on page 617.

**Note:**

Boot volume backup size may be larger than the source boot volume size. See Boot Volume Backup Size on page 616 for more information. See also Boot volume backup size larger than expected.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.
When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volumes.
2. Click the boot volume that you want to create a backup for.
3. Click Create Manual Backup.
4. Enter a name for the backup. Avoid entering confidential information.
5. Select the backup type, either incremental or full. See Boot Volume Backup Types on page 615 for information about backup types.
6. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click Create Backup.

The backup is completed when its icon no longer lists it as CREATING in the Boot Volume Backup list.

Using the API

To back up a boot volume, use the following operation:

- CreateBootVolumeBackup

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For more information about backups, see Overview of Block Volume Backups on page 540 and Restoring a Backup to a New Volume on page 557.

Restoring a Boot Volume

You can use a boot volume backup to create an instance or you can attach it to another instance as a data volume. However before you can use a boot volume backup, you need to restore it to a boot volume.

You can restore a boot volume from any of your incremental or full boot volume backups. Both backup types enable you to restore the full boot volume contents to the point-in-time snapshot of the boot volume when the backup was taken. You don't need to keep the initial full backup or subsequent incremental backups in the backup chain and restore them in sequence, you only need to keep the backups taken for the times you care about. See Boot Volume Backup Types on page 615 for information about full and incremental backup types.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volume Backups.
2. Choose your Compartment.
3. In the list of boot volume backups, click the Actions icon (three dots) for the boot volume backup you want to restore and then click **Create Boot Volume**.

4. Specify a name for the boot volume, select the availability domain to use, and optionally choose a backup policy for scheduled backups. See **Policy-Based Backups** on page 547 for more information about scheduled backups and volume backup policies. Avoid entering confidential information.

5. You can restore a boot volume backup to a larger volume size. To do this, check **Custom Block Volume Size (GB)** and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you restore the block volume backup to a larger size volume, you need to extend the volume's partition, see **Extending the Partition for a Boot Volume** on page 612 for more information.

6. Click **Create Boot Volume**.

   The boot volume will be ready to use once its icon no longer lists it as **PROVISIONING** in the details page for the boot volume.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

To restore a boot volume backup, use the **CreateBootVolume** operation and specify **BootVolumeSourceFromBootVolumeBackupDetails** for **CreateBootVolumeDetails**.

**Next Steps**

After you have restored the boot volume backup, you can:

- Use the boot volume to create an instance, for more information, see **Creating an Instance** on page 695.
- Attach the boot volume to an instance as a data volume, for more information, see **Attaching a Volume** on page 517.

Making a boot volume backup while an instance is running creates a crash-consistent backup, meaning the data is in the identical state it was in at the time the backup was made. This is the same state it would be in the case of a loss of power or hard crash. In most cases you can use the restored boot volume to create an instance, however to ensure a bootable image, you should create a custom image from your instance. For information about creating custom images, see **Managing Custom Images** on page 665.

**Copying a Boot Volume Backup Between Regions**

You can copy boot volume backups from one region to another region using the Oracle Cloud Infrastructure Block Volume service. For more information, see **Copying Boot Volume Backups Across Regions** on page 616.

**Note:**

Limitations for Copying Boot Volume Backups Across Regions

When copying boot volume backups across regions in your tenancy, you can only copy one backup at a time from a specific source region.

You can only copy boot volume backups for instances based on **Oracle-Provided Images** on page 629. If you try to copy a boot volume for an instance based on other image types, such as Marketplace images, the request will fail with an error.

You cannot add compatible shapes in the destination region for boot volume backups, the shape compatibility list is from the source region and cannot be changed.

When you create an instance from the Console and specify a boot volume backup that was copied from another region as the image source, you may encounter a message indicating that there was an error loading the source image. You can ignore this error message and click **Create Instance** to finish the instance creation process and launch the instance.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: The first two statements listed in the *Let volume admins manage block volumes, backups, and volume groups* on page 2146 policy lets the specified group do everything with boot volumes and boot volume backups with the exception of copying boot volume backups across regions. The aggregate resource type *volume-family* does not include the *BOOT_VOLUME_BACKUP_COPY* permission, so to enable copying boot volume backups across regions you need to ensure that you include the third statement in that policy, which is:

```
Allow group VolumeAdmins to use boot-volume-backups in tenancy where request.permission='BOOT_VOLUME_BACKUP_COPY'
```

To restrict access to just creating and managing boot volume backups, including copying boot volume backups between regions, use the policy in *Let boot volume backup admins manage only backups* on page 2147. The individual resource type *boot-volume-backups* includes the *BOOT_VOLUME_BACKUP_COPY* permission, so you do not need to specify it explicitly in this policy.

If you are copying volume backups encrypted using Vault between regions or you want the copied volume backup to use Vault for encryption in the destination region, you need to use a policy that allows the Block Volume service to perform cryptographic operations with keys in the destination region. For a sample policy showing this, see *Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools* on page 2153.

** Restricting Access **

The specific permissions needed to copy volume backups across regions are:

- **Source region**: *BOOT_VOLUME_BACKUP_READ*, *BOOT_VOLUME_BACKUP_COPY*
- **Destination region**: *BOOT_VOLUME_BACKUP_CREATE*

**Sample Policies**

To restrict a group to specific source and destination regions for copying volume backups

In this example, the group is restricted to copying volume backups from the UK South (London) region to the Germany Central (Frankfurt) region.

```
Allow group MyTestGroup to read boot-volume-backups in tenancy where all {request.region='lhr'}
Allow group MyTestGroup to use boot-volume-backups in tenancy where all {request.permission='BOOT_VOLUME_BACKUP_COPY', request.region = 'lhr',}
Allow group MyTestGroup to manage boot-volume-backups in tenancy where all {request.permission='BOOT_VOLUME_BACKUP_CREATE', request.region = 'fra'}
```

To restrict some source regions to specific destination regions while enabling all destination regions for other source regions

In this example, the following is enabled for the group:

- Manage volume backups in all regions.
- Copy volume backups from the US West (Phoenix) and US East (Ashburn) regions to any destination regions.
- Copy volume backups from the Germany Central (Frankfurt) and UK South (London) regions only to the Germany Central (Frankfurt) or UK South (London) regions.

```
Allow group MyTestGroup to read boot-volume-backups in tenancy where all {request.region='lhr'}
Allow group MyTestGroup to manage boot-volume-backups in tenancy where any {request.permission!='BOOT_VOLUME_BACKUP_COPY'}
```
Allow group MyTestGroup to use boot-volume-backups in tenancy where all
{request.permission='BOOT_VOLUME_BACKUP_COPY', any {request.region='lhr',
request.region='fra'}, any{target.region='fra', target.region='lhr'}}
Allow group MyTestGroup to use boot-volume-backups in tenancy where all
{request.permission='BOOT_VOLUME_BACKUP_COPY', any {request.region='phx',
request.region='iad'}}

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volume Backups.
   A list of the boot volume backups in the compartment you're viewing is displayed. If you don't see the one you're looking for, make sure you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the Actions icon (three dots) for the boot volume backup you want to copy to another region.
3. Click Copy to Another Region.
4. Enter a name for the backup and choose the region to copy the backup to. Avoid entering confidential information.
5. In the Encryption section select whether you want the boot volume backup to use the Oracle-provided encryption key or your own Vault encryption key. If you select the option to use your own key, paste the OCID for encryption key from the destination region.
6. Click Copy Boot Volume Backup.
7. Confirm that the source and destination region details are correct in the confirmation dialog and then click OK.

Using the API
To copy a boot volume backup to another region, use the following operation:

• CopyBootVolumeBackup

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Next Steps
After copying the boot volume backup, switch to the destination region in the Console and verify that the copied backup appears in the list of boot volume backups for that region. You can then restore the backup using the steps in Restoring a Boot Volume on page 618.

For more information about backups, see Overview of Boot Volume Backups on page 615.

Cloning a Boot Volume
You can create a clone from a boot volume using the Oracle Cloud Infrastructure Block Volume service. Cloning enables you to make a copy of an existing boot volume without needing to go through the backup and restore process. For more information about the Block Volume service, see Overview of Block Volume on page 500 and the Block Volume FAQ.

A boot volume clone is a point-in-time direct disk-to-disk deep copy of the source boot volume, so all the data that is in the source boot volume when the clone is created is copied to the boot volume clone. Any subsequent changes to the data on the source boot volume are not copied to the boot volume clone. Since the clone is a copy of the source boot volume it will be the same size as the source boot volume unless you specify a larger volume size when you create the clone.

The clone operation occurs immediately and you can use the cloned boot volume as soon as the state changes to available.

There is a single point-in-time reference for a source boot volume while it is being cloned, so if you clone a boot volume while the associated instance is running, you need to wait for the first clone operation to complete from the source before creating additional clones. You also need to wait for any backup operations to complete as well.
You can only create a clone for a boot volume within the same region, availability domain, and tenant. You can create a clone for a boot volume between compartments as long as you have the required access permissions for the operation.

**Differences Between Boot Volume Backups and Clones**

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

<table>
<thead>
<tr>
<th></th>
<th>Volume Backup</th>
<th>Volume Clone</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.</td>
<td>Creates a single point-in-time copy of a volume without having to go through the backup and restore process.</td>
</tr>
<tr>
<td><strong>Use case</strong></td>
<td>Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.</td>
<td>Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.</td>
</tr>
<tr>
<td><strong>Speed</strong></td>
<td>Slower (minutes or hours)</td>
<td>Faster (seconds)</td>
</tr>
<tr>
<td><strong>Cost</strong></td>
<td>Lower cost</td>
<td>Higher cost</td>
</tr>
<tr>
<td><strong>Storage location</strong></td>
<td>Object Storage</td>
<td>Block Volume</td>
</tr>
<tr>
<td><strong>Retention policy</strong></td>
<td>Policy-based backups expire, manual backups do not expire</td>
<td>No expiration</td>
</tr>
<tr>
<td><strong>Volume groups</strong></td>
<td>Supported. You can back up a volume group.</td>
<td>Supported. You can clone a volume group.</td>
</tr>
</tbody>
</table>

For more information about boot volume backups, see [Overview of Boot Volume Backups](#) on page 615 and [Backing Up a Boot Volume](#) on page 617.

**Using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Boot Volumes** list, click the boot volume that you want to clone.
3. In **Resources**, click **Boot Volume Clones**.
4. Click **Create Clone**.
5. Specify a name for the clone. Avoid entering confidential information.
6. If you want to clone the boot volume to a larger size volume, select **Custom Boot Volume Size (GB)** and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you clone the boot volume to a larger size volume, you need to extend the volume's partition. See [Extending the Partition for a Boot Volume](#) on page 612 for more information.
7. Click **Create Clone**.

The boot volume is ready use when its icon lists it as **AVAILABLE** in the **Boot Volumes** list.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To create a clone from a boot volume, use the CreateBootVolume operation and specify BootVolumeSourceFromBootVolumeDetails for CreateBootVolumeDetails.

Next Steps

After you have cloned a boot volume backup, you can:

• Use the boot volume to create an instance. For more information, see Creating an Instance on page 695.
• Attach the boot volume to an instance as a data volume. For more information, see Attaching a Volume on page 517.

Making a boot volume clone while an instance is running creates a crash-consistent clone, meaning the data is in the identical state it was in at the time the clone was made. This is the same state it would be in the case of a loss of power or hard crash. In most cases you can use the cloned boot volume to create an instance, however to ensure a bootable image, you should create a custom image from your instance. For information about creating custom images, see Managing Custom Images on page 665.

Detaching a Boot Volume

If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume using the steps described in this topic. Then you can attach it to another instance as a data volume to troubleshoot it.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to attach and detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

You can detach a boot volume from an instance only when the instance is stopped. See Stopping and Starting an Instance on page 779 for information about managing an instance's state.

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Choose your Compartment.
3. Click the instance that you want to detach the boot volume from.
5. Click the Actions icon (three dots) for the boot volume, and then click Detach Boot Volume. Confirm when prompted.

You can now attach the boot volume to another instance. For more information, see Attaching a Volume on page 517.

Using the API

To delete an attachment, use the following operation:

• DetachBootVolume

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Deleting a Boot Volume

When you terminate an instance, you choose to delete or preserve the associated boot volume. For more information, see Terminating an Instance on page 783. You can also delete a boot volume if it has been detached from the associated instance. See Detaching a Boot Volume on page 623 for how to detach a boot volume.

Caution:

You cannot undo this operation. Any data on a volume will be permanently deleted once the volume is deleted. You will also not be able to restart the associated instance.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups on page 2146 lets the specified group do everything with block volumes and backups.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Boot Volumes.
2. Choose your Compartment.
3. In the Boot Volumes list, find the volume you want to delete.
4. Click the Actions icon (three dots) for the boot volume.
5. Click Terminate and confirm the selection when prompted.

Using the API

Use the DeleteBootVolume operation to delete a boot volume.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Boot Volume Metrics

You can monitor the health, capacity, and performance of your Compute instances by using metrics, alarms, and notifications.

The Block Volume service provides a set of metrics that apply to both boot volumes and block volumes. For more information, see Block Volume Metrics on page 585.

Recovering a Corrupted Boot Volume for Linux-Based Instances

If your instance fails to boot successfully or boots with the boot volume set to read-only access, the instance's boot volume may be corrupted. While it is rare, boot volume corruption can occur in the following scenarios:

- When an instance experiences a forced shutdown using the API.
- When an instance experiences a system hang due to an operating system or software error and a graceful reboot or shutdown of the instance times out, and then a forced shutdown occurs.
- When an error or outage occurs in the underlying infrastructure and there were critical disk writes pending in the system.
Compute

**Important:**

In most cases a simple reboot will resolve boot volume corruption issues, so this is the first action you should take when troubleshooting this.

This topic describes how to determine if your Linux-based instance's boot volume is corrupted and what steps to take to troubleshoot and recover the corrupted boot volume. For Windows instances, see Recovering a Corrupted Boot Volume for Windows Instances on page 628.

**Detecting Boot Volume Corruption**

Boot volume corruption can prevent an instance from booting successfully, so you may not be able to connect to the instance using SSH. Instead, you can use the instance console connection feature to connect to the malfunctioning instance. For more information about using this feature, see Troubleshooting Instances Using Instance Console Connections on page 813.

This section describes how to use a serial console connection to detect if boot volume corruption has occurred.

**Tip:**

If you have already confirmed your instance's boot volume is corrupted or if you are using an imported custom image, proceed to the Recovering the Boot Volume on page 626 section, which describes how to use a second instance along with standard file system tools to both detect and repair boot volume corruption.

1. Create a serial console connection for the instance.
2. Connect to the instance through serial console.
   
   At this point, it's normal for the serial console to appear to hang, as the system may have already crashed.
3. Reboot the instance from the Console.
4. Once the reboot process starts, switch back to the terminal window, and you should see system messages from the instance start to appear in the window.
5. Monitor the messages that appear as the system is starting up. Most operating systems will set the boot volume to read-only as soon as disk corruption is detected to prevent writes from further corrupting the volume, so look for messages that indicate the boot volume is in read-only mode. Following are some examples:
   
   • On an instance with iSCSI-attached boot volumes, the `iscsiadm` service will fail to attach a volume because the volume is in read-only mode. This will typically prevent instances from continuing to boot. The serial console may display a message similar to the following:

   ```
   iscsiadm: Maybe you are not root?
   iscsiadm: Could not lock discovery DB: /var/lock/iscsi/lock.write: Read-only file system
   touch: cannot touch '/var/lock/subsys/iscsid': Read-only file system
   touch: cannot touch '/var/lock/subsys/iscsi': Read-only file system
   ```
   
   • On an instance with paravirtualized-attached boot volumes, the system may continue the boot process, but will be in a degraded state because nothing can be written to the boot drive. The serial console may display error messages similar to the following:

   ```
   [FAILED] Failed to start Create Volatile Files and Directories. See 'systemctl status systemd-tmpfiles-setup.service' for details.
   ...
   [ 27.160070] cloud-init[819]: os.chmod(path, real_mode)
   [ 27.166027] cloud-init[819]: OSError: [Errno 30] Read-only file system: '/var/lib/cloud/data'
   ```
   
   The error messages and system behavior described here are the most commonly seen for boot volume corruption, however depending on the operating system, you may see different error messages and system behavior. If you don't see the ones described here, consult the documentation for your operating system for additional troubleshooting information.
Recovering the Boot Volume

To troubleshoot and recover the corrupted boot volume, you need to detach the boot volume from the instance and then attach the boot volume to a second instance as a data volume.

Detaching the Boot Volume

If you have detected that your instance's boot volume is corrupted, you need to detach the boot volume from the instance before you can begin troubleshooting and recovery steps.

1. Stop the instance.
2. Detach the boot volume from the instance.

Attaching the Boot Volume as a Data Volume to a Second Instance

For the second instance, we recommend that you use an instance running an operating system that most closely matches the operating system for the boot volume's instance. You should only attach boot volumes for Linux-based instances to other Linux-based instances. The second instance must be in the same availability domain and region as the boot volume's instance. If no existing instance is available, create a new Linux instance using the steps described in Creating an Instance on page 695. Once you have the second instance, make sure you can log into the instance and that it is functional before proceeding with the recovery steps. For steps to access the instance, see Connecting to a Linux Instance on page 734. After you have confirmed that the instance is functional, perform the following steps.

1. Run the `lsblk` command and make note of the drives that are currently on the instance, for example:

```
lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sda      8:0    0 46.6G  0 disk
##sda2   8:2    0    8G  0 part [SWAP]
##sda3   8:3    0 38.4G  0 part /
##sda1   8:1    0  200M  0 part /boot/efi
```

2. Attach the boot volume to the second instance as a data volume. For more information, see Attaching a Volume on page 517.

   To attach the boot volume as a data volume
   a. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
   b. Click the instance that you want to attach a volume to.
   c. Under Resources, click Attached Block Volumes.
   d. Click Attach Block Volume.
   e. Select the volume attachment type. If Paravirtualized attachments are available for this instance, we recommend that you select this attachment type for this procedure.

      If you select iSCSI as the volume attachment type, you need to connect to the volume, see Connecting to a Volume on page 524 for more information.
   f. In the Block Volume Compartment drop-down list, select the compartment.
   g. Choose the Select Volume option and then select the volume from the Boot Volume section of the Block Volume drop-down list.
   h. Select Read/Write as the access type.
   i. Click Attach.

      When the volume's icon no longer lists it as Attaching, proceed with the next steps.

3. Run the `lsblk` command again to confirm that the boot volume now shows up as a volume attached to the instance. In this sample output for the `lsblk`, the boot volume attached as a data volume shows up as sdb:

```
lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sdb     8:16   0 46.6G  0 disk
```
4. Run the `fsck` command on the volume’s root partition. The root partition is usually the largest partition on the volume.

The following sample for the `fsck` command shows the output when there are no errors or corruption present on the partitions for an Oracle 7.6 instance:

```
sudo fsck -V /dev/sdb1
fsck from util-linux 2.23.2
[/sbin/fsck.vfat (1) -- /boot/efi] fsck.vfat /dev/sdb1
fsck.fat 3.0.20 (12 Jun 2013)
/dev/sdb1: 17 files, 2466/51145 clusters

sudo fsck -V /dev/sdb2
fsck from util-linux 2.23.2

sudo fsck -V /dev/sdb3
fsck from util-linux 2.23.2
[/sbin/fsck.xfs (1) -- /] fsck.xfs /dev/sdb3
If you wish to check the consistency of an XFS filesystem or repair a damaged filesystem, see xfs_repair(8).
```

If errors are present on a partition, you will usually be prompted to repair the errors. Following is an example of an interactive repair session of a corrupt ext4 boot volume for an Ubuntu instance:

```
sudo fsck -V /dev/sdb1
fsck from util-linux 2.31.1
[/sbin/fsck.ext4 (1) -- /] fsck.ext4 /dev/sdb1
e2fsck 1.44.1 (24-Mar-2018)
One or more block group descriptor checksums are invalid. Fix<y> yes
Group descriptor 92 checksum is 0xe9a1, should be 0x1f53. FIXED.
Pass 1: Checking inodes, blocks, and sizes
Pass 2: Checking directory structure
Pass 3: Checking directory connectivity
Pass 4: Checking reference counts
Pass 5: Checking group summary information
Block bitmap differences: Group 92 block bitmap does not match checksum. FIXED.
cloudimg-rootfs: ***** FILE SYSTEM WAS MODIFIED *****
cloudimg-rootfs: 75336/5999616 files (0.1% non-contiguous),
798678/12181243 blocks
```

**Note:**

XFS file systems will usually auto-repair their contents when the system boots up, fixing any corruption during the boot process. You can use the `xfs_repair` command to force a repair for scenarios where boot volume corruption is preventing the auto-repair functionality from working, as shown in the following example:

```
sudo xfs_repair /dev/sdb3
Phase 1 - find and verify superblock...
Phase 2 - using internal log
```
Recovering a Corrupted Boot Volume for Windows Instances

If your instance fails to boot successfully or boots with the boot volume set to read-only access, the instance's boot volume may be corrupted. While it is rare, boot volume corruption can occur in the following scenarios:

• When an instance experiences a forced shutdown using the API.
• When an instance experiences a system hang due to an operating system or software error and a graceful reboot or shutdown of the instance times out, and then a forced shutdown occurs.
• When an error or outage occurs in the underlying infrastructure and there were critical disk writes pending in the system.

Important:

In most cases a simple reboot will resolve boot volume corruption issues, so this is the first action you should take when troubleshooting this.

This topic describes how to determine if your Windows instance's boot volume is corrupted and what steps to take to troubleshoot and recover the corrupted boot volume. For Linux-based instances, see Recovering a Corrupted Boot Volume for Linux-Based Instances on page 624.

Detecting Boot Volume Corruption

When Windows operating systems detect boot volume corruption, the instance is usually able to recover from it by automatically repairing the file system. You can use a VNC console connection to verify that the instance isn't experiencing a system hang while repairing the file system, or to detect if there are other issues. VNC console connections enable you to see what's displayed through the VGA port, for more information about the VNC console, see Troubleshooting Instances Using Instance Console Connections on page 813.

Important:

VNC console connections only work for virtual machine (VM) instances launched on October 13, 2017 or later, and bare metal instances launched on February 21, 2019 or later. If your instance does not support VNC console connections, proceed to Recovering the Boot Volume on page 629.

1. Create a VNC console connection for the instance.
2. Connect to the instance through VNC console.

Check what is displayed in the VNC console to see if the instance is stuck in the boot process or if it is in the recovery partition.

Tip:

For Windows Server 2012 and later versions, if the instance has booted into the recovery partition it may be possible to directly perform the steps to recover the boot volume in the recovery partition.

Detaching the Boot Volume

If you have detected that your instance's boot volume is corrupted, you need to detach the boot volume from the instance before you can begin troubleshooting and recovery steps.

1. Stop the instance.
2. Detach the boot volume from the instance.
Computing

Recovering the Boot Volume

To troubleshoot and recover the corrupted boot volume, you need to attach the boot volume to a second instance as a data volume. For the second instance we recommend that you use an instance running an operating system that most closely matches the operating system for the boot volume's instance, and you should only attach boot volumes for Windows instances to other Windows instances. The second instance must be in the same availability domain and region as the boot volume's instance. If no existing instance is available create a new Windows instance using the steps described in Creating an Instance on page 695.

Once you have the second instance, make sure you can log in to the instance and that it is functional before proceeding with the recovery steps. After you have confirmed that the instance is functional perform the following steps.

1. Attach the boot volume to the second instance as a data volume. For more information, see Attaching a Volume on page 517.

   To attach the boot volume as a data volume
   a. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
   b. Click the instance that you want to attach a volume to.
   c. Under Resources, click Attached Block Volumes.
   d. Click Attach Block Volume.
   e. Select iSCSI for the volume attachment type.
   f. In the Block Volume Compartment drop-down list, select the compartment.
   g. Choose the Select Volume option and then select the volume from the Boot Volume section of the Block Volume drop-down list.
   h. Select Read/Write as the access type.
   i. Click Attach.

When the volume's icon no longer lists it as Attaching, proceed with the next steps.

2. Connect to the second instance, see Connecting to a Windows Instance on page 735 for more information.

3. Connect to the volume, see Connecting to a Volume on a Windows Instance on page 526 for more information.

   Since you are attaching a boot volume as a data volume you must also run the Connect-IscsiTarget and set IsMultiEnabled to true. For example:

   ```powershell
   Set-Service -Name msiscsi -StartupType Automatic
   Start-Service msiscsi
   New-IscsiTargetPortal -TargetPortalAddress 169.254.2.4
   Connect-IscsiTarget -NodeAddress iqn.2015-02.oracle.boot:uefi -TargetPortalAddress 169.254.2.4 -IsPersistent $True -IsMultipathEnabled $True
   ```

4. Open Computer Management and navigate to Storage, and then Disk Management.

5. Select the new disk and mark it Online.

6. Click This PC and then right-click on the new disk and select Properties.

7. Navigate to Tools, Error Checking, and then Check.

8. Select Scan Drive and fix issues as they come up.

9. Mark the new disk Offline.

10. Open iscsi initiator with administrator privileges.

11. In Favorite Targets, remove the iscsi target of the attached volume.

Oracle-Provided Images

An image is a template of a virtual hard drive. The image determines the operating system and other software for an instance. The following table lists the platform images that are available in Oracle Cloud Infrastructure. For specific
image and kernel version details, along with changes between versions, see the Oracle-Provided Image Release Notes.

<table>

| Ubuntu 20.04 LTS | Canonical-Ubuntu-20.04-<date>-<number> | Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. For more information, see [https://www.ubuntu.com](https://www.ubuntu.com).  
Minimal Ubuntu is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. For more information, see [https://wiki.ubuntu.com/Minimal](https://wiki.ubuntu.com/Minimal). |
| Ubuntu 18.04 LTS | Canonical-Ubuntu-18.04-<date>-<number> | Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. For more information, see [https://www.ubuntu.com](https://www.ubuntu.com).  
Minimal Ubuntu is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. For more information, see [https://wiki.ubuntu.com/Minimal](https://wiki.ubuntu.com/Minimal).  
GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA. |
| Ubuntu 16.04 LTS | Canonical-Ubuntu-16.04-<date>-<number> | Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. For more information, see [https://www.ubuntu.com](https://www.ubuntu.com).  
Minimal Ubuntu is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. For more information, see [https://wiki.ubuntu.com/Minimal](https://wiki.ubuntu.com/Minimal).  
GPU shapes are supported with this image. For Minimal Ubuntu, you must install the appropriate GPU drivers from NVIDIA. |
You also can create custom images of your boot disk OS and software configuration for launching new instances.

**Essential Firewall Rules**

All Oracle-provided images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance’s boot and block volumes.

- We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
- We recommend that you do not create custom images without these rules unless you understand the security risks.
- Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See Ubuntu instance fails to reboot after enabling Uncomplicated Firewall (UFW) for more information.

**User Data**

Oracle-provided images give you the ability to run custom scripts or supply custom metadata when the instance launches. To do this, you specify a custom user data script in the **Initialization Script** field when you create the instance. For more information about startup scripts, see cloud-init for Linux-based images and cloudbase-init for Windows-based images.

**OS Updates for Linux Images**

Oracle Linux and CentOS images are preconfigured to let you install and update packages from the repositories on the Oracle public yum server. The repository configuration file is in the /etc/yum.repos.d directory on your instance. You can install, update, and remove packages by using the yum utility.
On Oracle Autonomous Linux images, Oracle Ksplice is installed and configured by default to run automatic updates.

**Note:**

OS Security Updates for Oracle Linux and CentOS images

After you launch an instance using Oracle Linux or CentOS images, you are responsible for applying the required OS security updates published through the Oracle public yum server. For more information, see Installing and Using the Yum Security Plugin.

The Ubuntu image is preconfigured with suitable repositories to allow you to install, update, and remove packages.

**Note:**

OS Security Updates for the Ubuntu image

After you launch an instance using the Ubuntu image, you are responsible for applying the required OS security updates using the `sudo apt-get upgrade` command.

**Linux Kernel Updates**

Oracle Linux images on Oracle Cloud Infrastructure include Oracle Linux Premier Support at no extra cost. This gives you all the services included with Premier Support, including Oracle Ksplice. Ksplice enables you to apply important security and other critical kernel updates without a reboot. For more information, see About Oracle Ksplice and Ksplice Overview.

Ksplice is available for Linux instances launched on or after February 15, 2017. For instances launched before August 25, 2017, you must install Ksplice before running it. See Installing and Running Oracle Ksplice on page 664 for more information.

**Note:**

Ksplice Support

Oracle Ksplice is not supported for CentOS and Ubuntu images, or on Linux images launched before February 15, 2017.

**Configuring Automatic Package Updating on Instance Launch**

You can configure your instance to automatically update to the latest package versions when the instance first launches using a cloud-init startup script. To do this, add the following code to the startup script:

```
package_upgrade: true
```

The upgrade process starts when the instance launches and runs in the background until it completes. To verify that it completed successfully, check the cloud-init logs in `/var/log`.

See User Data on page 632 and Cloud config examples - Run apt or yum upgrade for more information.

**Linux Image Details**

See Lifetime Support Policy: Coverage for Oracle Linux and Oracle VM for details about the Oracle Linux support policy.

**Users**

For instances created using Oracle Linux and CentOS images, the username `opc` is created automatically. The `opc` user has `sudo` privileges and is configured for remote access over the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the `/home/opc/.ssh/authorized_keys` file.
For instances created using the Ubuntu image, the username \texttt{ubuntu} is created automatically. The \texttt{ubuntu} user has \texttt{sudo} privileges and is configured for remote access over the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the \texttt{/home/ubuntu/.ssh/authorized_keys} file.

Note that \texttt{root} login is disabled.

\textbf{Remote Access}

Access to the instance is permitted only over the SSH v2 protocol. All other remote access services are disabled.

\textbf{Firewall Rules}

Instances created using Oracle-provided images have a default set of firewall rules that allow only SSH access. Instance owners can modify those rules as needed, but must not restrict link local traffic to address 169.254.0.2 in accordance with the warning in Essential Firewall Rules on page 632.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

\textbf{Disk Partitions}

Starting with Oracle Linux 8.x, the main disk partition is managed using Logical Volume Management (LVM). This gives you increased flexibility to create and resize partitions to suit your workloads. In addition, there is no dedicated swap partition. Swap is now handled by a file on the file system, giving you more detailed control over swap.

\textbf{Cloud-init Compatibility}

Instances created using Oracle-provided images are compatible with cloud-init. When launching an instance with the Core Services API, you can pass cloud-init directives with the metadata parameter. For more information, see LaunchInstance.

\textbf{Oracle Autonomous Linux}

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Important:} \\
Beginning with the December 2020 Oracle Autonomous Linux platform image, the image is based on Unbreakable Enterprise Kernel (UEK) 6 and is configured to use the standard Oracle Linux yum repositories. The Autonomous Linux repository (\texttt{al7}) is deprecated and all customers with existing Oracle Autonomous Linux instances are migrated to the new repositories automatically. \\
\hline
\end{tabular}
\end{center}

The following repositories are enabled by default beginning with the December 2020 Oracle Autonomous Linux platform image:

- \texttt{ol7\textunderscore UEKR6}
- \texttt{ol7\textunderscore addons}
- \texttt{ol7\textunderscore ksplice}
- \texttt{ol7\textunderscore latest}
- \texttt{ol7\textunderscore oci\textunderscore included}
- \texttt{ol7\textunderscore optional\textunderscore latest}
- \texttt{ol7\textunderscore software\textunderscore collections}
- \texttt{ol7\textunderscore x86\textunderscore 64\textunderscore userspace\textunderscore ksplice}

The image includes the release packages for the \texttt{ol7\_developer} and \texttt{ol7\_developer\_EPEL} repositories, but these repositories are disabled by default.
For existing Oracle Autonomous Linux instances, after yum migration, the `ol7_developer` and `ol7_developer_EPEL` repositories are not available. If you need packages from these repositories, you can install the appropriate release package to obtain the correct repository configuration before enabling the repository by using the following commands:

```
sudo yum install oraclelinux-developer-release-el7
sudo yum install oracle-epel-release-el7
```

**Note:**

Packages found in either the `ol7_developer` and `ol7_developer_EPEL` repositories are considered unsupported and are only entitled to basic installation support. Content from these repositories is not recommended for production environments and is intended for developer purposes only.

To verify that your Oracle Autonomous Linux instance has been migrated to the new repositories, use the following command:

```
yum repolist
```

For example:

```
# yum repolist
Loaded plugins: langpacks, ulninfo
repo id                                           repo name
status                                                                                          
ol7_UEKR6/x86_64                                  Latest Unbreakable Enterprise Kernel Release 6 for Oracle Linux 7Server (x86_64) 197
ol7_addons/x86_64                                 Oracle Linux 7Server Add ons (x86_64) 473
ol7_ksplice                                       Ksplice for Oracle Linux 7Server (x86_64) 9,655
ol7_latest/x86_64                                 Oracle Linux 7Server Latest (x86_64) 21,367
ol7_oci_included/x86_64                           Oracle Software for OCI users on Oracle Linux 7Server (x86_64) 680
ol7_optional_latest/x86_64                        Oracle Linux 7Server Optional Latest (x86_64) 15,491
ol7_software_collections/x86_64                   Software Collection Library release 3.0 packages for Oracle Linux 7 (x86_64) 15,375
ol7_x86_64_userspace_ksplice                       Ksplice aware userspace packages for Oracle Linux 7Server (x86_64) 447
repolist: 63,685
```

**Note:**

For existing Oracle Autonomous Linux instances, after yum migration, the UEK6 repository is enabled and the next daily update installs the latest UEK6. After reboot, the instance boots into UEK6.
For more information about installing and configuring Oracle Autonomous Linux, see Getting Started: Deploying and Configuring Oracle Autonomous Linux on Oracle Cloud Infrastructure and Oracle Autonomous Linux for Oracle Cloud Infrastructure.

Oracle Instant Client 18.3 basic package cannot be updated to Version 19.5 because of changes in packaging. To update Oracle Instant Client on Oracle Autonomous Linux images that were launched before March 18, 2020, you must first manually remove the Oracle Instant Client 18.3, and then install 19.5. Use the following commands:

```
sudo yum remove oracle-instantclient18.3-basic
sudo yum install oracle-instantclient19.5-basic
```

On Oracle Autonomous Linux images that were launched after March 18, 2020, Oracle Instant Client is not installed by default. To install Oracle Instant Client 19.5, you must manually install the package. Use the following command:

```
sudo yum install oracle-instantclient19.5-basic
```

On Oracle Autonomous Linux images that were launched after December 9, 2020, the Oracle Instant Client repository (ol7_oracleinstant_client) is not available by default. To add the repository, you must first install the oracle-release-el7 release package and then enable the ol7_oracle_instantclient repository. You can then install the appropriate Oracle Instant Client version package. Use the following commands:

```
sudo yum install oracle-release-el7
sudo yum-config-manager --enable ol7_oracle_instantclient
```

Oracle Autonomous Linux instances cannot be managed by the OS Management service.

For more information about using Oracle Autonomous Linux, see Known Issues.

**OCI Utilities**

Instances created using Oracle Linux include a preinstalled set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools.

For more information, see the OCI Utilities on page 642 reference.

**Windows OS Updates for Windows Images**

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the instance’s network security group or the security list used by the instance’s subnet to allow instances to access Windows update servers.

**Windows Image Details**

**Windows Editions**

Depending on whether you create a bare metal instance or a virtual machine (VM) instance, different editions of Windows Server are available as Oracle-provided images. Windows Server Standard edition is available only for VMs. Windows Server Datacenter edition is available only for bare metal instances.

**Users**

For instances created using Oracle-provided Windows images, the username opc is created automatically. When you launch an instance using the Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

**Remote Access**

Access to the instance is permitted only through a Remote Desktop connection.
Firewall Rules

Instances created using the Windows image have a default set of firewall rules that allow Remote Desktop protocol or RDP access on port 3389. Instance owners can modify these rules as needed, but must not restrict link local traffic to 169.254.169.253 for the instance to activate with Microsoft Key Management Service (KMS). This is how the instance stays active and licensed.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

User Data on Windows Images

On Windows images custom user data scripts are executed using cloudbase-init, which is the equivalent of cloud-init on Linux-based images. All Oracle-provided Windows images on Oracle Cloud Infrastructure include cloudbase-init installed by default. When an instance launches, cloudbase-init runs PowerShell, batch scripts, or additional user data content. See cloudbase-init Userdata for information about supported content types.

You can use user data scripts to perform various tasks, such as:

- Enable GPU support using a custom script to install the applicable GPU driver.
- Add or update local user accounts.
- Join the instance to a domain controller.
- Install certificates into the certificate store.
- Copy any required application workload files from the Object Storage service directly to the instance.

Caution:

Do not include anything in the script that could trigger a reboot, because this could impact the instance launch, causing it to fail. Any actions requiring a reboot should only be performed after the instance state is **RUNNING**.

Windows Remote Management

**Windows Remote Management** (WinRM) is enabled by default on Oracle-provided Windows images. WinRM provides you with the capability to remotely manage the operating system.

To use WinRM you need to add a stateful ingress security rule for TCP traffic on destination port 5986. You can implement this security rule in either a network security group that the instance belongs to, or a security list that is used by the instance's subnet.

Caution:

The following procedure allows WinRM connections from 0.0.0.0/0, which means any IP address, including public IP addresses. To allow access only from instances within the VCN, change the source CIDR value to the VCN's CIDR block. For more information, see Security Recommendations on page 3696.

To enable WinRM access

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN that you're interested in.
3. To add the rule to a network security group that the instance belongs to:
   a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
   b. Click **Add Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: TCP
      - **Source Port Range**: All
      - **Destination Port Range**: 5986
      - **Description**: An optional description of the rule.
   d. When done, click **Add**.

4. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
   b. Click **Add Ingress Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: TCP
      - **Source Port Range**: All
      - **Destination Port Range**: 5986
      - **Description**: An optional description of the rule.
   d. When done, click **Add Ingress Rules**.

To use WinRM on an instance

1. Get the instance's public IP address.
2. Open Windows PowerShell on the Windows client that you're using to connect to the instance.
3. Run the following command:

   ```powershell
   # Get the public IP from your OCI running windows instance
   $ComputerName = Public IP Address

   # Store your username and password credentials (default username is opc)
   $c = Get-Credential

   # Options
   $opt = New-PSSessionOption -SkipCACheck -SkipCNCheck -SkipRevocationCheck

   # Create new PSSession (Pre-requisite: ensure network security group or security list has Ingress Rule for port 5986)
   $PSSession = New-PSSession -ComputerName $ComputerName -UseSSL -SessionOption $opt -Authentication Basic -Credential $c

   # Connect to Instance PSSession
   Enter-PSSession $PSSession

   # To close connection use: Exit-PSSession
   ```

You can now remotely manage the Windows instance from your local PowerShell client.
Operating System Lifecycle and Support Policy

When an operating system reaches the end of its support lifecycle, the OS vendor (such as Microsoft) no longer provides security updates for the OS. You should upgrade to the latest version to remain secure.

Here's what you should expect when an OS version reaches the end of its support lifecycle:

• Oracle Cloud Infrastructure no longer provides new images for the OS version. Images that were previously published are deprecated, and are no longer updated.
• Although you can continue to run instances that use deprecated images, Oracle Cloud Infrastructure does not provide any support for operating systems that have reached the end of the support lifecycle.
• If you have an instance that runs an OS version that will be deprecated, and you want to launch new instances with this OS version after the end of support, you can create a custom image of the instance and then use the custom image to launch new instances in the future. For custom Linux images, you must purchase extended support from the OS vendor. For custom Windows images, see Can I purchase Microsoft Extended Security Updates for end-of-support Windows OSs? on page 809. Oracle Cloud Infrastructure does not provide any support for custom images that use end-of-support operating systems.

Be aware of these end-of-support dates:

• CentOS 6: Support ended on November 30, 2020.
• Ubuntu 14.04: Support ended on April 19, 2019.

Using NVIDIA GPU Cloud with Oracle Cloud Infrastructure

NVIDIA GPU Cloud (NGC) is a GPU-accelerated cloud platform optimized for deep learning and scientific computing. This topic provides an overview of how to use NGC with Oracle Cloud Infrastructure.

