Rules must also specify an action to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions. The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions
Events

Region Availability

Events is currently available in all regions of the commercial realm. See the Oracle Cloud Infrastructure Government Cloud on page 174 section for information about availability in Government Cloud regions.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: You must write IAM policy that authorize users to work with rules. For more information, see Events and IAM Policies on page 2399.

Limits on Events Resources

The Events service has a limitation of 50 rules per tenancy.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Service Gateway and Events

The Events service also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Events public endpoints from private IP addresses in private subnets. For example, you can manage rules over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Events. See Access to Oracle Services: Service Gateway on page 4127 for details.

Getting Started with Events

This topic introduces you to creating automation with Events. You create a simple rule that sends a notification whenever someone creates a bucket in a particular compartment in your tenancy.

Setting Up for Events

To try out the Events service for this tutorial, you must have these things set up first:

- Create IAM policy for Events
Events

• Create a topic and subscription to use as an action

**Important:**

A tenancy administrator must configure your tenancy for Events. These configurations give you access to an Oracle Cloud Infrastructure tenancy with the necessary IAM policy and a resource to use as an action.

Create Users, Groups, and Compartments

You can use existing users, groups, and compartments or make new ones.

**To create groups and users**

If suitable users and groups for assigning users permissions to work with rules don't already exist, log in to the Console as a tenancy administrator and create them.

1. Log in to the Console as a tenancy administrator.
2. If you need a group for Events, perform these steps:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**. A list of the groups in your tenancy is displayed.
   b. Click **Create Group** and create a new group (see **To create a group** on page 3116). Give the group a meaningful name and description. Avoid entering confidential information.
3. If you need user accounts for Events, perform these steps:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
   b. Click **Create User** and create one or more new users (see To create a user on page 3113).

4. If users haven't been added to groups already, perform these steps:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**. A list of the groups in your tenancy is displayed.
   b. Click the group you want to use for Events.
   c. Click **Add User to Group**.
   d. Select the users from the drop-down list, and then click **Add**.

**To create a compartment**

If suitable compartment for rules and the resources that emit events doesn't already exist, log in to the Console as a tenancy administrator and create it.

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**. A list of the compartments in your tenancy is displayed.
3. Click **Create Compartment** and create a new compartment (see To create a compartment on page 3137). Give the compartment a meaningful name and description. Avoid entering confidential information.

**Identity**

<table>
<thead>
<tr>
<th>Compartments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Users</td>
</tr>
<tr>
<td>Groups</td>
</tr>
<tr>
<td>Dynamic Groups</td>
</tr>
<tr>
<td>Policies</td>
</tr>
<tr>
<td>Compartment</td>
</tr>
</tbody>
</table>

**Create IAM Policy for Events**

Before users can start using Events to create automation, as a tenancy administrator you must create IAM policy:

**To create a policy that allows users to create and manage rules**

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**. A list of the policies in the compartment you're viewing is displayed.
3. Select the root compartment.
4. Click **Create Policy**.
5. Enter the following:

   - **Name**: A meaningful name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A meaningful description. You can change this later if you want to.
   - **Statement**: Enter the following policy statements to give users in the group the ability to manage and create rules:

     This line gives the user inspect access to resources in compartments to select actions.
     
     ```
     allow group <RuleAdmins> to inspect compartments in tenancy
     ```

     This line gives the user access to defined tags to apply filter tags to rules.
     
     ```
     allow group <RuleAdmins> to use tag-namespaces in tenancy
     ```

     These lines give the user access to Streaming resources for actions
     
     ```
     allow group <RuleAdmins> to inspect streams in tenancy
     allow group <RuleAdmins> to use stream-push in tenancy
     allow group <RuleAdmins> to use stream-pull in tenancy
     ```

     These lines give the user access to Functions resources for actions.
     
     ```
     allow group <RuleAdmins> to use virtual-network-family in tenancy
     ```
allow group <RuleAdmins> to manage function-family in tenancy

This line gives the user access to Notifications topics for actions.

allow group <RuleAdmins> to use ons-topic in tenancy

This line gives the user access to rules for Events.

allow group <RuleAdmins> to manage cloudevents-rules in tenancy

6. Click Create.

Create Notifications Topic and Subscription

If a suitable Notifications topic doesn't already exist, then you must log in to the Console as a tenancy administrator and create it. Whether you use an existing topic or create a new one, add an email address as a subscription so that you can monitor that email account for notifications.

To create a topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click Create Topic at the top of the topic list.

![Create Topic dialog box](image)

3. In the Create Topic dialog box, configure your topic.
   - Name: Required. Specify a friendly name for the topic. It must be unique; validation is case-sensitive. Avoid entering confidential information.
   - Description: Optional. Enter a description for the topic.
4. Click Create.

To create a subscription

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click the name of the topic that you created in the previous step or the topic you intend to use for this tutorial.
3. On the topic detail page, click **Create Subscription**.

4. In the **Create Subscription** dialog box, select **Email**, and then type an email address.

5. Click **Create**. The subscription has been created and a subscription confirmation URL will be sent. The subscription remains in "Pending" status until it has been confirmed.

**To confirm a subscription**
- In the confirmation email sent to the address you specified in the previous procedure, click the confirmation URL.

**Using the Console to Create a Rule**

Use the Console to create a rule with a pattern that matches bucket creation events emitted by Object Storage. Specify the Notifications topic you created as an action to deliver matching events. To test your rule, create a bucket. Object Storage emits an event which triggers the action. Check the email specified in the subscription to receive your notification.

**To create a rule**
1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.

Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   • **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   • **Description**: Specify a description of what the rule does. You can change this description later.
4. In **Event Matching**, select **Event Type**.
   a. In **Service Name**, select **Object Storage**.
   b. In **Event Type**, select **Object Storage - Create Bucket**.
5. In **Actions**, specify the actions to trigger when the filter finds a match:
   a. In **Action Type**, select **Notifications**.
   b. In **Notifications Compartment**, select the compartment that contains the topic.
   c. In **Topic**, select the topic.
6. Click **Create Rule**.

**To create a bucket**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.

4. In the **Create Bucket** dialog, specify the attributes of the bucket:
   • **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   • **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     • **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     • **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the Archive tier is not immediate. You must restore archived data before it’s accessible.
5. Click **Create Bucket**.
To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

Tip:

You will receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Using the CLI to Create a Rule

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

To create an action file

1. Create a file and add the following content.

```json
{
    "actions": [
        {
            "actionType": "ONS",
```
Tip: You can specify functions, streams, or topics as an action.

Example action file template

```json
{
    "actions": [
        {
            "actionType": "FAAS",
            "description": "string",
            "functionId": "<function_OCID>",
            "isEnabled": true
        },
        {
            "actionType": "ONS",
            "description": "string",
            "isEnabled": true,
            "topicId": "<topic_OCID>
        },
        {
            "actionType": "OSS",
            "description": "string",
            "isEnabled": true,
            "streamId": "<stream_OCID>
        }
    ]
}
```

2. Fill in `<topic_OCID>` with actual topic OCID value from your tenancy.
3. Add a description.
4. Save the file with `action.json` as the file name.

**To create a rule**

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether the rule is evaluated.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see the example command below for usage).
- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any child compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with `ACTIVE` indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name CLI-created_rule
--is-enabled true --condition "{"eventType": ["com.oraclecloud.objectstorage.createbucket"]}" --compartment-
```
id <compartment_OCID> --actions <path_to_json_formatted_actions_file> --wait-for-state=ACTIVE

**Note:**
Replace the values in `<compartment_OCID>` and `<path_to_json_formatted_actions_file>` with the actual values from your tenancy and local file system.

When you run the preceding command, the CLI prompts you about the rule and its display:

```
Action completed. Waiting until the resource has entered state: ACTIVE
{
  "data": {
    "actions": {
      "actions": [
        {
          "action-type": "ONS",
          "description": "Notifications action",
          "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
          "lifecycle-message": null,
          "lifecycle-state": "ACTIVE",
          "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
        }
      ],
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{eventType: ["com.oraclecloud.objectstorage.createbucket"]},"
      "defined-tags": {},
      "description": null,
      "display-name": "CLI-created_rule",
      "freeform-tags": {},
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-message": null,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-04-25T01:32:56.855000+00:00"
    },
    "etag": "<unique_ID>--gzip"
  }
}
```

To create a bucket

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.
4. In the **Create Bucket** dialog, specify the attributes of the bucket:
   - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     - **Standard**: is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     - **Archive**: is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it’s accessible.
5. Click **Create Bucket**.
To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

| Tip: |
| You receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule. |

Matching Events with Filters

This topic describes how to match events with pattern filters in rules to build automation.

Background

To understand filtering, it’s helpful to review the structure of an actual event message. Events uses JSON objects to represent events. This is an event:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.objectstorage.deletebucket",
    "source": "objectstorage",
    "eventTypeVersion": "1.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_bucket",
        "resourceId": "ocid1.compartment.oc1..<unique_ID>",
        "availabilityDomain": "NfHZ:PHX-AD-2",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess",
            "eTag": "f8ff6e9-f602-460f-a6c0-00b5abfa24c7"
        }
    }
}
```

Two key points to remember about all events:

- Events all have the same set of top-level attributes, which are known as the event envelope. With one exception, most of these top-level attributes are not that useful for creating filters. The exception is `eventType`, which identifies the type of event included in the payload.
- The payload of the event appears within the `data` attribute. The information in this field depends on which service produced the event and the event type requested. The information in the payload is useful for isolating one event from another with a filter.
For more information about the envelope, see Contents of an Event Message on page 2412. For a list of all the services that produce events, see Services that Produce Events on page 2414.

**Event Matching with Filters**

Rules use filters to select events and route them for delivery to action resources. A rule is represented as a JSON object, similar to an event. The filter is an attribute of the rule, and the attribute is named condition. A filter either matches an event or it does not.

A few important things to remember about filters:

- Fields not mentioned in a filter are ignored. You can create a valid filter that matches all event messages with two curly brackets.
- For a filter to match an event, the event must contain all the field names listed in the filter. Field names must appear in the filter with the same nesting structure used in the event.
- Rules apply to events in the compartment in which you create them and any child compartments. This means that a filter specified by a rule only matches events emitted from resources in the same compartment or any child compartments.
- Wildcard matching is supported with the asterisk (*) character. See Examples of Wildcard Matching in Filters on page 2397.

**Examples of Simple Filters**

The following filter matches every event in the compartment and any child compartments where you create the rule.

```json
{
  ...
  "condition": "{}"
}
```

When you add fields to the filter, you limit the events that the filter can match. For example, the following filter matches only deletebucket events.

```json
{
  ...
  "condition": "{ 
    "eventType": "com.oraclecloud.objectstorage.deletebucket"
  }"
}
```

To create a filter for more than one event type, use an array in eventType. The following filter matches deletebucket and createbucket events.

```json
{
  ...
  "condition": "{ 
    "eventType": [ 
      "com.oraclecloud.objectstorage.deletebucket",
      "com.oraclecloud.objectstorage.createbucket"
    ]
  }"
}
```
Examples of Filters with Event Payload Attributes

Both of the following filters would match the event at the top of the page. The first because filter specifies two fields and both fields appear in the event, the second because the "NoPublicAccess" type appears in the event.

The important thing to note is how the field names in the filter match the nesting structure of the event.

```
{
  ...
  "condition": "{
    "data": {
      "compartmentName": "example_name",
      "resourceName": "my_bucket"
    }
  }
}
```

Neither of the following filters would match the event at the top of this page. The first because the filter specifies a PublicAccessType not found in the event. The second because the event specifies a name for different bucket.

```
{
  ...
  "condition": "{
    "data": {
      "additionalDetails": {
        "publicAccessType": "NoPublicAccess"
      }
    }
  }
}
```

```
{
  ...
  "condition": "{
    "data": {
      "additionalDetails": {
        "publicAccessType": "PublicAccess"
      }
    }
  }
}
```

```
{
  ...
  "condition": "{
    "data": {
      "additionalDetails": {
        "publicAccessType": "NoPublicAccess"
      }
    }
  }
}
```
Examples of Arrays in Filters

Arrays in filters match events if any of the values in the filter match a value in an event. The following filter would match the event at the top of the page because the name of the bucket in the event is included in an array in the filter.

```json
{
  ...
  "condition": "{ "data": { "resourceName": [ "my_bucket_2", "my_bucket_1", "my_bucket" ], "additionalDetails": { "namespace": "example_namespace", "publicAccessType": "NoPublicAccess" } } }"}
}
```

You can use an array in `eventType` (or any of the top-level fields), the event payload as shown in the preceding example, or both the event payload and a top-level field.

```json
{
  ...
  "condition": "{ "eventType": [ "com.oraclecloud.objectstorage.deletebucket", "com.oraclecloud.objectstorage.createbucket" ], "data": { "resourceName": [ "my_bucket_2", "my_bucket_1", "my_bucket" ], "additionalDetails": { "namespace": "example_namespace", "publicAccessType": "NoPublicAccess" } } }"}
}
```

Examples of Wildcard Matching in Filters

The following are a few things to consider about wildcard matching with filters.

- Use the wildcard only in attribute values. You cannot use the asterisk for matching in keys.
- An attribute value with only an asterisk matches all values for the associated attribute name, but not null.
- The period character has no special meaning in a filter.

You can add the asterisk at the start of a string, in the middle, or at the end. All of the filters that follow match the event at the top of the page.

- The first matches because the wildcard in `displayName` matches the bucket naming pattern.
• The second one matches because the `publicAccessType` uses a wildcard. Because of the use of the wildcard, these first two filters would also match events from buckets with a similar naming pattern and would include events from buckets with or without public access.

• The third one matches because the event type includes all types of bucket events.

```json
{
...
"condition": "{
    "data": {
        "resourceName": "my_bucket*",
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess"
        }
    }
}"}
```

```json
{
...
"condition": "{
    "data": {
        "resourceName": ["my_bucket_2", "my_bucket_1", "my_bucket"],
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "*"
        }
    }
}"}
```

```json
{
...
"condition": "{
    "eventType": "com.oraclecloud.objectstorage.*bucket",
    "data": {
        "resourceName": ["my_bucket_2", "my_bucket_1", "my_bucket"],
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess"
        }
    }
}"}
```
Events and IAM Policies

This topic describes how an administrator must write IAM policy for the Events service. If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For more details about how to write IAM policy for Events, see Details for the Events Service on page 2962.

Allow Users to Work with Rules

These IAM policies allow users to manage or list rules.

Let users list rules in a compartment

Type of access: Ability to list Events rules.
Where to create the policy: In the tenancy.

```
Allow group RuleReaders to read cloudevents-rules in tenancy
```

The preceding policy allows RuleReaders to list rules in the tenancy.