NVIDIA makes available on Oracle Cloud Infrastructure a customized Compute image that is optimized for the NVIDIA Tesla Volta and Pascal GPUs. Running NGC containers on this instance provides optimum performance for deep learning jobs.

Prerequisites

• An Oracle Cloud Infrastructure tenancy with a GPU quota. For more information about quotas, see Compute Quotas on page 247.
• A cloud network to launch the instance in. For information about setting up cloud networks, see Using the Console on page 2824 in VCNs and Subnets on page 2821.
• A key pair, to use for connecting to the instance via SSH. For information about generating a key pair, see Managing Key Pairs on Linux Instances on page 693.
• Security group and policy configured for the File Storage service. For more information, see Managing Groups on page 2419, Getting Started with Policies on page 2135, and Details for the File Storage Service on page 2273.
• An NGC API key for authenticating with the NGC service.

To generate your NGC API key

1. Sign in to the NGC website.
2. On the NGC Registry page, click Get API Key.
3. Click Generate API Key and then click Confirm to generate the key. If you have an existing API key it will become invalid once you generate a new key.

Launching an Instance Based on the NGC Image

Using the Console

1. Open the Console. For steps, see Signing In to the Console on page 41.
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
3. Select a Compartment that you have permission to work in.
4. Click **Create Instance**.
5. Enter a name for the instance. Avoid entering confidential information.
6. In the **Placement and hardware** section, make the following selections:
   a. Select the **Availability Domain** that you want to create the instance in.
   b. In the **Shape** section, click **Change Shape**. Then, do the following:
      1. For **Instance type**, select **Virtual Machine** or **Bare Metal Machine**.
      2. Select a GPU shape for the instance. For more information about GPU shapes, see virtual machine GPU shapes and bare metal GPU shapes.

     | Important: |
     |------------|
     | In order to access the GPU shapes, your tenancy must have a GPU quota. If your tenancy does not have a GPU quota, the GPU shapes will not be in the shape list. See Prerequisites on page 639 for more information. |

   3. Click **Select Shape**.
   c. To select the NGC image, do the following:
      1. Under **Image**, click **Change Image**.

     | Important: |
     |------------|
     | In order to access the NVIDIA GPU Cloud images, your tenancy must have a GPU quota and you must select a GPU shape. |

      2. In the **Image source** list, select **Oracle Images**.
      3. Select the check box next to **NVIDIA GPU Cloud Machine Image**.
      4. Review and accept the terms of use, and then click **Select Image**.

   7. In the **Networking** section, leave **Select existing virtual cloud network** selected, and then select the virtual cloud network (VCN) compartment, VCN, subnet compartment, and subnet.

   8. In the **Add SSH keys** section, upload the public key portion of the key pair that you want to use for SSH access to the instance. Browse to the key file that you want to upload, or drag and drop the file into the box.

   9. Click **Create**.

You should now see the NGC instance with the state of **Provisioning**. After the state changes to **Running**, you can connect to the instance. For general information about launching Compute instances, see Creating an Instance on page 695.

See the following topics for steps to access and work with the instance:

- Connecting to an Instance on page 733
- Stopping and Starting an Instance on page 779
- Terminating an Instance on page 783

When you connect to the instance using SSH, you are prompted for the NGC API key. If you supply the API key at the prompt, the instance automatically logs you in to the NGC container registry so that you can run containers from the registry. You can choose not to supply the API key at the prompt and still log in to the instance. You can then log in later to the NGC container registry. See Logging in to the NGC Container Registry for more information.

**Using the CLI**

Oracle Cloud Infrastructure provides a **Command Line Interface (CLI)** on page 4192 you can use to complete tasks. For more information, see Quickstart on page 4195 and Configuring the CLI on page 4202.

Use the **launch** command to create an instance, specifying image for **sourceType** and the image OCID `ocid1.image.oc1..aaaaaaaaknl6phck7e3iuii4r4axpwhenw5qtnnsk3tqppajdjb5nhoma3q` in **InstanceSourceDetails** for **LaunchInstanceDetails**.
Using the File Storage Service for Persistent Data Storage

You can use the File Storage service for data storage when working with NGC. For more information, see Overview of File Storage on page 1920. See the following tasks for creating and working with the File Storage service:

- Creating File Systems on page 1948
- Using the Console on page 1956
- Using the API on page 1979
- Managing File Systems on page 1970
- Using the Command Line Interface (CLI) on page 1976

Using the Block Volume Service for Persistent Data Storage

You can use the Block Volume service for data storage when working with NGC. For more information, see Overview of Block Volume on page 500. See the following tasks for creating and working with the Block Volume service:

- Creating a Volume on page 515
- Attaching a Volume on page 517
- Connecting to a Volume on page 524

You can also use the CLI to manage block volumes, see the volume commands.

Examples of Running Containers

You first need to log into the NGC container registry. You can skip this section if you provided your API key when logging into the instance via SSH. If you did not provide your API key when connecting to your instance, then you must perform this step.

To log into the NGC container registry

1. Run the following Docker command:

   
   ```
   docker login nvcr.io
   ```

2. When prompted for a username, enter $oauthtoken.
3. When prompted for a password enter your NGC API key.

At this point you can run Docker commands and access the NGC container registry from the instance.

Example: MNIST Training Run Using PyTorch Container

This sample demonstrates running the MNIST example under PyTorch. This example downloads the MNIST dataset from the web.

1. Pull and run the PyTorch container with the following Docker commands:

   ```
   docker pull nvcr.io/nvidia/pytorch:17.10
   docker run --gpus all --rm -it nvcr.io/nvidia/pytorch:17.10
   ```

2. Run the MNIST example with the following commands:

   ```
   cd /opt/pytorch/examples/mnist
   python main.py
   ```

Example: MNIST Training Run Using TensorFlow Container

This sample demonstrates running the MNIST example under TensorFlow. This example downloads the MNIST dataset from the web.

1. Pull and run the TensorFlow container with the following Docker commands:

   ```
   docker pull nvcr.io/nvidia/tensorflow:17.10
   docker run --gpus all --rm -it nvcr.io/nvidia/tensorflow:17.10
   ```
2. Run the MNIST_with_summaries example with the following commands:

```
   cd /opt/tensorflow/tensorflow/examples/tutorials/mnist
   python mnist_with_summaries.py
```

**OCI Utilities**

Instances created using Oracle-Provided Images on page 629 based on Oracle Linux include a pre-installed set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools that can help with managing block volumes (attach, remove, and automatic discovery), secondary VNIC configuration, discovering the public IP address of an instance, and retrieving instance metadata.

The following table summarizes the components that are included in the OCI utilities.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ocid</td>
<td>The service component of oci-utils, which runs as a daemon started via systemd. This service scans for changes in the iSCSI and VNIC device configurations and caches the OCI metadata and public IP address of the instance.</td>
</tr>
<tr>
<td>oci-growfs</td>
<td>Expands the root filesystem of the instance to its configured size.</td>
</tr>
<tr>
<td>oci-iscsi-config</td>
<td>Lists or configures iSCSI devices attached to a compute instance. If no command line options are specified, lists devices that need attention.</td>
</tr>
<tr>
<td>oci-metadata</td>
<td>Displays metadata for the compute instance. If no command line options are specified, lists all available metadata. Metadata includes the instance OCID, display name, compartment, shape, region, availability domain, creation date, state, image, and any custom metadata that you provide, such as an SSH public key.</td>
</tr>
<tr>
<td>oci-network-config</td>
<td>Lists or configures virtual network interface cards (VNICs) attached to the Compute instance. When a secondary VNIC is provisioned in the cloud, it must be explicitly configured on the instance using this script or similar commands.</td>
</tr>
<tr>
<td>oci-network-inspector</td>
<td>Displays a detailed report for a given compartment or network.</td>
</tr>
<tr>
<td>oci-notify</td>
<td>Sends a message to a Oracle Cloud Infrastructure Notifications service topic.</td>
</tr>
<tr>
<td>oci-public-ip</td>
<td>Displays the public IP address of the current system in either human-readable or JSON format.</td>
</tr>
</tbody>
</table>

**Installing the OCI Utilities**

The OCI utilities (oci-utils) are automatically included with instances launched with Oracle Linux 7 and later images. They are not currently available on other distributions.

Much of the OCI utilities functionality requires that you have the Oracle Cloud Infrastructure SDK for Python and the Oracle Cloud Infrastructure CLI installed and configured.
To install the Oracle Cloud Infrastructure SDK and CLI using `yum`, install the required packages corresponding to the image used by the instance.

**Oracle Linux 7**

```bash
sudo yum install python36-oci-sdk python36-oci-cli
```

**Oracle Linux 8**

```bash
sudo yum install python3-oci-sdk python3-oci-cli
```

For configuration information, see the Oracle Cloud Infrastructure SDK for Python documentation and the documentation for configuring the Oracle Cloud Infrastructure CLI.

**Updating the OCI Utilities**

To update to the latest version of `oci-utils`:

```bash
sudo yum update oci-utils
```

**Using the OCI Utilities**

To use the OCI utilities, you first need to start the `ocid` service:

```bash
sudo systemctl start ocid.service
```

Example output:

```
Redirecting to /bin/systemctl start ocid.service
```

**The ocid Daemon**

**Description**

The `ocid` daemon is the service component of the `oci-utils`. It monitors for changes in the VNIC and iSCSI configuration of the instance and attempts to automatically attach or detach devices as they appear or disappear - for example, when they are created or deleted using the Oracle Cloud Infrastructure Console, CLI, or the API.

**Configuration**

The `ocid` daemon requires root privileges. You can configure root privileges for `ocid` using one of the following methods:

- Run the `oci setup config` configuration command as root to create SDK configuration files for the host. For more information, see SDK and CLI Configuration File on page 4184.
- Use instance principals by adding the instance to a dynamic group that was granted access to Oracle Cloud Infrastructure services. For more information, see Managing Dynamic Groups on page 2422.
- Configure `oci-utils` to allow root to use a non-privileged user's Oracle Cloud Infrastructure configuration files. For more information, see the configuration file located in the `/etc/oci-utils.conf.d` directory of the instance.

**Usage**

To start the `ocid` daemon using `systemd`:

```bash
service ocid start
```
To set `ocid` to start automatically during system boot:

```
sudo systemctl enable ocid.service
```

### oci-growfs

**Description**

Expands the root filesystem of the instance to its configured size. This command must be run as root.

**Usage**

`oci-growfs [-y] [-n] [-h]`

**Options**

- `-y`  
  Answer 'yes' to all prompts.

- `-n`  
  Answer 'no' to all prompts.

- `-h` | `--help`  
  Display a summary of the command line options.

**Example**

```
# sudo /usr/libexec/oci-growfs
CHANGE: disk=/dev/sda partition=3: start=17188864 old:  
  size=80486399, end=97675263 new:  size=192526302, end=209715166
Confirm? [y/n]: y
CHANGED: disk=/dev/sda partition=3: start=17188864 old:  
  size=80486399, end=97675263 new:  size=192526302, end=209715166
meta-data=/dev/sda3 isize=256 agcount=4, agsize=2515200
  bsize=4096 blocks=10060800, imaxpct=25
  sunit=0 swidth=0 blocks change from 10060800 to 24065787
```

### oci-iscsi-config

**Description**

Lists and configures iSCSI devices attached to a Compute instance running in Oracle Cloud Infrastructure. When run without any command line options, `oci-iscsi-config` lists devices that need attention.

**Usage**

```
ocsi-iscsi-config [-i|--interactive] [-s|--show] [-a | --attach IQN ]
 [-d IQN | --detach IQN ] [--username username] [--password password]
[---help] oci-iscsi-config [-s|--show] [-c | --create-volume size]
```
Compute

[--volume-name name] [--destroy-volume OCID]

**Options**

-i | --interactive
Run in interactive mode. This option displays devices that need attention and offers to attach and configure them. Requires root privileges.

-s | --show
List all devices. If ocid is not running, then root privileges are required.

-a | --attach target
Attempt to attach the device with the given IQN (a unique ID assigned to a device) or Oracle Cloud Identifier (OCID). When using an IQN, the volume must already be attached (assigned) to the instance in the Console. The Oracle Cloud Infrastructure SDK for Python is required for selecting volumes using their OCID. This option can be used multiple times to attach multiple devices at the same time. Requires root privileges.

-d | --detach device
Detach the device with the given IQN (a unique ID assigned to a device). If the volume (or any partition of the volume) is mounted, this option attempts to unmount it first. This option can be used multiple times to detach multiple devices at the same time. Requires root privileges.

-c | --create-volume size
Create a volume of SIZE gigabytes and attach it to the current instance. This option requires the Oracle Cloud Infrastructure SDK for Python to be installed and configured.

--destroy-volume OCID
Destroy the block storage volume with the given OCID. Be sure that the volume is not attached to any instances before performing this operation.

**Caution:**

This action is irreversible.

--volume-name name
Set the display name for the volume. This option is used with the --create-volume option. Avoid entering confidential information.

--username name
Use the specified username as the CHAP username when authentication is needed for attaching a device. This option is not needed when the Oracle Cloud Infrastructure SDK for Python is available.

--password password
Use the supplied password as the CHAP password when authentication is needed for attaching a device. This option is not needed when the Oracle Cloud Infrastructure SDK for Python is available.

--help
Display a summary of the command line options.
Examples

Displaying iSCSI configuration

The oci-iscsi-config utility works with the ocid daemon to monitor device creation and deletion through the command line, Console, or SDK and automatically discover those changes. You can use the --show option to display a list of all devices attached to an instance:

```bash
# oci-iscsi-config -s
For full functionality of this utility the ocid service must be running
The administrator can start it using this command:
sudo systemctl start ocid.service
ocid already running.
Currently attached iSCSI devices:

Target iqn.2015-02.oracle.boot:uefi
Persistent portal: 169.254.0.2:3260
Current portal: 169.254.0.2:3260
State: running
Attached device: sda
Size: 46.6G
Partitions: Device Size Filesystem Mountpoint
sda1 544M vfat /boot/efi
sda2 8G swap [SWAP]
sda3 38G xfs /
```

The following example shows the output of the --show option after adding a 50-GB block volume using the Console:

```bash
# oci-iscsi-config --show
Currently attached iSCSI devices:

Target iqn.2015-12.com.oracleiaas:abcdefghijklmnopqrstuvwxyz1234567890
Persistent portal: 169.254.2.2:3260
Current portal: 169.254.2.2:3260
State: running
Attached device: sdb
Size: 50G
File system type: Unknown
Mountpoint: Not mounted

Target iqn.2015-02.oracle.boot:uefi
Persistent portal: 169.254.0.2:3260
Current portal: 169.254.0.2:3260
State: running
Attached device: sda
Size: 46.6G
Partitions: Device Size Filesystem Mountpoint
sda1 544M vfat /boot/efi
sda2 8G swap [SWAP]
sda3 38G xfs /
```

Creating a volume

The following example shows how to create a volume:

```bash
# oci-iscsi-config --create-volume 50
For full functionality of this utility the ocid service must be running
```
The administrator can start it using this command:
`sudo systemctl start ocid.service`

Creating a new 50 GB volume
`Volume abcdefghijklmnopqrstuvwxyz1234567890123456789012345678901234 created`

Deleting a volume

The following example shows how to destroy a volume:

```
# oci-iscsi-config --destroy-volume ocid1.volume.oc1.phx.exampleuniqueID
```

oci-metadata

**Description**
Displays metadata for an Oracle Cloud Infrastructure Compute instance.

For more information about instance metadata, see [Getting Instance Metadata](#) on page 757.

**Usage**
```
oci-metadata [-h] [-j] [-g key] [--help]
```

**Options**

-h | --human-readable
Display human readable output (default).

-j | --json
Display output in JSON.

-g | --get key
Retrieve data only for the specified key.

--help
Display a summary of the command line options.

**Examples**

Getting all metadata for the instance

Running `oci-metadata` with no options returns all metadata for the instance:

```
# oci-metadata
Instance details:
  Display Name: my-example-instance
  Region: phx - us-phoenix-1 (Phoenix, AZ, USA)
  Canonical Region Name: us-phoenix-1
  Availability Domain: cumS:PHX-AD-1
  Fault domain: FAULT-DOMAIN-3
  OCID: ocid1.instance.oc1.phx.exampleuniqueID
  Compartment OCID: ocid1.compartment.oc1..exampleuniqueID
  Instance shape: VM.Standard2.1
  Image ID: ocid1.image.oc1.phx.exampleuniqueID
  Created at: 1569529065596
  state: Running
```
agentConfig:
  managementDisabled: False
  monitoringDisabled: False
Instance Metadata:
  ssh_authorized_keys: example-key
Networking details:
  VNIC OCID: ocid1.vnic.oc1.phx.exampleuniqueID
  VLAN Tag: 2392
  Private IP address: 10.0.0.16
  MAC address: 02:00:17:03:D8:FE
  Subnet CIDR block: 10.0.0.0/24
  Virtual router IP address: 10.0.0.1

Getting only specific metadata
The following example shows how to retrieve metadata for a specified key by using the --get parameter:

# oci-metadata --get state
Instance details:
Instance state: Running

oci-network-config

Description
Configures network interfaces for an Oracle Cloud Infrastructure Compute instance.

Usage
  [--del-private-ip ip_address] [--private-ip ip_address] [--subnet subnet] [--vnic-name name]
  [-r] [-X | --exclude item] [-I | --include item] [--quiet]

Options

-s | --show
Show information on all provisioning and interface configuration. If no options are specified, the oci-network-config utility defaults to this option.

--create-vnic
Create a new virtual network interface card (VNIC) and attach it to this instance.

--detach-vnic OCID
Detach and delete the VNIC with the given Oracle Cloud Identifier (OCID) or primary IP address. Cannot be the primary VNIC for the instance.

--add-private-ip OCID
Add a secondary private IP to an existing VNIC.
--del-private-ip ip_address
Delete the secondary private IP address with the given IP address.

--private-ip ip_address
Assign the given private IP address to the VNIC. Used with the --create-vnic and --add-private-ip options.

--subnet subnet
Connect the new VNIC to the specified subnet. Used with the --create-vnic option.

--vnic-name name
Display name for the new VNIC. Used with the --create-vnic option. Avoid entering confidential information.

--assign-public-ip
Assign a public IP address to the new VNIC. Used with the --create-vnic option.

--vnic OCID
Assign the private IP address to the given VNIC. Used with the --add-private-ip option.

-a | --auto | -c | --configure
Add IP configuration for VNICs that are not configured and delete IP configuration for VNICs that are no longer provisioned.

-d | --deconfigure
Deconfigure all VNICs (except the primary). If used with the -e option, only the secondary IP addresses are deconfigured.

-e ip_address VNIC_OCID
Secondary private IP address to configure or deconfigure. Used with --configure and --deconfigure options.

-n | -ns format
When configuring, place interfaces in namespace identified by the given format. Format can include $nic and $vltag variables.

-r | --sshd
Start sshd in namespace (if -n is present).

-X | --exclude item
Persistently exclude the given item from automatic configuration or deconfiguration. Use the --include option to include the item again.

-I | --include item
Include an item that was previously excluded using the --exclude option in automatic configuration/deconfiguration.
-q | --quiet
Do not display information messages.

-h | --help
Display a summary of the command line options.

Examples

Displaying current network configuration
Running the `oci-network-config` command with no options returns the network configuration of the current instance:

```
VNIC configuration for instance my-test-instance-20180622-1222

VNIC 1 (primary): my-test-instance-20180622-1222
Hostname: my-test-instance-20180622-1222
OCID: ocid1.vnic.oc1.phx.uniqueID
MAC address: 00:00:00:00:00:01
Public IP address: 203.0.113.2
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)
```

Operating System level network configuration

```
 | IFACE | ADDR | SPREFIX | SBITS | VIRTRT | NS | IND |
---|---|---|---|---|---|---|---
- | 10.0.0.3 | 10.0.0.0 | 24 | 10.0.0.1 | - | - |
0 | ens3 | - | - | UP | 00:00:00:00:00:01 |
```

Creating a VNIC
This example creates a VNIC named MY_NEW_VNIC and attaches it to the instance:

```
# sudo oci-network-config --create-vnic --vnic-name MY_NEW_VNIC
Info: creating VNIC: 10.0.0.4
```

Running `oci-network-config` with the `-s` option shows information for the new VNIC:

```
# sudo oci-network-config -s
VNIC configuration for instance scottb-instance-20180622-1222

VNIC 1 (primary): scottb-instance-20180622-1222
Hostname: scottb-instance-20180622-1222
OCID: ocid1.vnic.oc1.phx.uniqueID
MAC address: 00:00:00:00:00:01
Public IP address: 203.0.113.254
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)

VNIC 2: MY_NEW_VNIC
Hostname: scottb-instance-20180622-1222-mynewvnic
OCID: ocid1.vnic.oc1.phx.uniqueID
MAC address: None
Public IP address: None
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)
```
Detaching a VNIC

To detach a VNIC from the instance, use the `--detach-VNIC` option. The given VNIC cannot be the primary VNIC for the instance:

```
sudo oci-network-config --detach-vnic 00:00:00:00:02
```

oci-network-inspector

**Description**

Displays a detailed report for a given compartment or network.

**Usage**

```
oci-network-inspector [-C OCID] [-N OCID] [--help]
```

**Options**

```
-C  |  --compartment OCID
```

Show report for the specified compartment.

```
-N  |  --vcn OCID
```

Show report for the specified virtual cloud network.

```
-h  |  --help
```

Display a summary of the command line options.

**Examples**

**Displaying a detailed report for a specified compartment**

Running the `oci-network-inspector` command and specifying an OCID with the `-C` parameter returns a detailed network report for that compartment:

```
$ oci-network-inspector -C ocid1.compartment.oc1..example_OCID

Compartment: scottb_sandbox (ocid1.compartment.oc1..example_OCID)

vcn: scottb_vcn

Security List: Default Security List for scottb_vcn

**oci-notify**

**Description**

Sends a message to a Oracle Cloud Infrastructure Notifications service topic. This command must be run as root.
A message is composed of a message header (subject) and file. The Notifications service configuration for the topic
determines where and how the messages are delivered. Topics are configured for the Notification service using the
Oracle Cloud Infrastructure Console, API, or CLI.

For more information about the Notifications service, including how to create topics, see Notifications Overview.

Usage

oci-notify [-c topic_OCID] [-t subject -f file] [-h]

Options

-c topic_OCID
Write the topic to the /etc/oci-utils/oci.conf file. The path to the configuration file can be overridden by
using OCI_CONFIG_DIR environment variable.

For topic_OCID, specify the Oracle Cloud Identifier (OCID) associated with the Notifications service topic.

-t subject -f file
Publish the contents of specified file with the specified subject to the topic, which is sent to each subscription for the
topic.

For subject, enter an appropriate subject to be used as the message header (for example, 'log messages' if you
are sending log files). The subject must be enclosed in either single or double quotation marks. Message headers are
truncated to 128 characters.

Note:
When the message is published, the oci-notify utility prepends the
instance name to the subject of the message, for example, <instance
name>:log messages.

For file, enter the full or relative directory path, HTTP, or FTP URL of the message file to be sent. Large files are split
into 64-KB chunks.

Note:
The oci-notify utility writes log and error messages to the /var/log/
oci-notify.log file.

-h | help
Display a summary of the command line options.

Examples

Configuring a Topic on an Instance

The following example shows how to write the OCID of a configured Notifications service topic to the oci.conf file. Once configured, you can publish messages to the configured topic.

```
sudo oci-notify -c ocid1.onstopic.oc1..example_OCID
```

Publishing a Message to a Topic

The following example shows how to send the contents of the /var/log/messages file with the subject
'logging messages' to the configured topic:

```
sudo oci-notify -t 'logging messages' -f /var/log/messages
```
The following example shows how to send the contents of the /proc/meminfo file with the subject 'memory information' to the configured topic:

```
sudo oci-notify -t 'memory information' -f /proc/meminfo
```

The following example shows how to send the contents of the /tmp/uptrack-show file with the subject 'installed Ksplice updates' to the configured topic:

```
sudo oci-notify -t 'installed Ksplice updates' -f /tmp/uptrack-show
```

oci-public-ip

Description
Displays the public IP address of the current system in either human-readable or JSON format.

The oci-public-ip utility uses the Oracle Cloud Infrastructure SDK to discover the IP address. If the IP address cannot be obtained through this method, the oci-public-ip utility then tries the Session Traversal Utilities for NAT (STUN) protocol as a last resort to discover the IP address. For more information on STUN, see the STUN Wikipedia article.

Usage

Options

- **h | --human-readable**
  Display human readable output (default).

- **j | --json**
  Display output in JSON.

- **g | get**
  Print the IP address only.

- **a | all**
  Display all public IP addresses.

- **s | --sourceip source_IP**
  Specify the source IP address to use.

- **S | --stun-server STUN_server**
  Specify the STUN server to use.

- **L | --list-servers**
  Print a list of known STUN servers and exit.

  --instance-id OCID
  Display the public IP address of the given instance instead of the current one. Requires the Oracle Cloud Infrastructure SDK for Python to be installed and configured.
**--help**
Display a summary of the command line options.

**Examples**

**Displaying current IP address**
Running the `oci-public-ip` command with no options returns the IP address of the current instance:

```bash
# oci-public-ip
Public IP address: 203.0.113.2
```

**Displaying the IP address of another instance**
You can pass in the OCID of a running instance with the `--instance-id` option to return the IP address for that instance:

```bash
# oci-public-ip --instance-id ocid1.instance.oc1.phx.example_OCID
Public IP address: 203.0.113.2
```

**Listing STUN servers**
Use the `--list-servers` option to return a list of STUN servers:

```bash
# oci-public-ip --list-servers
stun.stunprotocol.org
stun.counterpath.net
stun.voxgratia.org
stun.callwithus.com
stun.ekiga.net
stun.ideasip.com
stun.voipbuster.com
stun.voiparound.com
stun.voipstunt.com
```

**Compute Shapes**
A shape is a template that determines the number of CPUs, amount of memory, and other resources that are allocated to an instance.

This topic provides basic information about the shapes that are available for bare metal instances, virtual machines (VMs), and dedicated virtual machine hosts.

**Flexible Shapes**
A flexible shape is a shape that lets you customize the number of OCPUs and the amount of memory when launching or resizing your VM. When you create a VM instance using the flexible shape, you select the number of OCPUs and the amount of memory that you need for the workloads that run on the instance. The network bandwidth and number of VNICs scale proportionately with the number of OCPUs. This flexibility lets you build VMs that match your workload, enabling you to optimize performance and minimize cost.

Currently, flexible memory is available on VM.Standard.E3.Flex instances that run on AMD Rome processors. For this VM and processor combination, you can select from 1 to 64 OCPUs. The amount of memory allowed is based on the number of OCPUs selected. For each OCPU, you can select up to 64 GB of memory, with a maximum of 1024 GB total. The minimum amount of memory allowed is either 1 GB or a value matching the number of OCPUs, whichever is greater. For example, if you select 25 OCPUs, the minimum amount of memory allowed is 25 GB.
These resources are billed at a per-second granularity with a one-minute minimum. Optimize your costs by choosing the shape that matches your workload and by changing the shape when your workload changes. For example, you can configure the VM to maximize compute processing power by choosing a low core-to-memory ratio. Or, for applications like in-memory databases or big data processing engines, configure an instance with a high core-to-memory ratio. Modify the OCPUs and memory as your workload changes, scaling up to increase performance or scaling down to reduce costs.

The VM.Standard.E3.Flex shape, a VM standard shape, is a flexible shape.

**Note:**
When a new region becomes available, it might take a few weeks before host capacity for flexible shapes also becomes available.

**Supported Images**
The following Oracle-provided platform images are compatible with flexible shapes. Use an image that was published in March 2020 (for Linux images) or April 2020 (for Windows images) or later.

**Images**
- Oracle Autonomous Linux 7.x
- Oracle Linux 8.x
- Oracle Linux 7.x
- Oracle Linux 6.x (VMs only)
- CentOS 8.x
- CentOS 7.x
- Ubuntu 18.04
- Ubuntu 16.04
- Windows Server 2019 (VMs only)
- Windows Server 2016 (VMs only)
- Windows Server 2012 (VMs only)

Custom images are also supported, depending on the image. You must add flexible shape compatibility to the custom image, and then test the image on the flexible shape to ensure that it actually works on the shape.

**Bare Metal Shapes**
The following shapes are available for bare metal instances:

- **Standard Shapes** on page 656
- **Dense I/O Shapes** on page 657
- **GPU Shapes** on page 657
- **HPC Shapes** on page 658

Network bandwidth is based on expected bandwidth for traffic within a VCN. To determine which physical NICs are active for a shape, refer to the network bandwidth specifications in the following tables. If the network bandwidth is listed as "2 x `<bandwidth>` Gbps," it means that both NIC 0 and NIC 1 are active.

**Standard Shapes**
Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel or AMD processors.

These are the bare metal standard series:
- **BM.Standard2**: X7-based standard compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.
Dense I/O Shapes

Designed for large databases, big data workloads, and applications that require high-performance local storage. Dense I/O shapes include locally-attached NVMe-based SSDs.

This is the bare metal dense I/O series:

- **BM.DenseIO2**: X7-based dense I/O compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

<table>
<thead>

<td>27 total (1 on the first physical NIC, 26 on the second)</td>
</tr>
</tbody>
</table>

GPU Shapes

Designed for hardware-accelerated workloads. GPU shapes include Intel or AMD CPUs and NVIDIA graphics processors.

These are the bare metal GPU series:

- **BM.GPU3**: X7-based GPU compute.
  - GPU: NVIDIA Tesla V100 16 GB
  - CPU: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

- **BM.GPU4**: E2-based GPU compute.
  - GPU: NVIDIA A100 40 GB
  - CPU: AMD EPYC 7542. Base frequency 2.9 GHz, max boost frequency 3.4 GHz.
<table>

**HPC Shapes**

Designed for high-performance computing workloads that require high frequency processor cores and cluster networking for massively parallel HPC workloads.

This is the bare metal HPC series:

- **BM.HPC2**: X7-based high frequency compute. Processor: Intel Xeon Gold 6154. Base frequency 3.0 GHz, max turbo frequency 3.7 GHz.

**VM Shapes**

The following shapes are available for VMs:

- **Standard Shapes** on page 658
- **Dense I/O Shapes** on page 659
- **GPU Shapes** on page 660

Network bandwidth is based on expected bandwidth for traffic within a VCN.

**Standard Shapes**

Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel or AMD processors.

These are the VM standard series:

- **VM.Standard2**: X7-based standard compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.
- **VM.Standard.E3**: E3-based standard compute, with a flexible number of OCPUs. Processor: AMD EPYC 7742. Base frequency 2.25 GHz, max boost frequency 3.4 GHz.

<td>-</td>
</tr>
</tbody>
</table>

1: Instances are billed for the full amount of memory that you provision. Usable memory is reduced by up to 256 MB per instance. This difference is due to memory reserved to support the VM on the hypervisor.

### Dense I/O Shapes

Dense I/O Shapes are designed for large databases, big data workloads, and applications that require high-performance local storage. Dense I/O shapes include locally-attached NVMe-based SSDs.

This is the VM dense I/O series:

- **VM.DenseIO2**: X7-based dense I/O compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

<table>

</tr>
</tbody>
</table>

- **DVH.Standard2.52**: X7-based VM host
  - Billed OCPU: 52
  - Usable OCPU: 48
  - Supported Shapes for Hosted VMs: VM.Standard2
**Upgrading from a Previous Generation Shape**

To upgrade from a previous generation shape to a current generation shape, you can do the following things:

- For supported VM instances, **change the shape of the instance**.
- For bare metal instances and VM instances that don't support changing the shape, **terminate the instance but DO NOT delete the boot volume**. Then, **use the boot volume to create a new instance**.

**Previous Generation Bare Metal Shapes**

These are the previous generation bare metal shape series.

**BM.Standard1**

*Newer shape recommendation:* BM.Standard2 or BM.Standard.E3 series

*End of orderability date:* December 31, 2020

X5-based standard compute. Processor: Intel Xeon E5-2699 v3. Base frequency 2.3 GHz, max turbo frequency 3.6 GHz.

<table>
<thead>

## Installing and Running Oracle Ksplice

Oracle Ksplice lets you apply important security updates and other critical kernel updates without a reboot. For more information, see [About Oracle Ksplice](#) and [Ksplice Overview](#).

This topic describes how to install and configure Ksplice. Ksplice is available for Oracle Linux instances that were launched on or after February 15, 2017. Ksplice is installed on instances that were launched on or after August 25, 2017, so you just need to run it on these instances to install the available Ksplice patches. For instances that were launched before August 25, 2017, you must install Ksplice before running it.

On Oracle Autonomous Linux images, Ksplice is installed and configured by default to run automatic updates.

### Installing Ksplice on instances launched before August 25, 2017

To install Ksplice, you must connect to your Linux instance by using a Secure Shell (SSH). See [Connecting to an Instance](#) for more information.

1. Use the following SSH command to access the instance.

   ```bash
   ssh -l opc@<public-ip-address>
   ```

   `<public-ip-address>` is your instance IP address that you retrieved from the Console, see [Getting the Instance Public IP Address](#) on page 67.

2. Run the following SSH commands to sudo to the root:

   ```bash
   sudo bash
   ```

3. Download the Ksplice installation script with the following SSH command:

   ```bash
   ```

4. Once the script is downloaded, use the following SSH command to install Ksplice:

   ```bash
   sh install-uptrack-oc
   ```

## Running Ksplice

To run Ksplice, you must connect to your Linux instance using a Secure Shell (SSH) connection. See [Connecting to an Instance](#) on page 733 for more information.
1. Use the following SSH command to access the instance.

```bash
ssh -l opc <public-ip-address>
```

`<public-ip-address>` is the instance IP address that you retrieved from the Console, see Getting the Instance Public IP Address on page 67.

2. Run the following SSH commands to sudo to the root:

```bash
sudo bash cd
```

3. To install available Ksplice patches, run the following SSH command:

```bash
uptrack-upgrade
```

**Automatic Updates**

To configure automatic updates, set the value of `autoinstall` to `yes` in `/etc/uptrack/uptrack.conf`.

**Note:**

OS Security Updates for Oracle Linux images

Oracle Linux images are updated regularly with the necessary patches, but after you launch an instance using these images, you are responsible for applying the required OS security updates published through the Oracle public Yum server. For more information, see Installing and Using the Yum Security Plugin.

**Managing Custom Images**

Oracle Cloud Infrastructure uses images to launch instances. You specify an image to use when you launch an instance.

You can create a custom image of a bare metal instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image.

For details on Windows images, see Creating Windows Custom Images on page 668.

Custom images do not include the data from any attached block volumes. For information about backing up volumes, see Backing Up a Volume on page 546.

**Tip:**

Follow industry-wide hardware failure best practices to ensure the resilience of your solution in the event of a hardware failure. Some best practices include:

- Design your system with redundant compute nodes in different availability domains to support failover capability.
- Create a custom image of your system drive each time you change the image.
- Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let image admins manage custom images on page 2144 includes the ability to create, delete, and manage custom images.

The policy in Let users launch compute instances on page 2143 includes the ability to create an instance using any custom image. The policy in Let users launch compute instances from a specific custom image on page 2144 restricts the ability to create an instance from a custom image on an image-by-image basis.

Tip:

When users create a custom image from an instance or launch an instance from a custom image, the instance and image don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Limitations and Considerations

- Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme. See IP Addresses Reserved for Use by Oracle on page 2754 for more information.
- Before you create a custom image of an instance, you must disconnect all iSCSI attachments and remove all iscsid node configurations from the instance. For steps, see Disconnecting From a Volume on page 562.
- When you create an image of a running instance, the instance shuts down and remains unavailable for several minutes. The instance restarts when the process completes.
- You cannot create additional custom images of an instance while the instance is engaged in the image creation process. When you start to create a custom image, the system implements a 20-minute timeout, during which you cannot create another image of the same instance. You can, however, create images of different instances at the same time.
- Custom images are available to all users authorized for the compartment in which the image was created.
- Custom images inherit the compatible shapes that are set by default from the base image.
- The maximum size for importing a custom image is 400 GB.
- The maximum size for custom exported images is 400 GB.
- You cannot create an image of an Oracle Database instance.
- If you use a custom image and update the OS kernel on your instance, you must also upload the update to the network drive. See OS Kernel Updates on page 691 for more information.

For information about how to deploy any version of any operating system that is supported by the Oracle Cloud Infrastructure hardware, see Bring Your Own Image (BYOI) on page 675.

X5 and X7 Compatibility for Custom Images

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. Oracle Cloud Infrastructure recommends for X7 hosts that you use the Oracle-provided images for X7. See Oracle-Provided Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

- No Windows versions are cross-compatible.
- Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
• Oracle Linux 6, Oracle Linux 7, Ubuntu 16.04, CentOS 7, and CentOS 8 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:

  • Oracle Linux
    ```
yum update
    ```
  • CentOS 7, CentOS 8
    ```
yum update
    ```
  • Ubuntu 16.04
    ```
    apt-get update
    apt-get dist-upgrade
    ```

If you attempt to use an X6 image on non-X6 hardware, note the following:

• Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.
• Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
• Oracle Linux 7, Ubuntu 18.04, and Ubuntu 16.04 are cross-compatible. Use the Oracle-provided images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

• Network device drivers
• NVMe drive device drivers
• GPU device drivers

Additional updates might be required depending on how you have customized the image.

**Using the Console**

**To create a custom image**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you want to use as the basis for the custom image.
3. Click **More Actions**, and then click **Create Custom Image**.
4. In the **Create in Compartment** list, select the compartment to create the custom image in.
5. Enter a **Name** for the image. You can change the name later, if needed. You cannot use the name of an Oracle-provided image for a custom image. Avoid entering confidential information.
6. **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Custom Image**.

To track the progress of the operation, you can monitor the associated work request. For more information, see **Using the Console to View Work Requests** on page 260.

**Note:**

If you see a message indicating that you are at the limit for custom images, you must delete at least one image before you can create another. Or, you can request a service limit increase.

**To launch an instance from a custom image**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click the custom image that you're interested in.
3. Click **Create Instance**.
4. Provide additional launch options as described in **Creating an Instance** on page 695.
To edit the name or compatible shapes for a custom image

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. Click the custom image that you're interested in.
3. Click Edit Details.
4. Edit the name, or add and remove compatible shapes for the custom image. Avoid entering confidential information.
5. To configure the minimum and maximum number of OCPUs that users can select when they use this image on a flexible shape, click the down arrow in the row for the shape, and then enter the minimum and maximum OCPU counts.
6. Click Save Changes.

**Note:**
After you add shape compatibility to an image, test the image on the shape to ensure that the image actually works on the shape. Some images (especially Windows) might never be cross-compatible with other shapes because of driver or hardware differences.

To manage tags for a custom image

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. Click the custom image that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click More Actions, and then click Add tags to add new ones.

For more information, see Resource Tags on page 211.

To delete a custom image

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. Click the custom image that you're interested in.
3. Click More Actions, and then click Delete. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations to manage custom images:

- CreateImage
- GetImage
- ListImages
- UpdateImage
- DeleteImage
- AddImageShapeCompatibilityEntry
- ListImageShapeCompatibilityEntries
- GetImageShapeCompatibilityEntry
- RemoveImageShapeCompatibilityEntry

Creating Windows Custom Images

You can create a Windows custom image of a bare metal or virtual machine (VM) instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image. For information about custom images, see Managing Custom Images on page 665. For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 803.
Windows supports two kinds of images: generalized and specialized. Generalized images are images that have been cleaned of instance-specific information. Specialized images are point-in-time snapshots of the boot disk of a running instance, and are useful for creating backups of an instance. Oracle Cloud Infrastructure supports bare metal and VM instances launched from both generalized and specialized custom Windows images.

**Generalized images**

A generalized image has a generalized OS disk, cleaned of computer-specific information. The images are generalized using Sysprep. Generalized images can be useful in scenarios such as quickly scaling an environment. Generalized images can be configured to preserve the existing opc user's account, including the password, at the time the image is created, or configured to recreate the opc user account, including generating a new, random password that you retrieve using the API. For background information, see [Sysprep (Generalize) a Windows installation](#).

**Specialized images**

A specialized image has an OS disk that is already fully installed, and is essentially a copy of the original bare metal or VM instance. Specialized images are intended to be used for backups so that you can recover from a failure. Specialized images are useful when you are testing a task and may need to roll back to known good configuration. Specialized images are not recommended for cloning multiple identical bare metal instances or VMs in the same network because of issues with multiple computers having the same computer name and ID. When creating a specialized image, you must remember the opc user's password; a new password is not generated when the instance launches, and it cannot be retrieved from the console or API.

**Creating a Generalized Image**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating a generalized image from an instance will render the instance non-functional, so you should first create a custom image from the instance, and then launch a new instance from the custom image. Steps 1 - 2 describe how to do this. This is the instance that you'll generalize. Alternatively, you can make a backup image of the instance that you can use to launch a replacement instance if needed.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you upgrade to PowerShell 5.0/WMF 5.0, you may encounter an issue where Sysprep fails which will prevent the image generalization process from completing. If this occurs, you may not be able to log into instances launched from the custom image. See <a href="#">Unable to log in to instance launched from new generalized Windows custom image</a> for more information and how to work around the issue.</td>
</tr>
</tbody>
</table>

1. Create the new image using [To create a custom image](#).
2. Launch an instance from the new image using [To launch an instance from a custom image](#).
3. Connect to the instance using a Remote Desktop client.
4. Go to [Windows Generalized Image Support Files](#) on page 831 and download to the instance the file matching the instance shape.
5. Right-click the file, and then click Run as administrator.
6. Extract the files to C:\Windows\Panther. The following files are extracted into the Panther folder for all Windows Server versions:
   - Generalize.cmd
   - Specialize.cmd
   - unattend.xml
   - Post-Generalize.ps1
7. Optional: If you want to preserve the opc user account, edit C:\Program Files\bmcs \imageType.json and change the imageType setting to custom. A new password is not created and the password is not retrievable from the console or API.

If you want to configure the generalized image to recreate the opc user account when a new instance is launched from the image, leave the imageType setting defaulted to general. The new account's password can be retrieved through the API using GetInstanceDefaultCredentials.

8. Right-click Generalize.cmd, and then click Run as administrator. Keep in mind the following outcomes of running this command:

   • Your connection to the Remote Desktop client might immediately be turned off and you will be logged out of the instance. If this does not occur, you should log out of the instance yourself.
   • Because sysprep generalize turns off Remote Desktop, you won't be able to log in to the instance again.
   • Creating a generalized image essentially destroys the instance's functionality.

   You should wait for a few minutes before proceeding to the following step to ensure the generalization process has completed.

9. Create the new image using To create a custom image.

10. After you create an image from an instance that has been generalized, we recommend that you terminate the instance. Although it may appear to be running, it won't be fully operable.

Creating a Specialized Image

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When creating a specialized image, you must remember the opc user's password. It cannot be retrieved from the Console or API.</td>
</tr>
</tbody>
</table>

You create a specialized image the same way you create other custom images. For steps, see Managing Custom Images on page 665.

Image Import/Export

Oracle Cloud Infrastructure Compute lets you share custom images across tenancies and regions using image import/export.

Linux-Based Operating Systems

The following operating systems support image import/export:

   • Oracle Linux 6.x
   • Oracle Linux 7.x
   • Oracle Linux 8.x
   • CentOS 7
   • CentOS 8
   • Ubuntu 16.04 and later

For more information about Oracle-provided platform images, see Oracle-Provided Images on page 629.

Windows-Based Operating Systems

The following Windows versions support image import/export:

   • Windows Server 2012 Standard, Datacenter
   • Windows Server 2012 R2 Standard, Datacenter
   • Windows Server 2016 Standard, Datacenter
   • Windows Server 2019 Standard, Datacenter
Note:
When exporting Windows-based images, you are responsible for complying with the Microsoft Product Terms and all product use conditions, as well as verifying your compliance with Microsoft.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 803.

**Verify Your Windows Operating System**

When importing custom Windows images, ensure that the version you select matches the Windows image that you imported. Failure to provide the correct version and SKU information could be a violation of your Microsoft Licensing Agreement.

**Windows System Time Issue on Custom Windows Instances**

If you change the time zone from the default setting on Windows VM instances, when the instance reboots or syncs with the hardware clock, the system time will revert back to the time for the default time zone. However, the time zone setting will stay set to the new time zone, so the system clock will be incorrect. You can fix this by setting the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation registry key to 1.

Oracle-provided Windows images already have the RealTimeIsUniversal registry key set by default, but you must set this for any custom Windows images that you import.

To fix this issue for custom Windows images:

1. Open the Windows Registry Editor and navigate to the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation registry key.
2. Create a new DWORD key named RealTimeIsUniversal and set the value to 1.
3. Reboot the instance.
4. Reset the time and time zone manually.

**Bring Your Own Image Scenarios**

You can also use image import/export to share custom images from Bring Your Own Image (BYOI) on page 675 scenarios across tenancies and regions, so you don't need to recreate the image manually in each region. You must go through the steps required to manually create the image in one of the regions, but after this is done, you can export the image, making it available for import in additional tenancies and regions. Export the image in the .oci format, which is a file format that contains a QCOW2 image file and Oracle Cloud Infrastructure-specific metadata.

**Best practices for replicating an image across regions**

You can replicate an image from one region to another region using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image on page 672.
2. Copy the image to an Object Storage bucket in the destination region. For steps, see Copying Objects on page 3487.
3. Obtain the URL path to the image object. For steps, see To view object details on page 3423.
4. In the destination region, import the image. Use the URL path as the Object Storage URL. For steps, see Importing an Image on page 673.

**Best practices for sharing an image across tenancies**

You can replicate an image from one tenancy to another tenancy using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image on page 672.
2. Create a pre-authenticated request with read-only access for the image in the destination region. For steps, see Working with Pre-Authenticated Requests on page 3483.
3. In the destination tenancy, import the image. Use the pre-authenticated request URL as the Object Storage URL. For steps, see Importing an Image on page 673.

Object Storage Service URLs
When you import or export custom images using the Console, you might need to specify the Object Storage URL pointing to the location that you want to import the image from or export the image to. Object Storage URLs are structured as follows:

https://<host_name>/n/<namespace_name>/b/<bucket_name>/o/<object_name>

For example:

https://objectstorage.us-phoenix-1.oraclecloud.com/n/MyNamespace/b/MyBucket/o/MyCustomImage.qcow2

Pre-Authenticated Requests
When using import/export across tenancies, you need to use an Object Storage pre-authenticated request. See Working with Pre-Authenticated Requests on page 3483 for steps to create a pre-authenticated request. When you go through these steps, after you click Create Pre-Authenticated Request, the Pre-Authenticated Request Details dialog box opens. You must make a copy of the pre-authenticated request URL displayed here, because this is the only time this URL is displayed. This is the Object Storage URL that you specify for import/export.

Note:

Pre-authenticated requests for a bucket

With image export, if you create the pre-authenticated request for a bucket, you need to append the object name to the generated URL. For example:

/o/MyCustomImage.qcow2

Exporting an Image
You can use the Console or API to export images, and the exported images are stored in the Oracle Cloud Infrastructure Object Storage service. To perform an image export, you need write access to the Object Storage bucket for the image. For more information, see Overview of Object Storage on page 3392 and Let users write objects to Object Storage buckets on page 2149.

To export an image using the Console
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. Click the custom image that you're interested in.
3. Click Export.
4. Specify the Object Storage location to export the image to:
   - **Export to an Object Storage bucket**: Select a bucket. Then, enter a name for the exported image. Avoid entering confidential information.
   - **Export to an Object Storage URL**: Enter the Object Storage URL.

5. In the **Image format** list, select the format that you want to export the image to. The following formats are available:
   - Oracle Cloud Infrastructure file with a QCOW2 image and OCI metadata (.oci). Use this format to export a custom image that you want to import into other tenancies or regions.
   - QEMU Copy On Write (.qcow2)
   - Virtual Disk Image (.vdi) for Oracle VM VirtualBox
   - Virtual Hard Disk (.vhd) for Hyper-V
   - Virtual Machine Disk (.vmdk)

6. Click **Export Image**.

After you click **Export Image**, the image state changes to **Exporting**. You can still launch instances while the image is exporting, but you can't delete the image until the export has finished. To track the progress of the operation, you can monitor the associated work request. For more information, see **Using the Console to View Work Requests** on page 260.

When the export is complete, the image state changes to **Available**. If the image state changes to **Available**, but you don't see the exported image in the Object Storage location you specified, this means that the export failed, and you will need to go through the steps again to export the image.

**Importing an Image**

You can use the Console or API to import exported images from Object Storage. To import an image, you need read access to the Object Storage object containing the image. For more information, see **Let users download objects from Object Storage buckets** on page 2149.

**To import an image using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click **Import Image**.
3. In the **Create in Compartment** list, select the compartment that you want to import the image to.
4. Enter a **Name** for the image. Avoid entering confidential information.
5. Select the **Operating System**:
   - For Linux images, select **Linux**.
   - For Windows images, select **Windows**. Select the **Operating System Version**, and then certify that the selected operating system complies with Microsoft licensing agreements.
6. Specify the **Object Storage location** to import the image from:
   - **Import from an Object Storage bucket**: Select the **Bucket** that contains the image. In the **Object Name** list, select the image file.
   - **Import from an Object Storage URL**: Enter the **Object Storage URL** of the image. When importing across tenancies, you must specify a pre-authenticated request URL.
7. In the **Image Type** section, select the format of the image.
8. **Select the Launch Mode:**

- For custom images where the image type is `.oci`, the launch mode is disabled. Oracle Cloud Infrastructure selects the appropriate launch mode based on the launch mode for the source image.
- For custom images exported from Oracle Cloud Infrastructure where the image type is QCOW2, select **Native Mode**.
- To import other custom images, select **Paravirtualized Mode** or **Emulated Mode**. For more information, see *Bring Your Own Image (BYOI)* on page 675.

9. **Show Tagging Options:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see *Resource Tags* on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

10. **Click Import Image.**

After you click **Import Image**, you'll see the imported image in the **Custom Images** list for the compartment, with a state of **Importing**. To track the progress of the operation, you can monitor the associated work request. For more information, see *Using the Console to View Work Requests* on page 260.

When the import completes successfully, the state changes to **Available**. If the state does not change, or no entry appears in the **Custom Images** list, the import failed. If the import failed, ensure you have read access to the Object Storage object, and that the object contains a supported image.

**Editing Image Details**

You can edit the details of custom images, such as the image name and compatible shapes for the image. For more information, see *To edit the name or compatible shapes for a custom image* on page 668 in *Managing Custom Images* on page 665.

**Managing Tags for an Image**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see *Resource Tags* on page 211.

**To manage tags for an image**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click the image that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **More Actions**, and then click **Add tags** to add new ones.

**Using the API**

For information about using the API and signing requests, see *REST APIs* on page 4368 and *Security Credentials* on page 179. For information about SDKs, see *Software Development Kits and Command Line Interface* on page 4225.

Use the following API operations for custom image import/export:

- **ExportImage**: Exports a custom image to Object Storage.
- **CreateImage**: To import an exported image, specify **ImageSourceDetails** in the request body.
- **AddImageShapeCompatibilityEntry**: Adds a shape to the compatible shapes list for the image.
- **ListImageShapeCompatibilityEntries**
- **GetImageShapeCompatibilityEntry**
- **RemoveImageShape CompatibilityEntry**: Removes a shape from the compatible shapes list for the image.

**X5 and X7 Compatibility for Image Import/Export**

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. Oracle Cloud Infrastructure
recommends for X7 hosts that you use the Oracle-provided images for X7. See Oracle-Provided Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

- No Windows versions are cross-compatible.
- Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
- Oracle Linux 6, Oracle Linux 7, Ubuntu 16.04, CentOS 7, and CentOS 8 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:
  - **Oracle Linux**
    ```
    yum update
    ```
  - **CentOS 7, CentOS 8**
    ```
    yum update
    ```
  - **Ubuntu 16.04**
    ```
    apt-get update
    apt-get dist-upgrade
    ```

If you attempt to use an X6 image on non-X6 hardware, note the following:

- Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.
- Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
- Oracle Linux 7, Ubuntu 18.04, and Ubuntu 16.04 are cross-compatible. Use the Oracle-provided images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

- Network device drivers
- NVMe drive device drivers
- GPU device drivers

Additional updates might be required depending on how you have customized the image.

**Bring Your Own Image (BYOI)**

The Bring Your Own Image (BYOI) feature enables you to bring your own versions of operating systems to the cloud as long as the underlying hardware supports it. The services do not depend on the OS you run.

The BYOI feature does the following things:

- Enables virtual machine cloud migration projects.
- Supports both old and new operating systems.
- Encourages experimentation.
- Increases infrastructure flexibility.

**Note:**

Licensing Requirements

You must comply with all licensing requirements when you upload and start instances based on OS images that you supply.
Bringing Your Own Image

A critical part of any lift-and-shift cloud migration project is the migration of on-premises virtual machines (VMs) to the cloud. You can import your on-premises virtualized root volumes to Oracle Cloud Infrastructure using the custom image import feature, and then launch Compute instances using those images.

You can import Windows and Linux-based custom images and use them to launch VMs on Oracle Cloud Infrastructure. Bringing your own image to a bare metal instance is not supported.

- **Windows images**

  These Windows versions support custom image import:
  - Windows Server 2008 R2 Standard, Enterprise, Datacenter
  - Windows Server 2012 Standard, Datacenter
  - Windows Server 2012 R2 Standard, Datacenter
  - Windows Server 2016 Standard, Datacenter
  - Windows Server 2019 Standard, Datacenter

  For steps to import a Windows image, see Importing Custom Windows Images on page 677.

  Bring your own license (BYOL) for Windows Server is not permitted when launching a VM instance on a shared host. For more information about BYOL and the licensing requirements for Windows images, see Licensing Options for Microsoft Windows on page 809 and Microsoft Licensing on Oracle Cloud Infrastructure on page 803.

- **Linux images**

  These Linux distributions support custom image import:

<table>
<thead>
<tr>
<th>Linux Distribution</th>
<th>Supported Versions</th>
<th>Preferred Launch Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>CentOS</td>
<td>7 or later</td>

</tbody>
</table>

  You might also have success importing other distributions of Linux.

  For steps to import a Linux-based image, see Importing Custom Linux Images on page 682.
Bringing Your Own Hypervisor Guest OS

You can bring your own hypervisor guest OS using Kernel-based Virtual Machine (KVM) or Hyper-V.

**Note:**

Bring your own hypervisor deployment of ESXi on bare metal Compute instances is not supported. ESXi is supported only by provisioning an Oracle Cloud VMware Solution software-defined data center (SDDC). See Oracle Cloud VMware Solution on page 4026 for more information.

Bringing Your Own KVM

You can bring your own operating system images or older operating systems, such as Ubuntu 6.x, RHEL 3.x, and CentOS 5.4, using KVM on bare metal instances.

To bring your own KVM, first create a bare metal instance using the KVM image from Marketplace. Then, copy your on-premises guest OS to KVM on the bare metal instance.

For more information, see the following resources:

- Getting Started: Oracle Linux KVM Image for Oracle Cloud Infrastructure
- Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC

Bringing Your Own Hyper-V

You can bring your own operating system images or older operating systems, such as Windows Server 2003 and Windows Server 2008, using Hyper-V on bare metal instances.

To bring your own Hyper-V, first create a bare metal instance using the Oracle-provided Windows Server Datacenter platform image. Oracle Cloud Infrastructure will issue a license for Windows Server when the instance is launched. Then, copy your on-premises guest OS to Hyper-V on the bare metal instance. No additional license is required because Windows Server Datacenter includes unlimited virtual machines.

Be aware of the following considerations:

- Oracle Cloud Infrastructure will issue a license when you launch an instance using a custom image. If you want to bring your own license (BYOL) for Windows Server, you must activate Windows Server with your own license. For steps, see Activating Licenses on a Dedicated Host on page 811.
- Importing your own ISO image is not supported.

For a list of supported Hyper-V guests, see the following resources:

- Supported Windows guest operating systems for Hyper-V on Windows Server
- Supported Linux and FreeBSD virtual machines for Hyper-V on Windows

For more information about deploying Hyper-V, see Deploying Hyper-V on Oracle Cloud Infrastructure.

Importing Custom Windows Images

The Compute service enables you to import Windows images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 803.

**Supported Operating Systems**

These Windows versions support custom image import:

- Windows Server 2008 R2 Standard, Enterprise, Datacenter
- Windows Server 2012 Standard, Datacenter
• Windows Server 2012 R2 Standard, Datacenter
• Windows Server 2016 Standard, Datacenter
• Windows Server 2019 Standard, Datacenter

Note:
• Oracle Cloud Infrastructure has tested the operating systems listed previously and will support customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using RDP.
• For OS editions not listed previously, Oracle Cloud Infrastructure will provide commercially reasonable support to customers in an effort to get instances that are launched from these images accessible via RDP.
• Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance.
• Oracle Cloud Infrastructure licenses and charges the Windows licensing fee for all instances launched using an imported Windows OS image. This applies whether or not those instances are registered with Oracle Cloud Infrastructure’s Microsoft Key Management service.
• The Oracle Cloud Agent (used for monitoring) is not supported on Windows Server 2008 R2.

Windows Source Image Requirements

Custom images must meet the following requirements:
• The maximum image size is 400 GB.
• The image must be set up for BIOS boot.
• Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image’s boot volume.
• The minimum boot volume size is 256 GB. For more information, see Custom Boot Volume Sizes on page 610.
• The boot process must not require additional data volumes to be present for a successful boot.
• The disk image cannot be encrypted.
• The disk image must be a VMDK or QCOW2 file.
  • Create the image file by cloning the source volume, not by creating a snapshot.
  • VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
• The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete. You can attach additional VNICs after you launch the imported instance.
• The network configuration must not hardcode the MAC address for the network interface.

Preparing Windows VMs for Import

Before you can import a custom Windows image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work.

You can perform the tasks described in this section on the running source system. If you have concerns about modifying the live source system, you can export the image as-is, import it into Oracle Cloud Infrastructure, and then launch an instance based on the custom image. You can then connect to the instance using the VNC console and perform the preparation steps.
Important:

The system drive where Windows is installed will be imported to Oracle Cloud Infrastructure. All partitions on the drive will follow through the imported image. Any other drives will not be imported and you must recreate them on the instance after import. You will then need to manually move the data on the non-system drives.

To prepare a Windows VM for import:

1. Follow your organization’s security guidelines to ensure that the Windows system is secured. This can include, but is not limited to the following tasks:
   - Install the latest security updates for the operating system and installed applications.
   - Enable the firewall, and configure it so that you only enable the rules which are needed.
   - Disable unnecessary privileged accounts.
   - Use strong passwords for all accounts.
2. Configure Remote Desktop Protocol (RDP) access to the image:
   a. Enable Remote Desktop connections to the image.
   b. Modify the Windows Firewall inbound port rule to allow RDP access for both Private and Public network location types. When you import the image, the Windows Network Location Awareness service will identify the network connection as a Public network type.
3. Determine whether the current Windows license type is a volume license by running the following command in PowerShell:
   ```powershell
   Get-CimInstance -ClassName SoftwareLicensingProduct | where {$_._PartialProductKey} | select ProductKeyChannel
   ```
   If the license is not a volume license, after you import the image, you will update the license type.
4. If you plan to launch the imported image on more than one VM instance, create a generalized image of the boot disk. A generalized image is cleaned of computer-specific information, such as unique identifiers. When you create instances from a generalized image, the unique identifiers are regenerated. This prevents two instances that are created from the same image from colliding on the same identifiers.
5. Create a backup of the root volume.
6. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
7. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.
8. Download the Oracle Windows VirtIO drivers:
   a. Sign in to the Oracle Software Delivery Cloud site.
   b. In the All Categories list, select Release.
   c. Type Oracle Linux 7.7 in the search box and click Search.
   d. Add REL: Oracle Linux 7.7.x to your cart, and then click Continue.
   e. In the Platforms/Languages list, select x86 64 bit. Click Continue.
   f. Accept the license agreement and then click Continue.
   g. Select the check box next to Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5. Clear the other check boxes.
   h. Click Download and then follow the prompts.
9. Install the Oracle VirtIO drivers for Windows:
   a. Follow the prompts in the installation wizard. On the Installation Type page, select Custom, as shown in the following screenshot.
   ![Drivers Installer](image)
   b. Reboot the VM.
10. Stop the VM.
11. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

**Importing a Windows-Based VM**

After you prepare a Windows image for import, follow these steps to import the image:

1. **Upload the image file to an Object Storage bucket.** You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:
   ```bash
   oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
   ```
2. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
3. Click Import Image.
4. In the Create in Compartment list, select the compartment that you want to import the image to.
5. Enter a Name for the image. Avoid entering confidential information.
6. For the Operating System, select Windows.
7. In the Operating System Version list, select the version of Windows.
8. Confirm that you chose the operating system version that complies with your Microsoft licensing agreement, and then select the compliance check box.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure to provide the correct version and SKU information could be a violation of your Microsoft Licensing Agreement.</td>
</tr>
</tbody>
</table>

9. Select the Import from an Object Storage bucket option.
10. Select the Bucket that you uploaded the image to.
11. In the Object Name list, select the image file that you uploaded.
12. For the Image Type, select the file type of the image, either VMDK or QCOW2.
13. In the Launch Mode area, select Paravirtualized Mode.
14. Show Tagging Options: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
15. Click Import Image.

The imported image appears in the Custom Images list for the compartment, with a state of Importing. When the import completes successfully, the state changes to Available.

If the state doesn't change, or no entry appears in the Custom Images list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.

**Post-Import Tasks for Windows Images**

After you import a custom Windows-based image, do the following:

1. If you want to use the image on AMD or X6-based shapes, add the shapes to the image's list of compatible shapes.
2. Create an instance based on the custom image. For the image source, select Custom Images, and then select the image that you imported.
3. Enable Remote Desktop Protocol (RDP) access to the Compute instance.
4. Connect to the instance using RDP.
5. If the instance requires any remotely attached storage, such as block volumes or file storage, create and attach it.
6. Create and attach any required secondary VNICs.
7. Test that all applications are working as expected.
8. Reset any services that were set to start manually.
9. Register the instance with the Oracle-provided Key Management Service (KMS) server:

   a. On the instance, open PowerShell as Administrator.

   b. To set the KMS endpoint, run the following command:

```
slmgr /skms 169.254.169.253:1688
```

   c. If the Windows license type that you noted while preparing the image isn't a volume license, you must update the license type. Run the following command:

```
slmgr /ipk <setup key>
```

   <setup key> is the KMS client setup key that corresponds to the version of Windows that you imported:

<table>
<thead>
<tr>
<th>Windows Version</th>
<th>KMS Client Setup Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Server 2008 R2 Standard</td>
<td>YC6KT-GKW9T-YTKYR-T4X34-R7VHC</td>
</tr>
<tr>
<td>Windows Server 2008 R2 Enterprise</td>
<td>489J6-VHDMP-X63PK-3K798-CPX3Y</td>
</tr>
<tr>
<td>Windows Server 2008 R2 Datacenter</td>
<td>74YFP-3QFB3-KQT8W-PMXWJ-7M648</td>
</tr>
<tr>
<td>Windows Server 2012 Standard</td>
<td>XC9B7-NBPP2-83J2H-RHMBY-92BT4</td>
</tr>
<tr>
<td>Windows Server 2012 Datacenter</td>
<td>48HP8-DN98B-MYWDG-T2DCC-8W83P</td>
</tr>
<tr>
<td>Windows Server 2012 R2 Standard</td>
<td>D2N9P-3P6X9-2R39C-7RTCD-MDVIJX</td>
</tr>
<tr>

</tr>
<tr>
<td>Windows Server 2019 Standard</td>
<td>N69G4-B89J2-4G8F4-WWYCC-J464C</td>
</tr>
<tr>
<td>Windows Server 2019 Datacenter</td>
<td>WMDGN-G9PQG-XVVXX-R3X43-63DFG</td>
</tr>
</tbody>
</table>

   d. To activate Windows, run the following command:

```
slmgr /ato
```

   e. To verify the license status, run the following command:

```
Get-CimInstance -ClassName SoftwareLicensingProduct | where ($_.PartialProductKey) | select Description, LicenseStatus
```

If the LicenseStatus is 1, the instance is properly licensed. It might take up to 48 hours for the license status to update.

**Importing Custom Linux Images**

The Compute service lets you import Linux-based images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

**Supported Operating Systems**

You can launch imported Linux VMs in either paravirtualized mode or emulated mode. On AMD shapes, imported images are supported in paravirtualized mode only.

Paravirtualized mode offers better performance than emulated mode. We recommend that you use paravirtualized mode if your OS supports it. Linux-based operating systems running the kernel version 3.4 or later support paravirtualized drivers. You can verify your system's kernel version using the `uname` command.
To verify the kernel version using the `uname` command

Run the following command:

```
uname -a
```

The output should look similar to this sample:

```
Linux ip_bash 4.14.35-1818.2.1.el7uek.x86_64 #2 SMP Mon Aug 27 21:16:31 PDT 2018 x86_64 x86_64 x86_64 GNU/Linux
```

The kernel version is the number at the first part of the output string. In the sample output shown previously, the version is 4.14.35.

Linux Distributions that Support Custom Image Import

These Linux distributions support custom image import:

<table>
<thead>
<tr>
<th>Linux Distribution</th>
<th>Supported Versions</th>
<th>Preferred Launch Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>CentOS</td>
<td>7 or later</td>
<td>Paravirtualized</td>

<tr>
<td></td>
<td>12.04</td>
<td>Emulated</td>
</tr>
</tbody>
</table>

Note:

- Oracle Cloud Infrastructure has tested the operating systems listed in the previous table and will support customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using SSH.
- For any OS version other than those covered by an official support service from Oracle (for example, Oracle Linux with Premier Support), Oracle Cloud Infrastructure will provide commercially reasonable support limited to getting an instance launched and accessible via SSH.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also
Compute

supports the instance. Customers running Oracle Linux on Oracle Cloud Infrastructure automatically have access to Oracle Linux Premier Support.

Tip:
If your image supports paravirtualized drivers, you can convert your existing emulated mode instances into paravirtualized instances. Create a custom image of your instance, export it to Object Storage, and then reimport it using paravirtualized mode.

Linux Source Image Requirements

Custom images must meet the following requirements:

- The maximum image size is 400 GB.
- The image must be set up for BIOS boot.
- Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image's boot volume.
- The boot process must not require additional data volumes to be present for a successful boot.
- The boot loader should use LVM or a UUID to locate the boot volume.
- The disk image cannot be encrypted.
- The disk image must be a VMDK or QCOW2 file.
  - Create the image file by cloning the source volume, not by creating a snapshot.
  - VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
- The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete. You can attach additional VNICs after you launch the imported instance.
- The network configuration must not hardcode the MAC address for the network interface.

We recommend that you enable certificate-based SSH, however this is optional. If you want your image to automatically use SSH keys supplied from the User Data field when you launch an instance, you can install cloud-init when preparing the image. See Creating an Instance on page 695 for more information about providing user data.

Preparing Linux VMs for Import

Before you import a custom Linux image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work. Do the following:

1. Optionally, configure your Linux image to support serial console connections. A console connection can help you remotely troubleshoot malfunctioning instances, such as an imported image that does not complete a successful boot.
2. Create a backup of the root volume.
3. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
4. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.
5. Stop the VM.
6. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

Importing a Linux-Based VM

After you prepare a Linux image for import, follow these steps to import the image:
1. **Upload the image file to an Object Storage bucket.** You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:

```
oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
```

2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.

3. Click **Import Image**.

4. In the **Create in Compartment** list, select the compartment that you want to import the image to.

5. Enter a **Name** for the image. Avoid entering confidential information.

6. For the **Operating System**, select **Linux**.

7. Select the **Import from an Object Storage bucket** option.

8. Select the **Bucket** that you uploaded the image to.

9. In the **Object Name** list, select the image file that you uploaded.

10. For the **Image Type**, select the file type of the image, either **VMDK** or **QCOW2**.

11. Depending on your image's version of Linux, in the **Launch Mode** area, select **Paravirtualized Mode** or **Emulated Mode**. If your image supports paravirtualized drivers, we recommend that you select paravirtualized mode.

12. **Show Tagging Options:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

13. Click **Import Image**.

The imported image appears in the **Custom Images** list for the compartment, with a state of **Importing**. When the import completes successfully, the state changes to **Available**.

If the state doesn’t change, or no entry appears in the **Custom Images** list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.

### Post-Import Tasks for Linux Images

After you import a custom Linux-based image, do the following:

1. If you want to use the image on AMD or X6-based **shapes**, add the shapes to the image's list of compatible shapes.
2. **Create an instance based on the custom image.** For the image source, select **Custom Images**, and then select the image that you imported.
3. **Connect to the instance using SSH.**
4. If the instance requires any remotely attached storage, such as **block volumes** or **file storage**, create and attach it. If you are using **iSCSI** on page 501 attachments, see **Recommended iSCSI Initiator Parameters for Linux-based Images** on page 506.
5. **Create and attach any required secondary VNICS.**
6. Test that all applications are working as expected.
7. Reset any services that were set to start manually.
8. If you enabled serial console access to the image, test it by creating a serial console connection to the instance.

See the **current issues and workarounds** for known issues with imported custom images.

### Enabling Serial Console Access for Imported Linux Images

You can configure your custom Linux image to support connections using the serial console feature in the Compute service.

For more information about serial console connections, and steps to troubleshoot if your image has network connectivity issues after it is launched, see **Troubleshooting Instances Using Instance Console Connections** on page 813.
The serial console connection in Oracle Cloud Infrastructure uses the first serial port, ttyS0, on the VM. The boot loader and the operating system should be configured to use ttyS0 as a console terminal for both input and output.

**Configuring the Boot Loader**

The steps to configure the boot loader to use ttyS0 as a console terminal for both input and output depend on the GRUB version. Run the following command on the operating system to determine the GRUB version:

```
grub install --version
```

If the version number returned is 2.x, use the steps for GRUB 2. For earlier versions, use the steps for GRUB.

**To configure GRUB2**

1. Run the following command to modify the GRUB configuration file:

   ```
sudo vi /etc/default/grub
```

2. Confirm that the configuration file contains the following:

   ```
GRUB_SERIAL_COMMAND="serial --unit=0 --speed=115200"
GRUB_TERMINAL="serial console"
```

3. Append the following to the end of the `GRUB_CMDLINE_LINUX` line:

   ```
console=tty1 console=ttyS0,115200
```

   If `GRUB_CMDLINE_LINUX` does not exist, create this line, using `GRUB_CMDLINE_OUTPUT` as a template.

4. Regenerate the GRUB2 configuration using the following command:

   ```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

   If you have a beta version of GRUB 2, use this command instead:

   ```
sudo grub-mkconfig -o /boot/grub/grub.cfg
```

**To configure GRUB**

1. Run the following command to modify the GRUB configuration file:

   ```
sudo vi /boot/grub/grub.conf
```

2. Add following after the line containing `timeout`:

   ```
serial --unit=0 --speed=115200
terminal --timeout=5 serial console
```

3. Append the following to each `kernel` line:

   ```
console=tty1 console=ttyS0,115200
```

**Configuring the Operating System**

The operating system may already be configured to usettyS0 as a console terminal for both input and output. To verify, run the following command:

```
sudo vi /etc/securetty
```

Check the file for `ttyS0`. If you don't see it, append `ttyS0` to the end of the file.
Validating Serial Console Access

After completing the steps to enable serial console access to the image, you should validate that serial console access is working by testing the image with serial console in your virtualization environment. Consult the documentation for your virtualization environment for steps to do this. Verify that the boot output displays in the serial console output and that there is interactive input after the image has booted.

Troubleshooting the Serial Console

If no output is displayed on the serial console, verify in the configuration for your virtualization environment that the serial console device is attached to the first serial port.

If the serial console displays output, but there is no interactive input available, check that there is a terminal process listening on the ttyS0 port. To do this, run the following command:

```
ps aux | grep ttyS0
```

This command should output a terminal process that is listening on the ttyS0 port. For example, if your system is using getty, you will see the following output:

```
/sbin/getty ttyS0
```

If you don't see this output, it is likely that a login process is not configured for the serial console connection. To resolve this, enable the init settings, so that a terminal process is listening on the ttyS0 at startup.

For example, if your system is using getty, add the following command to the init settings to run on system startup:

```
getty -L 9600 ttyS0 vt102
```

The steps to do this will vary depending on the operating system, so consult the documentation for the image's operating system.

Configuring Image Capabilities for Custom Images

Image capabilities are the configuration options available when launching an instance from an image. Some image capability examples are the firmware used to boot the instance, the volume attachment types supported, and so on. The full set of image capabilities provided by Oracle Cloud Infrastructure Compute are defined in the global image capability schema. You can also create your own custom image capability schemas based on the global image capability schema to specify and configure image capabilities for your custom images. Using these schemas, you can customize the image configuration and options available when users launch instances from your custom images.

You can configure image capability schemas using the REST APIs, SDKs, or the CLI.

**Caution:**

Using this feature allows you to customize image capabilities from the default capabilities that Oracle recommends and should be used for advanced custom image scenarios only. Ensure that you understand the optimal configuration options for your custom image.

Global Image Capability Schema

The following JSON is what's returned when you use the GetComputeGlobalImageCapabilitySchemaVersion API operation or the `global-image-capability-schema-version` CLI command. It represents the full set of image capabilities available for images. The default values specified for each element are the recommended values for each option. You can create a schema to customize these options, however they must be a subset, you cannot specify values that are not included in the global capabilities schema.
"Compute.Firmware": {
  "descriptorType": "enumstring",
  "values": [
    "BIOS",
    "UEFI_64"
  ],
  "defaultValue": "UEFI_64"
},
"Compute.LaunchMode": {
  "descriptorType": "enumstring",
  "values": [
    "NATIVE",
    "EMULATED",
    "PARAVIRTUALIZED",
    "CUSTOM"
  ],
  "defaultValue": "PARAVIRTUALIZED"
},
"Network.AttachmentType": {
  "descriptorType": "enumstring",

Schema Elements

The following list describes all the available elements in the global image capabilities schema.

- **Compute.Firmware**: The firmware used to boot the virtual machine instance. The default value is UEFI_64.
- **Compute.LaunchMode**: The configuration mode for launching instances. The default value is PARAVIRTUALIZED.
- **Network.AttachmentType**: The emulation type for the primary VNIC, which is automatically created and attached when the instance is launched. The default value is PARAVIRTUALIZED.
- **Storage.BootVolumeType**: Specifies the driver options for the image's boot volume. The default value is PARAVIRTUALIZED.
- **Storage.LocalDataVolumeType**: Specifies the driver options for the image to access local storage volumes. The default value is PARAVIRTUALIZED.
- **Storage.RemoteDataVolumeType**: Specifies the driver options for the image to access remote storage volumes. The default value is PARAVIRTUALIZED.
- **Storage.ConsistentVolumeNaming**: Specifies whether consistent device paths for iSCSI and paravirtualized attached block volumes are enabled for the image. If enabled, the image must support consistent device names. The default value is true.
- **Storage.ParaVirtualization.EncryptionInTransit**: Specifies whether in-transit encryption is enabled for the image's boot volume attachment. Applies only to paravirtualized boot volume attachments. The default value is true.
- **Storage.ParaVirtualization.AttachmentVersion**: Specifies the paravirtualization version for boot volume and block volume attachments. Applies only to paravirtualized volume attachments. The default value is 2.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

For administrators, the following policy provides full access to the image capability schema framework:

```
Allow group IAM_group_name to manage compute-image-capability-schema in tenancy
```

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. Click the custom image that you're interested in.
3. Click Edit Image Capabilities.
4. Edit the image capabilities you want to configure. See Schema Elements on page 689 for details about the image capabilities you can configure.
5. Click **Save Changes**.

### Using the CLI

For information about using the CLI, see [Command Line Interface (CLI)](page 4192). To work with image capability schemas using the CLI, open a command prompt and run any of the following commands.

To list out the global image capability schema:

```
oci compute global-image-capability-schema list
```

To list out the global image capability schema versions:

```
oci compute global-image-capability-schema-version list --global-image-capability-schema-id <GLOBAL_IMAGE_CAPABILITY_SCHEMA_ID>
```

To retrieve the global image capability schema version:

```
oci compute global-image-capability-schema-version get --global-image-capability-schema-id <GLOBAL_IMAGE_CAPABILITY_SCHEMA_ID> --global-image-capability-schema-version-name <VERSION_NAME>
```

To list the image capability schemas in the specified compartment:

```
oci compute image-capability-schema list --compartment-id <COMPARTMENT_ID>
```

To retrieve the image capability schema for the specified ID:

```
oci compute image-capability-schema get --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID>
```

To update the specified image capability schema:

```
oci -d compute image-capability-schema update --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID> --schema-data file://<SCHEMA_DATA_FILE>.json
```

To create an image capability schema:

```
```

When you create the schema, you specify the image OCID for the custom image you want to apply the image capability schema to.

To delete the specified image capability schema:

```
oci -d compute image-capability-schema delete --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID>
```

### Using the API

For information about using the API and signing requests, see [REST APIs](page 4368) and [Security Credentials](page 179). For information about SDKs, see [Software Development Kits and Command Line Interface](page 4225).

Use the following API operations for working with image capability schemas:

- ListComputeGlobalImageCapabilitySchemas
- ListComputeGlobalImageCapabilitySchemaVersions
- GetComputeGlobalImageCapabilitySchema
OS Kernel Updates

**Note:**

This topic applies only to Linux instances that were launched before February 15, 2017. Linux instances launched on or after February 15, 2017 boot directly from the image and do not require further action for kernel updates.

Oracle Cloud Infrastructure boots each instance from a network drive. This configuration requires additional actions when you update the OS kernel.

Oracle Cloud Infrastructure uses Unified Extensible Firmware Interface (UEFI) firmware and a Preboot eXecution Environment (PXE) interface on the host server to load iPXE from a Trivial File Transfer Protocol (TFTP) server. The iPXE implementation runs a script to boot Oracle Linux. During the boot process, the system downloads the kernel, the initrd file, and the kernel boot parameters from the network. The instance does not use the host's GRUB boot loader.

Normally, the `yum update kernel-uek` command edits the GRUB configuration file, either `grub.cfg` or `grub.conf`, to configure the next boot. Since bare metal instances do not use the GRUB boot loader, changes to the GRUB configuration file are not implemented. When you update the kernel on your instance, you also must upload the update to the network to ensure a successful boot process. The following approaches address this need:

- Instances launched from an Oracle-provided image include an Oracle yum plug-in that seamlessly handles the upload when you run the `yum update kernel-uek` command.
- If you use a custom image based on an Oracle-provided image, the included yum plug-in will continue to work, barring extraordinary changes.
- If you install your own package manager, you must either write your own plug-in or upload the kernel, initrd, and kernel boot parameters manually.

**Oracle Yum Plug-in**

On instances launched with an Oracle-provided image, you can find the Oracle yum plug-in at:

```
/usr/share/yum-plugins/kernel-update-handler.py
```

The plug-in configuration is at:

```
/etc/yum/pluginconf.d
```

The plug-in looks for two variables in the `/etc/sysconfig/kernel` file, `UPDATEDEFAULT` and `DEFAULTKERNEL`. It picks up the updates only when the first variable is set to "yes" and the `DEFAULTKERNEL` value matches the kernel being updated. For example:

```
# UPDATEDEFAULT specifies if new-kernel-pkg should make
# new kernels the default
UPDATEDEFAULT=yes

# DEFAULTKERNEL specifies the default kernel package type
DEFAULTKERNEL=kernel-uek
```

Oracle-provided images incorporate the Unbreakable Enterprise Kernel (UEK). If you want to switch to a non-UEK kernel, you must update the `DEFAULTKERNEL` value to "kernel" before you run `yum update kernel`. 
Manual Updates

Tip:
Oracle recommends using the Oracle yum plug-in to update the kernel.

If you manually upload the updates, there are four relevant URLs:

- http://169.254.0.3/kernel
- http://169.254.0.3/initrd
- http://169.254.0.3/cmdline
- http://169.254.0.3/activate

The first three URLs are for uploading files (HTTP request type PUT). The fourth URL is for activating the uploaded files (HTTP request type POST). The system discards the uploaded files if they are not activated before the host restarts.