Let admins manage rules in a compartment

Type of access: Ability to manage Events rules, including creating, deleting, updating or moving rules to a different compartment.
Where to create the policy: In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

```
allow group <RuleAdmins> to inspect compartments in tenancy
```

This line gives the user access to defined tags to apply filter tags to rules.

```
allow group <RuleAdmins> to use tag-namespaces in tenancy
```

These lines give the user access to Streaming resources for actions.

```
allow group <RuleAdmins> to inspect streams in tenancy
allow group <RuleAdmins> to use stream-push in tenancy
allow group <RuleAdmins> to use stream-pull in tenancy
```

These lines give the user access to Functions resources for actions.

```
allow group <RuleAdmins> to use virtual-network-family in tenancy
allow group <RuleAdmins> to manage function-family in tenancy
```

This line gives the user access to Notifications topics for actions.

```
allow group <RuleAdmins> to use ons-topic in tenancy
```

This line gives the user manage access to rules for Events.

```
allow group <RuleAdmins> to manage cloudevents-rules in tenancy
```

Managing Rules for Events

This topic describes how to manage rules for the Events service. For more information about Events, see Overview of Events on page 2382.
Prerequisites for Creating Rules

- Action resources: You must have resources already set up to specify as an action. The Events service invokes the action specified in the rule by delivering the event message to action resources, which can include topics, streams, or functions. Every rule must have at least one action. The Events service can invoke any of the following services by delivering an event message for processing:
  - Notifications
  - Streaming
  - Functions
- IAM policies: To manage or list rules, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform a task and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information, see Events and IAM Policies on page 2399.
- Event messages: To create rules, the resources you want to monitor with the rule must emit events. For more information, see Services that Produce Events on page 2414.

Working with Rules

**Note:**
Each rule can have a maximum of 10 actions.

A typical workflow for setting up rule might follow this pattern:

1. **Identify action resources**
   
   Set up or identify whatever action resources you intend to use with the rule. For example, you might set up a Notifications topic and create subscriptions for the DevOps team so that they are notified when backups complete. If a topic already exists, you can use it instead of creating a topic. The resources you specify for actions do not have to be in the same compartment as the rule.

2. **Plan filtering**
   
   Ensure the resources that you want to monitor emit events to the Events service and plan your pattern matching strategy. For example, you might want to monitor backups on Autonomous Data Warehouse instances in the ABC compartment. Ensure Autonomous Data Warehouse instances emit an event type you can use to create the automation you require. Review the example JSON event to determine the best way to identify those resources in filters. See Matching Events with Filters on page 2394 and Services that Produce Events on page 2414.

3. **Create the rule**
   
   Rules apply to events in the compartment in which you create them and any child compartments. Create a rule in the compartment with the resource you want to monitor and specify where to deliver matching events. For example, in the ABC compartment, you might create a rule that filters for Autonomous Data Warehouse backup events. Since Events has no requirement about the location of action resources, you could specify a topic in the XYZ compartment as the resource to deliver any matching events.

Managing Tags for Rules

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 239.

Tags and Event Filtering

With Events, you can also use tags to target resources in your tenancy. You target resources by adding the tag to a filter in a rule. A filter tag helps you hone automation by targeting only resources that contain a particular tag. For example, let's say you have dozens of Database instances in your tenancy, but only a few of the most critical of these instances have the tag "Operations." You could create a rule that triggers a particular action for resources that only contain the "Operations" tag.
Policy for working with filter tags is no different from policy for working with tags.

**To manage filter tags**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click rule's name.
3. In the **Resources** menu, click **Event Matching**.
4. In the **Filter Tags** section, you can view or edit existing filter tags, or click **Add Filter Tag** to add new ones.

**To manage tags for rules**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click rule's name.
3. Click the **Tags** tab to view or edit existing tags, or click **Add Tags** to add new ones.

For more information, see Resource Tags on page 239.

**Move Rules to a Different Compartment**

You can move rules from one compartment to another. When you move a rule to a new compartment, you stop monitoring events from resources in the current compartment and begin monitoring events in the new compartment (and any child compartments). After you move the rule to the new compartment, inherent policies apply immediately and affect access to the rules through the Console. Moving rules doesn't affect access by the Events service to actions defined in rules. For more information, see Working with Compartments on page 3127.

**Monitoring Rules**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For more information about monitoring the rules you create, see Events Metrics on page 2525.

**Object Events and the Events Service**

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

**Using the Console**

**To create a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.
   
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   
   - **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description**: Specify a description of what the rule does. You can change this description later.
4. In Rule Conditions, create a filter:

To add an event type
a. Select Event Type.
b. Select a Service Name.
c. In Event type, select one or more event types for this service.
d. Click + Another Condition and select Event Type to add event types for a different service.

This filter will match events of the event types you specify.

To add an attribute
You must first select an event type to add an attribute.

a. Select Attribute.
b. Select an Attribute Name. Attribute values are optional.
c. Enter an Attribute Value. Attribute values are optional.
d. Click + Another Condition and select Attribute to add another attribute.

This filter will match events of the event types with the attributes you specify.

To add a filter tag

a. Select Filter Tag
b. Select a Tag Namespace.

To specify a free-form tag, select None (apply a free-form tag).
c. Select a Tag Key.
d. Enter a Tag Value. Tag values are optional.
e. Click + Another Condition and select Filter Tag to add another filter tag.

This filter will match events with the tags you specify.

Filter tags help you to hone automation by targeting only resources that contain a particular tag. If you want to use tags to organize your rules, use resource tags instead. For more information, see Managing Tags for Rules on page 2400.

Tip:
You can leave this field entirely blank to match all events. See Matching Events with Filters on page 2394.

To validate this rule
You can only evaluate a rule against one event type at a time. To test different event types, repeat these steps as necessary.

a. Click Validate Rule. The Test Rule panel opens.
b. In Service Name, select a service if necessary.
c. In Event Type, select an event type, if necessary. A example event appears based on the selections you made. Edit the values in the event to match the values for any attributes and tags you added to your rule. For more information, see Contents of an Event Message on page 2412.
d. Click Check if Example Event Matches Rule. If the rule doesn't match, use the rule editor to modify any of the following:
   • Add or remove event types
   • Add or remove values or attributes
   • Add or remove tags
   • Insert wildcards

   For more information, see Matching Events with Filters on page 2394.
e. Click Close.
To view reference events
a. Click View example events (JSON). The View Example Events panel opens.
b. In Service Name, select a service if necessary.
c. In Event Type, select an event type, if necessary. An example event appears based on the selections you made. Use the events viewer to browse reference events.
d. Click Done.

For more information, see Contents of an Event Message on page 2412 and Matching Events with Filters on page 2394.

To add an attribute
5. In Actions, specify the actions resources to trigger when the filter finds a match:

To select a topic
a. Select Notifications.
b. Select the Notifications Compartment.
c. Select the Topic.
d. Click + Another Action and select Notifications to add another topic.

To select a stream
a. Select Streaming.
b. Select the Stream Compartment.
c. Select the Stream.
d. Click + Another Action and select Streaming to add another stream.

To select a function
a. Select Functions.
b. Select the Function Compartment.
c. Select a Function Application.
d. Select the Function.
e. Click + Another Action and select Functions to add another function.

6. Click Create Rule.

To edit a rule
2. Choose a Compartment that has the rule you want to edit.
3. For the rule you want to edit, click the Actions icon (three dots), and then click Edit.
4. Make your changes and click Save Changes.

To disable or enable a rule
2. Choose a Compartment that has the rule you want to work with.
3. For the rule, you want change, click the Actions icon (three dots), and then take one of the following actions:
   - Click Disable
   - Click Enable
4. Confirm when prompted.

To move a rule to a different compartment
2. In the Scope section, select a compartment.
3. Find the rule in the list, click the the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

To validate a rule

You can only evaluate a rule against one event type at a time. Repeat as necessary to test different event types.

2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to test.
3. Click Validate Rule.
4. Take one or more of the following actions:
   • If there are no event types in the rule, select the service and event type you want to test.
   • If you want to test a different event type than the one selected by default, select the service and event type you want to test.
   • If you added attribute values or filter tags to the rule, edit the example data in the event to match the values in your rule.
5. Click Check if Example Event Matches Rule.

For more information, see Matching Events with Filters on page 2394 and Contents of an Event Message on page 2412.

To delete a rule

2. Choose the Compartment that has rule you want to delete.
3. For the rule you want to delete, click the Actions icon (three dots), and then click Delete.
4. Confirm when prompted.

To add an action to a rule

2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Click Add.
   • The Add Action box appears. Configure the action resources:
     To select a topic
     a. Select Notifications.
     b. Select the Notifications Compartment.
     c. Select the Topic.
     To select a stream
     a. Select Streaming.
     b. Select the Stream Compartment.
     c. Select the Stream.
     To select a function
     a. Select Functions.
     b. Select the Function Compartment.
     c. Select a Function Application.
     d. Select the Function.
     • Action State: Select to enable the action. Clear to disable.
5. Click Add Action.

To edit an action

2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and click Edit. The Edit Action box appears.
6. Make your changes and click Save Changes.

To enable or disable an action
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and specify Enable or Disable.
6. Confirm when prompted.

To remove an action
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Actions.
4. Select an action.
5. Go to Actions and click Remove.
6. Confirm when prompted.

Each rule must have one action.

To add event types to a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Click Add Event Type.
5. In Service Name, select a service.
6. In Event Type, select an event type for this service.
7. Click Add Event Type.

To edit event types for a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Select an event type.
5. Click Edit. The Edit Event Type box appears.
6. Make your changes and click Save Changes.

To remove event types for a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Select the check box next to the event types you want to remove.

Tip:
To select the entire list, select the check box in the header row.
5. Click Remove.
6. Confirm when prompted.

To add attributes to a rule
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Attribute**. The **Add Attribute** box appears. Configure the attribute:
   - **Attribute Name**: Specify an attribute or tag to narrow matching results.
     - Select an attribute name. The list of attribute names is based on the event types you selected. If you select no event types, you cannot add an attribute.
     - If you specify an attribute here, you limit the events that match this rule.
   - **Attribute Values**: Specify one or more values for the attribute name.
     a. Enter a value. As you type, the value appears under the field with (New) appended. Select the value with (New) appended to add the value to **Attribute Values**.
     b. Enter more values for attribute name in the same manner as before.

   ![ATTRIBUTE VALUES](image)

Here are some things to consider about attribute values:

- Use an asterisk to create a wildcard. See [Examples of Wildcard Matching in Filters](#) on page 2397.
- Multiple values for an attribute name broaden your results. If any of the values you enter here match a value in an event, the rule matches. See [Examples of Arrays in Filters](#) on page 2397.

5. Click **Add attribute**.

**To edit attributes for a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select an attribute.
5. Click **Edit**. The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

**To remove attributes for a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the attributes you want to remove.

   | Tip:  
   | To select the entire list, select the check box in the header row.

5. Click Remove.
6. Confirm when prompted.

To add filter tags to a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Click Add Filter Tag.
5. In Tag Namespace, do one of the following:
   • Select a namespace to add a defined tag as a filter.
   • Select None (apply a free-form tag) to add a free-form tag as a filter.
6. In Tag Key, do one of the following:
   • Select the tag key for the defined tag.
   • Enter the tag key for the free-form tag.
7. Enter a Value.
8. Click Add Filter Tag.

To edit filter tags for a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Select a filter tag.
5. Click Edit. The Edit Attribute box appears.
6. Make your changes and click Save Changes.

To remove filter tags for a rule
2. Choose a Compartment you have permission to work in, and then click the Name of the rule you want to update.
3. In the Resources menu, click Event Matching.
4. Select the check box next to the filter tags you want to remove.

   | Tip:  
   | To select the entire list, select the check box in the header row.

5. Click Remove.
6. Confirm when prompted.

Using the Command Line Interface (CLI)

When you use the CLI to create a rule, you work a little differently than using the Console.

• To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
• To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.
To create an action JSON file

To specify the actions for your rule, use a JSON formatted file. For more information, see Advanced JSON Options on page 5340.

1. Create a file and add the following content. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```json
{
    "actions": [
        {
            "actionType": "FAAS",
            "description": "string",
            "functionId": "<functionOCID>",
            "isEnabled": true
        },
        {
            "actionType": "ONS",
            "description": "string",
            "isEnabled": true,
            "topicId": "<topicOCID>"
        },
        {
            "actionType": "OSS",
            "description": "string",
            "isEnabled": true,
            "streamId": "<streamOCID>"
        }
    ]
}
```

2. Edit the file and remove any objects you don't want to use as an action. For example, if you wanted to only use Notifications as an action, then you would delete all the other objects.

```json
{
    "actions": [
        {
            "actionType": "ONS",
            "description": "string",
            "isEnabled": true,
            "topicId": "<topicOCID>"
        }
    ]
}
```

3. Edit the file and fill in any variables with actual values from your tenancy, as shown in the following example.

```json
{
    "actions": [
        {
            "actionType": "ONS",
            "description": "string",
            "isEnabled": true,
            "topicId": "<topicOCID>"
        }
    ]
}
```

4. Add a description.

5. Save the file as action.json
6. To create a rule and specify Notifications as an action, run the following command.

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json
```

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether Events should evaluate the rule.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

Examples

The following example shows how to pass a simple condition that matches all events. Everything between the double quotes (" ") is a string, while the brackets { } indicate JSON:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

To pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character. For example:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{"eventType"[:"com.oraclecloud.objectstorage.createobject"]}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

In PowerShell, to escape double quotes, you must use two characters: The backslash (\) and the back tick (`). For example, in Windows PowerShell:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{\"eventType\":[\"com.oraclecloud.objectstorage.createobject\"]}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

Tip:

The condition option does not support using a file to pass the JSON formatted string.

For information on creating filters, see Matching Events with Filters on page 2394.

- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any subordinate compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name <friendly_name> --is-enabled true
```
To delete a rule
Open a command prompt and run `oci events rule delete` to delete a single rule. For example:

`oci events rule delete --rule-id <rule_OCID>`

The command returns a prompt, asking for confirmation. Type `y` to delete the rule.

To get rule metadata
You can get rule metadata using the CLI. The Console displays this metadata in the Rule Details tab.

Open a command prompt and run `oci events rule get` to get information about a single rule. For example:

`oci events rule get --rule-id <rule_OCID>`

The command returns the following information:

```
{
   "data": {
      "actions": {
         "actions": [
            {
               "action-type": "ONS",
               "description": null,
               "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
               "lifecycle-message": null,
               "lifecycle-state": "ACTIVE",
               "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
            }
         ],
         "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
         "condition": "\n"com.oraclecloud.databaseservice.autonomous.datawarehouse.backup.end\n\"\n\"CustomEventType\"\n\"
\"defined-tags": null,
"description": null,
"display-name": "rule_name",
"freeform-tags": null,
"id": "ocid1.eventrule.oc1.phx.<unique_ID>",
"is-enabled": true,
"lifecycle-message": null,
"lifecycle-state": "ACTIVE",
"time-created": "2019-01-23T00:48:20.155000+00:00"
},
"etag": "<unique_ID>--gzip"
}
```

To get a list of rules
Open a command prompt and run `oci events rule list` to list the rules in a compartment. For example:

`oci events rule list --compartment-id <compartment_OCID>`
The command returns the following information:

```
{
  "data": [
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": "Example_Rule",
      "display-name": "rule_1",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:10:53.562000+00:00"
    },
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": null,
      "display-name": "rule_2",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:27:25.099000+00:00"
    },
    ...
  ]
}
```

To update a rule

Open a command prompt and run `oci events rule update` to update a rule.

To update the condition for a rule:

```
oci events rule update --rule-id <rule_OCID> --condition <json_formatted_string>
```

For example:

```
oci events rule update --rule-id ocid1.eventrule.oc1.phx.<unique_ID> --condition "{}" --wait-for-state=ACTIVE
```

The previous command would update the condition of the rule to use an empty JSON string. The CLI updates the rule, waits for the rule to update and change to the active state (only if you used the `--wait-for-state` option), then displays the updated rule.

Use the following options to update a rule:

- `display-name`
Events

- description
- is-enabled
- condition
- actions
- freeform-tags
- defined-tags

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage rules:

- ChangeRuleCompartment
- CreateRule
- DeleteRule
- GetRule
- UpdateRule
- ListRules

Contents of an Event Message

This topic describes the contents of an event message. Every event message includes two main parts:

- Envelope: a container for all event messages
- Payload: the data from the resource emitting the event message

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloudEventsVersion</td>
<td>The version of the CloudEvents specification.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Events uses version 0.1 specification of the CloudEvents event envelope.</td>
</tr>
<tr>
<td>contentType</td>
<td>Set to application/json. The content type of the data contained in the data attribute.</td>
</tr>
<tr>
<td>data</td>
<td>The payload of the event. All of the information within data comes from the resource emitting the event. See the following table for more detail on the structure of the payload.</td>
</tr>
<tr>
<td>eventID</td>
<td>The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.</td>
</tr>
<tr>
<td>eventTime</td>
<td>The time of the event, expressed in RFC 3339 timestamp format.</td>
</tr>
</tbody>
</table>
### Events

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventType</td>
<td>The type of event that happened. For a list of all services that produce events and the even types that those services track, see <a href="#">Services that Produce Events</a> on page 2414.</td>
</tr>
<tr>
<td>eventTypeVersion</td>
<td>The version of the event type.</td>
</tr>
<tr>
<td>extensions</td>
<td>The OCID of the compartment from which the event originates. If the event originates from the root compartment of the tenancy, then this attribute specifies a tenancy OCID. This attribute is mandatory in the Oracle Cloud Infrastructure implementation of the <a href="#">CloudEvents</a> specification.</td>
</tr>
<tr>
<td>source</td>
<td>The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.</td>
</tr>
</tbody>
</table>

### Payload

The data in these fields depends on which service produced the event and the event type it defines.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compartmentId</td>
<td>The OCID of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>compartmentName</td>
<td>The name of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>resourceName</td>
<td>The name of the resource emitting the event.</td>
</tr>
<tr>
<td>resourceId</td>
<td>An OCID or an ID for the resource emitting the event.</td>
</tr>
<tr>
<td>availabilityDomain</td>
<td>The availability domain of the resource emitting the event.</td>
</tr>
<tr>
<td>freeFormTags</td>
<td>Free-form tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>definedTags</td>
<td>Defined tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>additionalDetails</td>
<td>A container for attributes unique to the resource emitting the event. In the example bucket event that follows, the payload includes three Object Storage attributes:</td>
</tr>
<tr>
<td></td>
<td>• namespace</td>
</tr>
<tr>
<td></td>
<td>• publicAccessType</td>
</tr>
<tr>
<td></td>
<td>• eTag</td>
</tr>
<tr>
<td></td>
<td>To determine what attributes are included for other resources, retrieve an event or consult the reference samples listed on <a href="#">Services that Produce Events</a> on page 2414.</td>
</tr>
</tbody>
</table>
Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

An Example Event

The following is an example bucket event emitted by Object Storage.

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.deletebucket",
  "source": "objectstorage",
  "eventTypeVersion": "1.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "NfHZ:PHX-AD-2",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

Services that Produce Events

This topic lists the Oracle Cloud Infrastructure services that emit events:

- Analytics Cloud
- API Gateway
- Application Migration
- Bastion
- Big Data
- Block Volume
- Blockchain Platform
- Budgets
- Cloud Guard on page 2428
- Compute
- Container Engine for Kubernetes
- Content Management
About Event Types and Example Reference Events

Services emit event messages by resource type. Event messages use a combination of an event type and a data payload (from the resource) to identify state changes.

In this section:

- Event types are organized by service, then by resource type
- There is one reference example per resource type if the payload contains the same attributes for all event types

See Matching Events with Filters on page 2394 and Contents of an Event Message on page 2412.

Analytics Cloud

For details about events emitted by Analytics Cloud, see Service Events.

API Gateway

API Gateway resources that emit events:

- API Gateway Certificate Event Types on page 2416
- API Deployment Event Types on page 2417
- API Gateway Event Types on page 2418
- API Event Types on page 2419
API Gateway Certificate Event Types

These are the event types that API Gateway certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.begin</td>
</tr>
<tr>
<td>Change Certificate Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.end</td>
</tr>
<tr>
<td>Create Certificate Begin</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.begin</td>
</tr>
<tr>
<td>Create Certificate End</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.end</td>
</tr>
<tr>
<td>Delete Certificate Begin</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.begin</td>
</tr>
<tr>
<td>Delete Certificate End</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.end</td>
</tr>
<tr>
<td>Update Certificate Begin</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.begin</td>
</tr>
<tr>
<td>Update Certificate End</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.end</td>
</tr>
</tbody>
</table>

API Gateway Certificate Example

This is an example event for API Gateway certificates:

```json
{
    "eventType": "com.oraclecloud.apigateway.creategatewaycertificate.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceId": "ocid1.apigatewaycertificate.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
API Deployment Event Types

These are the event types that API deployments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Deployment Compartment Begin</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.begin</td>
</tr>
<tr>
<td>Change Deployment Compartment End</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.end</td>
</tr>
<tr>
<td>Create Deployment Begin</td>
<td>com.oraclecloud.apigateway.createdeployment.begin</td>
</tr>
<tr>
<td>Create Deployment End</td>
<td>com.oraclecloud.apigateway.createdeployment.end</td>
</tr>
<tr>
<td>Delete Deployment Begin</td>
<td>com.oraclecloud.apigateway.deletedeployment.begin</td>
</tr>
<tr>
<td>Delete Deployment End</td>
<td>com.oraclecloud.apigateway.deletedeployment.end</td>
</tr>
<tr>
<td>Update Deployment Begin</td>
<td>com.oraclecloud.apigateway.updatedeployment.begin</td>
</tr>
<tr>
<td>Update Deployment End</td>
<td>com.oraclecloud.apigateway.updatedeployment.end</td>
</tr>
</tbody>
</table>

API Deployment Example

This is an example event for API deployments:

```json
{
    "eventType": "com.oraclecloud.apigateway.createdeployment.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_Deployment",
        "resourceId": "ocid1.apideployment.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventId": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
API Gateway Event Types

These are the event types that API gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Gateway Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.begin</td>
</tr>
<tr>
<td>Change Gateway Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.end</td>
</tr>
<tr>
<td>Create Gateway Begin</td>
<td>com.oraclecloud.apigateway.creategateway.begin</td>
</tr>
<tr>
<td>Create Gateway End</td>
<td>com.oraclecloud.apigateway.creategateway.end</td>
</tr>
<tr>
<td>Delete Gateway Begin</td>
<td>com.oraclecloud.apigateway.deletegateway.begin</td>
</tr>
<tr>
<td>Delete Gateway End</td>
<td>com.oraclecloud.apigateway.deletegateway.end</td>
</tr>
<tr>
<td>Update Gateway Begin</td>
<td>com.oraclecloud.apigateway.updategateway.begin</td>
</tr>
<tr>
<td>Update Gateway End</td>
<td>com.oraclecloud.apigateway.updategateway.end</td>
</tr>
</tbody>
</table>

Gateway Example

This is an example event for API gateways:

```json
{
    "eventType": "com.oraclecloud.apigateway.creategateway.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_Gateway",
        "resourceId": "ocid1.apigateway.oc1.phx..<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
API Event Types

These are the event types that API resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change API Compartment Begin</td>
<td>com.oraclecloud.apigateway.changeapicompartment.begin</td>
</tr>
<tr>
<td>Change API Compartment End</td>
<td>com.oraclecloud.apigateway.changeapicompartment.end</td>
</tr>
<tr>
<td>Create API Begin</td>
<td>com.oraclecloud.apigateway.createapi.begin</td>
</tr>
<tr>
<td>Create API End</td>
<td>com.oraclecloud.apigateway.createapi.end</td>
</tr>
<tr>
<td>Delete API Begin</td>
<td>com.oraclecloud.apigateway.deleteapi.begin</td>
</tr>
<tr>
<td>Delete API End</td>
<td>com.oraclecloud.apigateway.deleteapi.end</td>
</tr>
<tr>
<td>Update API Begin</td>
<td>com.oraclecloud.apigateway.updateapi.begin</td>
</tr>
<tr>
<td>Update API End</td>
<td>com.oraclecloud.apigateway.updateapi.end</td>
</tr>
</tbody>
</table>

API Example

This is an example event for API resources:

```json
{
    "eventType": "com.oraclecloud.apigateway.createapi.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2020-09-09T12:00:00.000Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_API",
        "resourceId": "ocid1.apigatewayapi.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventId": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Application Migration

For details about events emitted by Application Migration, see Service Events.
**Bastion**

For details about events emitted by Bastion, see [Bastion Events](#).

**Big Data**

For details about events emitted by Big Data, see [Service Events](#).

**Block Volume**

Block Volume resources that emit events:

- [Block Volume Event Types](#) on page 2420 and [Block Volume Backup Event Types](#) on page 2422
- [Boot Volume Event Types](#) on page 2423 and [Boot Volume Backup Event Types](#) on page 2424
- [Volume Groups and Volume Group Backups](#) on page 2425

**Block Volume Event Types**

These are the event types that block volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changecompartmentbegin</td>
</tr>
<tr>
<td>Change Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changecompartmentend</td>
</tr>
<tr>
<td>Create Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createvolume.begin</td>
</tr>
<tr>
<td>Create Volume End</td>
<td>com.oraclecloud.blockvolumes.createvolume.end</td>
</tr>
<tr>
<td>Delete Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolume.begin</td>
</tr>
<tr>
<td>Delete Volume End</td>
<td>com.oraclecloud.blockvolumes.deletevolume.end</td>
</tr>
<tr>
<td>Delete Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletelkmskey.begin</td>
</tr>
<tr>
<td>Update Volume</td>
<td>com.oraclecloud.blockvolumes.updatevolume</td>
</tr>
<tr>
<td>Update Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolume.begin</td>
</tr>
<tr>
<td>Update Volume End</td>
<td>com.oraclecloud.blockvolumes.updatevolume.end</td>
</tr>
<tr>
<td>Update Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.begin</td>
</tr>
<tr>
<td>Update Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.end</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide
**Block Volume Example**

This is a reference event for block volumes:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createvolume.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_volume",
        "resourceId": "ocid1.volume.oc1..<unique_ID>",
        "availabilityDomain": "<availability_domain>",
    }
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    }
}
```
# Block Volume Backup Event Types

These are the event types that block volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumebackupcompartment</td>
</tr>
<tr>
<td>Copy Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.begin</td>
</tr>
<tr>
<td>Copy Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.begin</td>
</tr>
<tr>
<td>Create Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.createvolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Delete Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.begin</td>
</tr>
<tr>
<td>Delete Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.end</td>
</tr>
<tr>
<td>Delete Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Update Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackup</td>
</tr>
<tr>
<td>Update Volume Backup Policy</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackuppolicy</td>
</tr>
</tbody>
</table>

## Block Volume Backup Example

This is a reference event for block volume backups:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createvolumebackup.end",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_volumebackup via policy:gold",
        "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
        "additionalDetails": {
            "sourceType": "SCHEDULED",
            "volumeId": "ocid1.volume.oc1..<unique_ID>",
        }
    }
}
```
### Boot Volume Event Types

These are the event types that boot volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.begin</td>
</tr>
<tr>
<td>Change Boot Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.end</td>
</tr>
<tr>
<td>Create Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.begin</td>
</tr>
<tr>
<td>Create Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.begin</td>
</tr>
<tr>
<td>Delete Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume</td>
</tr>
<tr>
<td>Update Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.begin</td>
</tr>
<tr>
<td>Update Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.end</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.end</td>
</tr>
</tbody>
</table>

### Boot Volume Example

This is a reference event for boot volumes:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createbootvolume.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```
Events

"eventTime": "2019-01-10T21:19:24Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "my_volume",
  "resourceId": "ocid1.volume.oc1..<unique_ID>",
  "availabilityDomain": "<availability_domain>",
}
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}

Boot Volume Backup Event Types

These are the event types that boot volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changebootvolumebackupcompartment</td>
</tr>
<tr>
<td>Copy Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.copybootvolumebackupbegin</td>
</tr>
<tr>
<td>Copy Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.copybootvolumebackupend</td>
</tr>
<tr>
<td>Create Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackupbegin</td>
</tr>
<tr>
<td>Create Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackupend</td>
</tr>
<tr>
<td>Delete Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackupbegin</td>
</tr>
<tr>
<td>Delete Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackupend</td>
</tr>
<tr>
<td>Update Boot Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumebackup</td>
</tr>
</tbody>
</table>

Boot Volume Backup Example

This is a reference event for boot volume backups:

{
  "eventType": "com.oraclecloud.blockvolumes.createbootvolume.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "BlockVolumes",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_volumebackup via policy:gold",
  }
}
Volume Groups and Volume Group Backups

These are the event types that volume groups and volume group backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Group Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupcompartment</td>
</tr>
<tr>
<td>Change Volume Group Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupbackupcompartment</td>
</tr>
<tr>
<td>Create Volume Group</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup</td>
</tr>
<tr>
<td>Create Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.begin</td>
</tr>
<tr>
<td>Create Volume Group End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.end</td>
</tr>
<tr>
<td>Create Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.begin</td>
</tr>
<tr>
<td>Create Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.end</td>
</tr>
<tr>
<td>Delete Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.begin</td>
</tr>
<tr>
<td>Delete Volume Group End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.end</td>
</tr>
<tr>
<td>Delete Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.begin</td>
</tr>
<tr>
<td>Delete Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.end</td>
</tr>
<tr>
<td>Update Volume Group</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroup</td>
</tr>
<tr>
<td>Update Volume Group Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroupbackup</td>
</tr>
</tbody>
</table>

Volume Group Example
This is a reference event for volume groups:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createvolumegroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "resourceName": "my_volumegroup",
        "resourceId": "ocid1.volumegroup.oc1..<unique_ID>",
        "availabilityDomain": "<availability_domain>",
    }
}
```

**Blockchain Platform**

For details about events emitted by Blockchain Platform, see Service Events.