The kernel and initrd are simple file uploads. The cmdline upload must contain the kernel boot parameters found in the `grub.cfg` or `grub.conf` file, depending on the Linux version. The following example is an entry from the `/boot/efi/EFI/redhat/grub.cfg` file in Red Hat Linux 7. The highlighted text represents the parameters to upload.

```
kernel /boot/vmlinuz-4.1.12-37.5.1.el6uek.x86_64
ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_NO_LUKS
   KEYBOARDTYPE=pc KEYTABLE=us
   netroot=iscsi:@169.254.0.2::3260:iface1:eth0::iqn.2015-02.oracle.boot:uefi
   rd_NO_MD SYSFONT=latarcyrheb-sun16 ifname=eth0:90:e2:ba:a2:e3:80
   crashkernel=auto iscsi_initiator=iqn.2015-02.
   rd_NO_LVM ip=eth0:dhcp
   rd_NO_DM LANG=en_US.UTF-8 console=tty0 console=ttyS0,9600 iommu=on
```

The following command returns what is being uploaded to the cmdline file.

```
cat /tmp/cmdline
```

A typical response resembles the following.

```
ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_NO_LUKS
   KEYBOARDTYPE=pc KEYTABLE=us
   netroot=iscsi:@169.254.0.2::3260:iface1:eth0::iqn.2015-02.oracle.boot:uefi
   rd_NO_MD SYSFONT=latarcyrheb-sun16 ifname=eth0:90:e2:ba:a2:e3:80
   crashkernel=auto iscsi_initiator=iqn.2015-02.
   rd_NO_LVM ip=eth0:dhcp
   rd_NO_DM LANG=en_US.UTF-8 console=tty0 console=ttyS0,9600 iommu=on
```
The following commands update the cmdline and initrd files, and then activate the changes.

```bash
CKSUM=`md5sum /tmp/cmdline | cut -d ' ' -f 1`
sudo curl -X PUT --data-binary @/tmp/cmdline -H "Content-MD5: $CKSUM"
http://169.254.0.3/cmdline

CKSUM=`md5sum /boot/initramfs-3.8.13-118.8.1.el7uek.x86_64.img | cut -d ' ' -f 1`
sudo curl -X PUT --data-binary @/boot/initramfs-3.8.13-118.8.1.el7uek.x86_64.img -H "Content-MD5: $CKSUM"
http://169.254.0.3/initrd

sudo curl -X POST http://169.254.0.3/activate
```

### Managing Key Pairs on Linux Instances

Instances launched using Oracle Linux, CentOS, or Ubuntu images use an SSH key pair instead of a password to authenticate a remote user (see Security Credentials on page 179). A key pair consists of a private key and public key. You keep the private key on your computer and provide the public key when you create an instance. When you connect to the instance using SSH, you provide the path to the private key in the SSH command.

You can have as many key pairs as you want, or you can keep it simple and use one key pair for all or several of your instances.

If you're using OpenSSH to connect to an instance, you can use a key pair that is generated by Oracle Cloud Infrastructure at the time that you create the instance. OpenSSH should be installed on UNIX-based systems (including Linux and OS X), Windows 10, and Windows Server 2019.

To create your own key pairs, you can use a third-party tool such as OpenSSH on UNIX-style systems (including Linux, Solaris, BSD, and OS X) or PuTTY Key Generator on Windows.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anyone who has access to the private key can connect to the instance. Store the private key in a secure location.</td>
</tr>
</tbody>
</table>

### Required SSH Public Key Format

If you provide your own key pair, it must use the OpenSSH format.

A public key has the following format:

```
<key_type> <public_key> <optional_comment>
```

For example, an RSA public key looks like this:

```
ssh-rsa AAAAB3BzaC1yc2EAAAADAQABAAABAQD9BrwrUilDki6P0+j2hwsjS2muM...
...yXDus/5Dr== rsa-key-20201202
```

For Oracle-provided images, these SSH key types are supported: RSA, DSA, DSS, ECDSA, and Ed25519. If you bring your own image, you're responsible for managing the SSH key types that are supported.

For RSA, DSS, and DSA keys, a minimum of 2048 bits is recommended. For ECDSA keys, a minimum of 256 bits is recommended.
Prerequisites

- If you're using a UNIX-style system, you probably already have the `ssh-keygen` utility installed. To determine whether it's installed, type `ssh-keygen` on the command line. If it's not installed, you can download OpenSSH for UNIX from [http://www.openssh.com/portable.html](http://www.openssh.com/portable.html) and install it.
- If you're using a Windows operating system, you will need PuTTY and the PuTTY Key Generator. Download PuTTY and PuTTYgen from [http://www.putty.org](http://www.putty.org) and install them.

Creating an SSH Key Pair on the Command Line

1. Open a shell or terminal for entering the commands.
2. At the prompt, enter `ssh-keygen` and provide a name for the key when prompted. Optionally, include a passphrase.

   The keys will be created with the default values: RSA keys of 2048 bits.

Alternatively, you can type a complete `ssh-keygen` command, for example:

```
ssh-keygen -t rsa -N "" -b 2048 -C "<key_name>" -f <path/root_name>
```

The command arguments are shown in the following table:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-t rsa</code></td>
<td>Use the RSA algorithm.</td>
</tr>
<tr>
<td><code>-N &quot;&lt;passphrase&gt;&quot;</code></td>
<td>A passphrase to protect the use of the key (like a password). If you don't want to set a passphrase, don't enter anything between the quotes. A passphrase is not required. You can specify one as a security measure to protect the private key from unauthorized use. If you specify a passphrase, when you connect to the instance you must provide the passphrase, which typically makes it harder to automate connecting to an instance.</td>
</tr>
<tr>
<td><code>-b 2048</code></td>
<td>Generate a 2048-bit key. You don't have to set this if 2048 is acceptable, as 2048 is the default. A minimum of 2048 bits is recommended for SSH-2 RSA.</td>
</tr>
<tr>
<td><code>-C &quot;&lt;key_name&gt;&quot;</code></td>
<td>A name to identify the key.</td>
</tr>
<tr>
<td><code>-f &lt;path/root_name&gt;</code></td>
<td>The location where the key pair will be saved and the root name for the files.</td>
</tr>
</tbody>
</table>

Creating an SSH Key Pair Using PuTTY Key Generator

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, `C:\Program Files (x86)\PuTTY`. Double-click `puttygen.exe` to open it.
2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the **Key** menu, confirm that the default value of **SSH-2 RSA key** is selected.
   - For the **Type of key to generate**, accept the default key type of **RSA**.
   - Set the **Number of bits in a generated key** to 2048 if it is not already set.
3. Click **Generate**.
4. Move your mouse around the blank area in the PuTTY window to generate random data in the key.

When the key is generated, it appears under **Public key for pasting into OpenSSH authorized_keys file**.

5. A Key comment is generated for you, including the date and time stamp. You can keep the default comment or replace it with your own more descriptive comment.

6. Leave the Key passphrase field blank.

7. Click Save private key, and then click Yes in the prompt about saving the key without a passphrase.

The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.

You can name the key anything you want, but use the .ppk file extension. For example, mykey.ppk.

8. Select all of the generated key that appears under **Public key for pasting into OpenSSH authorized_keys file**, copy it using Ctrl + C, paste it into a text file, and then save the file in the same location as the private key.

(Do not use Save public key because it does not save the key in the OpenSSH format.)

You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of .pub. For example, mykey.pub.

9. Write down the names and location of your public and private key files. You will need the public key when launching an instance. You will need the private key to access the instance via SSH.

Now that you have a key pair, you're ready to launch instances as described in Creating an Instance on page 695.

**Creating an Instance**

Use the steps in this topic to create a bare metal or virtual machine (VM) Compute instance.

**Tip:**

If this is your first time creating an instance, consider following the Getting Started Tutorial for a guided workflow through the steps required to create an instance.

When you create an instance, the instance is automatically attached to a virtual network interface card (VNIC) in the cloud network's subnet and given a private IP address from the subnet's CIDR. You can let the IP address be automatically assigned, or you can specify a particular address of your choice. The private IP address lets instances within the cloud network communicate with each other. If you've set up the cloud network for DNS, instances can instead use fully qualified domain names (FQDNs).

If the subnet is public, you can optionally assign the instance a public IP address. A public IP address is required to communicate with the instance over the internet, and to establish a Secure Shell (SSH) or Remote Desktop Protocol (RDP) connection to the instance from outside the cloud network.

**Note:**

Partner images and pre-built Oracle enterprise images are not available in Government Cloud realms.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

**Tip:**

When you create an instance, several other resources are involved, such as an image, a cloud network, and a subnet. Those other resources can be in the same **compartment** with the instance or in other compartments. You must have the required level of access to each of the compartments involved in
In order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

For administrators: The simplest policy to enable users to create instances is listed in Let users launch compute instances on page 2143. It gives the specified group general access to manage instances and images, along with the required level of access to attach existing block volumes to the instances. If the group needs to create block volumes, they'll need the ability to manage block volumes (see Let volume admins manage block volumes, backups, and volume groups on page 2146).

To require that legacy instance metadata service endpoints are disabled on any new instances that are created, use the following policy:

```
Allow group InstanceLaunchers to manage instances in compartment ABC where request.instanceOptions.areLegacyEndpointsDisabled= 'true'
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Partner Image Catalog**

If the group needs to create instances based on partner images, they'll need the manage permission for app-catalog-listing to create subscriptions to images from the Partner Image catalog. See Let users list and subscribe to images from the Partner Image catalog on page 2145.

**Security Zones**

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to create instances:

- The boot volume for a compute instance in a security zone must also be in a security zone.
- A compute instance that isn't in a security zone can't use a boot volume that is in a security zone.
- A compute instance in a security zone must use subnets that are also in a security zone.
- All compute instances in a security zone must be created using an Oracle-provided image. You can't create a compute instance from a custom image in a security zone.

**Recommended Networking Launch Types**

When you launch a VM instance, by default, Oracle Cloud Infrastructure chooses a recommended networking type for the VNIC based on the instance shape and OS image. The networking interface handles functions such as disk input/output and network communication. The following options are available:

- **Paravirtualized networking**: For general purpose workloads such as enterprise applications, microservices, and small databases. Paravirtualized networking also provides increased flexibility to use the same image across different hardware platforms. Linux images with paravirtualized networking support live migration during infrastructure maintenance.
- **Hardware-assisted (SR-IOV) networking**: Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases. Hardware-assisted (SR-IOV) networking uses the VFIO driver framework.

**Note:**

On Windows Server 2012 R2 images, SR-IOV networking is only supported on the VM.Standard2 and VM.DenseIO2 shapes.

The following table lists the default and supported networking types for VM shapes.
<table>
<thead>
<tr>
<th>Shape series</th>
<th>Default Networking Type</th>
<th>Supported Networking Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard.E2</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Due to driver support, the Windows Server 2012 platform image supports paravirtualized networking only.</td>
</tr>
<tr>
<td>VM.DenseIO1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU2</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
</tbody>
</table>

To use paravirtualized networking, you must also use an image that supports paravirtualized networking. Paravirtualized networking is supported on these Oracle-provided images:

- **Oracle Linux 8**: All images.
- **Oracle Linux 7, Oracle Linux 6**: Images published in March 2019 or later.
- **CentOS 8**: All images.
- **CentOS 7**: Images published in July 2019 or later.
- **Ubuntu 18.04, Ubuntu 16.04**: Images published in March 2019 or later.
- **Windows Server 2019**: All images.
- **Windows Server 2016**: Images published in August 2019 or later.

SR-IOV networking is supported on all Oracle-provided images, except for Windows Server 2019 when launched using a VM.Standard2 shape. On Windows Server 2012 R2, SR-IOV networking is only supported on the VM.Standard2 and VM.DenseIO2 shapes.

You can create an instance that uses a specific networking type instead of the default. However, depending on compatibility between the shape and image that you choose, the instance might not launch properly. You can test whether it succeeded by connecting to the instance. If the connection fails, the networking type is not supported. Relaunch the instance using a supported networking type.

**Creating a Linux Instance**

Use the following steps to create a Linux instance.

**Prerequisites**

Before you start, you need these things:

- If you want to use your own Secure Shell (SSH) key to connect to the instance using SSH, you need the public key from the SSH key pair that you plan to use. The key must be in OpenSSH format. For more information, see Managing Key Pairs on Linux Instances on page 693.

**To create a Linux instance**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click Create Instance.
3. Enter a name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.

4. Select the compartment to create the instance in.

   The other resources that you choose can come from different compartments.

5. In the **Placement and hardware** section, make the following selections:

   a. Select the **Availability domain** that you want to create the instance in.

      **Note:**

      If you're creating an instance from a boot volume, you must create the instance in the same availability domain as the boot volume.

   b. **Choose a fault domain**: The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. To change the fault domain for a VM instance after you create the instance, edit the fault domain. For more information, see Fault Domains on page 182 and Best Practices for Your Compute Instance on page 594.

   c. By default, an Oracle Linux 7.x **image** is used to boot the instance. To select a different image or a boot volume, in the **Image** section, click **Change Image**. Then, select an **Image source** from the list. The following options are available:

      - **Platform Images**: Pre-built images for Oracle Cloud Infrastructure. To select a different OS version or image build, select the check box next to an image, and then select a value from the lists in the row for the image. To see which shapes are compatible with an OS version and image build, click **Advanced Options**. For more information about platform images, see Oracle-Provided Images on page 629.
      - **Oracle Images**: Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
      - **Partner Images**: Trusted third-party images published by Oracle partners. Click the down arrow in the row for an image to view more details about the image, or to change the image build. For more information, see Overview of Marketplace on page 2650 and Working with Listings on page 2651.
      - **Custom Images**: Custom images created or imported into your Oracle Cloud Infrastructure environment. For more information, see Managing Custom Images on page 665.
      - **Boot Volumes**: Boot volumes that are available for creating a new instance in your Oracle Cloud Infrastructure environment. For more information, see Boot Volumes on page 609.
      - **Image OCID**: Create an instance using a specific version of an image by providing the image **OCID**. To determine the image OCID for Oracle-provided images, see Oracle-Provided Image Release Notes.

   Choose an image or boot volume, and then click **Select Image**.

   d. In the **Shape** section, click **Change Shape**. Then, do the following:

      1. In the **Instance type** section, select **Virtual Machine** or **Bare Metal Machine**.
      2. If you're creating a virtual machine, in the **Shape series** section, select a processor group, and then choose a **shape**. The following options are available:

         - **AMD Rome**: The **flexible shapes**, which uses the current generation AMD processor and has a customizable number of OCPUs and amount of memory.

         - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.

         - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For each OCPU, you can select up to 64 GB of memory, with a maximum of 1024 GB total. The minimum amount of memory allowed is either 1 GB or a value matching the number
of OCPUs, whichever is greater. For example, if you select 25 OCPUs, the minimum amount of memory allowed is 25 GB.

The other resources scale proportionately.

- **Intel Skylake**: Standard shapes that use the current generation Intel processor and have a fixed number of OCPUs.
- **Specialty and Legacy**: Standard shapes with previous generation Intel and AMD processors, the Always Free VM.Standard.E2.1.Micro shape, Dense I/O shapes, GPU shapes, and HPC shapes.

If a shape is disabled, it means that the shape is either incompatible with the image that you selected previously, or not available in the current availability domain. If you don't see a shape, it means that you don't have service limits for the shape. You can request a service limit increase.

For more information about shapes, see Compute Shapes on page 655.

3. Click **Select Shape**.

6. In the **Networking** section, decide whether you want to **Select an existing virtual cloud network**, **Create a new virtual cloud network and subnet**, or **Enter a subnet OCID**, and then configure the network details for the instance.

**Select existing virtual cloud network**

Make the following selections:

- **Virtual cloud network in <compartment_name>**: Select the cloud network. If necessary, click **Change compartment** to switch to the compartment that contains the cloud network.
- **Subnet**: A subnet within the cloud network that the instance is attached to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.

If choosing **Select existing subnet**, for **Subnet in <compartment_name>**, select the subnet. If necessary, click **Change compartment** to switch to the compartment that contains the correct subnet.

If choosing **Create new public subnet**, enter the following:

- **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
- **Create in compartment**: Specify the compartment where you want to put the subnet.
- **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.

**Create new virtual cloud network and subnet**

Make the following selections:

- **New virtual cloud network name**: A friendly name for the network. Avoid entering confidential information.
- **Create in compartment**: Specify the compartment where you want to put the new network.
- **Subnet**: A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional"
Compute

after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.

Leave Create new public subnet selected, and enter the following:

- **Subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
- **Create in compartment**: Specify the compartment where you want to put the subnet.
- **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.

**Enter subnet OCID**

For Subnet OCID, enter the subnet OCID.

7. If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the Assign a public IPv4 address option. For more information, see Access to the Internet on page 2752.

8. In the Add SSH keys section, generate an SSH key pair or upload your own public key. Select one of the following options:

- **Generate SSH keys**: Oracle Cloud Infrastructure generates an RSA key pair for the instance. Click Save Private Key, and then save the private key on your computer. Optionally, click Save Public Key and then save the public key.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anyone who has access to the private key can connect to the instance.</td>
</tr>
<tr>
<td>Store the private key in a secure location.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To use a key pair that is generated by Oracle Cloud Infrastructure, you must access the instance from a system that has OpenSSH installed. UNIX-based systems (including Linux and OS X), Windows 10, and Windows Server 2019 should have OpenSSH. For more information, see Managing Key Pairs on Linux Instances on page 693.</td>
</tr>
</tbody>
</table>

- **Choose SSH key files**: Upload the public key portion of your key pair. Either browse to the key file that you want to upload, or drag and drop the file into the box. To provide multiple keys, press and hold down the Command key (on Mac) or the CTRL key (on Windows) while selecting files.

- **Paste SSH keys**: Paste the public key portion of your key pair in the box.

- **No SSH keys**: Select this option only if you do not want to connect to the instance using SSH. You cannot provide a public key or save the key pair that is generated by Oracle Cloud Infrastructure after the instance is created.

9. In the Boot volume section, configure the size and encryption options for the instance's boot volume:

- To specify a custom size for the boot volume, select the Specify a custom boot volume size check box. Then, enter a custom size from 50 GB to 32 TB. The specified size must be larger than the default boot volume size for the selected image. See Custom Boot Volume Sizes on page 610 for more information.

- For VM instances, you can optionally select the Use in-transit encryption check box. See Block Volume Encryption on page 504 for more information. If you are using your own Vault service encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.

- Boot volumes are encrypted by default, but you can optionally use your own Vault service encryption key to encrypt the data in this volume. To use the Vault service for your encryption needs, select the Encrypt this volume with a key that you manage check box. Then, select the Vault compartment and Vault that contain the master encryption key you want to use. Also select the Master encryption key compartment and Master
encryption key. For more information about encryption, see Overview of Vault on page 3952. If you enable this option, this key is used for both data at rest encryption and in-transit encryption.

- The Block Volume elastic performance feature lets you change the volume performance for boot volumes. When you create an instance, its boot volume is configured with the default volume performance set to Balanced. After you launch the instance, you can modify the performance setting. For steps to modify the performance setting, see Changing the Performance of a Volume on page 582. For more information about this feature, see Block Volume Elastic Performance on page 581.

10. (Optional) To configure advanced networking and management settings, click Show Advanced Options. The following options are available:

- On the Management tab, you can configure the following:
  - **Require an authorization header:** Select this check box to require that all requests to the instance metadata service (IMDS) use the version 2 endpoint and include an authorization header. Requests to IMDSv1 are denied. The image must support IMDSv2. For more information, see Getting Instance Metadata on page 757.
  - **Initialization Script:** User data to be used by cloud-init to run custom scripts or provide custom cloud-init configuration. Browse to the file that you want to upload, or drag and drop the file into the box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the cloud-init documentation. The total maximum size for user data and other metadata that you provide is 32,000 bytes.
  - **Restore instance lifecycle state after infrastructure maintenance:** By default, if a VM instance is running when a maintenance event affects the underlying infrastructure, the instance is rebooted after it is recovered. Clear this check box if you want the instance to be recovered in the stopped state.
  - **Tagging:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- On the Networking tab, you can configure the following:
  - **Private IP Address:** An available private IP address of your choice from the subnet's CIDR. If you don't specify a value, the private IP address is automatically assigned.
  - **Hostname:** A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see DNS in Your Virtual Cloud Network on page 2910.
  - **Launch Options:** The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types on page 696.

- On the Placement tab, you can choose to launch the instance on a dedicated virtual machine host. This lets you run the instance in isolation, so that it is not running on shared infrastructure. To do this, select the Dedicated host option, and then select a dedicated virtual machine host from the drop-down list. Before you can place an instance on a dedicated virtual machine host, you must create a dedicated virtual machine host in the same availability domain and fault domain as the instance. You can only place an instance on a dedicated virtual machine host at the time that you create the instance. For more information, see Dedicated Virtual Machine Hosts on page 729.

- On the Oracle Cloud Agent tab, choose which plugins you want to enable when the instance is launched. Plugins collect performance metrics, install OS updates, and perform other instance management tasks. For more information, see Managing Plugins with Oracle Cloud Agent on page 740.

Important:

Be aware of the following:

- After you create the instance, you might need to perform additional configuration tasks before you can use each plugin.
- Oracle Autonomous Linux instances cannot be managed by the OS Management service. See this known issue for more information.
11. Click **Create**.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

After the instance is provisioned, details about it appear in the instance list. To view more details, including IP addresses, click the instance name.

When the instance is fully provisioned and running, you can connect to it using SSH as described in Connecting to an Instance on page 733.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume on page 500.

For steps to let additional users connect to the instance, see Adding Users on an Instance on page 737.

**Creating a Windows Instance**

Use the following steps to create a Windows instance.

**Prerequisites**

Before you start, you need these things:

- A VCN security rule that enables Remote Desktop Protocol (RDP) access so that you can connect to your instance. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Rules on page 2833. You can implement...
To enable RDP access

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you’re not sure which compartment to use, contact an administrator.
3. Click the cloud network that you’re interested in.
4. To add the rule to a network security group that the instance belongs to:
   a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
   b. Click **Add Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click **Add**.
5. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
   b. Click **Add Ingress Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click **Add Ingress Rules**.

To create a Windows instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click **Create Instance**.
3. Enter a name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.
   **Important:**
   Use only these ASCII characters in the instance name: uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), and hyphens (-). See this [known issue](#) for more information.
4. Select the compartment to create the instance in.
   The other resources that you choose can come from different compartments.
5. In the **Placement and hardware** section, make the following selections:

   a. Select the **Availability domain** that you want to create the instance in.

   ![](image)

   **Note:**
   
   If you're creating an instance from a boot volume, you must create the instance in the same availability domain as the boot volume.

   b. **Choose a fault domain**: The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. To change the fault domain for a VM instance after you create the instance, edit the fault domain. For more information, see **Fault Domains** on page 182 and **Best Practices for Your Compute Instance** on page 594.

   c. In the **Image** section, you choose the **image** that's used to boot the instance. Click **Change Image**. Then, select an **Image source** from the list. The following options are available:

   - **Platform Images**: Pre-built images for Oracle Cloud Infrastructure. To select a different OS version or image build, select the check box next to an image, and then select a value from the lists in the row for the image. To see which shapes are compatible with an OS version and image build, click **Advanced Options**. For more information about platform images, see **Oracle-Provided Images** on page 629.
   
   - **Oracle Images**: Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
   
   - **Partner Images**: Trusted third-party images published by Oracle partners. Click the down arrow in the row for an image to view more details about the image, or to change the image build. For more information, see **Overview of Marketplace** on page 2650 and **Working with Listings** on page 2651.
   
   - **Custom Images**: Custom images created or imported into your Oracle Cloud Infrastructure environment. For more information, see **Managing Custom Images** on page 665.
   
   - **Boot Volumes**: Boot volumes that are available for creating a new instance in your Oracle Cloud Infrastructure environment. For more information, see **Boot Volumes** on page 609.
   
   - **Image OCID**: Create an instance using a specific version of an image by providing the image **OCID**. To determine the image OCID for Oracle-provided images, see **Oracle-Provided Image Release Notes**.

   Choose an image or boot volume, and then click **Select Image**.

   d. In the **Shape** section, click **Change Shape**. Then, do the following:

   1. In the **Instance type** section, select **Virtual Machine** or **Bare Metal Machine**.
   2. If you're creating a virtual machine, in the **Shape series** section, select a processor group, and then choose a **shape**. The following options are available:

   - **AMD Rome**: The **flexible shapes**, which uses the current generation AMD processor and has a customizable number of OCPUs and amount of memory.

     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.
     
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For each OCPU, you can select up to 64 GB of memory, with a maximum of 1024 GB total. The minimum amount of memory allowed is either 1 GB or a value matching the number...
of OCPUs, whichever is greater. For example, if you select 25 OCPUs, the minimum amount of memory allowed is 25 GB.

The other resources scale proportionately.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For Windows Server 2019 instances using the VM.Standard.E3.Flex shape, allocate a maximum of 32 OCPUs to the instance. See this known issue for more information.</td>
</tr>
</tbody>
</table>

- **Intel Skylake**: Standard shapes that use the current generation Intel processor and have a fixed number of OCPUs.

- **Specialty and Legacy**: Standard shapes with previous generation Intel and AMD processors, the Always Free VM.Standard.E2.1.Micro shape, Dense I/O shapes, GPU shapes, and HPC shapes.

If a shape is disabled, it means that the shape is either incompatible with the image that you selected previously, or not available in the current availability domain. If you don't see a shape, it means that you don't have service limits for the shape. You can request a service limit increase.

For more information about shapes, see Compute Shapes on page 655.

3. Click Select Shape.

6. In the Networking section, decide whether you want to Select an existing virtual cloud network, Create a new virtual cloud network and subnet, or Enter a subnet OCID, and then configure the network details for the instance.

**Select existing virtual cloud network**

Make the following selections:

- **Virtual cloud network in <compartment_name>**: Select the cloud network. If necessary, click Change compartment to switch to the compartment that contains the cloud network.

- **Subnet**: A subnet within the cloud network that the instance is attached to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.

If choosing Select existing subnet, for Subnet in <compartment_name>, select the subnet. If necessary, click Change compartment to switch to the compartment that contains the correct subnet.

If choosing Create new public subnet, enter the following:

- **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.

- **Create in compartment**: Specify the compartment where you want to put the subnet.

- **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.

**Create new virtual cloud network and subnet**

Make the following selections:

- **New virtual cloud network name**: A friendly name for the network. Avoid entering confidential information.

- **Create in compartment**: Specify the compartment where you want to put the new network.

- **Subnet**: A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional"
after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.

Leave Create new public subnet selected, and enter the following:

- **Subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
- **Create in compartment**: Specify the compartment where you want to put the subnet.
- **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 2750. For reference, here's a CIDR calculator.

**Enter subnet OCID**

For Subnet OCID, enter the subnet OCID.

7. If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the Assign a public IPv4 address option. For more information, see Access to the Internet on page 2752.

8. In the **Boot volume** section, configure the size and encryption options for the instance's boot volume:

- To specify a custom size for the boot volume, select the Specify a custom boot volume size check box. Then, enter a custom size from 50 GB (256 GB for Oracle-provided Windows images) to 32 TB. The specified size must be larger than the selected image's default boot volume size. See Custom Boot Volume Sizes on page 610 for more information.
- For VM instances, you can optionally select the Use in-transit encryption check box. See Block Volume Encryption on page 504 for more information. If you are using your own Vault service encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.
- Boot volumes are encrypted by default, but you can optionally use your own Vault service encryption key to encrypt the data in this volume. To use the Vault service for your encryption needs, select the Encrypt this volume with a key that you manage check box. Then, select the Vault compartment and Vault that contain the master encryption key you want to use. Also select the Master encryption key compartment and Master encryption key. For more information about encryption, see Overview of Vault on page 3952.
- The Block Volume elastic performance feature lets you change the volume performance for boot volumes. When you create an instance, its boot volume is configured with the default volume performance set to Balanced. After you launch the instance, you can modify the performance setting. For steps to modify the performance setting, see Changing the Performance of a Volume on page 582. For more information about this feature, see Block Volume Elastic Performance on page 581.

9. (Optional) To configure advanced networking and management settings, click Show Advanced Options. The following options are available:

- On the Management tab, you can configure the following:
  - **Choose a fault domain**: The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. You can change the fault domain for a VM instance after you create the instance. For more information about fault domains, see Fault Domains on page 182 and Best Practices for Your Compute Instance on page 594.
  - **Require an authorization header**: Select this check box to require that all requests to the instance metadata service (IMDS) use the version 2 endpoint and include an authorization header. Requests to IMDSv1 are denied. The image must support IMDSv2. For more information, see Getting Instance Metadata on page 757.
  - **Initialization Script**: User data to be used by cloudbase-init to run custom scripts or provide custom cloudbase-init configuration. Browse to the file that you want to upload, or drag and drop the file into the box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the...
cloudbase-init documentation. The total maximum size for user data and other metadata that you provide is 32,000 bytes.

Caution:

Do not include anything in the script that could trigger a reboot, because this could impact the instance launch and cause it to fail. Any actions requiring a reboot should only be performed once the instance state is Running.

- **Restore instance lifecycle state after infrastructure maintenance**: By default, if a VM instance is running when a maintenance event affects the underlying infrastructure, the instance is rebooted after it is recovered. Clear this check box if you want the instance to be recovered in the stopped state.

- **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

- On the Networking tab, you can configure the following:
  - **Private IP address**: An available private IP address of your choice from the subnet's CIDR. If you don’t specify a value, the private IP address is automatically assigned.
  - **Hostname**: A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see DNS in Your Virtual Cloud Network on page 2910.
  - **Launch Options**: The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types on page 696.

- On the Placement tab, you can choose to launch the instance on a dedicated virtual machine host. This lets you run the instance in isolation, so that it is not running on shared infrastructure. To do this, select the Dedicated host option, and then select a dedicated virtual machine host from the drop-down list. Before you can place an instance on a dedicated virtual machine host, you must create a dedicated virtual machine host in the same availability domain and fault domain as the instance. You can only place an instance on a dedicated virtual machine host at the time you create the instance. For more information, see Dedicated Virtual Machine Hosts on page 729.

- On the Oracle Cloud Agent tab, choose which plugins you want to enable when the instance is launched. Plugins collect performance metrics, install OS updates, and perform other instance management tasks. For more information, see Managing Plugins with Oracle Cloud Agent on page 740.

Important:

After you create the instance, you might need to perform additional configuration tasks before you can use each plugin.

10. Click Create.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

After the instance is provisioned, details about it appear in the instance list. To view more details, including IP addresses and the initial Windows password, click the instance name.

When the instance is fully provisioned and running, you can connect to it using Remote Desktop as described in Connecting to an Instance on page 733.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume on page 500.

For steps to let additional users connect to the instance, see Adding Users on an Instance on page 737.
Managing Tags for an Instance

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

To manage tags for an instance

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click More Actions, and then click Add tags to add new ones.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage instances:

- ListInstances
- LaunchInstance
- GetInstance
- UpdateInstance
- TerminateInstance
- GetInstanceDefaultCredentials

You can also launch instances from images that are published by Oracle partners in the Partner Image catalog. Use these APIs to work with the Partner Image catalog listings:

- AppCatalogListing
- AppCatalogListingResourceVersion
- AppCatalogListingResourceVersionAgreements
- AppCatalogListingResourceVersionSummary
- AppCatalogListingSummary
- AppCatalogSubscription

Managing Compute Instances

You can simplify the management of your Compute instances using resources such as instance configurations and instance pools.

An instance configuration is a template that defines the settings to use when creating Compute instances.

An instance pool is a group of instances within the same region that are created from the same instance configuration and managed as a group.

Instance Configurations

An instance configuration defines the settings to use when creating Compute instances, including details such as the base image, shape, and metadata. You can also specify the associated resources for the instance, such as block volume attachments and network configuration.

For steps to create an instance configuration, see Creating an Instance Configuration on page 710.

To modify an existing instance configuration, create a new instance configuration with the desired settings.

For steps to delete an instance configuration, see Deleting an Instance Configuration on page 717.

Use these API operations to work with instance configurations:

- CreateInstanceConfiguration
• **DeleteInstanceConfiguration**
• **GetInstanceConfiguration**
• **UpdateInstanceConfiguration**
• **ListInstanceConfigurations**

**Instance Pools**

Instance pools let you create multiple Compute instances from the same instance configuration, within the same region. They also enable integration with other services, such as the Load Balancing service and IAM service, making it easier to manage groups of instances.

You create an instance pool using an existing instance configuration. For steps, see Creating an Instance Pool on page 711.

You can automatically adjust the number of instances in an instance pool based on performance metrics or a schedule. To do this, you enable autoscaling for the instance pool. For background information and steps, see Autoscaling on page 718.

After you have created an instance pool, you can update the size and attach or detach load balancers from the Console. To update additional settings, you need to use the CLI, API, or SDKs.

If you need to update the instance configuration, create a new instance configuration and then update the instance pool to use the new instance configuration. For more information, see Updating an Instance Pool on page 713.

A cluster network is a special kind of instance pool that is designed for massive, high-performance computing jobs. For more information, see Managing Cluster Networks on page 726.

For steps to delete an instance pool, see Deleting an Instance Pool on page 718.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you delete an instance pool all of its resources will be permanently deleted, including associated instances, attached boot volumes, and block volumes.</td>
</tr>
</tbody>
</table>

**Instance Pool Lifecycle States**

The following list describes the different lifecycle states for instance pools.

- **Provisioning**: When you create an instance pool, this is the first state the instance pool is in. Instances for the instance pool are being configured based on the specified instance configuration.
- **Starting**: The instances are being launched. At this point, the only action you can take is to terminate the instance pool.
- **Running**: The instances are created and running.
- **Stopped**: The instances are in the process of being shut down.
- **Stopped**: The instances are shut down.
- **Scaling**: After an instance pool has been created, if you update the instance pool size, it will go into this state while creating instances (for increases in pool size) or terminating instances (for decreases in pool size). At this point, the only action you can take is to terminate the instance pool.
- **Terminating**: The instances and associated resources are being terminated.
- **Terminated**: The instance pool, all its instances and associated resources are terminated.

When working with instance configurations and instance pools, keep the following in mind:

- You can't delete an instance configuration if it is associated with at least one instance pool.
- You can use the same instance configuration for multiple instance pools. However, an instance pool can have only one instance configuration associated with it.
- If the instance pool has been in the scaling or provisioning state for an extended period of time, it might be because the number of instances that were requested has exceeded your tenancy's service limits for that
availability domain. For information about how to check your service limits, and steps to request a service limit increase, see Service Limits on page 215. If this occurs, you need to terminate the instance pool and re-create it.

- If you modify the instance configuration for an instance pool, existing instances that are part of that pool will not change. Any new instances that are created after you modify the instance configuration will use the new instance configuration. New instances will not be created unless you have increased the size of the instance pool or terminate existing instances.
- If you decrease the size of an instance pool, the oldest instances are terminated first.

Use these API operations to manage instance pools:

- CreateInstancePool
- GetInstancePool
- ResetInstancePool
- SoftresetInstancePool
- StartInstancePool
- StopInstancePool
- TerminateInstancePool
- UpdateInstancePool
- ListInstancePools
- ListInstancePoolInstances
- AttachLoadBalancer
- DetachLoadBalancer
- GetInstancePoolLoadBalancerAttachment

Creating an Instance Configuration

Instance configurations let you define the settings to use when creating Compute instances.

You use an instance configuration when you want to create one or more instances in an instance pool. For background information about instance pools, see Managing Compute Instances on page 708.

You can also use an instance configuration to launch individual instances that are not part of a pool. To do this, use the SDKs, command line interface (CLI), or API.

In the Console, you create an instance configuration using an existing Compute instance as a template. If you want to create an instance configuration by specifying a list of configuration settings, use the SDKs, CLI, or API.

When you create an instance configuration using an existing instance as a template, be aware of the following information:

- The instance configuration does not include any information from the instance's boot volume, such as installed applications, binaries, and files on the instance. To create an instance configuration that includes the custom setup from an instance, you must first create a custom image from the instance, and then use the custom image to launch a new instance. Finally, create the instance configuration based on the instance that you created from the custom image.
- The instance configuration does not include the contents of any block volumes that are attached to the instance. To include block volume contents with an instance configuration, first create a backup of the attached block volumes. Then, use the SDKs, CLI, or API to create the instance configuration, specifying the block volume backups in the list of configuration settings.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.
Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

Using the Console

To create an instance configuration

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance whose image you want to use as a template to create the instance configuration.
3. Click More Actions, and then click Create Instance Configuration.
4. Select the compartment you want to create the instance configuration in.
5. Specify a name for the instance configuration. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
6. Show Tagging Options: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.
7. Click Create Instance Configuration.

To manage tags for an instance configuration

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Configurations.
2. Click the instance configuration that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

For more information, see Resource Tags on page 211.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the CreateInstanceConfiguration operation to create an instance configuration.

Creating an Instance Pool

Use instance pools to create multiple compute instances from the same configuration, within the same region. You can manage the instances in an instance pool as a group. For more information about instance pools and instance configurations, see Managing Compute Instances on page 708.

Optionally, you can associate one or more load balancers with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set. After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance. For background information about the Load Balancing service, see Overview of Load Balancing on page 2480.

Instance pools are supported for virtual machine (VM) and bare metal instances.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.
Tagging Resources
You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

Distributing Instances Across Fault Domains for High Availability
By default, the instances in a pool are distributed across all fault domains in a best-effort manner based on capacity. If capacity isn't available in one fault domain, the instances are placed in other fault domains to allow the instance pool to launch successfully.

In a high availability scenario, you can require that the instances in a pool are evenly distributed across each of the fault domains that you specify. When sufficient capacity isn't available in one of the fault domains, the instance pool will not launch or scale successfully, and a work request for the instance pool will return an “out of capacity” error. To fix the capacity error, either wait for capacity to become available, or use the UpdateInstancePool operation to update the placement configuration (the availability domain and fault domain) for the instance pool.

Prerequisites
Before you can create an instance pool, you need:

- An instance configuration. An instance configuration is a template that defines the settings to use when creating instances. When you create the instance pool, monitoring will be enabled by default on instances that support monitoring, regardless of the settings in the instance configuration. For more information, see Creating an Instance Configuration on page 710.

  Note:
  You cannot create an instance pool from an instance configuration where the image source is a boot volume.

- If you want to associate the instance pool with a load balancer, you need a load balancer and backend set. For steps to create a load balancer, see Managing Load Balancers on page 2494.

Using the Console
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click Create Instance Pool.
3. On the Add Basic Details page, do the following:
   a. Select the compartment to create the instance pool in.
   b. Enter a name for the instance pool. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   c. Select the Instance configuration that you want to use.
   d. Specify the targeted Number of instances for the instance pool.
   e. Show Tagging Options: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.
4. Click Next.
5. On the Configure Pool Placement page, select the location where you want to place the instances. Do the following:
   a. Select the Availability domain to launch the instances in.
   b. For the Fault domains box, do one of the following things:
      - If you want the system to make a best effort to distribute instances across fault domains based on capacity, leave the box blank.
      - If you want to require that the instances in the pool are distributed evenly in one or more fault domains, select the fault domains to place the instances in. The pool will not launch or scale successfully if sufficient
Compute capacity is unavailable in the selected fault domains. For more information, see Distributing Instances Across Fault Domains for High Availability on page 712.

c. In the Primary VNIC section, configure the network details for the instances:

- **Virtual cloud network:** The virtual cloud network (VCN) to create the instances in.
- **Subnet:** A subnet within the cloud network to attach the instances to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 2752. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 2822.

d. If secondary VNICs are defined by the instance configuration, a Secondary VNIC section appears. Select the secondary VCN and subnet for the instance pool.

e. If you want the instance pool to create instances in more than one availability domain, click + Another Availability Domain. Then, repeat the previous steps.

6. If you want to associate a load balancer with the instance pool, select the Attach a load balancer check box. Then, do the following:

   a. Select the Load balancer to associate with the instance pool.
   b. Select the Backend set on the load balancer to add instances to.
   c. In the Port box, enter the server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   d. In the VNIC list, select the VNIC to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.
   e. If you want to associate additional load balancers with the instance pool, click + Another Load Balancer. Then, repeat the previous steps. Do this for each additional load balancer you want to associate with the instance pool.

For background information about load balancers, see Overview of Load Balancing on page 2480.

7. Click Next.

8. Review the instance pool details, and then click Create.

   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create and manage instance pools:

- CreateInstancePool
- AttachLoadBalancer
- DetachLoadBalancer
- GetInstancePoolLoadBalancerAttachment

Updating an Instance Pool

You can update the number of instances for an instance pool.

Optionally, you can associate a load balancer with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set. After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance. For background information about the Load Balancing service, see Overview of Load Balancing on page 2480.

To update other settings for an instance pool, use the command line interface (CLI), SDKs, or REST APIs.
Compute

You can automatically adjust the number of instances in an instance pool based on performance metrics or a schedule. To do this, you enable autoscaling for the instance pool. For background information and steps, see Autoscaling on page 718.

See Managing Compute Instances on page 708 for more information about instance pools and instance configurations.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.

**Tagging Resources**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

**Using the Console**

*To update the instance pool size*

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the name of the instance pool that you're interested in.
3. Click Edit.
4. Specify the updated number of instances for the instance pool, and then click Save Changes.

When you update the instance pool size, it triggers a scaling event. Keep the following in mind:

- If the instance pool lifecycle state is **RUNNING**, the instance pool will create new instances or terminate existing instances at that time, to match the new size of the instance pool. Instances are terminated in the order that they were created, first-in, first-out.
- If the instance pool lifecycle state is **STOPPED**, for an increase in size, new instances will be configured for the instance pool, but won’t be launched. For a decrease in size, the instances will be terminated.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

**Important:**

If the instance pool has been in the scaling or provisioning state for an extended period of time, it may be because the number of instances requested has exceeded your tenancy’s service limits for that shape and availability domain. Check your tenancy’s service limits for Compute.

To attach a load balancer to an instance pool

You must have a load balancer and backend set to associate with the instance pool. For steps to create a load balancer, see Managing Load Balancers on page 2494.

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the name of the instance pool that you're interested in.
4. Click **Attach a Load Balancer**.
5. Enter the following:
   - **Load balancer**: The load balancer to associate with the instance pool.
   - **Backend set**: The name of the backend set on the load balancer to add instances to.
   - **Port**: The server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   - **VNIC**: The VNIC to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.
6. Click **Attach**.
   
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.
7. If you want to associate additional load balancers with the instance pool, click + **Another Load Balancer**. Then, repeat the previous steps. Do this for each additional load balancer you want to associate with the instance pool.

**To detach a load balancer from an instance pool**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the name of the instance pool that you're interested in.
3. Under **Resources**, click **Load Balancers**.
4. Click the Actions icon (three dots) for the load balancer you want to detach.
5. Click **Detach Load Balancer**, and then click **Detach** to confirm.
   
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

**To manage tags for an instance pool**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **More Actions**, and then click **Add tags** to add new ones.
   
   For more information, see Resource Tags on page 211.

**Using the API**
To update other instance pool configuration settings, use the CLI, SDKs, or REST APIs. For information about using the CLI, see Command Line Interface (CLI) on page 4192. For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For instance pool configuration settings, such as the instance configuration, display name, tags, or availability domain selections, use the **UpdateInstancePool** operation.

To manage the load balancers that are associated with an instance pool, use the **AttachLoadBalancer** and **DetachLoadBalancer** operations.

To update the configuration that is used by an instance pool when creating instances, you can do either of the following things:
- Create a new instance configuration with the desired settings. You can do this using the Console. For steps, see Creating an Instance Configuration on page 710. To do this using the API, use the CreateInstanceConfiguration operation.
- Update the existing instance configuration for the instance pool. You can only update the display name and tags of existing instance configurations. For any other updates, create a new instance configuration with the settings you want to use. To update the display name or tags, use the UpdateInstanceConfiguration operation. You cannot use the Console to update instance configuration settings.
Stopping and Starting the Instances in an Instance Pool

You can stop and start the instances in an instance pool as needed to update software or resolve error conditions.

Stopping or Restarting an Instance Using the Instance's OS

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Resource Billing for Stopped Instances

For both VM and bare metal instances, billing depends on the shape that you use to create the instance:

- **Standard shapes**: Stopping an instance pool pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes**: Billing continues for stopped instance pools because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **GPU shapes**: Billing continues for stopped instance pools because GPU resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **HPC shapes**: Billing continues for stopped instance pools because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.

For more information about Compute pricing, see Compute Pricing. For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure? on page 805.

Using the Console

**To start all instances in a pool**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the instance pool that you're interested in.
3. Click Start.

**To stop all instances in a pool**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the instance pool that you're interested in.
3. Click Stop.
4. Click **Stop** again.

   The instances are shut down immediately, without waiting for the operating system to respond.

**To reboot all instances in a pool**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Reboot**.
4. By default, the Console gracefully restarts the instances by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instances are powered off and then powered back on.

   **Note:**

   If the applications that run on the instances take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, **shut down the instances using the commands available in the OS** before you restart the instance using the Console.

   If you want to reboot the instances immediately, without waiting for the OS to respond, select the **Force reboot the instance pool by immediately powering off every instance in the pool, then powering them back on** checkbox.

5. Click **Reboot Instance Pool**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To manage the lifecycle state of the instances in an instance pool, use these operations:

- StartInstancePool
- StopInstancePool
- ResetInstancePool
- SoftresetInstancePool

**Deleting an Instance Configuration**

You can permanently delete instance configurations that you no longer need.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.

**Using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Configurations**.
2. Click the instance configuration that you're interested in.
3. Click **Delete**, and then confirm when prompted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the **DeleteInstanceConfiguration** operation to delete an instance configuration.
Deleting an Instance Pool

You can permanently delete instance pools that you no longer need.

Caution:
When you delete an instance pool, the resources that were created by the pool are permanently deleted, including associated instances, attached boot volumes, and block volumes.

If an autoscaling configuration applies to the instance pool, the autoscaling configuration will be deleted asynchronously after the pool is deleted. You can also manually delete the autoscaling configuration.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the instance pool that you're interested in.
3. Click More Actions, and then click Terminate.
4. Confirm when prompted.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the TerminateInstancePool operation to delete an instance pool.

Autoscaling

Autoscaling lets you automatically adjust the number of Compute instances in an instance pool. This helps you provide consistent performance for your end users during periods of high demand, and helps you reduce your costs during periods of low demand.

You can apply the following types of autoscaling to an instance pool:

- **Metric-based autoscaling**: An autoscaling action is triggered when a performance metric meets or exceeds a threshold.
- **Schedule-based autoscaling**: Autoscaling events take place at the specific times that you schedule.

Autoscaling is supported for virtual machine (VM) and bare metal instance pools that use Standard, DenseIO, and GPU shapes.

How Autoscaling Works: the Basics

You use autoscaling configurations to automatically manage the size of your instance pools. When autoscaling automatically provisions instances in an instance pool, the pool *scales out*. When autoscaling removes instances from the pool, the pool *scales in*.

When an instance pool scales in, instances are terminated in this order: the number of instances is balanced across availability domains, and then balanced across fault domains. Finally, within a fault domain, the oldest instance is terminated first.
An autoscaling configuration includes one or more autoscaling policies. These policies define the criteria that trigger autoscaling actions and the actions to take. Each autoscaling configuration can either have one metric-based autoscaling policy, or multiple schedule-based autoscaling policies. You can add a maximum of 50 schedule-based autoscaling policies to an autoscaling configuration.

Each instance pool can have only one autoscaling configuration.

**Metric-Based Autoscaling**

In metric-based autoscaling, you choose a performance metric to monitor, and set thresholds that the performance metric must reach to trigger an autoscaling event. When system usage meets a threshold, autoscaling dynamically resizes the instance pool in near-real time. As load increases, the pool scales out. As load decreases, the pool scales in.

**Tip:**

Avoid changing the value assigned to the initial number of instances after the pool has scaled. Lowering this value after the number of instances in the pool size has increased will cause instances in the pool to terminate. If you need to change this value, the new value should equal or exceed the number of instances currently in the pool.

Metric-based autoscaling relies on performance metrics that are collected by the Monitoring service, such as CPU utilization. These performance metrics are aggregated into one-minute time periods and then averaged across all instances in the instance pool. When three consecutive values (that is, the average metrics for three consecutive minutes) meet the threshold, an autoscaling event is triggered.

A cooldown period between metric-based autoscaling events lets the system stabilize at the updated level. The cooldown period starts when the instance pool reaches the Running state. Autoscaling continues to evaluate performance metrics during the cooldown period. When the cooldown period ends, autoscaling adjusts the instance pool's size again if needed.

**Schedule-Based Autoscaling**

Schedule-based autoscaling is ideal for instance pools where demand behaves predictably based on a schedule, such as a month, date, or time of day. Schedules can be recurring or one-time. For example:

- An instance pool has heavy use during business hours. The pool has lighter use on evenings and weekends. You can schedule the pool to scale out on weekday mornings, and to scale in on weekday evenings.
- An instance pool has high demand on New Years Eve. You can schedule the pool to scale out every year on December 30, and to scale in on January 2.
- You’re releasing a new application that runs in the instance pool, and expect that many people will start using the application after the public announcement. In advance, you can schedule the pool to scale out on the day of release.

A schedule-based autoscaling configuration can have multiple autoscaling policies, each with a different schedule and target pool size. If you want to configure scale-in and scale-out events, you must create at least two separate policies. One policy defines the target pool size and schedule for scaling in. The other policy defines the target pool size and schedule for scaling out.

After a schedule-based autoscaling policy is executed, the instance pool stays at the target pool size until something else changes the pool size, such as a different autoscaling policy. However, if you manually change the pool size, schedule-based autoscaling does not readjust the pool size until the next scheduled autoscaling policy is executed.

You define autoscaling schedules using cron expressions. Autoscaling uses the Quartz cron implementation. You can use an online cron expression generator to verify your cron expressions; one example is FREEFORMATTER.

Provide all times in UTC.

**Note:**

Schedule-based autoscaling configurations include an attribute for cooldown period, which you'll see in the Console and when using the API, SDKs, and...
About Cron Expressions

A cron expression is a string composed of six or seven fields that represent the different parts of a schedule, such as hours or days of the week. Cron expressions use this format:

<second> <minute> <hour> <day of month> <month> <day of week> <year>

The following table lists the values and special characters that are allowed for each field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Allowed Values</th>
<th>Allowed Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second</td>
<td>0</td>
<td>None</td>
</tr>
<tr>
<td><strong>Note:</strong> When using the API, CLI, or SDKs for autoscaling, you must specify 0 as the value for seconds, even though other values will create a valid cron expression. You don't need to provide any value for seconds when using the Console.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Minute</td>
<td>0-59</td>
<td>* - , /</td>
</tr>
<tr>
<td>Hour</td>
<td>0-23</td>
<td>* - , /</td>
</tr>
<tr>
<td>Day of the month</td>
<td>1-31</td>
<td>* - , ? / L W</td>
</tr>
<tr>
<td>Month</td>
<td>1-12 or JAN-DEC</td>
<td>* - , /</td>
</tr>
<tr>
<td>Day of the week</td>
<td>1-7 or SUN-SAT</td>
<td>* - , ? / L #</td>
</tr>
<tr>
<td>Year</td>
<td>1970-2099</td>
<td>* - , /</td>
</tr>
</tbody>
</table>

The special characters are described in the following table.

<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Indicates all values for a field.</td>
<td>* in the month field means every month.</td>
</tr>
<tr>
<td>-</td>
<td>Indicates a range of values.</td>
<td>8-17 in the hour field means hours 8 through 17, or 8 a.m. through 5 p.m.</td>
</tr>
<tr>
<td>,</td>
<td>Indicates multiple values.</td>
<td>3,5 in the day-of-the-week field means Tuesday and Thursday.</td>
</tr>
<tr>
<td>?</td>
<td>Indicates no specific values.</td>
<td>0 0 10 ? * MON * means 10 a.m. on every Monday.</td>
</tr>
<tr>
<td>/</td>
<td>Use n/m to indicate increments. The value before the slash is the start time, and the number after the slash is the value to increment by.</td>
<td>0/20 in the minute field means the minutes 0, 20, and 40.</td>
</tr>
<tr>
<td>Special Character</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>L</td>
<td>Last day of the week or last day of the month. Use <code>xL</code> in the day-of-the-week field to indicate the last <code>x</code> day of the month. Use <code>L-n</code> in the day-of-the-month field to indicate an offset of <code>n</code> days from the last day of the month. Do not use <code>L</code> with multiple values or a range of values.</td>
<td>L in the day-of-the-month field means January 31, February 28 in non-leap years, and so on. 6L in the day-of-the-week field means the last Friday of the month. L-5 means 5 days before the last day of the month.</td>
</tr>
<tr>
<td>W</td>
<td>The weekday (Monday - Friday) that is nearest to the given day. The value does not cross months. Do not use <code>W</code> with multiple values or a range of values.</td>
<td>10W means the nearest weekday to the 10th of the month. If the 10th is a Saturday, it means Friday the 9th. If the 10th is a Sunday, it means Monday the 11th. If the 10th is a Wednesday, it means Wednesday the 10th.</td>
</tr>
<tr>
<td>#</td>
<td>Use <code>x#n</code> to indicate the <code>n</code>th <code>x</code> day of the month.</td>
<td>5#2 means the second Thursday of the month.</td>
</tr>
</tbody>
</table>
Example Cron Expressions

Use these example cron expressions as a starting point to create your own autoscaling schedules. Combine each cron expression with a target pool size to create an autoscaling policy. Then, include one or more autoscaling policies in an autoscaling configuration.

Goal: A one-time schedule with only one scaling event. At 11:00 p.m. on December 31, 2020, scale an instance pool to 100 instances. You'll need one autoscaling policy.

- Policy 1:
  - **Target pool size:** 100 instances
  - **Execution time:** 11:00 p.m. on the 31st day of December, in 2020
  - **Cron expression:** 0 0 23 31 12 ? 2020

Goal: A one-time schedule with a scale-out event and a scale-in event. At 10:00 a.m. on March 1, 2021, scale out to 75 instances. At 4 p.m. on March 7, 2021, scale in to 30 instances. You'll need two autoscaling policies.

- Policy 1 - scale out:
  - **Target pool size:** 75 instances
  - **Execution time:** 10:00 a.m. on the 1st day of March, in 2021
  - **Cron expression:** 0 0 10 1 3 ? 2021

- Policy 2 - scale in:
  - **Target pool size:** 30 instances
  - **Execution time:** 4:00 p.m. on the 7th day of March, in 2021
  - **Cron expression:** 0 0 16 7 3 ? 2021

Goal: A recurring daily schedule. On weekday mornings at 8:30 a.m., scale out to 10 instances. On weekday evenings at 6 p.m., scale in to two instances. You'll need two autoscaling policies.

- Policy 1 - morning scale out:
  - **Target pool size:** 10 instances
  - **Execution time:** 8:30 a.m. on every Monday through Friday, in every month, in every year
  - **Cron expression:** 0 30 8 ? * MON-FRI *

- Policy 2 - evening scale in:
  - **Target pool size:** 2 instances
  - **Execution time:** 6:00 p.m. on every Monday through Friday, in every month, in every year
  - **Cron expression:** 0 0 18 ? * MON-FRI *

Goal: A recurring weekly schedule. On Tuesdays and Thursdays, scale the pool to 30 instances. On all other days of the week, scale the pool to 20 instances. You'll need two autoscaling policies.

- Policy 1 - Tuesday and Thursday:
  - **Target pool size:** 30 instances
  - **Execution time:** 1 a.m. on every Tuesday and Thursday, in every month, in every year
  - **Cron expression:** 0 0 1 ? * TUE,THU *

- Policy 2 - all other days:
  - **Target pool size:** 20 instances
  - **Execution time:** 1 a.m. on Sunday through Monday, Wednesday, and Friday though Saturday, in every month, in every year
  - **Cron expression:** 0 0 1 ? * SUN-MON,WED,FRI-SAT *

Goal: A recurring monthly schedule. On all days of the month, set the pool size to 20 instances. On the 15th day of the month, scale out to 40 instances. You'll need two autoscaling policies.

- Policy 1 - daily pool size:
Compute

- **Target pool size**: 20 instances
- **Execution time**: Midnight on every day, in every month, in every year
- **Cron expression**: `0 0 0 * * ? *`
- Policy 2 - scale out:
  - **Target pool size**: 40 instances
  - **Execution time**: 12:05 a.m. on the 15th day of the month, in every month, in every year
  - **Cron expression**: `0 5 0 15 * ? *`

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to autoscaling configurations, see [Let users manage Compute autoscaling configurations](#) on page 2145.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see [Resource Tags](#) on page 211.

**Prerequisites**

- You have an instance pool. Optionally, you can attach a load balancer to the instance pool.
- For metric-based autoscaling, monitoring is enabled on the instances in the instance pool, and the Monitoring service is receiving metrics that are emitted by the instance. When you initially create an instance pool using instances that support monitoring, monitoring is enabled by default, regardless of the settings in the pool’s instance configuration.
- You have sufficient service limits to create the maximum number of instances that you want to scale to.

**Using the Console**

To create a metric-based autoscaling configuration

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Autoscaling Configurations.
2. Click Create Autoscaling Configuration.
3. On the Add Basic Details page, do the following:
   a. Enter a name for the autoscaling configuration. Avoid entering confidential information.
   b. Select the compartment to create the autoscaling configuration in.
   c. Select the Instance pool to apply the autoscaling configuration to.
   d. Show Tagging Options: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
4. Click Next.
5. On the **Configure Autoscaling Policy** page, select **Metric-Based Autoscaling**. Then, do the following:
   
a. Enter a name for the autoscaling policy. Avoid entering confidential information.
   
b. In the **Cooldown in seconds** box, enter the minimum amount of time to wait between scaling events. The cooldown period gives the system time to stabilize before rescaling. The minimum value is 300 seconds, which is also the default.
   
c. Select the **Performance metric** that triggers an increase or decrease in the number of instances in the instance pool.
   
d. In the **Scale-out rule** area, specify the threshold that the performance metric must reach to increase the pool size. Select a **Scale-out operator** and **Threshold percentage**. Then, enter the **Number of instances to add** to the pool.
   
   For example, when CPU utilization is greater than 90%, add 10 instances to the pool.
   
e. In the **Scale-in rule** area, specify the threshold that the performance metric must reach to decrease the pool size. Select a **Scale-in operator** and **Threshold percentage**. Then, enter the **Number of instances to remove** from the pool.
   
   For example, when CPU utilization is less than 20%, remove 5 instances from the pool.
   
f. In the **Scaling limits** area, specify the number of instances in the instance pool:
   
   - **Minimum number of instances**: The minimum number of instances that the pool is allowed to decrease to.
   
   - **Maximum number of instances**: The maximum number of instances that the pool is allowed to increase to.

   **Important:**
   
   The number of instances that can be provisioned is also limited by your tenancy’s service limits.

   - **Initial number of instances**: The number of instances to launch in the instance pool immediately after autoscaling is enabled. After autoscaling retrieves performance metrics, the number of instances is automatically adjusted from this initial number to a number that is based on the scaling limits that you set.

6. Click **Next**.

7. Review the autoscaling configuration, and then click **Create**.

   Autoscaling runs. The cooldown period starts when the instance pool's state changes from **Scaling** to **Running**.

### To create a schedule-based autoscaling configuration

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.

2. Click **Create Autoscaling Configuration**.

3. On the **Add Basic Details** page, do the following:

   a. Enter a name for the autoscaling configuration. Avoid entering confidential information.

   b. Select the compartment to create the autoscaling configuration in.

   c. Select the **Instance pool** to apply the autoscaling configuration to.

   d. **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

4. Click **Next**.
5. On the **Configure Autoscaling Policy** page, select **Schedule-Based Autoscaling**. Then, do the following:
   
a. Enter a name for the autoscaling policy. Avoid entering confidential information.
   
b. In the **Target pool size** box, enter the number of instances that the pool should scale to at the scheduled time.
   
   **Important:**
   
The number of instances that can be provisioned is also limited by your tenancy’s *service limits*.
   
c. In the **Execution schedule** area, define the schedule for implementing this autoscaling policy in UTC. Use a Quartz cron expression. For more information about cron expressions, see *About Cron Expressions* on page 720.
   
d. To schedule additional scaling events, click **+ Another Policy** and then repeat the previous steps.

6. When you're finished, click **Next**.

7. Review the autoscaling configuration, and then click **Create**.

   Autoscaling runs at the scheduled time.

### To edit an autoscaling configuration

You can change these characteristics of an autoscaling configuration:

- Name
- For metric-based autoscaling, the cooldown period between autoscaling actions

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Edit**.
5. Click **Save Changes**.

### To edit an autoscaling policy

You can change these characteristics of an autoscaling policy:

- Name
- For metric-based autoscaling:
  - Which performance metric triggers an autoscaling action
  - The minimum and maximum number of instances
  - The initial number of instances that the pool should have immediately after you update the autoscaling policy

   **Caution:**
   
   If you specify a smaller initial number of instances than the current pool size, instances will be terminated.

- Scale-out and scale-in operators and thresholds
- The number of instances to add or remove
- For schedule-based autoscaling, you can edit the target pool size or schedule for an existing policy, delete an existing policy, or add a new policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. In the **Autoscaling Policies** area, click **Edit**.
5. Click **Save Changes**.

### To enable or disable a schedule-based autoscaling policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. In the **Autoscaling Policies** area, under **Status**, toggle the **Enabled** or **Disabled** switch.

**To disable an autoscaling configuration**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Disable**, and then confirm when prompted.

**To delete an autoscaling configuration**
When you delete an autoscaling configuration, the instance pool remains in its most recent state.
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Delete**, and then confirm when prompted.

**To manage tags for an autoscaling configuration**
1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see **Resource Tags** on page 211.

**Using the API**
For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **Autoscaling API** to manage autoscaling configurations and policies.

To update the autoscaling configuration with a new instance pool, create a new instance configuration and then point the instance pool to the new configuration:

- First, create a new instance configuration with the desired settings. You can do this using the Console. For steps, see **Creating an Instance Configuration** on page 710. To do this using the API, use the **CreateInstanceConfiguration** operation.
- Next, update the instance pool used in the autoscaling configuration to point to the new instance configuration. To do this using the API, use the **UpdateInstancePool** operation to change the `instanceConfigurationId`. You cannot use the Console to update the instance configuration used by the instance pool.

**Managing Cluster Networks**
A cluster network is a pool of high performance computing (HPC) instances or GPU instances that are connected with a high-bandwidth, ultra low-latency network. Each node in the cluster is a bare metal machine located in close physical proximity to the other nodes. A remote direct memory access (RDMA) network between nodes provides latency as low as single-digit microseconds, comparable to on-premises HPC clusters.

Cluster networks are designed for highly demanding parallel computing workloads. For example:

- Computational fluid dynamics simulations for automotive or aerospace modeling
- Financial modeling and risk analysis
- Biomedical simulations
- Trajectory analysis and design for space exploration
- Artificial intelligence and big data workloads

Cluster networks are built on top of the **instance pools** feature. Most operations in the instance pool are managed directly by the cluster network, though you can monitor and add tags to the underlying instance pool.
For more information about how to access and store the data that you want to process in your cluster networks, see FastConnect Overview on page 3173, Overview of File Storage on page 1920, Overview of Object Storage on page 3392, and Overview of Block Volume on page 500.

**Supported Shapes**

The following shapes support cluster networks:

- BM.HPC2.36
- BM.GPU4.8

Typically, to be able to create the multiple HPC or GPU instances that are contained in a cluster network, you must request a service limit increase.

**Supported Regions and Availability Domains**

Cluster networks are supported in the following regions:

- Regions in the Oracle Cloud Infrastructure commercial realm:
  - Australia East (Sydney)
  - Australia Southeast (Melbourne)
  - Germany Central (Frankfurt)
  - Japan Central (Osaka)
  - Japan East (Tokyo)
  - Netherlands Northwest (Amsterdam)
  - South Korea Central (Seoul)
  - UK South (London)
  - US East (Ashburn)
  - US West (Phoenix)
  - US West (San Jose)
- Regions in the Government Cloud realms:
  - UK Gov South (London)
  - US Gov East (Ashburn)

The availability domain that you create the cluster network in must have cluster network-capable hardware.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For a typical policy that gives access to cluster networks, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2144.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 21.
Prerequisites

Create an instance configuration for the instance pool that is managed by the cluster network. To do this:

1. **Create an instance** with the following settings:
   - **Image or operating system**: Click *Change Image*, and then click *Oracle Images*. Select the Oracle HPC cluster networking image.
   - **Shape**: Click *Change Shape*. Select *Bare Metal Machine*. Then, select either the BM.HPC2.36 shape or the BM.GPU4.8 shape.
     
     For more information about these shapes, see *Compute Shapes* on page 655.

2. **Create an instance configuration** using the instance that you created in the previous step as a template.

   Optionally, you can delete the instance after you create the instance configuration.

Using the Console

To create a cluster network

1. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Cluster Networks*.

2. Click *Create Cluster Network*.

3. Enter a name for the cluster network. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.

4. Select the compartment to create the cluster network in.

5. Select the **Availability Domain** to run the cluster network in. Only the availability domains with cluster network-capable hardware can be selected.

6. In the **Configure networking** section, specify the network that you want to use to administer the cluster network. This network is separate from the closed RDMA network between nodes within the cluster. Enter the following information:
   
   - **Virtual cloud network**: The virtual cloud network (VCN) for the cluster network.
   - **Subnet**: The subnet for the cluster network.

7. In the **Configure instance pool** section, enter the following:
   
   - **Instance pool name**: A name for the instance pool that is managed by the cluster network. Avoid entering confidential information.
   
   - **Number of instances**: The number of instances in the pool.

   - **Instance configuration**: Select the instance configuration to use when creating the instances in the cluster network's instance pool, as described in the prerequisites.

8. **Show Tagging Options**: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see *Resource Tags* on page 211. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

9. Click *Create Cluster Network*.

   To track the progress of the operation, you can monitor the associated work request. For more information, see *Using the Console to View Work Requests* on page 260.

   For cluster networks with 10 or more instances, the cluster network is created if the required number of instances is available and at least 95% of the instances in the pool launch successfully. For cluster networks with less than 10 instances, all instances in the pool must launch successfully. If the cluster network fails to launch, wait a few minutes, and then try creating it again.

To edit the name of a cluster network

1. Open the navigation menu. Under *Core Infrastructure*, go to *Compute* and click *Cluster Networks*.

2. Click the cluster network that you're interested in.

3. Click *Edit Name*.

4. Enter a new name. Avoid entering confidential information.

5. Click *Save Changes*.
To manage tags for a cluster network

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see **Resource Tags** on page 211.

To delete a cluster network

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you delete a cluster network, all of its resources are permanently deleted, including associated instances, attached boot volumes, and block volumes.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click **Terminate**, and then confirm when prompted.

   To track the progress of the operation, you can monitor the associated work request. For more information, see **Using the Console to View Work Requests** on page 260.

Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to work with cluster networks:

- `CreateClusterNetwork`
- `GetClusterNetwork`
- `ListClusterNetworks`
- `ListClusterNetworkInstances`
- `UpdateClusterNetwork`
- `ChangeClusterNetworkCompartment`
- `TerminateClusterNetwork`

Dedicated Virtual Machine Hosts

The Oracle Cloud Infrastructure Compute service's dedicated virtual machine host feature gives you the ability to run Compute virtual machine (VM) instances on dedicated servers that are a single tenant and not shared with other customers. This feature lets you meet compliance and regulatory requirements for isolation that prevent you from using shared infrastructure. You can also use this feature to meet node-based or host-based licensing requirements that require you to license an entire server.

**Support and Limitations**

When you create a dedicated virtual machine host, you select a shape for the host. For the available shapes and shape details for dedicated virtual machine hosts, see **Dedicated Virtual Machine Host Shapes** on page 660. Note that there is a difference between the number listed for billed OCPUs compared to available OCPUs. This is because four OCPUs are reserved for virtual machine management.

You are billed for the dedicated virtual machine host as soon as you create it, but you are not billed for any of the individual VM instances you place on it. You will still be billed for image licensing costs if they apply to the image you are using for the VM instances.

For instances launched on a dedicated virtual machine host, all of the VM.Standard2 shapes are supported. For details about these shapes, see **VM Shapes** on page 658. Most of the Compute service features for VM instances are supported for instances running on dedicated virtual machine hosts, however the following features are not supported:
• Instance configurations
• Instance pools
• Autoscaling

Reboot migration is also not supported for dedicated virtual machine hosts. In this scenario, you need to manually migrate the instance. See Moving an Instance with Manual Migration on page 775 for this process.

You can mix VM instances with different shapes on the same dedicated virtual machine host. This might impact the maximum number of instances you can place on the dedicated virtual machine host. For more information, see Optimizing Capacity on your Dedicated Virtual Machine Host on page 733.

Managing Dedicated Virtual Machine Hosts

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The simplest policy to enable users to work with dedicated virtual machine hosts is listed in Let users manage Compute dedicated virtual machine hosts on page 2145. It gives the specified group access to launch instances on dedicated virtual machine hosts and manage dedicated virtual machine hosts.

See Let users launch Compute instances on dedicated virtual machine hosts on page 2146 for an example of a policy that allows users to launch instances on dedicated virtual machine hosts without giving them full administrator access to dedicated virtual machine hosts.

Creating a Dedicated Virtual Machine Host

You must create a dedicated virtual machine host before you can place any instances on it. When creating the dedicated virtual machine host, you select an availability domain and fault domain to launch it in. All the VM instances that you place on the host will subsequently be created in this availability domain and fault domain. You also select a compartment when you create the dedicated virtual machine host, but you can move the host to a new compartment later without impacting any of the instances placed on it. You can also create the instances in a different compartment than the dedicated virtual machine host, or move them to difference compartments after they have been launched.

To create a dedicated virtual machine host using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Dedicated Virtual Machine Hosts.
2. Click Create Dedicated Virtual Machine Host.
3. Enter the following information:
   • **Compartment**: The compartment for the dedicated virtual machine host.
   • **Name**: A user-friendly name or description. Avoid entering confidential information.
   • **Availability Domain**: The availability domain for the dedicated virtual machine host.
   • **Shape**: The shape to use for the dedicated virtual machine host.
4. Optionally, click Show Advanced Options. Then enter the following information:
   • **Fault Domain**: The fault domain for the dedicated virtual machine host.
   • **Tags**: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.
5. Click Create.

To create a dedicated virtual machine host using the CLI
Open a command prompt and run:

```
oci compute dedicated-vm-host create --dedicated-vm-host-shape DVH.Standard2.52 --wait-for-state ACTIVE --display-name <display_name> --availability-domain <availability_domain> --compartment-id <compartment_ID>
```

It can take up to 15 minutes for the dedicated virtual machine host to be fully created. It must be in the ACTIVE state before you can launch an instance on it.

To query the current state of a dedicated virtual machine host using the CLI, run the following command:

```
oci compute dedicated-vm-host get --dedicated-vm-host-id <dedicatedVMhost_ID>
```

**Deleting a Dedicated Virtual Machine Host**

**To delete a dedicated virtual machine host using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Dedicated Virtual Machine Hosts.
2. Click the dedicated virtual machine host that you want to delete.
3. Click Delete, and then confirm when prompted.

If you try to delete a dedicated virtual machine host that still has running instances hosted on it, the delete operation will fail. You need to ensure that all of the instances hosted on it have been terminated. To check if there are any instances still running on the dedicated virtual machine host, go to the Details page for the dedicated virtual machine host, and click Hosted Instances in the Resources section. Perform this step for each compartment in your tenancy that has instances running on the dedicated virtual machine host. To change the compartment for the Host Instances list, select a different compartment from the Table Scope drop-down list.

**To delete a dedicated virtual machine host using the CLI**

Open a command prompt and run:

```
oci compute dedicated-vm-host delete --dedicated-vm-host-id <dedicated_VM_host_ID>
```

Before you can delete a dedicated machine host, all of the instances running on it must be terminated.

To list the instances running on a dedicated virtual machine host using the CLI, run the following command:

```
oci compute dedicated-vm-host list --compartment-id <compartment_ID> --dedicated-vm-host-id <dedicatedVMhost_ID>
```

Run this command for every compartment in your tenancy that has instances running on the dedicated virtual machine host that you want to delete.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following operations for working with dedicated virtual machine hosts:

- CreateDedicatedVmHost
- DeleteDedicatedVmHost
- ListDedicatedVmHosts
- ListDedicatedVmHostShapes
- ListDedicatedVmHostInstances
- ListDedicatedVmHostInstanceShapes
- UpdateDedicatedVmHost
Compute

- ChangeDedicatedVmHostCompartment

Instances on Dedicated Virtual Machine Hosts

Placing an Instance on a Dedicated Virtual Machine Host

You place an instance on a dedicated virtual machine host at the time that you create the instance. The steps are the same as creating a regular instance, you just need specify that you want to create the instance on a dedicated virtual machine host when you create the instance. See Creating an Instance on page 695 for the steps to create an instance. Once you get to the Advanced Options section of the form, use the following steps to place the instance on a dedicated virtual machine host.

To place an instance on a dedicated virtual machine host using the Console

1. Perform the initial steps to create an instance based on an image and shape type that support placement on a dedicated virtual machine, until the advanced options.
2. Click Show Advanced Options, and then click the Placement tab.
3. Select the Dedicated host option.
4. Select the dedicated virtual machine host that you want to place the instance on.

Note:

Only dedicated virtual machine hosts with sufficient capacity to launch an instance based on the shape you have specified are displayed in the list. If you have a dedicated virtual machine host and it does not appear in the list, you must do one of the following things to place the instance on that dedicated virtual machine host:

- Terminate instances you no longer need on the dedicated virtual machine host to make capacity available.
- Choose another smaller shape for the instance you are trying to place on the dedicated virtual machine host.
- Create a new dedicated virtual machine host to place the instance on.

For more information, see Optimizing Capacity on your Dedicated Virtual Machine Host on page 733.

5. Click Create.

If you’re using the CLI or REST API to create the instance, pass the dedicated virtual machine host OCID in the optional parameter dedicatedVmHostId when you use the LaunchInstance operation. If you try to launch an instance with a shape that requires more capacity than what is available on the dedicated virtual machine host you are trying to place it on, the launch operation will fail. To avoid this, you can use the ListDedicatedVmHosts operation and pass the shape you want to use when launching the instance in the InstanceShapeNameQueryParam parameter. This will return all the dedicated virtual machine hosts that you can place the instance on.

The following example demonstrates how to call this operation in the CLI to return all the dedicated virtual machine hosts with sufficient capacity for you to place an instance launched using the VM.Standard2.16 shape:

```bash
oci compute dedicated-vm-host list --compartment-id <compartment_ID> --instance-shape-name VM.Standard2.16
```

Auditing your Dedicated Virtual Machine Host

To fully meet requirements for some compliance scenarios, you might be required to validate that your instances are running on a dedicated virtual machine host and not using shared infrastructure. The Oracle Cloud Infrastructure Audit service provides you with the functionality to do this. Use the steps described in Viewing Audit Log Events on page 494 to access the log events for the dedicated virtual machine host.

The steps described in the To search log events section walk you through how to retrieve the log events with the data you need to verify that your instances are running on a dedicated virtual machine host. For this procedure:
• Ensure that you select the dedicated virtual machine host's compartment and not the compartment for the instances that are hosted on it.

• Use the dedicated virtual machine host's OCID as the search keyword.

After you have retrieved the log events for the dedicated virtual machine host, view the log event lower-level details, and check the contents of the `responsePayload` property. This property should contain the OCIDs for the instances that are running on the dedicated virtual machine host.

**Optimizing Capacity on your Dedicated Virtual Machine Host**

When you place an instance on a dedicated virtual machine host using the Console, only dedicated virtual machine hosts with sufficient capacity to launch an instance based on the shape that you have specified are displayed in the **Dedicated Virtual Machine Host** drop-down list. If you don't see your dedicated virtual machine host in the list, to understand why, it can help to understand how instances are launched in this scenario.

When you place instances on a dedicated virtual machine host, Oracle Cloud Infrastructure launches the instances in a manner to optimize performance. For example, a dedicated virtual machine host created based on the **DVH.Standard2.52** shape has two sockets with 24 cores configured per socket. Instances are placed so that each instance will only use resources local to a single physical socket. In scenarios where you are creating and terminating instances with a mix of shapes, this can result in an inefficient distribution of resources, meaning that not all OCPUs on a dedicated virtual machine host are available to be used. In this scenario, it might appear that a dedicated virtual machine has enough OCPUs to launch an additional instance on it, but the instance will fail to launch because of the distribution of existing instances.

In this example, if you are launching instances using a shape with 16 OCPUs on a dedicated virtual machine host, you can only launch a maximum of two instances using that shape. You cannot launch a third instance with 16 OCPUs, even though the remaining number of OCPUs showing for the dedicated virtual machine host is 16. You can launch additional instances using shapes with a smaller number of OCPUs.

When designing your cloud footprint, we recommend that you plan to always launch the largest instance first.

**Connecting to an Instance**

You can connect to a running instance by using a Secure Shell (SSH) or Remote Desktop connection. Most UNIX-style systems include an SSH client by default. Windows 10 and Windows Server 2019 systems should include the **OpenSSH client**, which you'll need if you created your instance using the SSH keys generated by Oracle Cloud Infrastructure. For other Windows versions, you can download a free SSH client called PuTTY from [http://www.putty.org](http://www.putty.org).

**Required IAM Policy**

To connect to a running instance with SSH, you don't need an IAM *policy* to grant you access. However, to SSH you need the public IP address of the instance (see Prerequisites on page 734 below). If there's a policy that lets you launch an instance, that policy probably also lets you get the instance's IP address. The simplest policy that does both is listed in Let users launch compute instances on page 2143.

For administrators: Here's a more restrictive policy that lets the specified group get the IP address of existing instances and use power actions on the instances (e.g., stop, start, etc.), but not launch or terminate instances. The policy assumes the instances and the cloud network are together in a single compartment (XYZ):

```
Allow group InstanceUsers to read virtual-network-family in compartment XYZ
Allow group InstanceUsers to use instance-family in compartment XYZ
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.
Prerequisites

You'll need the following information to connect to the instance:

- The public IP address of the instance. You can get the address from the Instance Details page in the Console. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances. Then, select your instance. Alternatively, you can use the Core Services API ListVnicAttachments and GetVnic operations.
- The default username for the instance. If you used an Oracle-provided Linux, CentOS, or Windows image to launch the instance, the username is opc. If you used the Ubuntu image to launch the instance, the username is ubuntu.
- For Linux instances: The full path to the private key portion of the SSH key pair that you used when you launched the instance. For more information about key pairs, see Managing Key Pairs on Linux Instances on page 693.
- For Windows instances: If you're connecting to the instance for the first time, you will need the initial password for the instance. You can get the password from the Instance Details page in the Console.

Connecting to a Linux Instance

You connect to a Linux instance using SSH.

To connect to a Linux instance from a Unix-style system

1. Use the following command to set the file permissions so that only you can read the file:

   ```bash
   chmod 400 <private_key_file>
   ```

   `<private_key_file>` is the full path and name of the file that contains the private key associated with the instance you want to access.

2. Use the following SSH command to access the instance.

   ```bash
   ssh -i <private_key_file> <username>@<public-ip-address>
   ```

   `<private_key_file>` is the full path and name of the file that contains the private key associated with the instance you want to access.

   `<username>` is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

   `<public-ip-address>` is your instance IP address that you retrieved from the Console.

To connect to a Linux instance from a Windows system using OpenSSH

If the instance uses a key pair that was generated by Oracle Cloud Infrastructure, use the following procedure.