**Budgets**

Budgets resources that emit events:

- Alert Rule Event Types on page 2426
- Budget Event Types on page 2427
- Create Triggered Alert Event Types on page 2428

**Alert Rule Event Types**

These are the event types that alert rule emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Alert Rule</td>
<td>com.oraclecloud.budgets.createalertrule</td>
</tr>
<tr>
<td>Update Alert Rule</td>
<td>com.oraclecloud.budgets.updatealertrule</td>
</tr>
<tr>
<td>Delete Alert Rule</td>
<td>com.oraclecloud.budgets.deletealertrule</td>
</tr>
</tbody>
</table>

**Alert Rule Example**

This is a reference event for creating an alert:

```json
{
    "eventType": "com.oraclecloud.budgets.createalertrule",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "budgets",
    "eventID": "<unique_ID>",
    "eventTime": "2020-02-02T20:02:00Z",
    "contentType": "application/json",
    "data": {
```
### Events

```
"eventName": "CreateAlertRule",
"compartmentId": "ocid1.compartment.oc1..<unique_ID>",
"compartmentName": "example_compartment",
"resourceName": "alertrule20200202202002",
"resourceId": "ocid1.alertrule.oc1.phx.<unique_ID>",
"availabilityDomain": "availability_domain",
"additionalDetails": {
   "budgetId": "ocid1.budget.oc1.phx.<unique_ID>",
   "targetType": "COMPARTMENT"
}
},
"extensions": {
   "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```

### Budget Event Types

These are the event types that budget emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Budget</td>
<td>com.oraclecloud.budgets.createbudget</td>
</tr>
<tr>
<td>Update Budget</td>
<td>com.oraclecloud.budgets.updatebudget</td>
</tr>
<tr>
<td>Delete Budget</td>
<td>com.oraclecloud.budgets.deletebudget</td>
</tr>
</tbody>
</table>

### Budget Example

This is a reference event for updating a budget:

```
{
   "eventType": "com.oraclecloud.budgets.updatebudget",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "budgets",
   "eventID": "<unique_ID>",
   "eventTime": "2020-02-02T20:20:02.002Z",
   "contentType": "application/json",
   "data": {
      "eventName": "UpdateBudget",
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "My test budget",
      "resourceId": "ocid1.budget.oc1.phx.<unique_ID>",
      "availabilityDomain": "availability_domain",
      "additionalDetails": {
         "targetCompartmentId": "ocid1.tenancy.oc1..<unique_ID>",
         "targetType": "COMPARTMENT"
      }
   },
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```
Create Triggered Alert Event Types

This is the event type that the create triggered alert emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Triggered Alert</td>
<td>com.oraclecloud.budgets.createtriggeredalert</td>
</tr>
</tbody>
</table>

Create Triggered Alert Example

This is a reference event for creating a triggered alert:

```json
{
  "eventType": "com.oraclecloud.budgets.createtriggeredalert",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "budgets",
  "eventID": "<unique_ID>",
  "eventTime": "2020-02-02T20:20:02.002Z",
  "contentType": "application/json",
  "data": {
    "eventName": "CreateTriggeredAlert",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceId": "ocid1.triggeredalert.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain",
    "additionalDetails": {
      "budgetId": "ocid1.budget.oc1.phx.<unique_ID>",
      "alertRuleId": "ocid1.alertrule.oc1.phx.<unique_ID>"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Cloud Guard

Cloud Guard resources that emit events:

- Problems
- Targets

Problem Event Types

These are the event types that problems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detected-Problem</td>
<td>com.oraclecloud.cloudguard.problemdetected</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>com.oraclecloud.cloudguard.problemremediates</td>
</tr>
</tbody>
</table>

Detected-Problem Example

This is a reference event for detected problems:

```json
{
}
```
Remediated-Problem Example

This is a reference event for remediated problems:

```json
{
    "eventType": "com.oraclecloud.cloudguard.problemremediated",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "CloudGuardResponderEngine",
    "eventTime": "2020-09-02T18:47:00Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment_name",
        "resourceName": "problem_name",
        "resourceId": "ocid1.cloudguardproblem.oc1.iad.<unique_ID>",
        "additionalDetails": {
            "tenantId": "ocid1.tenancy.oc1..<unique_ID>",
            "problemDescription": "problem_description",
            "riskLevel": "CRITICAL",
            "problemRecommendation": "example_recommendation",
            "status": "RESOLVED",
            "problemType": "problem_type",
            "resourceName": "resource_name",
            "resourceId": "ocid1.vcn.oc1.iad.<unique_ID>",
            "resourceType": "resource_type",
            "targetId": "ocid1.cloudguardtarget.oc1..<unique_ID>",
            "labels": "label1, label2",
            "firstDetected": "2020-09-02T18:44:44.145Z",
            "lastDetected": "2020-09-02T18:44:44.568Z",
            "region": "us-ashburn-1"
        }
    },
    "eventId": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
Target Event Types
These are the event types that targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target-Information</td>
<td>com.oraclecloud.cloudguard.targetinformation</td>
</tr>
</tbody>
</table>

Target-Information Example
This is a reference event for target information:

```json
{
    "eventType": "com.oraclecloud.cloudguard.targetinformation",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "CloudGuard",
    "eventTime": "2020-02-11T01:29:51.404Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment_name",
        "resourceId": "ocid1.cloudguardtarget.oc1..<unique_ID>",
        "resourceName": "target_name",
        "additionalDetails": {
            "informationName": "information_name",
            "description": "example_description",
            "recommendation": "example_recommendation",
            "tenantId": "ocid1.tenancy.oc1...<unique_ID>",
            "detectorId": "detector_id",
            "detectorRuleId": "detector_rule_id",
            "status": "Open",
            "timeCreated": "2020-02-11T01:29:50.388Z",
            "region": "r2",
            "problemType": "problem_type"
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Compute
Compute resources that emit events:
- [Autoscaling Event Types](#) on page 2431
- [Capacity Reservation Event Types](#) on page 2432
Events

- Cluster Network Event Types on page 2433
- Console History Event Types on page 2434
- Image Event Types on page 2435
- Instance Event Types on page 2436
- Instance Configuration Event Types on page 2439
- Instance Console Connection Event Types on page 2440
- Instance Pool Event Types on page 2441
- Live Migration Event Types on page 2442

Autoscaling Event Types

These are the event types that autoscaling configurations and autoscaling policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Autoscaling Configuration Compartment</td>
<td>com.oraclecloud.autoscaling.changeautoscalingconfigurationcompartment</td>
</tr>
<tr>
<td>Create Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.createautoscalingconfiguration</td>
</tr>
<tr>
<td>Delete Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.deleteautoscalingconfiguration</td>
</tr>
<tr>
<td>Scaling Action</td>
<td>com.oraclecloud.autoscaling.scalingaction</td>
</tr>
<tr>
<td>Update Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.updateautoscalingconfiguration</td>
</tr>
<tr>
<td>Update Autoscaling Policy</td>
<td>com.oraclecloud.autoscaling.updateautoscalingpolicy</td>
</tr>
</tbody>
</table>

Autoscaling Example

This is a reference event for autoscaling:

```json
{
    "eventType": "com.oraclecloud.autoscaling.scalingaction",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "autoscaling",
    "eventTime": "2019-08-21T04:00:10.046Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example autoscaling configuration",
        "resourceId": "ocid1.autoscalingconfiguration.oc1.phx.<unique_ID>",
        "additionalDetails": {
            "policyName": "my_policy_name",
            "ruleName": "my_scale_up_condition",
            "actionType": "SCALE_OUT",
            "previousSize": 1,
            "newSize": 2
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
```
Capacity Reservation Event Types

These are the event types that capacity reservations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Capacity Reservation Compartment Begin</td>
<td>com.oraclecloud.computeapi.ChangeComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Change Capacity Reservation Compartment End</td>
<td>com.oraclecloud.computeapi.ChangeComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Create Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.CreateComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Create Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.CreateComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Delete Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.DeleteComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Delete Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.DeleteComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Update Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.UpdateComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Update Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.UpdateComputeCapacityReservation.end</td>
</tr>
</tbody>
</table>

Capacity Reservation Example

This is a reference event for capacity reservations:

```json
{
  "eventTime": "2019-08-20T21:58:13.554Z",
  "contentType": "application/json",
  "data": {
    "eventType": "com.oraclecloud.computeapi.CreateComputeCapacityReservation.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-20T21:58:13.554Z",
    "contentType": "application/json",
    "data": {
      "compartmentId": "ocid1.compartment.oc1.<unique_ID>"
    }
  }
}
```

"eventID": "<unique_ID>"
Cluster Network Event Types

These are the event types that cluster networks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Cluster Network Compartment</td>
<td>com.oraclecloud.computemanagement.changeclusternetworkcompartment</td>
</tr>
<tr>
<td>Create Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.begin</td>
</tr>
<tr>
<td>Create Cluster Network End</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.end</td>
</tr>
<tr>
<td>Terminate Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.begin</td>
</tr>
<tr>
<td>Terminate Cluster Network End</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.end</td>
</tr>
</tbody>
</table>

Cluster Networks Example

This is a reference event for most cluster network events:

```json
{
  "eventType": "com.oraclecloud.computemanagement.createclusternetwork.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeManagement",
  "eventTime": "2019-09-12T21:45:09.036Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_cluster_network",
    "resourceId": "ocid1.clusternetwork.oc1.uk-london-1.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Create cluster network end and terminate cluster network end don't include the availability domain.
Console History Event Types

These are the event types that console histories emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capture Console History Begin</td>
<td>com.oraclecloud.computeapi.captureconsolehistory.begin</td>
</tr>
<tr>
<td>Capture Console History End</td>
<td>com.oraclecloud.computeapi.captureconsolehistory.end</td>
</tr>
<tr>
<td>Delete Console History</td>
<td>com.oraclecloud.computeapi.deleteconsolehistory</td>
</tr>
<tr>
<td>Update Console History</td>
<td>com.oraclecloud.computeapi.updateconsolehistory</td>
</tr>
</tbody>
</table>

Console History Example

This is a reference event for console histories:

```json
{
   "eventType": "com.oraclecloud.computeapi.captureconsolehistory.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "ComputeApi",
   "eventTime": "2019-08-20T21:58:13.554Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceId": "ocid1.consolehistory.oc1.iad.<unique_ID>",
      "availabilityDomain": "<availability_domain>"
   },
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>
   }
}
```
Image Event Types

These are the event types that images emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.addimageshapecompatibility</td>
</tr>
<tr>
<td>Change Image Compartment</td>
<td>com.oraclecloud.computeapi.moveimage</td>
</tr>
<tr>
<td>Create Image Begin</td>
<td>com.oraclecloud.computeapi.createimage.begin</td>
</tr>
<tr>
<td>Create Image End</td>
<td>com.oraclecloud.computeapi.createimage.end</td>
</tr>
<tr>
<td>Delete Image</td>
<td>com.oraclecloud.computeapi.deleteimage</td>
</tr>
<tr>
<td>Export Image Begin</td>
<td>com.oraclecloud.computeapi.exportimage.begin</td>
</tr>
<tr>
<td>Export Image End</td>
<td>com.oraclecloud.computeapi.exportimage.end</td>
</tr>
<tr>
<td>Remove Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.removeimageshapecompatibility</td>
</tr>
<tr>
<td>Update Image</td>
<td>com.oraclecloud.computeapi.updateimage</td>
</tr>
</tbody>
</table>

Image Example

This is a reference event for most image events:

```json
{
  "eventType": "com.oraclecloud.computeapi.exportimage.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-27T04:12:37.397Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.tenancy.oc1..<unique_ID>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.tenancy.oc1..<unique_ID>"
  }
}
```

Change image compartment doesn't include the resource name or availability domain.
## Instance Event Types

These are the event types that Compute instances and instance attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.attachbootvolume.begin</td>
</tr>
<tr>
<td>Attach Boot Volume End</td>
<td>com.oraclecloud.computeapi.attachbootvolume.end</td>
</tr>
<tr>
<td>Attach Secondary VNIC Begin</td>
<td>com.oraclecloud.computeapi.attachvnic.begin</td>
</tr>
<tr>
<td>Attach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.attachvnic.end</td>
</tr>
<tr>
<td>Attach Volume Begin</td>
<td>com.oraclecloud.computeapi.attachvolume.begin</td>
</tr>
<tr>
<td>Attach Volume End</td>
<td>com.oraclecloud.computeapi.attachvolume.end</td>
</tr>
<tr>
<td>Change Instance Compartment Begin</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.begin</td>
</tr>
<tr>
<td>Change Instance Compartment End</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.end</td>
</tr>
<tr>
<td>Detach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.detachbootvolume.begin</td>
</tr>
<tr>
<td>Detach Boot Volume End</td>
<td>com.oraclecloud.computeapi.detachbootvolume.end</td>
</tr>
<tr>
<td>Detach Secondary VNIC Begin</td>
<td>com.oraclecloudcomputeapi.detachvnic.begin</td>
</tr>
<tr>
<td>Detach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.detachvnic.end</td>
</tr>
<tr>
<td>Detach Volume Begin</td>
<td>com.oraclecloud.computeapi.detachvolume.begin</td>
</tr>
<tr>
<td>Detach Volume End</td>
<td>com.oraclecloud.computeapi.detachvolume.end</td>
</tr>
<tr>
<td>Instance Action Begin</td>
<td>com.oraclecloud.computeapi.instanceaction.begin</td>
</tr>
<tr>
<td>Instance Action End</td>
<td>com.oraclecloud.computeapi.instanceaction.end</td>
</tr>
<tr>
<td>Instance Preemption Action</td>
<td>com.oraclecloud.computeapi.instancepreemptionaction</td>
</tr>
<tr>
<td>Launch Instance Begin</td>
<td>com.oraclecloud.computeapi.launchinstance.begin</td>
</tr>
<tr>
<td>Launch Instance End</td>
<td>com.oraclecloud.computeapi.launchinstance.end</td>
</tr>
</tbody>
</table>
**Compute Instance Example**

This is a reference event for most instance events (attach/detach volume and boot volume events don't include additional details):

```json
{
  "eventType": "com.oraclecloud.computeapi.launchinstance.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx..<unique_ID>"
    "availabilityDomain": "<availability_domain>",
    "additionalDetails": {
      "imageId": "ocid1.image.oc1.phx..<unique_ID>"
      "shape": "VM.Standard2.1",
      "type": "CustomerVmi"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for attach/detach VNIC events:

```json
{
  "eventType": "com.oraclecloud.computeapi.attachvnic.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>"
    "availabilityDomain": "<availability_domain>",
    "additionalDetails": {
      "subnetId": "ocid1.subnet.oc1.phx.<unique_ID>"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for instance action events:

```json
{
  "eventType": "com.oraclecloud.computeapi.instanceaction.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-16T12:07:14.623Z",
```
This is a reference event for instance preemption events:

```json
{
  "eventType": "com.oraclecloud.computeapi.instancepreemptionaction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2021-02-16T12:07:14.409Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "additionalDetails": {
      "preemptionAction": "TERMINATE"
    }
  },
  "eventID": "<unique_ID>"
}
```

This is an example of an event for a preempted instance:

```json
{
  "eventType": "com.oraclecloud.computeapi.instancepreemptionaction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2021-02-16T12:07:14.409Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "additionalDetails": {
      "preemptionAction": "TERMINATE"
    }
  },
  "eventID": "<unique_ID>"
}
```

This event is triggered when an instance is preempted by the compute service. The "preemptionAction" field indicates the action taken by the compute service when the instance was preempted. In this case, the action is "TERMINATE".