1. If this is the first time you are using this key pair, you must set the file permissions so that only you can read the file. Do the following:

   a. In Windows Explorer, navigate to the private key file, right-click the file, and then click Properties.

   c. Ensure that the Owner is your user account.

   d. Click Disable Inheritance, and then select Convert inherited permissions into explicit permissions on this object.

   e. Select each permission entry that is not your user account and click Remove.

   f. Ensure that the access permission for your user account is Full control.

   g. Save your changes.
2. To connect to the instance, open Windows PowerShell and run the following command:

```
ssh -i <private_key_file> <username>@<public-ip-address>
```

<private_key_file> is the full path and name of the file that contains the private key associated with the instance you want to access.

$username is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

<public-ip-address> is your instance IP address that you retrieved from the Console.

To connect to a Linux instance from a Windows system using PuTTY

SSH private key files generated by Oracle Cloud Infrastructure are not compatible with PuTTY. If you are using a private key file generated during the instance creation process you need to convert the file to a .ppk file before you can use it with PuTTY to connect to the instance.

Convert a generated .key private key file:

1. Open PuTTYgen.
2. Click Load, and select the private key generated when you created the instance. The extension for the key file is .key.
3. Click Save private key.
4. Specify a name for the key. The extension for new private key is .ppk.
5. Click Save.

Connect to the Linux instance using a .ppk private key file:

If the instance uses a key pair that you created using PuTTY Key Generator, use the following procedure.

1. Open PuTTY.
2. In the Category pane, select Session and enter the following:
   - Host Name (or IP address):
     <username>@<public-ip-address>
     <username> is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.
     <public-ip-address> is your instance public IP address that you retrieved from the Console
   - Port: 22
   - Connection type: SSH
3. In the Category pane, expand Window, and then select Translation.
4. In the Remote character set drop-down list, select UTF-8. The default locale setting on Linux-based instances is UTF-8, and this configures PuTTY to use the same locale.
5. In the Category pane, expand Connection, expand SSH, and then click Auth.
6. Click Browse, and then select your .ppk private key file.
7. Click Open to start the session.

If this is your first time connecting to the instance, you might see a message that the server's host key is not cached in the registry. Click Yes to continue the connection.

Tip:

If the connection fails, you may need to update your PuTTY proxy configuration.

Connecting to a Windows Instance

You can connect to a Windows instance using a Remote Desktop connection. Most Windows systems include a Remote Desktop client by default.
To enable Remote Desktop Protocol (RDP) access to the Windows instance, you need to add a stateful ingress security rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. You can implement this security rule in either a network security group that the Windows instance belongs to, or a security list that is used by the instance's subnet.

**To enable RDP access**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the cloud network that you're interested in.
4. To add the rule to a network security group that the instance belongs to:
   a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
   b. Click **Add Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click **Add**.
5. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
   b. Click **Add Ingress Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click **Add Ingress Rules**.

**Connecting to a Windows Instance from a Remote Desktop Client**

1. Open the Remote Desktop client.
2. In the **Computer** field, enter the public IP address of the instance. You can retrieve the public IP address from the Console.
3. The **User name** is opc. Depending on the Remote Desktop client you are using, you might have to connect to the instance before you can enter this credential.
4. Click **Connect** to start the session.
5. Accept the certificate if you are prompted to do so.
6. If you are connecting to the instance for the first time, enter the initial password that was provided to you by Oracle Cloud Infrastructure when you launched the instance. You will be prompted to change the password as
soon as you log in. Your new password must be at least 12 characters long and must comply with Microsoft's password policy.

Otherwise, enter the password that you created. If you are using a custom image, you might need to know the password for the instance that the image was created from. For details about Windows custom images, see Creating Windows Custom Images on page 668.

7. Press Enter.

Troubleshooting the SSH Connection

If you're unable to connect to your instance using SSH, follow these troubleshooting steps to identify common problems.

- **Verify your connection:** In your terminal window, run `nc <public ip> 22`.
  - **If the SSH banner displays:** You successfully connected to your instance using SSH. The underlying problem might be related to permissions. As a next step, verify your credentials. If the credentials you're using to SSH to the instance are incorrect, the connection fails.
    
    For Linux instances, you need the full path to the private key portion of the SSH key pair that you used when you launched the instance. For more information about key pairs, see Managing Key Pairs on Linux Instances on page 693. For Windows instances, if you're connecting to the instance for the first time, you need the initial password for the instance. You can get the password from the Instance Details page in the Console.
  - **If the SSH banner does not display:** A network issue might be preventing the SSH connection from succeeding. Review the following suggestions.
    
    - **Add a public IP address:** If your connection is routed over the internet, your instance must have a public IP address in order for you to connect to the instance. Without a public IP address, the instance is not reachable. For more information about how to manage public IPv4 addresses on instances, see Public IP Addresses on page 2875.
    
    - **Verify the network security lists:** Oracle Cloud Infrastructure provisions each cloud network with a default set of security lists to permit SSH traffic. If the security list that permits SSH connections is removed, you can’t access your instance. Ensure a security list that opens port 22 is present. You can use the Console to view and manage your security lists. For more information about security lists, see Security Lists on page 2850.
    
    - **Confirm that SSH is running on the instance:** The steps for confirming that SSH is running vary depending on the operating system. Review the documentation for your operating system to find information explaining how to confirm that SSH is running.
    
    - **Capture serial console history:** To capture your instance's serial console data history, use the `console-history` resource in the CLI. This information can help determine the cause of connectivity problems. For more information, see `console-history` and Command Line Interface (CLI) on page 4192.

    When using the CLI to capture the instance's serial console data history, you need to include the following option to ensure that full history is captured. Without this option, the data might be truncated: `--length 10000000`.

    - **Connect to the serial console:** Serial console connections allow you to remotely troubleshoot malfunctioning instances. For more information, see Troubleshooting Instances Using Instance Console Connections on page 813.

Adding Users on an Instance

You can add additional users to a Compute instance.

If you created your instance using an Oracle-provided Linux or CentOS image, you can use SSH to access your instance from a remote host as the `opc` user. If you created your instance using the Ubuntu image, you can use SSH to access your instance from a remote host as the `ubuntu` user. After signing in, you can add users to the instance.

If you created your instance using an Oracle-provided Windows image, you can create new users after you sign in to the instance through a Remote Desktop client.
Creating Additional Users on a Linux Instance

If you do not want to share your SSH key, you can create additional SSH-enabled users for a Linux instance. At a high level, you do the following things:

- Generate SSH key pairs for the users offline.
- Add the new users.
- Append a public key to the `~/.ssh/authorized_keys` file for each new user.

**Tip:**

If you re-create an instance from an Oracle-provided image, users and SSH public keys that you added or edited manually (that is, users that weren’t defined in the machine image) must be added again.

If you need to edit the `~/.ssh/authorized_keys` file of a user on your instance, start a second SSH session before you make any changes to the file and ensure that it remains connected while you edit the file. If the `~/.ssh/authorized_keys` file becomes corrupted or you inadvertently make changes that lock you out of the instance, you can use the backup SSH session to fix or revert the changes. Before closing the backup SSH session, test all changes you made by logging in with the new or updated SSH key.

The new users then can SSH to the instance using the appropriate private keys.

To create an additional SSH-enabled user:

1. Generate an SSH key pair for the new user.
2. Copy the public key value to a text file for use later in this procedure.
3. Log in to the instance.
4. Become the root user:

   sudo su

5. Create the new user:

   useradd <new_user>

6. Create a .ssh directory in the new user’s home directory:

   mkdir /home/<new_user>/.ssh

7. Copy the SSH public key that you saved to a text file into the /home/new_user/.ssh/authorized_keys file:

   echo <public_key> > /home/<new_user>/.ssh/authorized_keys

8. Change the owner and group of the /home/username/.ssh directory to the new user:

   chown -R <new_user>:<group> /home/<new_user>/.ssh

9. To enable sudo privileges for the new user, run the visudo command and edit the /etc/sudoers file as follows:

   a. In /etc/sudoers, look for:

      %<username> ALL=(ALL) NOPASSWD: ALL

   b. Add the following line immediately after the preceding line:

      %<group> ALL=(ALL) NOPASSWD: ALL

The new user can now sign in to the instance.

Creating Additional Users on a Windows Instance

1. Log in to the instance using a Remote Desktop client.
2. On the Start menu, click Control Panel.
3. Click User Accounts, and then click User Accounts again.
4. Click Manage User Accounts.
5. Click Manage Another Account.
6. Click Add User Account.
7. Enter a User name and Password.
8. Confirm the password, and then create a Password hint.
9. Click Next.
10. Verify the account, and then click Finish.

The new user can now sign in to the instance.

Displaying the Console for an Instance

You can capture and display the serial console data for an instance. The data includes configuration messages that occur when the instance boots, such as kernel and BIOS messages, and is useful for checking the status of the instance or diagnosing problems. Note that the raw console data, including multi-byte characters, is captured.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to manage console history data. If the specified group doesn’t need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368.

Use these API operations to manage the serial console logs:

- CaptureConsoleHistory
- DeleteConsoleHistory
- GetConsoleHistory
- GetConsoleHistoryContent
- ListConsoleHistories

**Managing Plugins with Oracle Cloud Agent**

Oracle Cloud Agent is a lightweight process that manages plugins running on compute instances. Plugins collect performance metrics, install OS updates, and perform other instance management tasks.

To use plugins on an instance, the Oracle Cloud Agent software must be installed on the instance, the plugins must be enabled, and the plugins must be running. You might need to perform additional configuration tasks before you can use certain plugins.

**Supported Images**

**Oracle Cloud Agent:** Oracle Cloud Agent is supported on current Oracle-provided images and on custom images that are based on current Oracle-provided images. Oracle Cloud Agent is installed by default on current Oracle-provided images.

If you use an older Oracle-provided image, you must manually install the Oracle Cloud Agent software. Select an image dated after November 15, 2018 (except Ubuntu, which must be dated after February 28, 2019).

You might have success manually installing Oracle Cloud Agent on other images, though it has not been tested on other operating systems and there is no guarantee that it will work. Oracle Cloud Agent is not supported on Windows Server 2008 R2 custom images.

**Plugins:** Plugins are installed as part of Oracle Cloud Agent. The plugins that are supported for an instance depend on the version of Oracle Cloud Agent and on the image that you use to create the instance. To determine which plugins are supported for a particular image, use the Console to create an instance. Or, use the ListInstanceagentAvailablePlugins API operation, providing the OS name and OS version of the image.

**Available Plugins**

Each Oracle Cloud Agent plugin provides functionality related to compute instances. This functionality can enable features that are part of the Compute service, and features that are part of other services.

The following Oracle Cloud Agent plugins are available.

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Description</th>
<th>Steps to Configure and Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Instance Monitoring</td>
<td>Emits metrics about the instance's health, capacity, and performance. These metrics are consumed by the Monitoring service.</td>
<td>See Enabling Monitoring for Compute Instances on page 783 and Compute Instance Metrics on page 788.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Description</td>
<td>Steps to Configure and Use</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td>Compute Instance Run Command</td>
<td>Runs scripts within the instance to remotely configure, manage, and troubleshoot the instance.</td>
<td>See Running Commands on an Instance on page 752.</td>
</tr>
<tr>
<td>Custom Logs Monitoring</td>
<td>Ingests custom logs into the Logging service.</td>
<td>See Custom Logs on page 2619.</td>
</tr>
<tr>
<td>OS Management Service Agent</td>
<td>Manages updates and patches for the operating system environment on the instance.</td>
<td>See OS Management.</td>
</tr>
</tbody>
</table>

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to enable and disable individual plugins, as well as start and stop all plugins on an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family. In addition, you must use the following policy to allow users to access the available plugins:

```
Allow group PluginUsers to read instance-agent-plugins in compartment ABC
```

If you're new to policies, see Getting started with policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Installing the Oracle Cloud Agent Software**

If you create an instance using a current Oracle-provided image or a custom image that's based on a current Oracle-provided image, then Oracle Cloud Agent is installed by default. No action is needed.

If you want to manually install the Oracle Cloud Agent software on an instance that uses another supported image, use the following steps.

**To manually install Oracle Cloud Agent on a legacy Linux instance**

1. Connect to the instance.
2. To download the Oracle Cloud Agent software, run one of the following scripts.

   **Oracle Autonomous Linux, Oracle Linux**

   a. To determine whether the Oracle Cloud Agent software is installed, run the following command:

      ```
      sudo yum info oracle-cloud-agent
      ```
      
      The command returns the Oracle Cloud Agent version that is currently installed.

   b. If Oracle Cloud Agent isn't installed, or if the installed version is not the latest version, install the latest version by running the following command:

      ```
      sudo yum install -y oracle-cloud-agent
      ```

      **Note:**

      If you don't have access to the yum repository that has Oracle Cloud Agent, run one of the following scripts.
### Oracle Linux 6.x

```
#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
  uKbXkuu61IVKkRdQhxpg9C4bvnaxr0dqatbtuzq2k2V0XZrQw2cKFuzla_9jRNQc/
  n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3749.el6.x86_64.rpm -v
```

### Oracle Autonomous Linux 7.x, Oracle Linux 7.x

```
#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
  U_9mEBnaTqVKe_HVI26djz88N4QXG0kDGTA3izpxKtc5OI44TuukvKzgVrlJP8B/
  n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
```

### Oracle Linux 8.x

```
#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
  tbPX4bNOSItrr3rIe2DTPj6F8n51HFKaSS81LHejzAu35tNuhxxfgyzUmo0QKCL9/
  n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v
```

### CentOS 7.x

```
#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
  U_9mEBnaTqVKe_HVI26djz88N4QxG0kDGTA3izpxKtc5OI44TuukvKzgVrlJP8B/n/
  imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
```

### CentOS 8.x

```
#!/bin/sh
cd ~
```
Compute

```bash
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/tbPX4bN0SLr3p3r3e2DtpJP6F8n5iHFkasaS81LHkejzAu35tNuhxxfgyzUmQKCL9/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v
```

**Ubuntu 16.04, Ubuntu 18.04**

**Note:**

To install Oracle Cloud Agent on instances that use Ubuntu images, **Snapcraft** must be installed on the instance. Install Snapcraft by running the following commands, in sequence:

```
sudo apt update

sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

This command installs and runs the Oracle Cloud Agent software.

3. To run the Oracle Cloud Agent software on the instance, enter one of the following commands.

**Oracle Linux**

```
sudo yum install -y <instance-agent-filename>
```

**CentOS**

```
sudo yum install -y <instance-agent-filename>
```

**Ubuntu**

No further action is needed. The command in the previous step installs and runs the software.

**To manually install Oracle Cloud Agent on a legacy Windows instance**

1. Connect to the instance.
2. Download the Oracle Cloud Agent software from the following URL:

   ```
   https://objectstorage.us-phoenix-1.oraclecloud.com/p/GvqT-zkjDRzemw0FP740k-uQHzAl130EeydBeEw_BezvpyfMGczffTCPjm0p/n/imagegen/b/agents/o/OracleCloudAgentSetup_v1.8.0.msi
   ```
3. As a user with administrative privileges, enter the following command to run the Oracle Cloud Agent software on the instance.

   ```
   msiexec /qb /i <instance-agent-filename>
   ```

**To install Oracle Cloud Agent using cloud-init when creating an instance using a legacy image**

If you want to install Oracle Cloud Agent on an instance that uses an older image as part of the instance launch, you can provide a cloud-init script (cloudbase-init on Windows instances) when you create the instance.

1. Follow the steps to [create an instance](#), until the advanced options.
2. Click **Show Advanced Options**.
3. On the Management tab, in the Initialization Script section, select Paste cloud-init script. Then, copy and paste one of the following scripts, depending on the image.

**Oracle Linux**

```
sudo yum install -y oracle-cloud-agent
```

**Note:**
If you don't have access to the yum repository that has Oracle Cloud Agent, copy and paste one of the following scripts.

**Oracle Linux 6.x**

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/UkBxKkuUa6TVKkRdQhxp9C4bvnaxr0dqatbtuzq2k2V0XZrQw2cKFuz1a_9jRNQc/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3749.el6.x86_64.rpm
yum install -y ~/oracle-cloud-agent-1.8.2-3749.el6.x86_64.rpm -v
```

**Oracle Linux 7.x**

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/U_9mEBnaTqVKu_HVI26djsZ8N4QxG0kDGTA3izpxKTC5O144TuukvKz9Vr1JP8B/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
```

**Oracle Linux 8.x**

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/tbPX4bN0SsLrp3rIe2DTPjP6F8n5iHFKaSS81LHejzAu35tNuhxxfgyzUm0QKCL9/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v
```

**CentOS 7.x**

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/U_9mEBnaTqVKu_HVI26djsZ8N4QxG0kDGTA3izpxKTC5O144TuukvKz9Vr1JP8B/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.8.2-3843.el7.x86_64.rpm -v
```

**CentOS 8.x**

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/tbPX4bN0SsLrp3rIe2DTPjP6F8n5iHFKaSS81LHejzAu35tNuhxxfgyzUm0QKCL9/n/imagegen/b/agents/o/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v
```
yum install -y ~/oracle-cloud-agent-1.8.2-3843.el8.x86_64.rpm -v

Ubuntu 16.04, Ubuntu 18.04

**Note:**
To install Oracle Cloud Agent on instances that use Ubuntu images, Snapcraft must be installed on the instance. Install Snapcraft by running the following commands, in sequence:

```
sudo apt update
sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

**Note:**
For legacy versions of Windows images, ensure that cloudbase-init is supported. See WinRM and cloudbase-init on Windows images.

```
#ps1_sysnative
cd \Users\opc\Desktop
Start-BitsTransfer -Source "https://objectstorage.us-phoenix-1.oraclecloud.com/p/GvqT-zkjDRzemw0FP740kJHxAl130EEyidJbeEw_BezvpszIMGczIffTCpnjm0p/n/imagegen/b/agents/o/OracleCloudAgentSetup_v1.8.0.msi" -Destination "c:\Users\opc\Desktop\OracleCloudAgentSetup.msi"
msiexec /i "c:\Users\opc\Desktop\OracleCloudAgentSetup.msi" /quiet /L*V /V "c:\Users\opc\Desktop\OracleCloudAgentSetup.log"
```

4. Click **Create**.

**Managing Plugins Using the Console**

**To see which plugins are enabled for an instance**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click the **Oracle Cloud Agent** tab.
   The list of plugins is displayed. Enabled plugins can have the following statuses:
   - **RUNNING**: The plugin is running.
   - **STOPPED**: The plugin is stopped.
   - **NOT_SUPPORTED**: The plugin is not supported on this platform.
   - **INVALID**: The plugin status is not recognizable by the service.

**To enable or disable a plugin**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click the **Oracle Cloud Agent** tab.
4. Toggle the **Enabled** or **Disabled** switch for the plugin.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functionality that depends on the plugin, such as monitoring, autoscaling, or OS management, will not work when the plugin is disabled.</td>
</tr>
</tbody>
</table>

It takes up to 10 minutes for the change to take effect.

5. If you enabled a plugin, if necessary, perform any configuration tasks that are required before you can use the plugin. For information about how to configure each plugin, see the documentation for each plugin in Available Plugins on page 740.

### To stop all plugins on an instance

You can stop all of the plugins that are running on an instance. Any individual plugins that are enabled on the instance remain enabled, but the plugin processes stop running. The plugin processes will only start running again after you restart all plugins.

For example, if you want to troubleshoot plugins, you can stop all plugins and then disable the plugins that you think might have an error. Reenable the plugins one-by-one, restarting the plugins after you enable each plugin, to determine which plugin has an issue. For more information about troubleshooting plugins, see Generating a Diagnostic File for Oracle Cloud Agent on page 751.

To stop all plugins on an instance:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click the **Oracle Cloud Agent** tab.
4. Click **Stop Plugins**.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functionality that depends on plugins, such as monitoring, autoscaling, and OS management, will not work when all plugins are stopped.</td>
</tr>
</tbody>
</table>

5. Click **Stop Plugins**.

It might take several minutes for all plugins to stop. Oracle Cloud Agent continues to run when plugins are stopped.

### To start all plugins on an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click the **Oracle Cloud Agent** tab.
4. Click **Start Plugins**.

It takes up to 10 minutes for the plugins to restart.

### Managing Plugins Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage Oracle Cloud Agent plugins:

- In the Core Services API:
  - **LaunchInstance** - enables or disables plugins, or stops all plugins, when you create an instance.
  - **GetInstance** and **ListInstances** - gets information about which plugins are enabled on an instance (or a list of instances).
  - **UpdateInstance** - enables or disables individual plugins, and stops or starts all plugins, for an existing instance.
• In the Oracle Cloud Agent API:
  • `ListInstanceAgentAvailablePlugins` - lists the plugins that are available for all instances. You can filter the results based on the image that you plan to use to launch an instance.
  • `ListInstanceAgentPlugins` - gets information about the plugins that are available on an existing compute instance.
  • `GetInstanceAgentPlugin` - gets information about a specific plugin on an existing compute instance.

**Updating the Oracle Cloud Agent Software**

We recommend always running the latest version of the Oracle Cloud Agent software.

If the instance can access the internet, then no action is needed. Oracle Cloud Agent periodically checks for newer versions and installs the latest version when an update is available.

If the instance does not have access to the internet, then you must manually update the Oracle Cloud Agent software. For example, a compute instance cannot access the internet if it does not have a public IP address, internet gateway, or service gateway. In this situation, Oracle Cloud Agent cannot complete its checks for newer versions.

*To see which version of Oracle Cloud Agent is installed*

**Connect to the instance** and then do one of the following things:

• For Oracle Linux and CentOS, run the following command:

  ```
  sudo yum info oracle-cloud-agent
  ```

• For Ubuntu, run the following command:

  ```
  snap info oracle-cloud-agent
  ```

• For Windows, do one of the following things:
  • In Control Panel, select **Programs and Features** and then find the version number provided for "Oracle Cloud Agent."
  • In PowerShell, run the following command:

    ```
    Get-WmiObject -Class Win32_Product | Where-Object { $_.Name -eq "Oracle Cloud Agent" }
    ```

    Example output:

    ```
    IdentifyingNumber : {exampleuniqueidentifier}
    Name              : Oracle Cloud Agent
    Vendor            : Oracle Corporation
    Version           : 0.0.10.0
    Caption           : Oracle Cloud Agent
    ```

*To manually update Oracle Cloud Agent on a compute instance*

Do one of the following things:

• Temporarily allow the instance to access the internet so that Oracle Cloud Agent can update itself.
• Redo the installation steps, using the latest version.

**Oracle Cloud Agent Release Notes**

**Linux versions**
<table>
<thead>
<tr>
<th>Version</th>
<th>Date</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 1.8.3    | January 13, 2021   | Ubuntu instances only:  
  • Adds support to enable or disable individual plugins.  
  • Adds two new metrics for monitoring.  
  • Fix for updater start in new images.  
  • Updater fix for signature verification on packages.  
  • Adds support for reattachable plugins so that Oracle Cloud Agent can be upgraded without stopping plugins. |
| 1.8.2    | January 13, 2021   | Compute Instance Monitoring:  
  • Improve filtering of UNIX disk devices. |
| 1.8.1    | January 13, 2021   | OS Management Service Agent:  
  • Disabled by default. |
| 1.8.0    | January 13, 2021   | Adds support to enable or disable individual plugins.  
  Adds two new metrics for monitoring.  
  OS Management Service Agent:  
  • Enabled by default. |
| 1.7.1    | December 17, 2020  | Fix for updater start in new images.  
  OS Management Service Agent disabled in US Government Cloud. |
| 1.7.0    | December 7, 2020   | Updater fix for signature verification on packages.  
  Custom Logs Monitoring:  
  • Bug fix for signature verification.  
  • Add default bucket namespace for non-commercial realms. |
<table>
<thead>
<tr>
<th>Version</th>
<th>Date</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 1.6.0   | November 6, 2020   | Adds support for reattachable plugins so that Oracle Cloud Agent can be upgraded without stopping plugins.  
Compute Instance Run Command:  
• Includes support for the run command feature in all regions in the Oracle Cloud Infrastructure commercial realm.  
Custom Logs Monitoring:  
• Enables package signature verification in CentOS.  
OS Management Service Agent:  
• Fixes the plugin to stop its process when it is requested to stop rather than staying up idle.  
• Fixes an upgrade kill cycle bug where OS Management upgrades Oracle Cloud Agent using yum, which then stops Oracle Cloud Agent, which stops the plugin. |
| 1.5.1   | October 27, 2020   | Includes support for the run command feature.                           |
| 1.4.1   | October 21, 2020   | Hotfix for agent termination of orphaned processes.                     |
| 1.4.0   | October 2, 2020    | Fixes in updater daemon and plugins to make them more resilient.        |
| 1.3.2   | September 9, 2020  | Fix auto update download directory permissions.                         
Minor enhancements to the Compute Instance Monitoring plugin. Enable additional plugins.  
Create grpc sockets in /var/lib/oracle-cloud-agent/tmp. |
| 1.2.0   | August 3, 2020     | Upgrade the agent to support plugins                                    |
| 0.0.19  | May 28, 2020       | Fix updater failing to run on images that mount a filesystem with noexec flag set, to /tmp.  
Use instance metadata to generate client side URLs.  
Includes support for the instance metadata service (IMDS) v2. |
| 0.0.18  | May 11, 2020       | Miscellaneous updates.                                                  |

### Generating a Diagnostic File for Oracle Cloud Agent

To make it easier for Oracle support to help you troubleshoot issues with the Oracle Cloud Agent software, you can install the Oracle Cloud Agent diagnostic tool on your compute instances. When you run the diagnostic tool, it generates a file that contains debugging information and logs for the plugins that are managed by Oracle Cloud Agent.

**To generate a diagnostic file on a Linux instance**

1. Connect to the instance.
2. Download the diagnostic tool by running the following command:

   ```bash
curl https://objectstorage.us-phoenix-1.oraclecloud.com/p/nBzj8SEG2UHheMQ7XDKFWjF0eCuqfnHHHe0UdifZC90DgmXihFvJ42xw81qV5Kh7/n/imagegen/b/agents/o/oca-diagnostic-util-linux-01-12-21 > oca-diag-01-12-21
   ```

3. Change the permissions on the diagnostic tool to make it an executable:

   ```bash
   chmod 744 ./oca-diag-01-12-21
   ```
4. Run the diagnostic tool:

```bash
./oca-diag-01-12-21
```

The tool generates a TAR file with a name in the format `oca-diag-<date>.<identifier>.tar.gz`. Provide the file when you open your support request.

**To generate a diagnostic file on a Windows instance**

1. Connect to the instance.
2. Open PowerShell as an administrator. Then, download the diagnostic tool by running the following command:

```powershell
$url = "https://objectstorage.us-phoenix-1.oraclecloud.com/p/P57bTyJBYq0U2zSfW6jChEd70nUY0q0P7tEN9fv_2nXP40asMoAFaEEpEftEh_B/n/imagegen/b/agents/o/oca-diagnostic-util-win-11-01-20.ps1"
$output_file = "C:\Users\opc\oca-diag-11-01-20.ps1"
$wc.DownloadFile($url, $output_file)
```

**Note:**

If you get an error when you try to download the diagnostic tool, it might be due to the Transport Layer Security (TLS) version. Run the following command, and then try downloading the diagnostic tool again.

```powershell
```

3. Change directories to the folder where the diagnostic tool is saved:

```bash
cd C:\Users\opc
```

4. Run the diagnostic tool:

```bash
./oca-diag-11-01-20.ps1
```

The tool generates a ZIP file and saves it to `C:\Users\opc\Desktop\`. Provide the file when you open your support request.

**Running Commands on an Instance**

You can remotely configure, manage, and troubleshoot compute instances by running scripts within the instance using the run command feature.

For example, the run command feature can help you automate tasks such as configuring secondary virtual network interface cards (VNICs), joining instances to an identity provider, troubleshooting SSH connectivity, or responding to cross-region disaster recovery scenarios.

You can run commands on an instance even when the instance does not have SSH access or open inbound ports.

The run command feature uses the Compute Instance Run Command plugin that is managed by the Oracle Cloud Agent software.

**Caution:**

Do not use the run command feature to provide or retrieve passwords, secrets, or other confidential information in plain text. To securely provide and retrieve confidential information, use an Object Storage location to store the script file and response. Use Oracle Cloud Infrastructure Vault to manage keys and secret credentials.
Supported Images
The run command feature is supported on compute instances that use the following Oracle-provided images:

- Oracle Autonomous Linux
- Oracle Linux
- CentOS
- Windows Server

Custom images that are based on a supported Oracle-provided image also support the run command feature.

Supported Regions
The run command feature is supported in all regions in the Oracle Cloud Infrastructure commercial realm.

Limitations and Considerations

- The maximum size for a script file that you upload directly to an instance in plain text is 4 KB. To provide a larger file, save the file in an Object Storage location.
- The output of a script when returned as plain text is limited to the last 1 KB. To save a larger response, save the output to an Object Storage location.
- When you use an Object Storage location to save the script file or response, the instance must have outbound connectivity such as a Network Access Translation (NAT) gateway, service gateway, or internet gateway. The instance must also allow egress traffic on port 443 for the Oracle Cloud Agent software, Object Storage, and IAM.
- Two scripts can run at a time by default. To change the default, update the run command configuration file:

```bash
cat /etc/oracle-cloud-agent/plugins/runcommand/config.yml
```

Set the following parameters:

```
logDir: /var/log/oracle-cloud-agent/plugins/runcommand
commandExecutionMaxWorkers: <number-of-parallel-scripts>
```

- A maximum of five scripts can be in flight at a time. A script is considered to be in flight if it has been received by the Compute Instance Run Command plugin, but not yet deleted from the queue.
- To perform long-running tasks, you should use the run command feature to schedule a cron job on the instance. Command orchestration is not supported.
- Each script runs once. If you want a script to run multiple times, use cron to configure a schedule for the script.
- Scripts that prompt for information are not supported. However, you can use the instance metadata service (IMDS) to programatically retrieve information about the instance that the script runs on.
- The exit codes that are returned are standard Linux error codes. An exit code of 0 indicates success.
- If you apply an optional timeout for a script, the default is 1 hour. The maximum is 24 hours.
- The maximum time that a script can run is 1 day.
- To monitor the resources that scripts consume, such as CPU utilization, use metrics.
- Canceling a script is a best-effort attempt. Commands can't be canceled after they have finished running or if they have expired.
- Script files and responses that are saved in plain text are retained for one month. Script files and responses that are saved in an Object Storage location are retained until you delete them.
- Do not run a script that causes the Oracle Cloud Agent software or the Compute Instance Run Command plugin to stop.

Running Commands with Administrator Privileges
If a command requires sudo permissions, you must grant sudo permissions to the Compute Instance Run Command plugin to be able to run the command. The plugin runs as the ocarun user.
You can use cloud-init to configure permissions at instance launch, or connect to an instance after it has launched and configure permissions manually. Do the following:

1. On the instance, create a sudoers configuration file for the Compute Instance Run Command plugin:

   `vi ./101-oracle-cloud-agent-run-command`

2. Allow the `ocarun` user to run all commands as sudo by adding the following line to the configuration file:

   `ocarun ALL=(ALL) NOPASSWD:ALL`

   You can optionally list specific commands. See the Linux man page for `sudoers` for more information.

3. Validate that the syntax in the configuration file is correct:

   `visudo -cf ./101-oracle-cloud-agent-run-command`

   If the syntax is correct, the follow message is returned:

   `./101-oracle-cloud-agent-run-command: parsed OK`

4. Add the configuration file to `/etc/sudoers.d`:

   `sudo cp ./101-oracle-cloud-agent-run-command /etc/sudoers.d/`

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: To write policy for the run command feature, do the following:

1. **Create a group** that includes the users who you want to allow to issue commands, cancel commands, and view the command output for the instances in a compartment. Then, write the following policy to grant access for the group:

   `Allow group RunCommandUsers to manage instance-agent-command-family in compartment ABC`

2. **Create a dynamic group** that includes the instances that you want to allow commands to run on. For example, a rule inside the dynamic group can state:

   `any { instance.id = 'ocid1.instance.oc1.phx.<unique_ID_1>', 'ocid1.instance.oc1.phx.<unique_ID_2>' }`

3. Write the following policy to grant access for the dynamic group:

   ```
   Note:
   If you create an instance and then add it to a dynamic group, it takes up to 30 minutes for the instance to start to poll for commands. If you create the dynamic group first and then create the instance, the instance starts to poll for commands as soon as the instance is created.
   ```

   `Allow dynamic-group RunCommandDynamicGroup to use instance-agent-command-execution-family in compartment ABC where request.instance.id=target.instance.id`
4. To allow the dynamic group to access the script file from an Object Storage bucket and save the response to an Object Storage bucket, write the following policies:

```plaintext
Allow dynamic-group RunCommandDynamicGroup to read objects in compartment ABC where all {target.bucket.name = '<bucket_with_script_file>'}
Allow dynamic-group RunCommandDynamicGroup to manage objects in compartment ABC where all {target.bucket.name = '<bucket_for_command_output>'}
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Prerequisites**

- The Compute Instance Run Command plugin must be enabled on the instance, and plugins must be running. For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 740.
- For Oracle-provided images that were released before October 2020, the Oracle Cloud Agent software must be updated to a version that supports the Compute Instance Run Command plugin (version 1.5.1 or later).
- You have prepared the script that you want to run. On Linux instances, the script runs in a Bash shell. On Windows instances, the script runs in a batch shell. We recommend that you test the command in a non-production environment before deploying it on instances that run production workflows.
- To provide the script file from an Object Storage location, upload the file to an Object Storage bucket in the same region as the target instance. Note the bucket and file name, or the Object Storage URL for the file. To use the same command across tenancies, create a pre-authenticated request that points to the file.
- To save the command output to an Object Storage location, create a bucket to save it in, in the same region as the target instance. Note the bucket name or the Object Storage URL for the bucket. You can optionally save the command output using a pre-authenticated request that points to an Object Storage location.

**Using the Console**

**To create a command to run on an instance**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
4. Click Create Command.
5. Enter a name for the command. Avoid entering confidential information.
6. In the Timeout in seconds box, enter the amount of time to give the Compute Instance Run Command plugin to run the command on the instance before timing out. The timer starts when the plugin starts the command. For no timeout, enter 0.
7. In the Add script section, upload the script that you want the Compute Instance Run Command plugin to run on the instance. Select one of the following options:
   - **Paste script**: Paste the command in the box.
   - **Select a file**: Upload the script as a text (.txt) file. Either browse to the file that you want to upload, or drag and drop the file into the box.
   - **Import from an Object Storage bucket**: Select the bucket that contains the script file. In the Object name box, enter the file name.
   - **Import from an Object Storage URL**: Enter the Object Storage URL for the script file.
8. In the **Output type** section, select the location to save the output of the command:
   - **Output as text**: The output is saved as plain text. You can review the output on the Instance Details page.
   - **Output to an Object Storage bucket**: The output is saved to an Object Storage bucket. Select a bucket. In the **Object name** box, enter a name for the output file. Avoid entering confidential information.
   - **Output to an Object Storage URL**: The output is saved to an Object Storage URL. Enter the URL.

9. Click **Create Command**.

**To view the output of a command**

If the command output was saved to an Object Storage location, either download the response object from the bucket where it was saved or navigate to the Object Storage pre-authenticated request URL.

If the command output was saved as a plain text file, do the following:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Run Command**.
4. Find the command in the list, click the Actions icon (three dots), and then click **View Command Details**.

**To cancel a command**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Run Command**.
4. Find the command in the list, click the Actions icon (three dots), and then click **Cancel Command**. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these API operations to work with the run command feature:

- CreateInstanceAgentCommand
- GetInstanceAgentCommand
- GetInstanceAgentCommandExecution

- CancelInstanceAgentCommand

**Troubleshooting the Compute Instance Run Command Plugin**

To troubleshoot the Compute Instance Run Command plugin, you can view the logs that the plugin generates. Connect to the instance and then use the following:

```
tail -f /var/log/oracle-cloud-agent/plugins/runcommand/runcommand.log
```

For easier visibility into the plugin's operations without having to connect to the instance, you can create custom logs using the Oracle Cloud Infrastructure Logging service.

**Log Errors**

This section describes how to resolve errors that appear in the log file.

**Failure to Poll**

If the Compute Instance Run Command plugin is failing to poll for commands, you might see the following error in the log file:

This error can occur when the dynamic group policy for the run command feature is not enabled or if the instance was recently added to the dynamic group. Instances don't belong to tenancy administrator groups by default, so you need to explicitly set dynamic group permissions for the instance. For instructions explaining how to enable the dynamic group policy, see Required IAM Policy on page 754.

When you create an instance and then add it to a dynamic group, it takes up to 30 minutes for the instance to start to poll for commands. If you create the dynamic group first and then create the instance, the instance starts to poll for commands as soon as the instance is created.

To test the dynamic group policy as soon as you add the instance to a dynamic group, restart the service manually using one of the following commands:

**Oracle Linux 6.x**

```
sudo initctl restart oracle-cloud-agent
```

**Oracle Linux 7.x and Oracle Linux 8.x**

```
sudo systemctl restart oracle-cloud-agent
```

**Windows Server**

```
net restart ocarun
```

### Getting Instance Metadata

The instance metadata service (IMDS) provides information about a running instance, including a variety of details about the instance, its attached virtual network interface cards (VNICs), and any custom metadata that you define. IMDS also provides information to cloud-init that you can use for various system initialization tasks.

You can find some of this information in the Console on the **Instance Details** page, or you can get all of it by logging in to the instance and using the metadata service. The service runs on every instance and is an HTTP endpoint listening on 169.254.169.254. If an instance has multiple VNICs, you must send the request using the primary VNIC.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To increase the security of metadata requests, we strongly recommend that you update all applications to use the IMDS version 2 endpoint, if supported by the image. Then, disable requests to IMDS version 1.</td>
</tr>
</tbody>
</table>

### Upgrading to the Instance Metadata Service v2

The instance metadata service is available in two versions, version 1 and version 2. IMDSv2 offers increased security compared to v1.

When you disable IMDSv1 and allow requests only to IMDSv2, the following things change:

- All requests must be made to the v2 endpoints (/opc/v2). Requests to the v1 endpoints (/opc/v1 and /openstack) are rejected with a 404 not found error.
- All requests to the v2 endpoints must include an authorization header. Requests that do not include the authorization header are rejected.
- Requests that are forwarded using the HTTP headers Forwarded, X-Forwarded-For, or X-Forwarded-Host are rejected.

To upgrade the instance metadata service on a compute instance, use the following high-level steps:

1. Verify that the instance uses an image that supports IMDSv2.
2. Identify requests to the legacy v1 endpoints.
3. Migrate all applications to support the v2 endpoints.
4. Disable all requests to the legacy v1 endpoints.

**Supported Images for IMDSv2**

IMDSv2 is supported on the following Oracle-provided platform images:

- Oracle Autonomous Linux 7.x images released in June 2020 or later
- Oracle Linux 8.x, Oracle Linux 7.x, and Oracle Linux 6.x images released in July 2020 or later

Other Oracle-provided platform images, most custom images, and most Marketplace images images do not support IMDSv2. Custom Linux images might support IMDSv2 if cloud-init is updated to version 20.03 or later and Oracle Cloud Agent is updated to version 0.0.19 or later. Custom Windows images might support IMDSv2 if Oracle Cloud Agent is updated to version 1.0.0.0 or later; cloudbase-init does not support IMDSv2.

**Identifying Requests to the Legacy IMDSv1 Endpoints**

To identify the specific IMDS endpoints that requests are being made to, and the agents that are making the requests, use the InstanceMetadataRequests metric.

To identify which versions of IMDS are enabled for an instance, do either of the following things:

- **Using the Console:**
  1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
  2. Click the instance that you're interested in.
  3. In the Instance Details section, next to Instance Metadata Service, note the version numbers.

- **Using the API:** Use the GetInstance operation or the ListInstances operation. In the response, the areLegacyImdsEndpointsDisabled attribute in the InstanceOptions object returns false if both IMDSv1 and IMDSv2 are enabled for the instance. It returns true if IMDSv1 is disabled.

**Disabling Requests to the Legacy IMDSv1 Endpoints**

After you migrate all applications so that they make requests only to the IMDSv2 endpoints, you should disable all requests to the legacy IMDSv1 endpoints.

**Important:**

Verify that the instance does not use the IMDSv1 endpoints before you disable requests to IMDSv1. If the instance still relies on IMDSv1 when you disable requests to it, you might lose some functionality.