---

Oracle Cloud Infrastructure User Guide 2438
Instance Configuration Event Types

These are the event types that Compute instance configurations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Instance Configuration Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstanceconfiguration</td>
</tr>
<tr>
<td>Create Instance Configuration</td>
<td>com.oraclecloud.computemanagement.createinstanceconfiguration</td>
</tr>
<tr>
<td>Delete Instance Configuration</td>
<td>com.oraclecloud.computemanagement.deleteinstanceconfiguration</td>
</tr>
<tr>
<td>Launch Instance Configuration Begin</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.begin</td>
</tr>
<tr>
<td>Launch Instance Configuration End</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.end</td>
</tr>
<tr>
<td>Update Instance Configuration</td>
<td>com.oraclecloud.computemanagement.updateinstanceconfiguration</td>
</tr>
</tbody>
</table>

Compute Instance Configuration Example

This is a reference event for most instance configuration events:

```json
{
   "eventType": "com.oraclecloud.computemanagement.createinstanceconfiguration",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "ComputeManagement",
   "eventTime": "2019-08-12T22:52:01.062Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "my_instance_configuration",
      "resourceId": "ocid1.instanceconfiguration.oc1.phx.<unique_ID>",
      "availabilityDomain": "<availability_domain>"
   },
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>
   }
}
```

Launch instance configuration end doesn't include the availability domain.
**Instance Console Connection Event Types**

These are the event types that Compute instance console connections emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.createinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Create Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.createinstanceconsoleconnection.end</td>
</tr>
<tr>
<td>Delete Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Delete Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.end</td>
</tr>
<tr>
<td>Update Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.updateinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Update Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.updateinstanceconsoleconnection.end</td>
</tr>
</tbody>
</table>

**Compute Instance Console Connection Example**

This is a reference event for instance console connections:

```json
{
  "eventType": "com.oraclecloud.computeapi.createinstanceconsoleconnection.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-12T14:47:35.762Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceId": "ocid1.instanceconsoleconnection.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
### Instance Pool Event Types

These are the event types that Compute instance pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer</td>
</tr>
<tr>
<td>Attach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer</td>
</tr>
<tr>
<td>Change Instance Pool Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstancepoolcompartment</td>
</tr>
<tr>
<td>Create Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.createinstancepool.begin</td>
</tr>
<tr>
<td>Create Instance Pool End</td>
<td>com.oraclecloud.computemanagement.createinstancepool.end</td>
</tr>
<tr>
<td>Detach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer</td>
</tr>
<tr>
<td>Detach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer</td>
</tr>
<tr>
<td>Reset Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.begin</td>
</tr>
<tr>
<td>Reset Instance Pool End</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.end</td>
</tr>
<tr>
<td>Soft Reset Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.softresetinstancepool.begin</td>
</tr>
<tr>
<td>Soft Reset Instance Pool End</td>
<td>com.oraclecloud.computemanagement.softresetinstancepool.end</td>
</tr>
<tr>
<td>Start Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.startinstancepool.begin</td>
</tr>
<tr>
<td>Start Instance Pool End</td>
<td>com.oraclecloud.computemanagement.startinstancepool.end</td>
</tr>
<tr>
<td>Stop Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.stopinstancepool.begin</td>
</tr>
<tr>
<td>Stop Instance Pool End</td>
<td>com.oraclecloud.computemanagement.stopinstancepool.end</td>
</tr>
<tr>
<td>Terminate Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.terminateinstancepool.begin</td>
</tr>
<tr>
<td>Terminate Instance Pool End</td>
<td>com.oraclecloud.computemanagement.terminateinstancepool.end</td>
</tr>
<tr>
<td>Update Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.updateinstancepool.begin</td>

<tr>
<td>Update Instance Pool End</td>
<td>com.oraclecloud.computemanagement.updateinstancepool.end</td>
</tr>
</tbody>
</table>
Compute Instance Pools Example

This is a reference event for most instance pool events:

```json
{
  "eventType": "com.oraclecloud.computemanagement.createinstancepool.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeManagement",
  "eventTime": "2019-08-12T22:52:01.343Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance_pool",
    "resourceId": "ocid1.instancepool.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_id>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

These instance pool events don't include the availability domain: create instance pool end, detach load balancer end, reset instance pool end, soft reset instance pool end, start instance pool end, stop instance pool end, terminate instance pool end, and update instance pool end.

**Live Migration Event Types**

These are the event types that live migrations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Live Migration Begin</td>
<td>com.oraclecloud.computeapi.livemigrate.begin</td>
</tr>
<tr>
<td>Live Migration End</td>
<td>com.oraclecloud.computeapi.livemigrate.end</td>
</tr>
</tbody>
</table>

**Live Migration Example**

This is a reference event for live migration:

```json
{
  "eventType": "com.oraclecloud.computeapi.livemigrate.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "additionalDetails": {
    "imageId": "ocid1.image.oc1.phx.<unique_ID>"
  },
  "shape": "VM.Standard2.1",
  "type": "CustomerVmi",
  "volumeId": "ocid1.volume.oc1..<unique_ID>"
}
```
Container Engine for Kubernetes

Container Engine for Kubernetes resources that emit events:

- [Cluster Event Types](#) on page 2443
- [Node Pool Event Types](#) on page 2444

Cluster Event Types

These are the event types that clusters emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Cluster Begin</td>
<td>com.oraclecloud.clustersapi.createcluster.begin</td>
</tr>
<tr>
<td>Delete Cluster Begin</td>
<td>com.oraclecloud.clustersapi.deletecluster.begin</td>
</tr>
<tr>
<td>Update Cluster Begin</td>
<td>com.oraclecloud.clustersapi.updatecluster.begin</td>
</tr>
</tbody>
</table>

Cluster Example

This is an example event for clusters:

```json
{
  "eventType": "com.oraclecloud.clustersapi.createcluster.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ClustersAPI",
  "eventId": "<unique_ID>",
  "eventTime": "2020-04-15T16:26:56.848Z",
  "contentType": "application/json",
  "data": {
    "eventGroupingId": "<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_cluster",
    "resourceId": "ocid1.cluster.oc1.iad.<unique_ID>",
    "availabilityDomain": "my_availability_domain",
    "freeformTags": null,
    "definedTags": null
  }
}
```
Node Pool Event Types

These are the event types that node pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.createnodepool.begin</td>
</tr>
<tr>
<td>Delete Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.deletenodepool.begin</td>
</tr>
<tr>
<td>Update Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.updatenodepool.begin</td>
</tr>
</tbody>
</table>

Node Pool Example

This is an example event for node pools:

```json
{
  "eventType": "com.oraclecloud.clustersapi.createnodepool.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ClustersAPI",
  "eventID": "<unique_ID>",
  "eventTime": "2020-04-15T16:26:59.418Z",
  "contentType": "application/json",
  "data": {
    "eventGroupingId": "<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_nodepool",
    "resourceId": "ocid1.nodepool.oc1.iad.<unique_ID>",
    "availabilityDomain": "my_availability_domain",
    "freeformTags": null,
    "definedTags": null
  }
}
```

Content Management

For details about events emitted by Content Management, see Service Events.

Data Catalog

For details about events emitted by Data Catalog, see Data Catalog Events.

Data Safe

For details about events emitted by Data Safe, see Oracle Data Safe Events in Oracle Cloud Infrastructure.

Data Science

Data Science resources that emit events:

- Project Event Types on page 2445
- Notebook Session Event Types on page 2446
- Model Event Types on page 2447
- Model Deployment Event Types on page 2448
### Project Event Types

These are the event types that projects emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Project</td>
<td><code>com.oraclecloud.datascience.createproject</code></td>
</tr>
<tr>
<td>Delete Project Begin</td>
<td><code>com.oraclecloud.datascience.deleteproject.begin</code></td>
</tr>
<tr>
<td>Delete Project End</td>
<td><code>com.oraclecloud.datascience.deleteproject.end</code></td>
</tr>
<tr>
<td>Update Project</td>
<td><code>com.oraclecloud.datascience.deleteproject.end</code></td>
</tr>
</tbody>
</table>

### Project Example

This is a reference event for projects:

```json
{
  "eventType": "com.oraclecloud.datascience.createproject",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "datascience",
  "eventTime": "2019-11-22T01:43:35.246Z",
  "eventID": "<unique_ID>",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example_project",
    "resourceId": "ocid1.datascienceproject.oc1.iad.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
  }
}
```
**Notebook Session Event Types**

These are the event types that notebook sessions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate Notebook Session Begin</td>
<td>com.oraclecloud.datascience.activatenotebooksession.begin</td>
</tr>
<tr>
<td>Activate Notebook Session End</td>
<td>com.oraclecloud.datascience.activatenotebooksession.end</td>
</tr>
<tr>
<td>Create Notebook Session Begin</td>
<td>com.oraclecloud.datascience.createnotebooksession.begin</td>
</tr>
<tr>
<td>Create Notebook Session End</td>
<td>com.oraclecloud.datascience.createnotebooksession.end</td>
</tr>
<tr>
<td>Deactivate Notebook Session Begin</td>
<td>com.oraclecloud.datascience.deactivatenotebooksession.begin</td>
</tr>
<tr>
<td>Deactivate Notebook Session End</td>
<td>com.oraclecloud.datascience.deactivatenotebooksession.end</td>
</tr>
<tr>
<td>Delete Notebook Session Begin</td>
<td>com.oraclecloud.datascience.deletenotebooksession.begin</td>
</tr>
<tr>
<td>Delete Notebook Session End</td>
<td>com.oraclecloud.datascience.deletenotebooksession.end</td>
</tr>
<tr>
<td>Update Notebook Session</td>
<td>com.oraclecloud.datascience.updatenotebooksession</td>
</tr>
</tbody>
</table>

**Notebook Session Example**

This is a reference event for notebook sessions:

```json
{
   "eventType": "com.oraclecloud.datascience.updatenotebooksession",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "datascience",
   "eventTime": "2019-11-22T01:43:35.246Z",
   "eventID": "<unique_ID>",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "example_notebook_session",
      "resourceId": "ocid1.datasciencenotebooksession.oc1.iad.<unique_ID>",
      "availabilityDomain": "<availability_domain>",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      }
   }
}
```
Events

```
"extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>
}
```

## Model Event Types

These are the event types that models emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate Model</td>
<td>com.oraclecloud.datascience.activatemodel</td>
</tr>
<tr>
<td>Create Model</td>
<td>com.oraclecloud.datascience.createmodel</td>
</tr>
<tr>
<td>Deactivate Model</td>
<td>com.oraclecloud.datascience.deactivatemodel</td>
</tr>
<tr>
<td>Delete Model</td>
<td>com.oraclecloud.datascience.deletemodel</td>
</tr>
<tr>
<td>Update Model</td>
<td>com.oraclecloud.datascience.updatemodel</td>
</tr>
</tbody>
</table>

## Model Example

This is a reference event for models:

```
{
    "eventType": "com.oraclecloud.datascience.deletemodel",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "datascience",
    "eventTime": "2019-11-22T01:43:35.246Z",
    "eventID": "<unique_ID>",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example_model",
        "resourceId": "ocid1.datasciencemodel.oc1.iad.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_ID>
        }
    }
}
```
Model Deployment Event Types

These are the event types that model deployments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate Model Deployment</td>
<td>com.oraclecloud.datascience.activatemodeldeployment.begin</td>
</tr>
<tr>
<td></td>
<td>com.oraclecloud.datascience.activatemodeldeployment.end</td>
</tr>
<tr>
<td>Create Model Deployment</td>
<td>com.oraclecloud.datascience.createmodeldeployment.begin</td>
</tr>
<tr>
<td></td>
<td>com.oraclecloud.datascience.createmodeldeployment.end</td>
</tr>
<tr>
<td>Deactivate Model Deployment</td>
<td>com.oraclecloud.datascience.deactivatemodeldeployment.begin</td>
</tr>
<tr>
<td></td>
<td>com.oraclecloud.datascience.deactivatemodeldeployment.end</td>
</tr>
<tr>
<td>Delete Model Deployment</td>
<td>com.oraclecloud.datascience.deletemodeldeployment.begin</td>
</tr>
<tr>
<td></td>
<td>com.oraclecloud.datascience.deletemodeldeployment.end</td>
</tr>
<tr>
<td>Update Model Deployment</td>
<td>com.oraclecloud.datascience.updatemodeldeployment.begin</td>
</tr>
<tr>
<td></td>
<td>com.oraclecloud.datascience.updatemodeldeployment.end</td>
</tr>
</tbody>
</table>

Model Deployment Example

This is a reference event for model deployments:

```json
"exampleEvent": {
    "eventType": "com.oraclecloud.datascience.createmodeldeployment.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "datascience",
    "eventTime": "2021-03-03T01:43:35.246Z",
    "eventID": "unique_ID",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID",
        "compartmentName": "example_compartment",
        "resourceName": "example_model_deployment",
        "resourceId": "ocid1.datasciencemodeldeployment.oc1.iad.unique_ID",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```

Data Transfer

Data Transfer resources that emit events:

- Jobs Event Types on page 2449
- Appliances Event Types on page 2450
- Packages Event Types on page 2451
Events

- Devices Event Types on page 2452
- Appliance Entitlements Event Types on page 2453
- Appliance Export Jobs Event Types on page 2454

Jobs Event Types

These are the event types that job events emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Job</td>
<td>com.oraclecloud.datatransferservice.addtransferjob</td>
</tr>
<tr>
<td>Update Transfer Job</td>
<td>com.oraclecloud.datatransferservice.updatetransferjob</td>
</tr>
<tr>
<td>Delete Transfer Job</td>
<td>com.oraclecloud.datatransferservice.deletetransferjob</td>
</tr>
<tr>
<td>Move Transfer Job</td>
<td>com.oraclecloud.datatransferservice.movetransferjob</td>
</tr>
</tbody>
</table>

Jobs Examples

```json
{
   "eventType": "com.oraclecloud.datatransferservice.addtransferjob",
   "source": "datatransferservice",
   "eventTypeVersion": "2.0",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "transfer_job",
      "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
      "availabilityDomain": "<availability_domain>",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "additionalDetails": {
         "deviceType": "APPLIANCE",
         "uploadBucketName": "example_bucket",
         "lifecycleState": "example_state"
      }
   }
}
```
**Appliances Event Types**

These are the event types that appliances emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.addtransferappliance</td>
</tr>
<tr>
<td>Update Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.updatetransferappliance</td>
</tr>
<tr>
<td>Delete Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.deletetransferappliance</td>
</tr>
</tbody>
</table>

**Appliances Example**

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferappliance",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "transfer_job",
        "resourceId": "ocid1.datatransferjob.oc1.phx..<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "applianceLabel": "example_label",
            "lifecycleState": "example_state"
        }
    }
}
```
Packages Event Types

These are the event types that packages emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Package</td>
<td>com.oraclecloud.datatransferservice.addtransferpackage</td>
</tr>
<tr>
<td>Update Transfer Package</td>
<td>com.oraclecloud.datatransferservice.updatetransferpackage</td>
</tr>
<tr>
<td>Delete Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
<tr>
<td>Attach Devices To Transfer Package</td>
<td>com.oraclecloud.datatransferservice.addtransferpackage</td>
</tr>
<tr>
<td>Detach Devices From Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
</tbody>
</table>

Packages Example

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferpackage",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "transfer_job",
        "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "packageLabel": "example_label",
            "lifecycleState": "example_state"
        }
    }
}
```
Devices Event Types

These are the event types that devices emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Device</td>
<td><code>com.oraclecloud.datatransferservice.addtransferdevice</code></td>
</tr>
<tr>
<td>Update Transfer Device</td>
<td><code>com.oraclecloud.datatransferservice.updatetransferdevice</code></td>
</tr>
<tr>
<td>Delete Transfer Device</td>
<td><code>com.oraclecloud.datatransferservice.deletetransferdevice</code></td>
</tr>
</tbody>
</table>

Devices Example

```json
{
  "eventType": "com.oraclecloud.datatransferservice.addtransferdevice",
  "source": "datatransferservice",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "transfer_job",
    "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "deviceLabel": "example_label",
      "lifecycleState": "example_state"
    }
  }
}
```
**Appliance Entitlements Event Types**

These are the event types that appliance entitlements emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.createtransferapplianceentitlement</td>
</tr>
<tr>
<td>Update Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.updatetransferapplianceentitlement</td>
</tr>
<tr>
<td>Delete Transfer Appliance Entitlement</td>
<td>com.oraclecloud.datatransferservice.updatetransferapplianceentitlement</td>
</tr>
</tbody>
</table>

**Appliance Entitlements Example**

```json
{
   "eventType": "com.oraclecloud.datatransferservice.createtransferapplianceentitlement",
   "source": "datatransferservice",
   "eventTypeVersion": "2.0",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "transfer_appliance_entitlement",
      "resourceId": "ocid1.datatransferapplianceentitlement.oc1.phx.<unique_ID>",
      "availabilityDomain": "<availability_domain>",
      "freeFormTags": { "Department": "Finance"
      },
      "definedTags": { "Operations": { "CostCenter": "42"
      } },
      "additionalDetails": { "requestorName": "Sample User",
      "requestorEmail": "sample.user@oracle.com",

</tbody>
</table>

**Data Guard Events**

For databases running on dedicated Exadata infrastructure, see Autonomous Database Critical and Information Event Types for details.

*Emitted by databases using shared Exadata infrastructure.*
Autonomous Database example event

This is a reference event for Autonomous Databases in the Oracle public cloud:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType":
        "com.oraclecloud.databaseservice.autonomous.database.backup.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T14:06:23Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_database",
        "resourceId": "ocid1.autonomousdatabase.oc1.phx..<unique_ID>",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeFormTags": {},
        "definedTags": {},
        "additionalDetails": {
            "cpuCoreCount": 1,
            "lifecycleState": "PROVISIONING",
            "dataStorageSizeInTBs": 1,
            "timeCreated": "2019-07-10T14:06:10.905Z",
            "timeUpdated": "2019-07-10T14:06:10.905Z",
            "serviceConsoleUrl": null,
            "licenseType": null,
            "workloadType": "<Data Warehouse | Transaction Processing>",
            "autonomousDatabaseType": "<Dedicated Infrastructure | Shared Infrastructure>"
        }
    }
}
```

Database Service: Autonomous Database Critical and Information Event Types

Autonomous Databases emit "critical" and "information" data plane events. Information events provide important details about the database lifecycle, such as the time when maintenance begins and maintenance ends, or notifications of connections from a new IP address.

Critical events on Autonomous Database are issues that cause disruption to the database.

Both the "information" and "critical" event types use an additionalDetails section of the event message to provide specific details about what is happening within the Autonomous Database emitting the event. Details about the conditions and operations that trigger these two event types follow below.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Database - Critical</td>
<td>com.oraclecloud.databaseservice.autonomous.database.backup.begin</td>
</tr>
<tr>
<td>Autonomous Database - Information</td>
<td>com.oraclecloud.databaseservice.autonomous.database.backup.begin</td>
</tr>
</tbody>
</table>
In the following example of a "critical" event, you can see within the additionalDetails section of the event message that this particular message concerns a "database down" condition that has just ended. The eventName and description fields provide information regarding the critical situation within the "adwfinance" database:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.autonomous.database.critical",
  "source": "DatabaseService",
  ...
  "additionalDetails": {
    "eventName": "DatabaseDownEnd",
    "dbName": "adwfinance",
    "description": "adwfinance is up and ready for user operations.",
    "workloadType": "Data Warehouse",
    "autonomousDatabaseType": "Shared Infrastructure"
  }
}
```

In the tables below, you can read about the conditions and operations that trigger "critical" and "information" event types. Each condition or operation is identified by a unique eventName value.

<table>
<thead>
<tr>
<th>Critical Event - EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AdminPasswordWarning</strong></td>
<td>Generated when Autonomous Database determines that the ADMIN password will expire after a 30 day grace period is complete. ADMIN passwords should be reset after no more than 360 days. The 30 day grace period begins after a password has been in use for 360 days. If the password is not reset during the grace period, the event is generated a second time, 30 days after the first event notification, to notify you that the password has expired and needs to be reset.</td>
</tr>
</tbody>
</table>
| **DatabaseDownBegin**               | The Autonomous Database instance cannot be opened, or the services such as high, low, medium, tp, or turgent are not started or available. The following conditions do not trigger DatabaseDownBegin:  
                        
  * Operations performed during the maintenance window  
  * Load balancer, network, or backup related issues  
  * A user stopping the instance  

  This event will not be triggered if you are using Autonomous Data Guard and the standby database is not available due to any of the above conditions. |
### Critical Event - EventName

<table>
<thead>
<tr>
<th>EventName</th>
<th>Description</th>
</tr>
</thead>
</table>
| DatabaseDownEnd        | The database is recovered from the down state, meaning the Autonomous Database instance is opened with its services, following a DatabaseDownBegin event. DatabaseDownEnd is triggered only if there was a preceding DatabaseDownBegin event. The following conditions do not trigger DatabaseDownEnd:  
  • Operations performed during the maintenance window  
  • A user starting the instance  
  If you are using Autonomous Data Guard and the primary database goes down, this triggers a DatabaseDownBegin event. If the system fails over to the standby database, this triggers a DatabaseDownEnd event. |

<table>
<thead>
<tr>
<th>EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WalletExpirationWarning</td>
<td>Generated when Autonomous Database determines that a wallet is due to expire in less than six (6) weeks. This event is reported at most once per week.</td>
</tr>
</tbody>
</table>

The following informational events are available for Autonomous Database:

<table>
<thead>
<tr>
<th>Information Event - EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DatabaseConnection</td>
<td>Generated if a connection is made to the database from a new IP address. A new IP address is defined as an address that has not connected to the database in the last 30 days.</td>
</tr>
<tr>
<td>MaintenanceBegin</td>
<td>Triggered when the maintenance starts and provides the start timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled start time.</td>
</tr>
<tr>
<td>MaintenanceEnd</td>
<td>Triggered when the maintenance ends and provides the end timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled end time.</td>
</tr>
<tr>
<td>NewMaintenanceSchedule</td>
<td>Generated when the maintenance date is updated and the new date is shown on the Oracle Cloud Infrastructure Console.</td>
</tr>
<tr>
<td>ScheduledMaintenanceWarning</td>
<td>Generated when the instance is 24 hours from a scheduled maintenance operation, and again when the instance is 1 hour (60 minutes) from the scheduled maintenance.</td>
</tr>
</tbody>
</table>

**Note:**

If you are using Autonomous Data Guard for shared Exadata infrastructure, any of the above listed events that occurs on the standby database does not trigger an Information event.
Database Service: Autonomous Container Database Event Types

These are the event types that Autonomous Container Databases emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Container Database - Change Compartment</td>
<td>com.oraclecloud.databaseservice.changeautonomouscontainerdatabasecompartmentbegin</td>
</tr>

### Autonomous Exadata Infrastructure resource example event

This is a reference event for Autonomous Exadata Infrastructure instances:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": 
    "com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin",
    "source": "databaseservice",
```
Database Service: Autonomous Exadata Infrastructure Critical and Warning Event Types

Critical and warning events are generic events for Autonomous Exadata Infrastructure. Critical events deliver information about critical conditions that need immediate attention.

<table>
<thead>
<tr>
<th>Critical Event—EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslCertificate.expired</td>
<td>This critical event indicates that the SSL certificate has expired. The infrastructure instance remains inaccessible until you renew the certificate.</td>
</tr>
</tbody>
</table>

Warning events deliver information about conditions that may lead to critical events if no action is taken.

<table>
<thead>
<tr>
<th>Warning Event—EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslCertificateExpiryReminder</td>
<td>This warning event generates an advisory message that repeats every week beginning six weeks (42 days) before the SSL certificate expires, and decreases the number of days until certificate expiry by 7 with each repetition, until you address the issue or the certificate expires.</td>
</tr>
</tbody>
</table>

In the following example of a critical event, the event message that the SSL certificate for the Autonomous Exadata Infrastructure has expired is located in the additionalDetails section. The description and eventName fields provide information regarding the critical situation within the dedicated Exadata infrastructure.

```json
{
    "eventType": "com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.critical",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "databaseservice",
    ...
    "additionalDetails": {
        "cpuCoreCount": 92,
        "lifecycleState": "PROVISIONING",
        "dataStorageSizeInTBs": null,
        "timeCreated": "2019-07-10T23:13:43.136Z",
        "timeUpdated": "2019-07-10T23:28:12.390Z",
        "serviceConsoleUrl": null,
        "licenseType": null,
        "dbName": null
    }
}
```
Database Service: Autonomous Data Guard Event Types for Dedicated Exadata Infrastructure

These are the event types that Autonomous Data Guard associations on dedicated Exadata infrastructure emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Data Guard Association - Create Begin</td>
<td>com.oraclecloud.databaseservice.createautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Create End</td>
<td>com.oraclecloud.databaseservice.createautonomousdataguardassociation.end</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Failover Begin</td>
<td>com.oraclecloud.databaseservice.failoverautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Failover End</td>
<td>com.oraclecloud.databaseservice.failoverautonomousdataguardassociation.end</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Reinstate Begin</td>
<td>com.oraclecloud.databaseservice.reinstateautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Reinstate End</td>
<td>com.oraclecloud.databaseservice.reinstateautonomousdataguardassociation.end</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Switchover Begin</td>
<td>com.oraclecloud.databaseservice.switchoverautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Switchover End</td>
<td>com.oraclecloud.databaseservice.switchoverautonomousdataguardassociation.end</td>
</tr>
</tbody>
</table>
**Database Service: DB System Event Types**

These are the event types that DB systems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB System - Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changedbsystemcompartment.begin</td>
</tr>
<tr>

<td>com.oraclecloud.databaseservice.changedbsystemcompartment.end</td>
</tr>
<tr>
<td>DB System - Create Begin</td>
<td>com.oraclecloud.databaseservice.launchdbsystem.begin</td>
</tr>
<tr>
<td>DB System - Create End</td>
<td>com.oraclecloud.databaseservice.launchdbsystem.end</td>
</tr>
<tr>
<td>DB System - Critical (see DB System Critical Event Details for more information)</td>
<td>com.oraclecloud.databaseservice.dbsystem.critical</td>
</tr>
<tr>
<td>DB System - Terminate Begin</td>
<td>com.oraclecloud.databaseservice.terminatedbsystem.begin</td>
</tr>
<tr>
<td>DB System - Terminate End</td>
<td>com.oraclecloud.databaseservice.terminatedbsystem.end</td>
</tr>
<tr>
<td>DB System - Update IORM Begin</td>
<td>com.oraclecloud.databaseservice.updateiormconfig.begin</td>
</tr>
<tr>
<td>DB System - Update IORM End</td>
<td>com.oraclecloud.databaseservice.updateiormconfig.end</td>
</tr>
</tbody>
</table>

**DB system example event**

This is a reference event for DB systems:

```json
{
    "cloudEventsVersion": "0.1",
    "contentType": "application/json",
    "data": {
        "additionalDetails": {
            "cpuCoreCount": 1,
            "dataStoragePercentage": 80,
            "dataStorageSizeInGBs": 256,
            "exadataIormConfig": "null",
            "licenseType": "LICENSE_INCLUDED",
            "lifecycleMessage": null,
            "lifecycleState": "PROVISIONING",
            "nsgIds": "null",
            "patchHistoryEntries": "null",
            "sshPublicKeys": "...",
            "version": null
        },
        "availabilityDomain": "XXIT:US-ASHBURN-AD-1",
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceId": "ocid1.dbsystem.oc1.iad.<unique_ID>",
        "resourceName": "myDBsystem"
    }
}
```
Database Service: DB System Critical Event Details

Note:
To receive DB system critical events for bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See AHF Telemetry Commands on page 2013 for details on enabling telemetry for bare metal and virtual machine DB systems.

The com.oraclecloud.databaseservice.dbsystem.critical event delivers information about several types of critical conditions and errors in the additionalDetails section of the critical event payload. The following table documents the sub-types of the DB system critical event.

<table>
<thead>
<tr>
<th>EventName (in additionalDetails)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITY.DG_STATUS</td>
<td>Data Guard error</td>
</tr>
<tr>
<td>ERRORS.ASM.ORA600</td>
<td>ORA-600 internal error</td>
</tr>
<tr>
<td>ERRORS.ASM.ORA7445</td>
<td>ORA-7445 error (unhandled exception in the Oracle source code)</td>
</tr>
</tbody>
</table>

See Database Critical example event for a JSON example of a critical event.

Database Service: Node (Virtual Machine) Event Types

These are the event types that database nodes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Node - Update Begin</td>
<td>com.oraclecloud.databaseservice.dbnodeaction.end</td>
</tr>
<tr>
<td>DB Node - Update End</td>
<td>com.oraclecloud.databaseservice.dbnodeaction.end</td>
</tr>
<tr>
<td>DB Node - Critical (see DB Node Critical Event Details for more information)</td>
<td>com.oraclecloud.databaseservice.dbnode.critical</td>
</tr>
</tbody>
</table>

DB system node example event

This is a reference event for DB system nodes:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.db.node.reboot.begin",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1.<unique_ID>"
  },
  "source": "DatabaseService"
}
```
"source": "databaseservice",
"eventTypeVersion": "2.0",
"eventTime": "2019-07-29T04:43:24Z",
"contentType": "application/json",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1.<unique_ID>"
},
"data": {
  "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
  "compartmentName": "example_compartment",
  "resourceName": "",
  "resourceId": "ocid1.dbnode.oc1.phx.<unique_ID>",
  "availabilityDomain": "TGjA:PHX-AD-2",
  "freeFormTags": null,
  "definedTags": null,
  "additionalDetails": {
    "cpuCoreCount": null,
    "lifecycleState": "STARTING",
    "dataStorageSizeInTBs": null,

    "hostName": "ora18c",
    "lifecycleDetails": null,
    "dbSystemId": "ocid1.dbsystem.oc1.phx.<unique_ID>",
    "dbHostId": "DbHost-<unique_ID>",
    "nodeNumber": null
  }
}

Database Service: DB Node Critical Event Details

Note:

To receive DB node critical events for bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See AHF Telemetry Commands on page 2013 for details on enabling telemetry for bare metal and virtual machine DB systems.