Do either of the following things:

- **Using the Console:**
  1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
  2. Click the instance that you're interested in.
  3. In the Instance Details section, next to Instance Metadata Service, click Edit.
  4. For Allowed IMDS version, select the Version 2 only option.
  5. Click Save Changes.

- **Using the API:** Use the UpdateInstance operation. In the request body, in the InstanceOptions object, pass the value true for the areLegacyImdsEndpointsDisabled attribute.

**Note:**

If you disable IMDSv1 on an instance that does not support IMDSv2, you might not be able to connect to the instance when you launch it. To reenable IMDSv1: using the Console, on the Instance Details page, next to Instance Metadata Service, click Edit. Select the Version 1 and version 2 option,
Required IAM Policy

No IAM policy is required if you're logged in to the instance and using cURL to get the metadata.

For administrators: Users can also get instance metadata through the Compute API (for example, with GetInstance). The policy in Let users launch compute instances on page 2143 covers that ability. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

To require that legacy IMDSv1 endpoints are disabled on any new instances that are created, use the following policy:

```
Allow group InstanceLaunchers to manage instances in compartment ABC
where request.instanceOptions.areLegacyEndpointsDisabled = 'true'
```

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Getting Instance Metadata on Oracle-Provided Images

You can get instance metadata for Oracle-provided images by using cURL on Linux instances. On Windows instances, you can use cURL (if supported by the Windows version) or an internet browser.

All requests to the instance metadata service v2 must include the following header:

```
Authorization: Bearer Oracle
```

Instance metadata accessed using IMDSv2 is available at the following root URLs:

- All of the instance information:
  

- Information about the VNICs that are attached to the instance:
  

Instance metadata accessed using IMDSv1 is available at the following root URLs. No header is necessary.

- All of the instance information:
  

- Information about the VNICs that are attached to the instance:
  

The values for specific metadata keys are available as sub-paths below the root URL.

To get instance metadata for Linux instances

1. Connect to a Linux instance using SSH.
2. Use cURL to issue a GET request to the instance metadata URL that you're interested in. For example:

   ```
```
To get instance metadata for Windows instances

The steps to get metadata on a Windows instance depend on which version of the instance metadata service you're requesting metadata from.

To get Windows instance metadata using IMDSv2:
1. Connect to a Windows instance by using a Remote Desktop connection.
2. Depending on whether your Windows version includes cURL, do either of the following:
   - If your Windows version includes cURL, use cURL to issue a GET request to the instance metadata URL that you're interested in. For example:
     
     ```bash
     ```
   - If your Windows version does not include cURL, you can get instance metadata in your internet browser. Navigate to the instance metadata URL that you're interested in, and pass a request that includes the authorization header. See the instructions for your browser for more information about including headers in a request. You might need to install a third-party browser extension that lets you include request headers.

To get Windows instance metadata using IMDSv1:
1. Connect to a Windows instance by using a Remote Desktop connection.
2. Open an internet browser and then navigate to the instance metadata URL that you're interested in.

Metadata Keys

The instance metadata includes default metadata keys that are defined by Compute and cannot be edited, as well as custom metadata keys that you create.

Some metadata entries are directories that contain additional metadata keys. In the following tables, entries with a trailing slash indicate a directory. For example, `regionInfo/` is a directory that contains other metadata keys.

Metadata Keys for an Instance

The following metadata is available about an instance. The paths are relative to `http://169.254.169.254/opc/v2/instance/`.

<table>
<thead>
<tr>
<th>Metadata Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>availabilityDomain</td>
<td>The availability domain the instance is running in. This name includes the tenancy-specific prefix for the availability domain name. Example: Uocm:PHX-AD-1</td>
</tr>
<tr>
<td>faultDomain</td>
<td>The name of the fault domain the instance is running in. Example: FAULT-DOMAIN-1</td>
</tr>
<tr>
<td>compartmentId</td>
<td>The OCID of the compartment that contains the instance.</td>
</tr>
<tr>
<td>displayName</td>
<td>The user-friendly name of the instance.</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname of the instance.</td>
</tr>
<tr>
<td>id</td>
<td>The OCID of the instance.</td>
</tr>
<tr>
<td>image</td>
<td>The OCID of the image used to boot the instance.</td>
</tr>
<tr>
<td>Metadata Entry</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>metadata/</td>
<td>A directory containing any custom metadata that you provide for the instance.</td>
</tr>
<tr>
<td></td>
<td>To query the metadata for a specific custom metadata key, use <code>metadata/&lt;key-name&gt;</code>, where <code>&lt;key-name&gt;</code> is the name of the key that you defined when creating the instance.</td>
</tr>
<tr>
<td>metadata/sshAuthorizedKeys</td>
<td>For Linux instances, the public SSH key that was provided when creating the instance.</td>
</tr>
<tr>
<td>metadata/user_data</td>
<td>User data to be used by cloud-init or cloudbase-init to run custom scripts or provide custom configuration.</td>
</tr>
<tr>
<td>region</td>
<td>The <code>region</code> that contains the availability domain the instance is running in.</td>
</tr>
<tr>
<td></td>
<td>For the us-phoenix-1 and us-ashburn-1 regions, <code>phx</code> and <code>iad</code> are returned, respectively. For all other regions, the full region identifier is returned.</td>
</tr>
<tr>
<td></td>
<td>Examples: <code>phx</code>, <code>eu-frankfurt-1</code></td>
</tr>
<tr>
<td>canonicalRegionName</td>
<td>The region identifier for the <code>region</code> that contains the availability domain the instance is running in.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>us-phoenix-1</code></td>
</tr>
<tr>
<td>ociAdName</td>
<td>The availability domain the instance is running in. This name is used internally and corresponds to the data center label.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>phx-ad-1</code></td>
</tr>
<tr>
<td>regionInfo/</td>
<td>A directory containing information about the <code>region</code> that contains the availability domain the instance is running in.</td>
</tr>
<tr>
<td>regionInfo/realmKey</td>
<td>The key for the <code>realm</code> that the region is in.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>ocl</code></td>
</tr>
<tr>
<td>regionInfo/realmDomainComponent</td>
<td>The domain for the realm.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>oraclecloud.com</code></td>
</tr>
<tr>
<td>regionInfo/regionKey</td>
<td>The 3-letter key for the <code>region</code>.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>PHX</code></td>
</tr>
<tr>
<td>regionInfo/regionIdentifier</td>
<td>The region identifier.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>us-phoenix-1</code></td>
</tr>
<tr>
<td>shape</td>
<td>The <code>shape</code> of the instance. The shape determines the number of CPUs and the amount of memory allocated to the instance. You can enumerate all available shapes by calling the <code>ListShapes</code> operation.</td>
</tr>
<tr>
<td>Metadata Entry</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>state</td>
<td>The current lifecycle state of the instance. For a list of allowed values, see Instance. Example: Running</td>
</tr>
<tr>
<td>timeCreated</td>
<td>The date and time the instance was created, in the format defined by RFC3339.</td>
</tr>
<tr>
<td>agentConfig/</td>
<td>A directory containing information about the Oracle Cloud Agent software running on the instance.</td>
</tr>
<tr>
<td>agentConfig/monitoringDisabled</td>
<td>A Boolean value indicating whether the Oracle Cloud Agent software can gather performance metrics and monitor the instance.</td>
</tr>
<tr>
<td>agentConfig/managementDisabled</td>
<td>A Boolean value indicating whether the Oracle Cloud Agent software can run all the available management plugins.</td>
</tr>
<tr>
<td>freeformTags/</td>
<td>A directory containing any free-form tags that are added to the instance.</td>
</tr>
<tr>
<td>definedTags/</td>
<td>A directory containing any defined tags that are added to the instance.</td>
</tr>
</tbody>
</table>

Here's an example response that shows all of the information for an instance:

```json
{
  "availabilityDomain" : "EMIr:PHX-AD-1",
  "faultDomain" : "FAULT-DOMAIN-3",
  "compartmentId" : "ocid1.tenancy.oc1..exampleuniqueID",
  "displayName" : "my-example-instance",
  "hostname" : "my-hostname",
  "id" : "ocid1.instance.oc1.phx.exampleuniqueID",
  "image" : "ocid1.image.oc1.phx.exampleuniqueID",
  "metadata" : {
    "ssh_authorized_keys" : "example-ssh-key"
  },
  "region" : "phx",
  "canonicalRegionName" : "us-phoenix-1",
  "ociAdName" : "phx-ad-1",
  "regionInfo" : {
    "realmKey" : "ocl",
    "realmDomainComponent" : "oraclecloud.com",
    "regionKey" : "PHX",
    "regionIdentifier" : "us-phoenix-1"
  },
  "shape" : "VM.Standard.E3.Flex",
  "state" : "Running",
  "timeCreated" : 1600381928581,
  "agentConfig" : {
    "monitoringDisabled" : false,
    "managementDisabled" : false
  },
  "freeformTags" : {
    "Department" : "Finance"
  },
  "definedTags" : {
    "Operations" : {
      "CostCenter" : "42"
    }
  }
}
```
Metadata Keys for Attached VNICs

The following metadata is available about the VNICs that are attached to the instance. The paths are relative to http://169.254.169.254/opc/v2/vnics/.

<table>
<thead>
<tr>
<th>Metadata Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vnicId</td>
<td>The OCID of the VNIC.</td>
</tr>
<tr>
<td>privateIp</td>
<td>The private IP address of the primary privateIp object on the VNIC. The address is within the CIDR of the VNIC’s subnet.</td>
</tr>
<tr>
<td>vlanTag</td>
<td>The Oracle-assigned VLAN tag of the attached VNIC. If the VNIC belongs to a VLAN as part of the Oracle Cloud VMware Solution, the vlanTag value is instead the value of the vlanTag attribute for the VLAN. See Vlan.</td>
</tr>
<tr>
<td>macAddr</td>
<td>The MAC address of the VNIC. If the VNIC belongs to a VLAN as part of the Oracle Cloud VMware Solution, the MAC address is learned. If the VNIC belongs to a subnet, the MAC address is a static, Oracle-provided value.</td>
</tr>
<tr>
<td>virtualRouterIp</td>
<td>The IP address of the virtual router.</td>
</tr>
<tr>
<td>subnetCidrBlock</td>
<td>The subnet’s CIDR block.</td>
</tr>
<tr>
<td>nicIndex</td>
<td>Which physical network interface card (NIC) the VNIC uses. Certain bare metal instance shapes have two active physical NICs (0 and 1). If you add a secondary VNIC to one of these instances, you can specify which NIC the VNIC will use. For more information, see Virtual Network Interface Cards (VNICs) on page 2855.</td>
</tr>
</tbody>
</table>

Here’s an example response that shows the VNICs that are attached to an instance:

```json
[ {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.3.6",
  "vlanTag" : 11,
  "macAddr" : "00:00:00:00:00:01",
  "virtualRouterIp" : "10.0.3.1",
  "subnetCidrBlock" : "10.0.3.0/24",
  "nicIndex" : 0
}, {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.4.3",
  "vlanTag" : 12,
  "macAddr" : "00:00:00:00:00:02",
  "virtualRouterIp" : "10.0.4.1",
  "subnetCidrBlock" : "10.0.4.0/24",
  "nicIndex" : 0
}
]```
Updating Instance Metadata

You can add and update custom metadata for a compute instance using the Command Line Interface (CLI) on page 4192 or REST APIs on page 4368.

When you create an instance using the LaunchInstance operation, you can specify custom metadata for the instance in the LaunchInstanceDetails datatype's metadata or extendedMetadata attributes.

To update an instance's metadata, use the UpdateInstance operation, specifying the custom metadata in the UpdateInstanceDetails datatype's metadata or extendedMetadata attributes.

The metadata attribute supports key/value string pairs. The extendedMetadata attribute supports nested JSON objects. The combined size of these two attributes can be a maximum of 32,000 bytes.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to update instance metadata. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Using the API

When you use the UpdateInstance operation, the instance's metadata will be the combination of the values specified in the UpdateInstanceDetails datatype's metadata or extendedMetadata attributes. Any set of key/value pairs specified for these attributes in the UpdateInstance operation will replace the existing values for these attributes, so you need to include all the metadata values for the instance in each call, not just the ones you want to add. If you leave the attribute empty when calling UpdateInstance, the existing metadata values in that attribute will be used. You cannot specify a value for the same metadata key twice, as this will cause the UpdateInstance operation to fail due to there being duplicate keys.

To understand this, consider the example scenario where you created an instance using the LaunchInstance operation and specified the following key/value pair for the metadata attribute:

"myCustomMetadataKey" : "myCustomMetadataValue"

If you then call the UpdateInstance operation, and add new metadata by specifying additional key/value pairs in the extendedMetadata attribute, but you leave the metadata attribute empty, do not include the myCustomMetadataKey key/value in the extendedMetadata attribute, as this will cause the operation to fail since that key already exists. If you do specify values for the metadata attribute, you need to include the myCustomMetadataKey key/value to maintain it in the instance's metadata. In this case, you can specify it in either of the attributes.

There are two reserved keys, user_data and ssh_authorized_keys, that can only be set for an instance at launch time, they cannot be updated later. If you use the metadata attribute to add or update metadata for an instance, you need to ensure that you include the values specified at launch time for both these keys, otherwise the UpdateInstance operation will fail.

Best Practices for Updating an Instance's Metadata

When using the UpdateInstance operation, we recommend the following:
• Use the GetInstance operation to retrieve the existing custom metadata for the instance to ensure that you include the values you want to maintain in the appropriate attributes when you call UpdateInstance. The metadata values are returned in the metadata and extendedMetadata attributes for the Instance. For a code example demonstrating this, see the UpdateInstanceExample in the SDK for Java on page 4225.
• Unless you are updating custom metadata that was added using the metadata attribute, use the extendedMetadata attribute to add custom metadata. Otherwise you need to include the launch time values for the user_data and ssh Authorized_keys reserved keys. If you use the metadata attribute to add values and you leave out the values for these reserved keys or specify different values for them, the UpdateInstance call will fail.

Editing an Instance

You can edit the properties of a compute instance without having to rebuild the instance or redeploy your applications.

On supported instances, you can edit the following properties:
• Name. See Renaming an Instance on page 765.
• The shape that's used for the instance. Changing the shape affects the processor, number of OCPUs, memory, and other resources that are allocated to the instance. This lets you scale up your Compute resources for increased performance, or scale down to reduce cost. See Changing the Shape of an Instance on page 766.
• The fault domain where the instance is placed. You can distribute your instances across fault domain to protect against unexpected hardware failures or maintenance outages. See Editing the Fault Domain for an Instance on page 768.
• The launch options for the instance, which include the following properties:
  • The networking type for the virtual network interface card (VNIC). The networking interface handles functions such as disk input/output and network communication. Choose between paravirtualized and hardware-assisted (SR-IOV) networking. Paravirtualized networking provides more management flexibility. SR-IOV networking offers better performance.
  • The boot volume attachment type. Choose between paravirtualized and iSCSI attachment types.

  See Editing the Launch Options for an Instance on page 769.
• Whether in-transit encryption is used for the boot volume or block volume. See Enabling In-Transit Encryption Between an Instance and Boot Volumes or Block Volumes on page 773.
• Whether a running instance is recovered to the same lifecycle state or stopped after a maintenance event affects the underlying infrastructure. See Setting Instance Availability During Maintenance Events on page 774.

When you edit an instance, the instance's OCID remains the same.

Renaming an Instance

You can rename an instance without changing its Oracle Cloud Identifier (OCID).

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to rename an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.
Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Enter a new name. Avoid entering confidential information.
5. Click Save Changes.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to rename an instance:

- UpdateInstance

Changing the Shape of an Instance

You can change the shape of a virtual machine (VM) instance without having to rebuild your instances or redeploy your applications. This lets you scale up your Compute resources for increased performance, or scale down to reduce cost.

When you change the shape of an instance, it affects the number of OCPUs, amount of memory, network bandwidth, and maximum number of VNICs for the instance. Optionally, you can select a shape that uses a different processor. The instance's public and private IP addresses, volume attachments, and VNIC attachments remain the same.

Supported Shapes

The shape series and image of the original shape determine which shapes you can select as a target for the new shape. You can resize instances that use these shapes:

- **VM.Standard.E2, VM.Standard2, VM.Standard.B1, and VM.Standard1 series:**
  - For Linux images, the shape can be changed to any fixed shape in the VM.Standard.E2, VM.Standard2, VM.Standard.B1, or VM.Standard1 series. The shape can also be changed to the VM.Standard.E3 series flexible shape.
  - For Windows images, the shape can be changed to a new shape only within the same series. For example, you can change a VM.Standard2.1 shape to a VM.Standard2.2 shape, but you can't change a VM.Standard2.1 shape to a VM.Standard1.1 shape.

- **VM.Standard.E3 series:** You can change the number of OCPUs and the amount of memory allocated to a VM.Standard.E3 series flexible shape. For Linux images, a flexible shape can also be changed to any fixed shape in the VM.Standard.E2, VM.Standard2, VM.Standard.B1, or VM.Standard1 series.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For Windows Server 2019 instances, resize a VM.Standard.E3 shape to a maximum of 32 OCPUs. See this known issue for more information.</td>
</tr>
</tbody>
</table>

- **VM.GPU3 series:** Can be changed to any shape in the VM.GPU3 series.

These shapes cannot be changed:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts
- Bare metal shapes
Limitations and Considerations

Be aware of the following information:

• The image that's used to launch the instance must be compatible with the new shape. To see which shapes are compatible, do either of the following things:
  
  • In the Console, on the Instance Details page, click the name of the image. Then, refer to the list of compatible shapes.
  
  • Using the API, call the ListShapes operation and pass the image OCID as a parameter.
  
  • Some Marketplace images cannot be resized because of licensing constraints. If you want to resize a Microsoft SQL Server image, contact support.
  
  • You must have sufficient service limits for the new shape. If you don't have service limits, the instance will remain with the original shape.
  
  • Different shapes are billed at different rates. When you change the shape of an instance, you are billed to the nearest second of usage for each shape that you use. For more information, see Compute Pricing and Resource Billing for Stopped Instances on page 780.
  
  • If the instance has secondary VNICs configured, you might need to reconfigure them after the instance is rebooted. For more information, see Virtual Network Interface Cards (VNICs) on page 2855.
  
  • If the instance is running when you change the shape, it is rebooted as part of the change shape operation. If the applications that run on the instance take a long time to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, shut down the instance using the commands available in the OS before you change the shape.
  
  • When you change the shape from one hardware series to a different series, some hardware details such as the network interface name might change. This might cause problems for some guest OSs, particularly if the OS has been customized. If the OS fails to boot after you change the shape, then you should change the instance back to the original shape.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to change the shape of an instance. If the specified group doesn’t need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Prerequisites

• If you want to change the instance to a smaller shape that supports fewer VNICs, detach the extra VNICs.

Using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click **Edit Shape**. Then, select the shape that you want to scale to. The following options are available:

- **AMD Rome**: The flexible shapes, which uses the current generation AMD processor and has a customizable number of OCPUs and amount of memory.
  
  - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.
  
  - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For each OCPU, you can select up to 64 GB of memory, with a maximum of 1024 GB total. The minimum amount of memory allowed is either 1 GB or a value matching the number of OCPUs, whichever is greater. For example, if you select 25 OCPUs, the minimum amount of memory allowed is 25 GB.

  The other resources scale proportionately.

- **Intel Skylake**: Standard shapes that use the current generation Intel processor and have a fixed number of OCPUs.

- **Specialty and Legacy**: Standard shapes with previous generation Intel and AMD processors.

5. Click **Change Shape**. If the instance is running, it is rebooted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to change the shape of an instance:

- **UpdateInstance**

**Editing the Fault Domain for an Instance**

You can change the fault domain where a virtual machine (VM) instance is placed.

A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. By properly leveraging fault domains you can increase the availability of applications running on Oracle Cloud Infrastructure. For more information and best practices, see Fault Domains on page 595.

**Supported Shapes**

You can change the fault domain for instances that use these shapes:

- VM.Standard.E3 series
- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard.B1 series
- VM.Standard1 series
- VM.DenseIO1 series
- VM.DenseIO2 series
- VM.GPU3 series

These shapes cannot be edited:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts
- Bare metal shapes

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and
which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to change
the fault domain for an instance. If the specified group doesn’t need to launch instances or attach volumes, you could
simplify that policy to include only manage instance-family, and remove the statements involving volume-
family and virtual-network-family.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For
reference material about writing policies for instances, cloud networks, or other Core Services API resources, see
Details for the Core Services on page 2181.

**Using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Edit Fault Domain. Then, select a new fault domain.
5. Click Save Changes.

   If the instance is running, it is rebooted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on
page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to change the fault domain for an instance:

- UpdateInstance

**Editing the Launch Options for an Instance**

You can tune the compatibility and performance of virtual machine (VM) instances by changing the networking type
or the boot volume attachment type.

**Networking Launch Types**

The networking interface handles functions such as disk input/output and network communication. The following
networking types are available:

- **Paravirtualized networking**: For general purpose workloads such as enterprise applications, microservices,
  and small databases. Paravirtualized networking also provides increased flexibility to use the same image across
different hardware platforms. Linux images with paravirtualized networking support live migration during
infrastructure maintenance.

- **Hardware-assisted (SR-IOV) networking**: Single root input/output virtualization. For low-latency workloads
  such as video streaming, real-time applications, and large or clustered databases. Hardware-assisted (SR-IOV)
  networking uses the VFIO driver framework.

  **Note:**

  On Windows Server 2012 R2 images, SR-IOV networking is only supported
  on the VM.Standard2 and VM.DenseIO2 shapes.

The following table lists the default and supported networking types for VM shapes.

<table>
<thead>
<tr>
<th>Shape series</th>
<th>Default Networking Type</th>
<th>Supported Networking Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>Shape series</td>
<td>Default Networking Type</td>
<td>Supported Networking Types</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>VM.Standard.E2</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
</tbody>
</table>

**Note:** Due to driver support, the Windows Server 2012 platform image supports paravirtualized networking only.

<table>
<thead>
<tr>
<th>Shape series</th>
<th>Default Networking Type</th>
<th>Supported Networking Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.DenseIO1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU2</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
</tbody>
</table>

To use paravirtualized networking, you must also use an image that supports paravirtualized networking. Paravirtualized networking is supported on these Oracle-provided images:

- **Oracle Linux 8:** All images.
- **Oracle Linux 7, Oracle Linux 6:** Images published in March 2019 or later.
- **CentOS 8:** All images.
- **CentOS 7:** Images published in July 2019 or later.
- **Ubuntu 18.04, Ubuntu 16.04:** Images published in March 2019 or later.
- **Windows Server 2019:** All images.
- **Windows Server 2016:** Images published in August 2019 or later.

SR-IOV networking is supported on all Oracle-provided images, except for Windows Server 2019 when launched using a VM.Standard2 shape. On Windows Server 2012 R2, SR-IOV networking is only supported on the VM.Standard2 and VM.DenseIO2 shapes.

### Boot Volume Attachment Types

The following boot volume attachment types are available:

- **iSCSI:** A TCP/IP-based standard used for communication between a volume and attached instance.
- **Paravirtualized:** A virtualized attachment available for VMs. This is the default for boot volumes and remote block storage volumes on Oracle-provided platform images.

### Supported Shapes

You can edit the launch options for instances that use these shapes:

- VM.Standard.E3 series
- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard.B1 series
- VM.Standard1 series
- VM.DenseIO1 series
- VM.DenseIO2 series
- VM.GPU3 series

These shapes cannot be edited:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts
Limitations and Considerations

**Caution:**

Some instances might not function properly if you change the networking type or the boot volume attachment type. This happens due to shape and image compatibility and driver support. After the instance reboots and is running, connect to it. If the connection fails or the OS doesn't behave as expected, the changes are not supported. Revert the instance to the original settings.

Before you change the networking type or the boot volume attachment type, you must ensure that paravirtualized drivers are installed on the image. The steps depend on the image:

**Oracle Linux 7.x, CentOS 8.x, CentOS 7.x, Ubuntu 20, Ubuntu 18, Ubuntu 16**

Paravirtualized drivers are installed on Oracle-provided platform images.

The Oracle VirtIO Drivers for Microsoft Windows release 1.1.5 must be installed on Oracle-provided platform images.

1. To determine whether the VirtIO drivers are installed, connect to the instance using a Remote Desktop connection. Then, do either of the following things:

   - Open `Control Panel > Program and Features`. If `Oracle Windows VirtIO Drivers` is installed, note the version number.
   - In Registry Editor, go to `HKEY_LOCAL_MACHINE\Software\Wow6432Node\Oracle Corporation\Oracle Windows VirtIO Drivers`. If the VirtIO drivers are installed, note the version number.

2. If the drivers are not installed or a version that is not 1.1.5 is installed, download Oracle VirtIO Drivers release 1.1.5:

   - Sign in to the [Oracle Software Delivery Cloud site](https://www.oracle.com/software-delivery-cloud/).
   - In the [All Categories](https://www.oracle.com/software-delivery-cloud/software.html) list, select [Release](https://www.oracle.com/software-delivery-cloud/released.html).
   - Type `Oracle Linux 7.7` in the search box and click [Search](https://www.oracle.com/software-delivery-cloud/search.html).
   - Add [REL: Oracle Linux 7.7.x](https://www.oracle.com/software-delivery-cloud/category/oracle-linux-x86-64.html) to your cart, and then click [Continue](https://www.oracle.com/software-delivery-cloud/continue.html).
   - In the [Platforms/Languages](https://www.oracle.com/software-delivery-cloud/platforms-languages.html) list, select [x86 64 bit](https://www.oracle.com/software-delivery-cloud/platforms-languages.html). Click [Continue](https://www.oracle.com/software-delivery-cloud/continue.html).
   - Accept the license agreement and then click [Continue](https://www.oracle.com/software-delivery-cloud/continue.html).
   - Select the check box next to [Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5](https://www.oracle.com/software-delivery-cloud/checkout.html). Clear the other check boxes.
   - Click [Download](https://www.oracle.com/software-delivery-cloud/download.html) and then follow the prompts.

3. Install the drivers and then restart the instance. For steps, see [Installing the Oracle VirtIO Drivers for Microsoft Windows on Existing Microsoft Windows Guests](https:// docs.oracle.com/en/database/oracle-cloud-infrastructure/user-guide/compute.html#GUID-16E6C470-13BB-452B-A77F-D9203B9435C1).

**Oracle Linux 6.x**

For Oracle-provided platform images, connect to the instance using a Secure Shell (SSH) connection. Then, run the following commands:

```
sudo bash
cd /boot/efi
echo "fs0:\EFI\redhat\grub.efi"> startup.nsh
chmod 500 startup.nsh
sync
```

**Images that are not Oracle-provided platform images**
To verify that your system has paravirtualized drivers installed, run the following command:

```
lsinitrd | grep virtio
```

- If paravirtualized drivers are installed, you will see multiple files listed with paths similar to `lib/modules/4.4.21-69-default/kernel/drivers/block/virtio_blk.ko`.
- If no files are listed, your system either does not support paravirtualized drivers, or does not have paravirtualized drivers installed. Refer to the documentation for your operating system for more information.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a `policy` by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which `compartment` you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to edit the launch options for an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage `instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Prerequisites**

- Detach (delete) all secondary VNICs and detach all block volumes. The primary VNIC and boot volume should remain attached.

**Using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Show Advanced Options.
5. To change the networking type, in the Networking type section, select from the following options:
   - **Hardware-assisted (SR-IOV) networking**: Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases.
   - **Paravirtualized networking**: For general purpose workloads such as enterprise applications, microservices, and small databases. The image must have paravirtualized drivers, as described in Limitations and Considerations on page 771.

   For more information, see Recommended Networking Launch Types on page 696.

6. To change the boot volume attachment type, in the Boot volume attachment type section, select from the following options:
   - **iSCSI**: A TCP/IP-based standard used for communication between a volume and attached instance.
   - **Paravirtualized**: A virtualized attachment available for VMs. This is the default for boot volumes and remote block storage volumes on Oracle-provided platform images.

7. Click Save Changes.

   If the instance is running, it is rebooted.

8. Connect to the instance after it reboots and is running. If the connection fails or the OS doesn't behave as expected, the changes are not supported. Revert the instance to the original settings.

9. If necessary, reattach any secondary VNICs and block volumes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use this API operation to edit the launch options for an instance:

- **UpdateInstance**

## Enabling In-Transit Encryption Between an Instance and Boot Volumes or Block Volumes

After you create a virtual machine (VM) instance, you can enable or disable in-transit encryption between the instance and its paravirtualized boot volume and block volume attachments.

All boot volume and block volume data at rest is always encrypted by the Oracle Cloud Infrastructure Block Volume service using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption. For more information, see [Block Volume Encryption](#) on page 504.

**Important:** See this [known issue](#) for more information about editing the in-transit encryption settings.

### Supported Shapes and Images

You can enable or disable in-transit encryption for existing instances that use these shapes:

- VM.Standard.E3 series
- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard.B1 series
- VM.Standard1 series
- VM.DenseIO1 series
- VM.DenseIO2 series
- VM.GPU3 series

In-transit encryption for boot volumes and block volumes is available for [Oracle-provided images](#). It is not supported in most cases for instances launched from custom images imported for "bring your own image" (BYOI) scenarios. To confirm support for certain Linux-based custom images, contact support.

These shapes cannot be edited:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts
- Bare metal shapes

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a [policy](#) by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which [compartment](#) you should work in.

For administrators: The policy in [Let users launch compute instances](#) on page 2143 includes the ability to change the shape of an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see [Getting Started with Policies](#) on page 2135 and [Common Policies](#) on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see [Details for the Core Services](#) on page 2181.

### Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Show Advanced Options.
5. Select the Use in-transit encryption check box.
6. Click Save Changes.

   If the instance is running, it is rebooted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to enable or disable in-transit encryption between an instance and its paravirtualized boot volume attachments:

- UpdateInstance

**Setting Instance Availability During Maintenance Events**

When the underlying infrastructure for a virtual machine (VM) instance needs to undergo planned maintenance or recover from an unexpected failure, Oracle Cloud Infrastructure automatically attempts to recover the instance by migrating it to healthy hardware. By default, the instance is recovered to the same lifecycle state as before the maintenance event. If you have an alternate process to recover the instance after a reboot migration, you can optionally configure the instance to remain stopped after it is migrated to healthy hardware. You can then restart the instance on your own schedule.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to edit the maintenance recovery action for an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Show Advanced Options.
5. For the Restore instance lifecycle state after infrastructure maintenance check box, select an option:
   - To reboot a running instance after it is recovered, select the check box.
   - To recover the instance in the stopped state, clear the check box.
6. Click Save Changes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use this API operation to edit the maintenance recovery action for an instance:

- UpdateInstance
Moving a Compute Instance to a New Host

This topic covers how to relocate a virtual machine or a bare metal instance by using reboot migration or a manual process.

**Note:**

- **Dedicated virtual machine hosts:** Dedicated virtual machine hosts do not support reboot migration. To relocate these instances, use the process described in Moving an Instance with Manual Migration on page 775.
- **Oracle Platform Services:**
  For instances that were created with Oracle Platform Services and located in the compartment ManagedCompartmentForPaaS, you must use the interface for the specific Platform Service to reboot the instances.

**Live Migration**

During an infrastructure maintenance event, where applicable, Oracle Cloud Infrastructure live migrates Standard VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. If a VM cannot be live migrated, there might be a short downtime while the instance is reboot migrated. You can avoid this downtime by proactively reboot migrating the instance.

**Reboot Migration**

For instances with a date in the **Reboot Maintenance** field (available in the Console, CLI, and SDKs), you can reboot your instance to move it to new infrastructure. After you reboot the instance, the **Reboot Maintenance** field is cleared. This change indicates that the instance was moved successfully.

**Prerequisites for Reboot Migration**

1. Prepare the instance for reboot migration:
   - Ensure that any remote block volumes defined in /etc/fstab use the recommended options.
   - Ensure that any File Storage service (NFS) mounts use the nofail option.
   - If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

**Moving an Instance with Reboot Migration**

After you complete the prerequisites:

1. Stop any running applications.
2. Reboot the instance.
3. Confirm that the **Reboot Maintenance** field no longer has a date.

**Limitations and Warnings for Manual Migration**

Be aware of the following limitations and warnings when performing a manual migration:

- Any public IP addresses assigned to your instance from a reserved public pool are retained. Any that were not assigned from a reserved public IP address pool will change. Private IP addresses do not change.
• MAC addresses, CPUIDs, and other unique hardware identifiers do change during the move. If any applications running on the instance use these identifiers for licensing or other purposes, be sure to take note of this information before moving the instance to help you manage the change.

Prerequisites for Manual Migration

1. Before moving the instance, document all critical details:
   • The instance's region, availability domain, and fault domain.
   • The instance's display name.
   • All private IP addresses, names, and subnets. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses.
   • All private DNS names. The instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses. Each private IP address can have a DNS name.
   • Any public IP addresses assigned from a reserved public pool. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary private IP addresses. Each VNIC and secondary private IP address can have an attached public IP address.
   • Any remote block volumes attached to the instance.
   • Any tags on the instance or attached resources.

2. Prepare the instance for manual migration:
   • Ensure that any remote block volumes defined in /etc/fstab use the recommended options.
   • Ensure that any File Storage service (NFS) mounts use the nofail option.
   • If you have statically defined any network interfaces belonging to secondary VNICs using their MAC addresses, such as those defined in /etc/sysconfig/network-scripts/ifcfg*, those interfaces will not start due to the change in the MAC address. Remove the static mapping.
   • If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

Moving an Instance Manually

After you complete the prerequisites:

1. Stop any running applications.
2. Ensure that those applications will not start automatically.

Caution:

When the relocated instance starts for the first time, remote block volumes, secondary VNICs, or any resource that relies on them, will not be attached. The absence of these resources can cause application issues.

3. If your instance has local NVMe storage (dense instances), you must back up this data:
   a. Create and attach one or more remote block volumes to the instance.
   b. Copy the data from the NVMe devices to the remote block volumes.
4. Unmount any remote block volumes or File Storage service (NFS) mounts.
5. Back up all remote block volumes. See Overview of Block Volume Backups on page 540 for more information.
6. Create a backup of the root volume.

Important:

Do not generalize or specialize Windows instances.
7. Terminate the instance:
   
   **Using the Console**
   
   To terminate the instance, follow the steps in Terminating an Instance on page 783, ensuring that the **Permanently delete the attached boot volume** check box is cleared. This preserves the boot volume that is associated with the instance.
   
   **Using the API**
   
   To terminate the instance, use the TerminateInstance operation and pass the preserveBootVolume parameter set to true in the request.
   
   **Using the CLI**
   
   To terminate the instance, use the terminate operation and set the preserve-boot-volume option to true.

8. Create a new instance using the boot volume from the terminated instance.

9. In the launch instance flow, specify the private IP address that was attached to the primary VNIC. If the public IP address was assigned from a reserved IP address pool, be sure to assign the same IP address.

10. When the instance state changes to **RUNNING**, stop the instance.

11. Recreate any secondary VNICs and secondary IP addresses.

12. Attach any remote block volumes.

   **Note:**
   
   This step includes any volumes used to back up local NVMe devices. Copy the data onto the NVMe storage on the new instance, and then detach the volumes.

13. Start the instance.

15. Configure the applications to start automatically, as required.

16. Recreate the required tags.

17. (Optional) After you confirm that the instance and applications are healthy, you can delete the volume backups.

### Moving Compute Resources to a Different Compartment

You can move Compute resources such as instances, instance pools, and custom images from one compartment to another.

When you move a Compute resource to a new compartment, associated resources such as boot volumes and VNICs are not moved.

After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. For more information, see Managing Compartments on page 2431.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: The following policies allow users to move Compute resources to a different compartment:

- Allow group ComputeCompartmentMovers to manage instance-family in tenancy
- Allow group ComputeCompartmentMovers to manage compute-management-family in tenancy
- Allow group ComputeCompartmentMovers to manage auto-scaling-configurations in tenancy
If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to move Compute resources from one compartment to another:

• You can't move a compute instance from a security zone to a standard compartment.
• You can't move a compute instance from a standard compartment to a compartment that is in a security zone.

Using the Console

To move an instance to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. In the List Scope section, select a compartment.
3. Click the instance that you're interested in.
4. Click More Actions, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests on page 260.

7. If there are alarms monitoring the instance, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 2737 for more information.
8. Optionally, move the resources that are attached to the instance to the new compartment.

To move an instance configuration to a different compartment

Note:

Most of the properties for an existing instance configuration, including the compartment, cannot be modified after you create the instance configuration. Although you can move an instance configuration to a different compartment, you will not be able to use the instance configuration to manage instance pools in the new compartment. If you want to update an instance configuration to point to a different compartment, you should instead create a new instance configuration in the target compartment. For steps, see Creating an Instance Configuration on page 710.

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Configurations.
2. In the List Scope section, select a compartment.
3. Click the instance configuration that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move an instance pool to a different compartment

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. In the List Scope section, select a compartment.
3. Click the instance pool that you're interested in.
4. Click More Actions, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. Optionally, update the instance pool with an instance configuration that points to the new compartment. Do the following:
   a. Create a new instance configuration in the new compartment. You can do this using the Console or the API. For steps, see Creating an Instance Configuration on page 710.
   b. Update the instance pool with the new instance configuration. You can do this using the API. For steps, see Updating an Instance Pool on page 713.
8. Optionally, move the instances and other resources that are associated with the instance pool to the new compartment.

To move an autoscaling configuration to a different compartment
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Autoscaling Configurations.
2. In the List Scope section, select a compartment.
3. Click the autoscaling configuration that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move a custom image to a different compartment
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Custom Images.
2. In the List Scope section, select a compartment.
3. Click the custom image that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move a cluster network to a different compartment
1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Cluster Networks.
2. In the List Scope section, select a compartment.
3. Click the cluster network that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. Optionally, move the instances and other resources that are associated with the cluster network to the new compartment.

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to move Compute resources to different compartments:
- ChangeInstanceCompartment
- ChangeInstanceConfigurationCompartment
- ChangeInstancePoolCompartment
- ChangeAutoScalingConfigurationCompartment
- ChangeImageCompartment
- ChangeClusterNetworkCompartment

Stopping and Starting an Instance
You can stop and start an instance as needed to update software or resolve error conditions.

For steps to manage the lifecycle state of instances in an instance pool, see Stopping and Starting the Instances in an Instance Pool on page 716.
Stopping or Restarting an Instance Using the Instance's OS

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to stop or start an existing instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

Resource Billing for Stopped Instances

For both VM and bare metal instances, billing depends on the shape that you use to create the instance:

- **Standard shapes**: Stopping an instance pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes**: Billing continues for stopped instances because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **GPU shapes**: Billing continues for stopped instances because GPU resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **HPC shapes**: Billing continues for stopped instances because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

For more information about Compute pricing, see Compute Pricing. For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure? on page 805.

Recovering a Virtual Machine (VM) During Planned Maintenance

Oracle Cloud Infrastructure performs routine data center maintenance on the physical infrastructure for VM instances. This maintenance includes tasks such as upgrading and replacing hardware or performing maintenance that halts power to the host. When an underlying infrastructure component needs to undergo maintenance, you are notified in advance before the impact to your instances.

During an infrastructure maintenance event, where applicable, Oracle Cloud Infrastructure live migrates Standard VM instances to a healthy physical VM host without disrupting running instances. If a VM instance cannot be live migrated, then the instance is stopped on the physical VM host that needs maintenance, reboot migrated to a healthy VM host, and then restarted. If you have an alternate process to recover the instances, you can optionally configure the instances to remain stopped after they are reboot migrated to healthy hardware.

If VM instances are scheduled for a maintenance reboot, you can proactively reboot (or stop and start) the instances at any time before the scheduled reboot. Proactively rebooting lets you control how and when your applications
experience downtime. Customer-managed VM maintenance is supported on Standard and GPU instance shapes, including Oracle-provided platform images and custom images that were imported from outside of Oracle Cloud Infrastructure.

To identify the VM instances that you can proactively reboot, do any of the following things:

**Using the Console: To see which instances in the current compartment are scheduled for a maintenance reboot**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

   If the instance has a maintenance reboot scheduled and can be proactively rebooted, a warning icon appears next to the instance name.

2. Click the instance that you're interested in, and then check the **Maintenance Reboot** field for the instance. This field displays the date and start time for the maintenance reboot.

**Using the API: To see which instances in a compartment are scheduled for a maintenance reboot**

Use the ListInstances operation. The `timeMaintenanceRebootDue` field for the Instance returns the date and start time for the maintenance reboot.

**Using Search: To find all instances that are scheduled for a maintenance reboot**

1. In the top navigation bar, click **Search for resources, services, and documentation**, and then click **Advanced Resource Query**.

2. Click **Select Sample Query**, and then click **Query for all instances which have an upcoming scheduled maintenance reboot**.

3. Click **Search**.

If you choose not to reboot before the scheduled time, then Oracle Cloud Infrastructure will migrate your instances within a 24-hour period after the scheduled time.

An instance is no longer impacted by a maintenance event when the **Maintenance Reboot** field for the instance is blank.

**VM Recovery Due to Infrastructure Failure**

When the underlying infrastructure of a VM instance fails due to software or hardware issues, Oracle Cloud Infrastructure automatically attempts to recover the instance.

Standard and GPU VM instances are recovered to another physical VM host using **reboot migration**. During the reboot, instance properties such as private and ephemeral public IP addresses, attached block volumes, and VNICs are preserved.

Dense I/O VM instances are recovered by rebooting the instance on the same physical host. If recovering a Dense I/O instance on the same physical host isn't possible, Oracle Cloud Infrastructure notifies you to terminate the instance within 14 days. If you don't terminate the instance before the deadline, Oracle Cloud Infrastructure will terminate it. The boot volume and remote attached data volume are preserved.

Oracle Cloud Infrastructure notifies you by email or **announcements** of any VM infrastructure failure events, with the status of the recovery action that was taken. You can also monitor the **instance status metric** to stay aware of any unexpected reboots.

Optionally, you can **configure your instances to remain stopped** after they are recovered.

**Hardware Reclamation for Stopped Bare Metal Instances**

When a bare metal instance remains in the stopped state for longer than 48 hours, the instance is taken offline and the physical hardware is reclaimed. The next time that you restart the instance, it starts on different physical hardware. There are no changes to the block volumes, boot volumes, and instance metadata, including the ephemeral and public IP addresses.

However, the following properties do change when a bare metal instance restarts on different physical hardware: the MAC addresses and the host serial number. You might also notice changes in the BIOS firmware version, BIOS settings, and CPU microcode. If you want to keep the same physical hardware, do not stop the instance using the
Console or the API, SDKs, or CLI. Instead, shut down the instance using the instance's OS. When you want to restart the instance, use the Console or the API, SDKs, or CLI.

This behavior applies to Linux instances that use the following shapes:

- BM.Standard1.36
- BM.Standard.B1.44
- BM.Standard2.52
- BM.Standard.E2.64

### Using the Console

#### To start an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click **Start**.

#### To stop an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click **Stop**.
4. By default, the Console gracefully stops the instance by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instance is powered off.

   **Note:**
   
   If the applications that run on the instance take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, shut down the instance using the commands available in the OS before you stop the instance using the Console.

   If you want to stop the instance immediately, without waiting for the OS to respond, select the **Force stop the instance by immediately powering off** check box.
5. Click **Stop Instance**.

#### To reboot an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click **Reboot**.
4. By default, the Console gracefully restarts the instance by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instance is powered off and then powered back on.

   **Note:**
   
   If the applications that run on the instance take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, shut down the instance using the commands available in the OS before you restart the instance using the Console.

   If you want to reboot the instance immediately, without waiting for the OS to respond, select the **Force reboot the instance by immediately powering off, then powering back on** check box.
5. Click **Reboot Instance**.
**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the InstanceAction operation to stop, start, or reboot an instance.

**Terminating an Instance**

You can permanently terminate (delete) instances that you no longer need. Any attached VNICs and volumes are automatically detached when the instance terminates. Eventually, the instance's public and private IP addresses are released and become available for other instances.

By default, the instance's boot volume is preserved when you terminate the instance. You can attach the boot volume to a different instance as a data volume, or use it to launch a new instance. If you no longer need the boot volume, you can permanently delete it at the same time that you terminate the instance.

**Caution:**

If your instance has NVMe storage, terminating the instance securely erases the NVMe drives. Any data that was on the NVMe drives becomes unrecoverable. Ensure that you back up any important data before you terminate an instance. For more information, see Protecting Data on NVMe Devices.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to terminate an instance (with or without an attached block volume).

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click More Actions, and then click Terminate.
4. If you want to delete the boot volume that is associated with the instance, select the Permanently delete the attached boot volume check box.
5. Click Terminate Instance.

Terminated instances temporarily remain in the list of instances with the state Terminated.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the TerminateInstance operation to terminate an instance.

**Enabling Monitoring for Compute Instances**

This topic describes how to enable monitoring, specifically for the compute instance metrics, on compute instances.
The compute instance metrics provide data about the activity level and throughput of the instance. These metrics are required to use features such as autoscaling, metrics, alarms, and notifications with compute instances. A compute instance emits these metrics only when the Compute Instance Monitoring plugin is enabled and running on the instance.

The Compute Instance Monitoring plugin is managed by the Oracle Cloud Agent software.

**Supported Images**

Compute instance metrics are supported on current Oracle-provided images and on custom images that are based on current Oracle-provided images.

If you use an older Oracle-provided image, you must manually install the Oracle Cloud Agent software before you can use the Compute Instance Monitoring plugin. Select an image dated after November 15, 2018 (except Ubuntu, which must be dated after February 28, 2019).

You might have success enabling compute instance metrics on other images that support the Oracle Cloud Agent software, though the Compute Instance Monitoring plugin has not been tested on other operating systems and there is no guarantee that it will work. Compute instance metrics are not supported on Windows Server 2008 R2 custom images.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: For more information about the IAM policies that are needed to create and update a compute instance, see Creating an Instance on page 695.

**Prerequisites**

- Service gateways or public IP addresses: The compute instance must have either a public IP address or a service gateway to be able to send compute instance metrics to the Monitoring service.

  If the instance does not have a public IP address, set up a service gateway on the virtual cloud network (VCN). The service gateway lets the instance send compute instance metrics to the Monitoring service without the traffic going over the internet. Here are special notes for setting up the service gateway to access the Monitoring service:

  - When creating the service gateway, enable the service label called All <region> Services in Oracle Services Network. It includes the Monitoring service.
  
  - When setting up routing for the subnet that contains the instance, set up a route rule with Target Type set to Service Gateway, and the Destination Service set to All <region> Services in Oracle Services Network.

  For detailed instructions, see Access to Oracle Services: Service Gateway on page 3256.

- Oracle Cloud Agent: The Oracle Cloud Agent software must be installed on the instance. Oracle Cloud Agent is installed by default on current Oracle-provided images. For steps to manually install Oracle Cloud Agent on older images, see Installing the Oracle Cloud Agent Software on page 741.

- Compute Instance Monitoring plugin: For the instance to emit the compute instance metrics, the Compute Instance Monitoring plugin must be enabled on the instance and plugins must be running. For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 740.

**Enabling Monitoring for a New Compute Instance**

To configure a new compute instance to emit the compute instance metrics, use the following steps.

**Creating a Monitoring-Enabled Instance Using the Console**

1. Follow the steps to create an instance, until the advanced options. Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.
2. Click **Show Advanced Options**.
3. On the **Oracle Cloud Agent** tab, select the **Compute Instance Monitoring** check box.

   **Note:**
   If you’re using an older Oracle-provided image or a custom image that is not based on a recent Oracle-provided image, you must manually install the Oracle Cloud Agent software. You can do this by providing a cloud-init script. For more information, see Installing the Oracle Cloud Agent Software on page 741. Compare the date of the image to the date listed in Supported Images.

4. Click **Create**.

   The newly created, monitoring-enabled instance emits compute instance metrics to the Monitoring service.

**Creating a Monitoring-Enabled Instance Using the API**

Use the **LaunchInstance** operation. Include the following parameters:

```json
{
   "agentConfig": {
      "isMonitoringDisabled": false,
      "areAllPluginsDisabled": false,
      "pluginsConfig": [
         {
            "name": "Compute Instance Monitoring",
            "desiredState": "ENABLED"
         }
      ]
   }
}
```

Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.

**Note:**
If you’re using an older Oracle-provided image or a custom image that is not based on a recent Oracle-provided image, you must manually install the Oracle Cloud Agent software. You can do this by providing a cloud-init script. For more information, see Installing the Oracle Cloud Agent Software on page 741. Compare the date of the image to the date listed in Supported Images.

**Enabling Monitoring for an Existing Compute Instance**

To configure an existing Compute instance to emit the compute instance metrics, use the following steps.

**To enable monitoring on an existing compute instance using the Console**

1. Install the Oracle Cloud Agent software, if it is not already installed.
2. Enable the Compute Instance Monitoring plugin.
3. Confirm that plugins are running on the instance.
4. Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.
5. To confirm that monitoring is enabled:
   a. Go to the Metrics page for the instance:
      1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
      2. Click the instance that you're interested in.
      3. Under **Resources**, click **Metrics**.
      4. In the **Metric Namespace** list, select **oci_computeagent**.
   b. If you see metric charts with data, then the Monitoring service is receiving compute instance metrics from this instance. For more information about these metrics, see **Compute Instance Metrics** on page 788.

   If monitoring is not enabled (and the instance uses a supported image), then a button is available to enable monitoring. Click **Enable monitoring**.

**To enable monitoring on an existing compute instance using the API**

1. Install the Oracle Cloud Agent software, if it is not already installed.
2. Use the **UpdateInstance** operation. Include the following parameters:

   ```json
   {  
     "agentConfig": {  
       "isMonitoringDisabled": false,  
       "areAllPluginsDisabled": false,  
       "pluginsConfig": [  
         {  
           "name": "Compute Instance Monitoring",  
           "desiredState": "ENABLED"  
         }  
       ]  
     }  
   }
   ```

3. Ensure that the instance has either a public IP address or a service gateway, as described in the **prerequisites**.

**Managing the Compute Instance Monitoring Plugin**

For an instance to emit the compute instance metrics, the Compute Instance Monitoring plugin must be enabled on the instance and plugins must be running.

If you want to temporarily prevent the instance from emitting compute instance metrics, you can disable the Compute Instance Monitoring plugin. You can also stop all of the plugins that run on the instance, including the Compute Instance Monitoring plugin.

**Caution:**

Functionality that depends on the plugin, such as monitoring and autoscaling, does not work when the plugin is disabled or stopped.

For more information about how to enable and run plugins, see **Managing Plugins with Oracle Cloud Agent** on page 740.

**Finding Out if Monitoring Has Your Metrics**

To determine whether Monitoring is receiving the compute instance metrics, you can either query the instance metrics, or view the instance properties to confirm that the Compute Instance Monitoring plugin is enabled and running.

**Using the Console: To find out whether Monitoring is receiving metrics by querying instance metrics**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the Metric Namespace list, select **oci_computeagent**.

If you see metric charts with data, then the Monitoring service is receiving metrics from this instance. For more information about these metrics, see Compute Instance Metrics on page 788.

If you see a message that monitoring is not enabled, or that the Oracle Cloud Agent software needs to be installed, then complete those tasks.

**Using the Console:** To find out whether the Compute Instance Monitoring plugin is enabled and running

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Click the Oracle Cloud Agent tab.
4. Confirm that the Compute Instance Monitoring plugin is enabled, and all plugins are running.

**Using the API:** To find out whether Monitoring is receiving metrics by querying instance metrics

Use the SummarizeMetricsData API operation. If metrics are returned, it indicates that the Monitoring service is receiving metrics from the instance.

**Using the API:** To find out whether the Compute Instance Monitoring plugin is enabled and running

Use the GetInstance operation (or ListInstances operation, for multiple instances).

In the response, if the `agentConfig` object returns the following values, it indicates that the Compute Instance Monitoring plugin is enabled and all plugins are running.

```
{
  "agentConfig": {
    "isMonitoringDisabled": false,
    "areAllPluginsDisabled": false,
    "pluginsConfig": [
      {
        "name": "Compute Instance Monitoring",
        "desiredState": "ENABLED"
      }
    ]
  }
}
```

**Not seeing metrics for your instance?**

If you don't see any metric charts, the instance might not be emitting metrics. See the following possible causes and resolutions.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Compute Instance Monitoring plugin is disabled on the instance or plugins are stopped.</td>
<td>Review the instance properties.</td>
<td>Enable the Compute Instance Monitoring plugin and start all plugins.</td>
</tr>
<tr>
<td>The instance cannot access the Monitoring service because its VCN does not use the internet.</td>
<td>Review the instance's IP address. If it's not public, then a service gateway is needed.</td>
<td>Set up a service gateway.</td>
</tr>
<tr>
<td>The instance does not use a supported image.</td>
<td>Review the supported images.</td>
<td>Create an instance with a supported image.</td>
</tr>
<tr>
<td>Older images and custom images: No Oracle Cloud Agent software exists on the instance.</td>
<td>Connect to the instance and look for the software.</td>
<td>Install the Oracle Cloud Agent software.</td>
</tr>
</tbody>
</table>
Possible cause | How to check | Resolution
--- | --- | ---
New instance in a new compartment: The IAM policies required for the instance to publish metrics to Monitoring are not yet initialized. | (not applicable) | Check back after 10 or 20 minutes.
More information: IAM policies are automatically created for new instances and are immediately available, unless the instances are in a new compartment. For a new instance in a new compartment, the policies can take up to 20 minutes to initialize, which delays the emission of metrics.

Compute Metrics

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

There are multiple Monitoring service metric namespaces related to Compute resources:

- **oci_computeagent**: Metrics related to the activity level and throughput of compute instances, as emitted by the Compute Instance Monitoring plugin. See Compute Instance Metrics on page 788.
- **oci_instancepools**: Metrics related to the lifecycle state of instances in instance pools. See Instance Pool Metrics on page 793.
- **oci_compute_infrastructure_health**: Metrics related to the up/down status, health, and maintenance status of compute instances. See Infrastructure Health Metrics on page 795.
- **oci_compute**: Metrics related to the instance metadata service (IMDS) that provides information about running compute instances. See Compute Management Metrics on page 798.

Compute Instance Metrics

You can monitor the health, capacity, and performance of your Compute instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace **oci_computeagent** (the Compute Instance Monitoring plugin on Compute instances).

You can view these metrics for individual Compute instances, and for all the instances in an instance pool.

Resources: Monitoring-enabled Compute instances.

**Overview of Metrics for an Instance and Related Resources**

This section gives an overall picture of the different types of metrics available for an instance and its storage and network devices. See the following diagram and table for a summary.
<table>
<thead>
<tr>
<th>Metric Namespace</th>
<th>Resource ID</th>
<th>Where Measured</th>
<th>Available Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>oci_computeagent</td>
<td>Instance OCID</td>
<td>On the instance. The metrics in this namespace are aggregated across all the related resources on the instance. For example, DiskBytesRead is aggregated across all the instance's attached storage volumes, and NetworkBytesIn is aggregated across all the instance's attached VNICs.</td>
<td>See Available Metrics: oci_computeagent on page 790.</td>
</tr>
<tr>
<td>oci_blockstore</td>
<td>Boot or block volume OCID</td>
<td>By the Block Volume service. The metrics are for an individual volume (either boot volume or block volume).</td>
<td>See Block Volume Metrics on page 585.</td>
</tr>
<tr>
<td>oci_vcn</td>
<td>VNIC OCID</td>
<td>By the Networking service. The metrics are for an individual VNIC.</td>
<td>See VNIC Metrics on page 3321.</td>
</tr>
</tbody>
</table>

**Prerequisites**

- IAM policies: To monitor resources, you must be given the required type of access in a *policy* written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, the Compute Instance Monitoring plugin must be enabled on the instance, and plugins must be running. The instance must also have either a service gateway or a public IP address to send...
metrics to the Monitoring service. For more information, see Enabling Monitoring for Compute Instances on page 783.

Available Metrics: oci_computeagent

The compute instance metrics help you measure activity level and throughput of compute instances. The metrics listed in the following table are available for any monitoring-enabled compute instance. You must enable monitoring on the instance to get these metrics.

The metrics in this namespace are aggregated across all the related resources on the instance. For example, DiskBytesRead is aggregated across all the instance's attached storage volumes, and NetworkBytesIn is aggregated across all the instance's attached VNICs.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions

<table>
<thead>
<tr>
<th>availabilityDomain</th>
<th>The availability domain where the instance resides.</th>
</tr>
</thead>
<tbody>
<tr>
<td>faultDomain</td>
<td>The fault domain where the instance resides.</td>
</tr>
<tr>
<td>imageId</td>
<td>The OCID of the image for the instance.</td>
</tr>
<tr>
<td>instancePoolId</td>
<td>The instance pool that the instance belongs to.</td>
</tr>
<tr>
<td>region</td>
<td>The region where the instance resides.</td>
</tr>
<tr>
<td>resourceDisplayName</td>
<td>The friendly name of the instance.</td>
</tr>
<tr>
<td>resourceId</td>
<td>The OCID of the instance.</td>
</tr>
<tr>
<td>shape</td>
<td>The shape of the instance.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>CpuUtilization</td>
<td>CPU Utilization</td>
<td>percent</td>
<td>Activity level from CPU. Expressed as a percentage of total time.</td>
<td>availabilityDomain</td>
</tr>
<tr>
<td>DiskBytesRead[1,3]</td>
<td>Disk Read Bytes</td>
<td>bytes</td>
<td>Read throughput. Expressed as bytes read per interval.</td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Dimensions</td>
</tr>
<tr>
<td>--------</td>
<td>---------------------</td>
<td>------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>DiskBytesWritten</td>
<td>Disk Write Bytes</td>
<td>bytes</td>
<td>Write throughput. Expressed as bytes written per interval.</td>
<td></td>
</tr>
<tr>
<td>DiskIopsRead(^1,(^3)</td>
<td>Disk Read I/O</td>
<td>operations</td>
<td>Activity level from I/O reads. Expressed as reads per interval.</td>
<td></td>
</tr>
<tr>
<td>DiskIopsWritten(^1)</td>
<td>Disk Write I/O</td>
<td>operations</td>
<td>Activity level from I/O writes. Expressed as writes per interval.</td>
<td></td>
</tr>
<tr>
<td>LoadAverage</td>
<td>Load Average</td>
<td>number of processes</td>
<td>Average system load calculated over a 1 minute period.</td>
<td></td>
</tr>
<tr>
<td>MemoryAllocationStalls</td>
<td>Memory Allocation Stalls</td>
<td>number of stalls</td>
<td>Number of times page reclaim was called directly.</td>
<td></td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>Memory Utilization</td>
<td>percent</td>
<td>Space currently in use. Measured by pages. Expressed as a percentage of used pages. For instance pools, the value is averaged across all instances in the pool.</td>
<td></td>
</tr>
<tr>
<td>NetworksBytesIn(^2)</td>
<td>Network Receive Bytes</td>
<td>bytes</td>
<td>Network receipt throughput. Expressed as bytes received.</td>
<td></td>
</tr>
<tr>
<td>NetworksBytesOut(^2)</td>
<td>Network Transmit Bytes</td>
<td>bytes</td>
<td>Network transmission throughput. Expressed as bytes transmitted.</td>
<td></td>
</tr>
</tbody>
</table>

\(^1\)This metric is a cumulative counter that shows monotonically increasing behavior for each session of the Oracle Cloud Agent software, resetting when the operating system is restarted.

\(^2\)The Networking service provides additional metrics (in the `oci_vcn` metric namespace) for each VNIC on the instance. For more information, see Networking Metrics on page 3320.

\(^3\)The Block Volume service provides additional metrics (in the `oci_blockstore` metric namespace) for each volume attached to the instance. For more information, see Block Volume Metrics on page 585.

**Using the Console**

*To view default metric charts for a single Compute instance*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select **oci_computeagent**.

The Metrics page displays a default set of charts for the current instance.

**Not seeing any metric charts for the instance?**

If you don't see any metric charts, the instance might not be emitting metrics. See the following possible causes and resolutions.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Compute Instance Monitoring plugin is disabled on the instance or plugins are stopped.</td>
<td>Review the instance properties.</td>
<td>Enable the Compute Instance Monitoring plugin and start all plugins.</td>
</tr>
<tr>
<td>The instance cannot access the Monitoring service because its VCN does not use the internet.</td>
<td>Review the instance's IP address. If it's not public, then a service gateway is needed.</td>
<td>Set up a service gateway.</td>
</tr>
<tr>
<td>The instance does not use a supported image.</td>
<td>Review the supported images.</td>
<td>Create an instance with a supported image.</td>
</tr>
<tr>
<td>Older images and custom images: No Oracle Cloud Agent software exists on the instance.</td>
<td>Connect to the instance and look for the software.</td>
<td>Install the Oracle Cloud Agent software.</td>
</tr>
<tr>
<td>New instance in a new <strong>compartment</strong>: The IAM <strong>policies</strong> required for the instance to publish metrics to Monitoring are not yet initialized. More information: IAM policies are automatically created for new instances and are immediately available, unless the instances are in a new compartment. For a new instance in a new compartment, the policies can take up to 20 minutes to initialize, which delays the emission of metrics.</td>
<td>(not applicable)</td>
<td>Check back after 10 or 20 minutes.</td>
</tr>
</tbody>
</table>

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view default metric charts for resources related to a Compute instance**

- **For an attached block volume**:
  
  While viewing the instance's details, under **Resources**, click **Attached Block Volumes**, and then click the volume that you're interested in. Click **Metrics** to see the volume's charts. For more information about the emitted metrics, see **Block Volume Metrics** on page 585.

- **For the attached boot volume**:
  
  While viewing the instance's details, under **Resources**, click **Boot Volume**, and then click the volume that you're interested in. Click **Metrics** to see the volume's charts. For more information about the emitted metrics, see **Block Volume Metrics** on page 585.

- **For an attached VNIC**:
  
  While viewing the instance's details, under **Resources**, click **Attached VNICs**, and then click the VNIC that you're interested in. Click **Metrics** to see the charts for the VNIC. For more information about the emitted metrics, see **Networking Metrics** on page 3320.

**To view default metric charts for all Compute instances in a compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select a compartment.
3. For Metric Namespace, select `oci_computeagent`.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

To view default metric charts for the instances in an instance pool

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the instance pool that you're interested in.
4. In the Metric Namespace list, select `oci_computeagent`.

   The Metrics page displays a default set of charts for the current instance pool.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Instance Pool Metrics

You can monitor the health, capacity, and performance of your Compute instance pools by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_instancepools`.

Resources: Compute instance pools.

Overview of Metrics: `oci_instancepools`

The instance pool metrics help you monitor the lifecycle state of instances in your instance pools.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: `oci_instancepools`

The metrics listed in the following table are automatically available for each instance pool that you create. You do not need to enable monitoring on the instances in the pool to get these metrics.

You also can use the Monitoring service to create custom queries.

Depending on the metric, the following dimensions are available:

**AvailabilityDomain**

The availability domain where the instance pool resides.
Compute

DisplayName
The friendly name of the instance pool.

FaultDomain
The fault domain where the instance pool resides.

region
The region where the instance pool resides.

resourceId
The OCID of the instance pool.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>InstancePoolSize</td>
<td>Instance Pool Size</td>
<td>instances</td>
<td>Number of instances in the pool.</td>
<td>DisplayName, region, resourceId</td>
</tr>
<tr>
<td>ProvisioningInstances</td>
<td>Provisioning</td>
<td>instances</td>
<td>Number of instances in the pool that are provisioning.</td>
<td>AvailabilityDomain, DisplayName, FaultDomain, region, resourceId</td>
</tr>
<tr>
<td>RunningInstances</td>
<td>Instances Running</td>
<td>instances</td>
<td>Number of running instances in the pool.</td>
<td>AvailabilityDomain, DisplayName, FaultDomain, region, resourceId</td>
</tr>
<tr>
<td>TerminatedInstances</td>
<td>Instances Terminated</td>
<td>instances</td>
<td>Number of instances in the pool that are terminating or terminated.</td>
<td>AvailabilityDomain, DisplayName, FaultDomain, region, resourceId</td>
</tr>
</tbody>
</table>

Using the Console
To view default metric charts for a single instance pool

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instance Pools.
2. Click the instance pool that you're interested in.
4. In the Metric Namespace list, select oci_instancepools.

The Metrics page displays a default set of charts for the current instance pool.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.
To view default metric charts for all instance pools in a compartment

1. Open the navigation menu. Under Solutions and Platform, go to Monitoring and click Service Metrics.
2. Select a compartment.
3. For **Metric Namespace**, select `oci_instancepools`.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Infrastructure Health Metrics**

You can monitor the health, capacity, and performance of the infrastructure for your Compute virtual machine (VM) and bare metal instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_compute_infrastructure_health`.

Resources: Compute instances.

**Overview of Metrics: oci_compute_infrastructure_health**

The Compute infrastructure health metrics help you monitor the status and health of Compute instances.

- **Instance health (up/down) status**: The `instance_status` metric lets you check whether a VM or bare metal instance is available (up) or unavailable (down) when in the running state.
- **Instance maintenance status**: The `maintenance_status` metric lets you monitor whether a VM instance is scheduled for planned infrastructure maintenance.
- **Bare metal infrastructure health status**: The `health_status` metric helps you monitor the health of the infrastructure for bare metal instances, including hardware components such as the CPU and memory.

Based on the value of the metrics, you can proactively move affected instances to healthy hardware and thereby minimize the impact on your applications.

**Required IAM Policy**

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_compute_infrastructure_health**

The metrics listed in the following table are automatically available for your instances. The `instance_status` metric is available for both VM and bare metal instances, the `maintenance_status` metric is available only for VM instances, and the `health_status` metric is available only for bare metal instances. You do not need to enable monitoring on the instance to get these metrics.

You also can use the Monitoring service to create custom queries.

The metric includes the following **dimensions**: 

---

**Oracle Cloud Infrastructure User Guide** 795
The type of hardware issue:

- **CPU**: A fault has been detected in one or more CPUs.
- **MEM–BOOT**: A fault in the memory subsystem was detected during instance launch or a recent reboot.
- **MEM–RUNTIME**: A fault in the memory subsystem was detected.
- **MGMT–CONTROLLER**: A fault in the instance management controller has been detected.
- **PCI**: A fault in the PCI subsystem has been detected.
- **PCI–NIC**: A fault in the instance network interface card (NIC) has been detected.
- **SDN–INTERFACE**: A fault in the instance software defined network interface has been detected.

For troubleshooting suggestions and more information about these hardware issues, see Compute Health Monitoring for Bare Metal Instances on page 801.

**resourceDisplayName**

The friendly name of the instance.

**resourceId**

The OCID of the instance.

**maintenanceDueTime**

The scheduled start time of the 24-hour maintenance window, in the format defined by RFC3339.

**computeMaintenanceAction**

The action that Oracle Cloud Infrastructure will perform on an instance during a scheduled maintenance event:

- **REBOOT**: The instance is migrated from the physical VM host that needs maintenance to a healthy VM host. If live migration is not possible, then the instance is reboot migrated.

**recommendedAction**

The action that you can take before the scheduled maintenance event, so that you can control how and when your applications experience downtime.

- **REBOOT**: You can proactively reboot the instance before the scheduled maintenance time. When you reboot an instance for maintenance, the instance is stopped on the physical VM host that needs maintenance, and then restarted on a healthy VM host. For more information, see Moving a Compute Instance to a New Host on page 775.

**Using the Console**

*To view infrastructure health metrics for a single Compute instance*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select **oci_compute_infrastructure_health**.

The Metrics page displays a default set of charts for the current instance.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

*To view infrastructure health metrics for all Compute instances in a compartment*

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select **oci_compute_infrastructure_health**.

The Service Metrics page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Compute Management Metrics

You can monitor requests to the instance metadata service on compute virtual machine (VM) and bare metal instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_compute.

Resources: compute instances.

Overview of Metrics: oci_compute

The instance metadata service (IMDS) provides metadata about an instance, its attached VNICS, and custom metadata that you supply. IMDS is available in two versions, version 1 and version 2. IMDSv2 offers increased security compared to the legacy v1.

Use the Compute management metric to identify requests to the legacy v1 endpoints. After you migrate any applications to support the v2 endpoints, you can disable all requests to the legacy v1 endpoints.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_compute

The metric listed in the following table is automatically available for your instances. You do not need to enable monitoring on the instance to get this metric.

You also can use the Monitoring service to create custom queries.

The metric includes the following dimensions:

- metadataVersion
  - The version of the instance metadata service that requests were made to.

- path
  - The URL path that instance metadata requests were made to.

- resourceId
  - The OCID of the instance.

- userAgent
  - The source of the instance metadata request.

- status
  - The HTTP response code for requests to instance metadata service.
## Compute NVMe Performance

The content in the sections below apply to **Category 7** and **Section 3.a** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Oracle Cloud Infrastructure provides a variety of instance configurations in both bare metal and virtual machine (VM) shapes. Each shape varies on multiple dimensions including memory, CPU cores, network bandwidth, and the option of local NVMe SSD storage found in DenseIO and HPC shapes.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for NVMe performance. Measuring performance is complex and open to variability.

An NVMe drive also has non-uniform drive performance over the period of drive usage. An NVMe drive performs differently when tested brand new compared to when tested in a steady state after some duration of usage. New drives have not incurred many write/erase cycles and the inline garbage collection has not had a significant impact on IOPS.

### Using the Console

**To view management metrics for a single compute instance**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you’re interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select **oci_compute**.

   The Metrics page displays a default set of charts for the current instance.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view management metrics for all compute instances in a compartment**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select **oci_compute**.

   The **Service Metrics** page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

### Oracle Cloud Infrastructure User Guide

<table>
<thead>
<tr>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>InstanceMetadataRequests V1 Versus V2</td>
<td>Sum</td>
<td>The number of requests to the instance metadata service, comparing the version 1 and version 2 endpoints.</td>
<td>metadataVersion path resourceId userAgent status</td>
</tr>
</tbody>
</table>
performance. To achieve the goal of reproducibility and reduced variability, our testing focuses on the steady state duration of the NVMe drive’s operation.

**Testing Methodology**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before running any tests, protect your data by making a backup of your data and operating system environment to prevent any data loss. The tests described in this document will overwrite the data on the disk, and cause data corruption.</td>
</tr>
</tbody>
</table>

**Summary:** To capture the IOPS measure, first provision a shape such as the BM.DenseIO2.52 shape, and then use the Gartner Cloud Harmony test suite to run tests on an instance running the latest supported Oracle Linux 7 image for each NVMe drive target.

**Instructions:**

1. Launch an instance based on the latest supported Oracle Linux 7 image and select a shape such as the BM.DenseIO2.52 shape. For instructions, see Creating an Instance on page 695.
2. Run the Gartner Cloud Harmony test suite tests on the instance for each NVMe drive target. The following is an example of a command that will work for all shapes and drives on the shape:

   ```
   sudo ./run.sh `ls /dev/nvme[0-9]n1 | sed -e 's/\//\--target=\//'` --nopurge --noprecondition --fio_direct=1 --fio_size=10g --test=iops --skip_blocksize=512b --skip_blocksize=8k --skip_blocksize=16k --skip_blocksize=32k --skip_blocksize=64k --skip_blocksize=128k --skip_blocksize=1m
   ```

The SLA for NVMe drive performance is measured against 4k block sizes with 100% random write workload on DenseIO shapes where the drive is in a steady state of operation.

**Performance Benchmarks**

The following table lists the minimum IOPS for the specified shape to meet the SLA, given the testing methodology with 4k block sizes for 100% random write tests using the tests described in the previous section.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Minimum Supported IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.DenseIO1.4</td>
<td>200k</td>
</tr>
<tr>
<td>VM.DenseIO1.8</td>
<td>250k</td>
</tr>
<tr>
<td>VM.DenseIO1.16</td>
<td>400k</td>
</tr>
<tr>
<td>BM.DenseIO1.36</td>
<td>2.5MM</td>
</tr>
<tr>
<td>VM.DenseIO2.8</td>
<td>250k</td>
</tr>
<tr>
<td>VM.DenseIO2.16</td>
<td>400k</td>
</tr>
<tr>
<td>VM.DenseIO2.24</td>
<td>800k</td>
</tr>
<tr>
<td>BM.DenseIO2.52</td>
<td>3.0MM</td>
</tr>
<tr>
<td>BM.HPC2.36</td>
<td>250k</td>
</tr>
</tbody>
</table>

Although the NVMe drives are capable of higher IOPS, Oracle Cloud Infrastructure currently guarantees this minimum level of IOPS performance.
Frequently Asked Questions

Q: I suspect a slowdown in my NVMe drive performance. Is there a SLA violation?
A: We test hosts on a regular basis to ensure that are our low-level software updates do not regress performance. If you have reproduced the testing methodology and your drive’s performance does not meet the terms in the SLA, please contact your Oracle sales team.

Q: Why does the testing methodology not represent a diversity of IO workloads such as random reads and writes to reflect real world IO?
A: We focused on reproducibility and we believe the tests provide a significant indicator of overall drive performance.

Q: Will Oracle Cloud Infrastructure change the tests in this document?
A: We will make changes to provide greater customer value through better guarantees and improved reproducibility.

Compute Health Monitoring for Bare Metal Instances

Compute health monitoring for bare metal instances is a feature that provides notifications about hardware issues with your bare metal instances. With the health monitoring feature, you can monitor the health of the hardware for your bare metal instances, including components such as the CPU, motherboard, DIMM, and NVMe drives. You can use the notifications to identify problems, letting you proactively redeploy your instances to improve availability.

Health monitoring notifications are emailed to the tenant administrator within one business day of the error occurring. This warning helps you to take action before any potential hardware failure and redeploy your instances to healthy hardware to minimize the impact on your applications.

You can also use the infrastructure health metrics available in the Monitoring service to create alarms and notifications based on hardware issues.

Error Messages and Troubleshooting

This section contains information about the most common health monitoring error messages and provides troubleshooting suggestions for you to try for your bare metal instance.

A fault has been detected in one or more CPUs

Fault class: CPU

Details: This error indicates that a processor or one or more cores have failed in your instance. Your instance might be inaccessible or there might be fewer available cores than expected.

Troubleshooting steps:
• If the instance is inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host on page 775.
• If your instance is available, check for the expected number of cores:
  • On Linux-based systems, run the following command:
    nproc --all
  • On Windows-based systems, open Resource Monitor.

  Compare the core count to the expected values documented in Compute Shapes on page 655. If the number of cores is less than expected and this reduction impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

A fault in the memory subsystem was detected during instance launch or a recent reboot

Fault class: MEM-BOOT

Details: This error indicates that one or more failed DIMMs were detected in your instance while the instance was being launched or rebooted. Any failed DIMMs have been disabled.
Troubleshooting steps: The total amount of memory in the instance will be lower than expected. If this impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

To check for the amount of memory in the instance:

- On Linux-based systems, run the following command:

  ```bash
  awk '$3=="kB"{${2=2/1024**2;${3="GB"}} 1}' /proc/meminfo | column -t | grep MemTotal
  ```

- On Windows-based systems, open Resource Monitor.

The expected values are documented in Compute Shapes on page 655.

A fault in the memory subsystem was detected

**Fault class:** MEM-RUNTIME

**Details:** This error indicates that one or more non-critical errors were detected on a DIMM in your instance. The instance might have unexpectedly rebooted in the last 72 hours.

**Troubleshooting steps:**

- If the instance has unexpectedly rebooted in the last 72 hours, one or more DIMMs might have been disabled. To check for the total amount of memory in the instance:

  ```bash
  awk '$3=="kB"{${2=2/1024**2;${3="GB"}} 1}' /proc/meminfo | column -t | grep MemTotal
  ```

- On Windows-based systems, open Resource Monitor.

  If the total memory in the instance is lower than expected, then one or more DIMMs have failed. If this impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

- If the instance has not unexpectedly rebooted, it is at increased risk of doing so. During the next reboot, one or more DIMMs might be disabled. We recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

A fault in the instance management controller has been detected

**Fault class:** MGMT-CONTROLLER

**Details:** This error indicates that a device used to manage your instance might have failed. You might not be able to use the Console, CLI, SDKs, or APIs to stop, start, or reboot your instance. This functionality will still be available from within the instance using the standard operating system commands. You also might not be able to create a console connection to your instance. You will still be able to terminate your instance.

**Troubleshooting steps:** If this loss of control impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

A fault in the PCI subsystem has been detected

**Fault class:** PCI

**Details:** This error indicates that one or more of the PCI devices in your instance have failed or are not operating at peak performance.

**Important:**

The PCI fault class will be deprecated in the future. You should migrate to the PCI-NIC fault class for similar functionality.

**Troubleshooting steps:**
• If you cannot connect to the instance over the network, the NIC might have failed. Use the Console or CLI to stop the instance and then start the instance. For steps, see Stopping and Starting an Instance on page 779.

If you're still unable to connect to the instance over the network, you might be able to connect to it using a console connection. Follow the steps in Connecting to the Serial Console on page 817 or Connecting to the VNC Console on page 822 to establish a console connection and then reboot the instance. If the instance remains inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host on page 775.

• An NVMe device may have failed.

  On Linux-based systems, run the command `sudo lsblk` to get a list of the attached NVMe devices.

  On Windows-based systems, open Disk Manager. Check the count of NVMe devices against the expected number of devices in Compute Shapes on page 655.

  If you determine that an NVMe device is missing from the list of devices for your instance, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

A fault in the instance network interface card (NIC) has been detected

**Fault class:** PCI-NIC

**Details:** This error indicates that one or more of the instance network interface card (NIC) devices in your instance have failed or are not operating at peak performance.

**Troubleshooting steps:** If you cannot connect to the instance over the network, the NIC might have failed. Use the Console or CLI to stop the instance and then start the instance. For steps, see Stopping and Starting an Instance on page 779.

If you're still unable to connect to the instance over the network, you might be able to connect to it using a console connection. Follow the steps in Connecting to the Serial Console on page 817 or Connecting to the VNC Console on page 822 to establish a console connection and then reboot the instance. If the instance remains inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host on page 775.

A fault in the instance software defined network interface has been detected

**Fault class:** SDN-INTERFACE

**Details:** If you cannot connect to the instance or if you're experiencing networking issues, the software-defined network interface device might have a fault.

**Troubleshooting steps:** Although restarting the instance might temporarily resolve the issue, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 775.

**Microsoft Licensing on Oracle Cloud Infrastructure**

This topic provides information about the licensing requirements to use Microsoft products on Oracle Cloud Infrastructure.

For more information about how to bring your own Microsoft licenses to Oracle Cloud Infrastructure, see Licensing Options for Microsoft Windows on page 809.

For information about how to move eligible Microsoft server application licenses to Oracle Cloud Infrastructure by enrolling in the License Mobility through Microsoft Software Assurance benefit, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 811.

**Using Microsoft Windows on Oracle Cloud Infrastructure: FAQ**

Oracle Cloud Infrastructure is licensed to provide Microsoft software offerings. Oracle is a member of the Microsoft Partner Network, licensed to sell Microsoft software under the Service Provider License Agreement (SPLA). Oracle is also an authorized Microsoft Authorized Mobility Partner with an active Premier Support for Partners agreement with Microsoft.

For the latest Microsoft licensing requirements, refer to the Microsoft Product Terms.
Compute

If you can't find the answer to your question here, or you need more assistance running Microsoft products on Oracle Cloud Infrastructure, contact Oracle Support.

**General Questions**

**What OS editions of Microsoft Windows Server are supported?**

**Oracle-provided images**

These Windows versions are available for Oracle-provided images:

- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

**Bring Your Own Image (BYOI)**

These Windows versions support custom image import:

- Windows Server 2008 R2 Standard, Enterprise, Datacenter
- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

If you don't need to migrate your Windows OS licenses, you can use the Bring Your Own Image process to migrate your Windows image to Oracle Cloud Infrastructure.

**Is Windows Server 2019 available as an Oracle-provided image?**

Yes, Windows Server 2019 is available as an Oracle-provided image.

**Is Windows Server 2019 available as a Bring Your Own Image (BYOI) image?**

Yes, you can import your own Windows Server 2019 image for virtual machines only. For source image requirements and steps to import an image, see Importing Custom Windows Images on page 677.