The com.oraclecloud.databaseservice.dbnode.critical event delivers information about critical conditions in the additionalDetails section of the DB node critical event payload. The following table documents the sub-types of the DB node critical event.

<table>
<thead>
<tr>
<th>EventName (in additionalDetails)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITY.CRS_STATUS</td>
<td>Cluster Ready Services clusterware error</td>
</tr>
</tbody>
</table>

See Database Critical example event for a JSON example of a critical event.
**Database Service: Oracle Database Home Event Types**

These are the event types that Oracle Database Homes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Home - Create Begin</td>
<td>com.oraclecloud.databaseservice.createdbhome.begin</td>
</tr>
<tr>
<td>DB Home - Create End</td>
<td>com.oraclecloud.databaseservice.createdbhome.end</td>
</tr>
<tr>
<td>DB Home - Patch Begin</td>
<td>com.oraclecloud.databaseservice.patchdbhome.begin</td>
</tr>
<tr>
<td>DB Home - Patch End</td>
<td>com.oraclecloud.databaseservice.patchdbhome.end</td>
</tr>
<tr>
<td>DB Home - Terminate Begin</td>
<td>com.oraclecloud.databaseservice.deletedbhome.begin</td>
</tr>
<tr>
<td>DB Home - Terminate End</td>
<td>com.oraclecloud.databaseservice.deletedbhome.end</td>

```

Database Service: Database Critical Event Details

**Note:**

This event type is emitted by Oracle Databases running on Exadata Cloud Service instances, bare metal DB systems, and virtual machine DB systems. To receive database critical events for databases in bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See [AHF Telemetry Commands](#) on page 2013 for details on enabling telemetry for bare metal and virtual machine DB systems.
The `com.oraclecloud.databaseservice.database.critical` event delivers information about several types of critical conditions and errors in the `additionalDetails` section of the Database critical event payload. The following table documents the sub-types of the Database Critical event.

<table>
<thead>
<tr>
<th>EventName (in additionalDetails)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRORS.DB.ARCHIVER_STUCK</td>
<td>Archiver stuck error</td>
</tr>
<tr>
<td>AVAILABILITY.DB_STATUS</td>
<td>Database availability error</td>
</tr>
<tr>
<td>ERRORS.DB.HANG</td>
<td>Database hang error</td>
</tr>
<tr>
<td>ERRORS.DB.ORA7445</td>
<td>ORA-7445 error (unhandled exception in the Oracle source code)</td>
</tr>
<tr>
<td>ERRORS.DB.ORA600</td>
<td>ORA-600 internal error</td>
</tr>
</tbody>
</table>

See [Database Critical example event](#) for a JSON example of a critical event.

**Database Critical example event**

The Database Critical, DB Node Critical, and DB System Critical events originate in the data plane and contain details about a critical condition in the `additionalDetails` section of the payload. See the preceding tables for details about these event subtypes.

This is a reference "critical" data plane event for DB systems, DB system nodes, and databases:

```json
{
    "eventType" : "com.oraclecloud.databaseservice.database.critical",
    "cloudEventsVersion" : "0.1",
    "eventTypeVersion" : "2.0",
    "source" : "DataPlane",
    "eventTime" : "2020-11-10T19:52:15Z",
    "contentType" : "application/json",
    "data" : {
        "compartmentId" : "ocid1.compartment.oc1.<unique_ID>",
        "compartmentName" : "VMDBSI-Dev",
        "resourceName" : "DB0422_iad3x7",
        "resourceId" : "ocid1.database.oc1.iad.<unique_ID>",
        "availabilityDomain" : "zvXp:US-ASHBURN-AD-3",
        "additionalDetails" : {
            "serviceType" : "dbcs",
            "hostName" : "singlenodegi-sales",
            "component" : "cdb",
            "instanceName" : "db0422",
            "dbName" : "db0422_iad3x7",
            "description" : "Database : DB0422_iad3x7 Instance : DB0422, status is online",
            "eventName" : "AVAILABILITY.DB_STATUS",
            "dbSystemId" : "ocid1.dbsystem.oc1.iad.<unique_ID>",
            "status" : "online"
        }},
    "eventID" : "91653791-7aab-45dd-b57f-e2e9013acdb9",
    "extensions" : {
        "compartmentId" : "ocid1.compartment.oc1.<unique_ID>"
    }
}
```
**Database Service: Pluggable Database Event Types**

These are the event types that Oracle pluggable databases in Oracle Cloud Infrastructure emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pluggable Database - Create Begin</td>
<td>com.oraclecloud.databaseservice.createpluggabledatabase.begin</td>
</tr>
<tr>
<td>Pluggable Database - Create End</td>
<td>com.oraclecloud.databaseservice.createpluggabledatabase.end</td>
</tr>
<tr>
<td>Pluggable Database - Delete Begin</td>
<td>com.oraclecloud.databaseservice.deletepluggabledatabase.begin</td>
</tr>
<tr>
<td>Pluggable Database - Delete End</td>
<td>com.oraclecloud.databaseservice.deletepluggabledatabase.end</td>
</tr>
<tr>
<td>Pluggable Database - Local Clone Begin</td>
<td>com.oraclecloud.databaseservice.localclonepluggabledatabase.begin</td>
</tr>
<tr>
<td>Pluggable Database - Local Clone End</td>
<td>com.oraclecloud.databaseservice.localclonepluggabledatabase.end</td>

## Database Service: External Database Event Types

These are the event types that external database resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Container Database - Change Compartment Begin</td>
<td>com.oraclecloud.databaseservice.changeexternalco</td>
</tr>
<tr>
<td>External Container Database - Change Compartment End</td>
<td>com.oraclecloud.databaseservice.changeexternalco</td>
</tr>
<tr>
<td>External Container Database - Create</td>
<td>com.oraclecloud.databaseservice.createexternalc</td>
</tr>
<tr>
<td>External Container Database - Delete Begin</td>
<td>com.oraclecloud.databaseservice.deleteexternalc</td>
</tr>
<tr>
<td>External Container Database - Delete End</td>
<td>com.oraclecloud.databaseservice.deleteexternalc</td>
</tr>
<tr>
<td>External Container Database - Disable Database Management Service Begin</td>
<td>com.oraclecloud.databaseservice.disabledatabase</td>
</tr>
<tr>
<td>External Container Database - Disable Database Management Service End</td>
<td>com.oraclecloud.databaseservice.disabledatabase</td>
</tr>
<tr>
<td>External Container Database - Enable Database Management Service Begin</td>
<td>com.oraclecloud.databaseservice.enabledatabase</td>
</tr>
<tr>
<td>External Container Database - Enable Database Management Service End</td>
<td>com.oraclecloud.databaseservice.enabledatabase</td>
</tr>
<tr>
<td>External Container Database - Scan Pluggable Databases Begin</td>
<td>com.oraclecloud.databaseservice.scanexternalco</td>
</tr>
<tr>
<td>External Container Database - Scan Pluggable Databases End</td>
<td>com.oraclecloud.databaseservice.scanexternalco</td>
</tr>
<tr>
<td>External Container Database - Update Begin</td>
<td>com.oraclecloud.databaseservice.updateexternalc</td>
</tr>
<tr>
<td>External Container Database - Update End</td>
<td>com.oraclecloud.databaseservice.updateexternalc</td>
</tr>
<tr>
<td>External Database Connector - Check Status Begin</td>
<td>com.oraclecloud.databaseservice.checkexternalda</td>
</tr>
<tr>
<td>External Database Connector - Check Status End</td>
<td>com.oraclecloud.databaseservice.checkexternalda</td>
</tr>
<tr>
<td>External Database Connector - Create Begin</td>
<td>com.oraclecloud.databaseservice.createexternald</td>
</tr>
<tr>
<td>External Database Connector - Create End</td>
<td>com.oraclecloud.databaseservice.createexternald</td>
</tr>
<tr>
<td>External Database Connector - Delete</td>
<td>com.oraclecloud.databaseservice.deleteexternald</td>
</tr>
</tbody>
</table>
External Database service example events

External Container Database Example

```json
{
    "compartmentId": "ocid1.compartment.oc1.......unique_id",
    "compartmentName": "example_name",
    "resourceName": "11092020_PKS_NCDB1",
    "resourceId": "ocid1.externalnoncontainerdatabase.oc1.......unique_id",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {},
    "definedTags": {},
    "additionalDetails": {
        "id": "ocid1.externalnoncontainerdatabase.oc1.......unique_id",

        "timeZone": "US/Pacific"
    }
}
```

Database Migration

For details about events emitted by Database Migration, see Database Migration Events.
Digital Assistant

For details about events emitted by Digital Assistant, see Events for Digital Assistant Instances.

File Storage

File Storage resources that emit events:

- File System Event Types on page 2481 and Snapshot Event Types on page 2482
- Mount Target Event Types on page 2483
- Export Event Types on page 2484 and Export Set Event Types on page 2484

File System Event Types

These are the event types that file systems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change File System Compartment</td>
<td>com.oraclecloud.filestorage.changefilesystemcomp</td>
</tr>
<tr>
<td>Create File System</td>
<td>com.oraclecloud.filestorage.createfilesystem</td>
</tr>
<tr>
<td>Delete File System</td>
<td>com.oraclecloud.filestorage.deletefilesystem</td>
</tr>
<tr>
<td>Update File System</td>
<td>com.oraclecloud.filestorage.updatefilesystem</td>
</tr>
</tbody>
</table>

File System Example

This is a reference event for file systems:

```json
{
    "eventType": "com.oraclecloud.filestorage.createfilesystem",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_filesystem",
        "resourceId": "ocid1.filesystem.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventId": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Snapshot Event Types

These are the event types that snapshots emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Snapshot</td>
<td>com.oraclecloud.filestorage.createsnapshot</td>
</tr>
<tr>
<td>Delete Snapshot</td>
<td>com.oraclecloud.filestorage.deletesnapshot</td>
</tr>
</tbody>
</table>

Snapshot Example

This is a reference event for snapshots:

```json
{
    "eventType": "com.oraclecloud.filestorage.createsnapshot",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_snapshot",
        "resourceId": "ocid1.snapshot.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Mount Target Event Types

These are the event types that mount targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Mount Target Compartment</td>
<td>com.oraclecloud.filestorage.changemounttargetcompartment</td>
</tr>
<tr>
<td>Create Mount Target</td>
<td>com.oraclecloud.filestorage.createmounttarget</td>
</tr>
<tr>
<td>Delete Mount Target</td>
<td>com.oraclecloud.filestorage.deletemounttarget</td>
</tr>
<tr>
<td>Update Mount Target</td>
<td>com.oraclecloud.filestorage.updatemounttarget</td>
</tr>
</tbody>
</table>

Mount Target Example

This is a reference event for mount targets:

```
{
  "eventType": "com.oraclecloud.filestorage.createmounttarget",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_mounttarget",
    "resourceId": "ocid1.mounttarget.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```
**Export Event Types**

These are the event types that exports emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Export</td>
<td>com.oraclecloud.filestorage.createexport</td>
</tr>
<tr>
<td>Delete Export</td>
<td>com.oraclecloud.filestorage.deleteexport</td>
</tr>
<tr>
<td>Update Export</td>
<td>com.oraclecloud.filestorage.updateexport</td>
</tr>
</tbody>
</table>

**Export Example**

This is a reference event for exports:

```json
{
    "eventType": "com.oraclecloud.filestorage.createexport",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>"",
        "compartmentName": "example_name",
        "resourceName": "my_export",
        "resourceId": "ocid1.export.oc1..<unique_id>"",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    },
    "eventID": "unique_ID",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>""
    }
}
```

**Export Set Event Types**

These are the event types that export sets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete Export Set</td>
<td>com.oraclecloud.filestorage.deleteexportset</td>
</tr>
<tr>
<td>Update Export Set</td>
<td>com.oraclecloud.filestorage.updateexportset</td>
</tr>
</tbody>
</table>

**Export Set Example**
Events

This is a reference event for export sets:

```
{  
    "eventType": "com.oraclecloud.filestorage.updateexportset",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": { 
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_exportset",
        "resourceId": "ocid1.exportset.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": { 
            "Department": "Finance"
        },
        "definedTags": { 
            "Operations": {
                "CostCenter": "42"
            }
        }
    }, 
    "eventID": "unique_ID",
    "extensions": { 
        "compartmentId": "ocid1.compartment.oc1..<unique_id>"
    }
}
```

Functions

Functions resources that emit events:

- Application Event Types on page 2485
- Function Event Types on page 2486

Application Event Types

These are the event types that applications emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Application Compartment</td>
<td>com.oraclecloud.functions.changeapplicationcompartment</td>
</tr>
<tr>
<td>Create Application</td>
<td>com.oraclecloud.functions.createapplication</td>
</tr>
<tr>
<td>Delete Application</td>
<td>com.oraclecloud.functions.deleteapplication</td>
</tr>
<tr>
<td>Update Application</td>
<td>com.oraclecloud.functions.updateapplication</td>
</tr>
</tbody>
</table>

Application Example

This is an example event for applications:

```
{  
    "eventType": "com.oraclecloud.functions.createapplication",
```
Events

"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "functions",
"eventTime": "2019-07-22T09:33:44.754Z",
"contentType": "application/json",
"data":{
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "my_compartment",
  "resourceName": "my-application",
  "resourceId": "ocid1.fnapp.oc1.phx..<unique_ID>",
  "availabilityDomain": "AD3"
},
"eventID": "<unique_ID>",
"extensions":{
  "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
}
}

Function Event Types

These are the event types that functions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Function</td>
<td>com.oraclecloud.functions.createfunction</td>
</tr>
<tr>
<td>Delete Function</td>
<td>com.oraclecloud.functions.deletefunction</td>
</tr>
<tr>
<td>Update Function</td>
<td>com.oraclecloud.functions.updatefunction</td>
</tr>
</tbody>
</table>

Function Example

This is an example event for functions:

```
{
  "eventType": "com.oraclecloud.functions.createfunction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "functions",
  "eventTime": "2019-07-22T09:33:44.754Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my-function",
    "resourceId": "ocid1.fnfunc.oc1.phx..<unique_ID>",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Health Checks

Health Checks resources that emit events:
HTTP Monitors Event Types

These are the event types that HTTP monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.createhttpmonitor</td>
</tr>
<tr>
<td>Delete HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.deletehttpmonitor</td>
</tr>
<tr>
<td>Update HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.updatehttpmonitor</td>
</tr>
</tbody>
</table>

HTTP Monitor Example

This is an example event for HTTP monitors:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createhttpmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:06:29.451Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_monitor",
    "resourceId": "ocid1.httpmonitor.oc1..<unique_ID>",
    "availabilityDomain": "AD1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```
Ping Monitor Event Types

These are the event types that ping monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Ping Monitor</td>
<td>com.oraclecloud.healthchecks.createpingmonitor</td>
</tr>
<tr>
<td>Delete Ping Monitor</td>
<td>com.oraclecloud.healthchecks.deletepingmonitor</td>
</tr>
<tr>
<td>Update Ping Monitor</td>
<td>com.oraclecloud.healthchecks.updatepingmonitor</td>
</tr>
</tbody>
</table>

Ping Monitor Example

This is an example event for ping monitors:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createpingmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:08:11.242Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_monitor",
    "resourceId": "ocid1.pingmonitor.oc1..<unique_ID>",
    "availabilityDomain": "AD1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```

IAM

IAM resources that emit events:

- Authentication Policy Event Types on page 2489
- Credentials Event Types on page 2490
- Dynamic Group Event Types on page 2491
- Group Event Types on page 2492
- Identity Provider Event Types on page 2494
- Multi-Factor Authentication TOTP Device Event Types on page 2496
- Policy Event Types on page 2497
- User Event Types on page 2498
Authentication Policy Event Types

This is the event type that authentication policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update Authentication Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</td>
</tr>
</tbody>
</table>

Authentication Policy Example

This is a reference event for authentication policy events:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": { 
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_compartment",
        "resourceId": "ocid1.compartment.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    },
    "extensions": { 
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
## Credentials Event Types

These are the event types that credentials emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Auth Token</td>
<td>com.oraclecloud.identityControlPlane.CreateAuthToken</td>
</tr>
<tr>
<td>Create Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.CreateCustomerSecretKey</td>
</tr>
<tr>
<td>Create or Reset Password</td>
<td>com.oraclecloud.identityControlPlane.CreateOrResetPassword</td>
</tr>
<tr>
<td>Create SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.CreateSmtpCredential</td>
</tr>
<tr>
<td>Create Swift Password</td>
<td>com.oraclecloud.identityControlPlane.CreateSwiftPassword</td>
</tr>
<tr>
<td>Delete API Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteApiKey</td>
</tr>
<tr>
<td>Delete Auth Token</td>
<td>com.oraclecloud.identityControlPlane.DeleteAuthToken</td>
</tr>
<tr>
<td>Delete Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteCustomerSecretKey</td>
</tr>
<tr>
<td>Delete SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.DeleteSmtpCredential</td>
</tr>
<tr>
<td>Delete Swift Password</td>
<td>com.oraclecloud.identityControlPlane.DeleteSwiftPassword</td>
</tr>
<tr>
<td>Update Auth Token</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthToken</td>
</tr>
<tr>
<td>Update Authentication Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</td>
</tr>
<tr>
<td>Update SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.UpdateSmtpCredential</td>
</tr>
<tr>
<td>Update Swift Password</td>
<td>com.oraclecloud.identityControlPlane.UpdateSwiftPassword</td>
</tr>
<tr>
<td>Upload API KEY</td>
<td>com.oraclecloud.identityControlPlane.UploadApiKey</td>
</tr>
</tbody>
</table>

### Credentials Example
This is a reference event for most credential events (create or reset password don't include additional details):

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.DeleteApiKey",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>
  }
}
```

### Dynamic Group Event Types

These are the event types that dynamic groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.CreateDynamicGroup</td>
</tr>
<tr>
<td>Delete Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteDynamicGroup</td>
</tr>
<tr>
<td>Update Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.UpdateDynamicGroup</td>
</tr>
</tbody>
</table>

### Dynamic Group Example

This is a reference event for dynamic groups:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateDynamicGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>
    }
  }
```

Oracle Cloud Infrastructure User Guide
Group Event Types

These are the event types that groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to Group</td>
<td>com.oraclecloud.identityControlPlane.AddUserToGroup</td>
</tr>
<tr>
<td>Create Group</td>
<td>com.oraclecloud.identityControlPlane.CreateGroup</td>
</tr>
<tr>
<td>Delete Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteGroup</td>
</tr>
<tr>
<td>Remove User From Group</td>
<td>com.oraclecloud.identityControlPlane.RemoveUserFromGroup</td>
</tr>
<tr>
<td>Update Group</td>
<td>com.oraclecloud.identityControlPlane.UpdateGroup</td>
</tr>
</tbody>
</table>

Group Example

This is a reference event for some groups (create, delete, and update events don't include additional details):

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.AddUserToGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_group",
    "resourceId": "ocid1.groupmembership.oc1.<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    }
  }
}
```
# Identity Provider Event Types

These are the event types that identity providers emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to IdP Group</td>
<td>com.oraclecloud.identityControlPlane.AddUserToIdpGroup</td>
</tr>
<tr>
<td>Create Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProvider</td>
</tr>
<tr>
<td>Create Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup</td>
</tr>
<tr>
<td>Create IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpGroupMapping</td>
</tr>
<tr>
<td>Create IdP User</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpUser</td>
</tr>
<tr>
<td>Delete Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProvider</td>
</tr>
<tr>
<td>Delete Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProviderGroup</td>
</tr>
<tr>
<td>Delete IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpGroupMapping</td>
</tr>
<tr>
<td>Delete IdP User</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpUser</td>
</tr>
<tr>
<td>Remove User From IdP Group</td>
<td>com.oraclecloud.identityControlPlane.RemoveUserFromIdpGroup</td>
</tr>
<tr>
<td>Reset IdP SCIM Client</td>
<td>com.oraclecloud.identityControlPlane.ResetIdpScim</td>
</tr>
<tr>
<td>Update Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdentityProvider</td>
</tr>
<tr>
<td>Update IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdpGroupMapping</td>
</tr>
</tbody>
</table>

## Identity Provider Example

The following reference events are for identity provider events that include additional details. Some identity providers events do not include additional details. These events are create, delete, and update identity providers, as well as delete identity provider group, delete IdP user, and reset IdP SCIM.

This is a reference event for adding and removing users from IdP groups:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.AddUserToIdpGroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
...}
```
This is a reference event for create, update, and delete IdP group mapping:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateIdpGroupMapping",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_group",
    "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for create IdP user and create IdP group:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateIdpgroup Mapping",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_identityprovider",
    "resourceId": "ocid1.idpgroupmapping.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "idpGroupName": "my_group",
      "groupId": "ocid1.group.oc1..<unique_ID>"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for create, update, and delete IdP group mapping:
Multi-Factor Authentication TOTP Device Event Types

These are the event types that MFA TOTP devices emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.ActivateMfaTotpDevice</td>
</tr>
<tr>
<td>Create MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.CreateMfaTotpDevice</td>
</tr>
<tr>
<td>Delete MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.DeleteMfaTotpDevice</td>
</tr>
<tr>
<td>Generate MFA TOTP Device Seed</td>
<td>com.oraclecloud.identityControlPlane.GenerateTotpDevice</td>
</tr>
</tbody>
</table>

Multi-Factor Authentication TOTP Devices Example

This is a reference event for MFA TOTP Devices:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_idpgroup",
    "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "externalIdentifier": "my_externalidentifier"
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
  }
}
```
Policy Event Types

These are the event types that policies emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Policy</td>
<td>com.oraclecloud.identityControlPlane.CreatePolicy</td>
</tr>
<tr>
<td>Delete Policy</td>
<td>com.oraclecloud.identityControlPlane.DeletePolicy</td>
</tr>
<tr>
<td>Update Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdatePolicy</td>
</tr>
</tbody>
</table>

Policy Example

This is a reference event for policies:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreatePolicy",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_policy",
        "resourceId": "ocid1.policy.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "userId": "ocid1.user.oc1..<unique_ID>
        }
    }
}"
```
User Event Types
These are the event types that users emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create User</td>
<td>com.oraclecloud.identityControlPlane.CreateUser</td>
</tr>
<tr>
<td>Delete User</td>
<td>com.oraclecloud.identityControlPlane.DeleteUser</td>
</tr>
<tr>
<td>Update User</td>
<td>com.oraclecloud.identityControlPlane.UpdateUser</td>
</tr>
<tr>
<td>Update User Capabilities</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserCapabilities</td>
</tr>
<tr>
<td>Update User State</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserState</td>
</tr>
</tbody>
</table>

User Example
This is a reference event for users:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateUser",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_user",
        "resourceId": "ocid1.user.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
        }
    }
}```
Integration
For details about events emitted by Oracle Integration, see Automating with Events.

Java Management
For details about events emitted by the Java Management service, see Service Events.

MySQL Database
For details about events emitted by MySQL Database, see Service Events.

Networking
Networking resources that emit events:
- DHCP Options Event Types on page 2499
- Dynamic Routing Gateway (DRG) Event Types on page 2500
- DRG Attachment Event Types on page 2501
- Internet Gateway Event Types on page 2502
- Local Peering Gateway (LPG) Event Types on page 2503
- NAT Gateway Event Types on page 2504
- Network Security Group (NSG) Event Types on page 2505
- Private IP Event Types on page 2506
- Public IP Event Types on page 2507
- Route Table Event Types on page 2508
- Security List Event Types on page 2509
- Service Gateway Event Types on page 2510
- Subnet Event Types on page 2511
- VCN Event Types on page 2512
- Virtual Network Interface Card (VNIC) Event Types on page 2512
- VLAN Event Types on page 2513

DHCP Options Event Types
These are the event types that sets of DHCP options emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change DHCP Options Compartment</td>
<td>com.oraclecloud.virtualnetwork.changedhcoptions</td>
</tr>
<tr>
<td>Create DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.createdhcoptions</td>
</tr>
<tr>
<td>Delete DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.deletedhcoptions</td>
</tr>
<tr>
<td>Update DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.updatedhcoptions</td>
</tr>
</tbody>
</table>

DHCP Options Example
This is a reference event for a set of DHCP options:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createdhcpoptions",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.dhcpoptions.oci.phx.<unique_ID>"",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>"
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>""
  }
}
```

### Dynamic Routing Gateway (DRG) Event Types

These are the event types that DRGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG</td>
<td>com.oraclecloud.virtualnetwork.createdrg</td>
</tr>
<tr>
<td>Delete DRG</td>
<td>com.oraclecloud.virtualnetwork.deletedrg</td>
</tr>
<tr>
<td>Update DRG</td>
<td>com.oraclecloud.virtualnetwork.updatedrg</td>
</tr>
</tbody>
</table>

### DRG Example

This is a reference event for a DRG:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createdrg",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.drg.oci.phx.<unique_ID>"",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>"
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>""
  }
}
```
DRG Attachment Event Types

These are the event types that DRG attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.createdrgattachment</td>
</tr>
<tr>
<td>Delete DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.deletedrgattachment</td>
</tr>
<tr>
<td>Update DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.updatedrgattachment</td>
</tr>
</tbody>
</table>

DRG Attachment Example

This is a reference event for a DRG attachment:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createdrgattachment",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.drgattachment.oci.phx..<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```
Internet Gateway Event Types

These are the event types that internet gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Internet Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeinternetgateway</td>
</tr>
<tr>
<td>Create Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.createinternetgateway</td>
</tr>
<tr>
<td>Delete Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.deleteinternetgateway</td>
</tr>
<tr>
<td>Update Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.updateinternetgateway</td>
</tr>
</tbody>
</table>

Internet Gateway Example

This is a reference event for an internet gateway:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createinternetgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.internetgateway.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventId": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Local Peering Gateway (LPG) Event Types

These are the event types that LPGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Local Peering Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changelocalpeeringgateway</td>
</tr>
<tr>
<td>Create Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.createlocalpeeringgateway</td>
</tr>
<tr>
<td>Delete Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.deletelocalpeeringgateway</td>
</tr>
<tr>
<td>Update Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.updatelocalpeeringgateway</td>
</tr>
</tbody>
</table>

LPG Example

This is a reference event for an LPG:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createlocalpeeringgateway",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceId": "ocid1.localpeeringgateway.oci.phx..<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
NAT Gateway Event Types

These are the event types that NAT gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change NAT Gateway Compartment</td>
<td>com.oraclecloud.natgateway.changenatgatewaycompartment</td>
</tr>
<tr>
<td>Create NAT Gateway</td>
<td>com.oraclecloud.natgateway.createnatgateway</td>
</tr>
<tr>
<td>Delete NAT Gateway</td>
<td>com.oraclecloud.natgateway.deletenatgateway</td>
</tr>
<tr>
<td>Update NAT Gateway</td>
<td>com.oraclecloud.natgateway.updatenatgateway</td>
</tr>
</tbody>
</table>

NAT Gateway Example

This is a reference event for NAT gateways:

```json
{
    "eventType": "com.oraclecloud.natgateway.createnatgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "natgateway",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.natgateway.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
### Network Security Group (NSG) Event Types

These are the event types that NSGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>

### NSG Example

This is a reference event for an NSG:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createnetworksecuritygroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.networksecuritygroup.oci.phx..<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
Private IP Event Types

These are the event types that private IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Private IP</td>
<td>com.oraclecloud.virtualnetwork.createprivateip</td>
</tr>
<tr>
<td>Delete Private IP</td>
<td>com.oraclecloud.virtualnetwork.deleteprivateip</td>
</tr>
<tr>
<td>Update Private IP</td>
<td>com.oraclecloud.virtualnetwork.updateprivateip</td>
</tr>
</tbody>
</table>

Private IP Example

This is a reference event for a private IP:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createprivateip",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.privateip.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
**Public IP Event Types**

These are the event types that public IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Public IP Compartment</td>
<td><code>com.oraclecloud.virtualnetwork.changepublicipcompartment</code></td>
</tr>
<tr>
<td>Create Public IP</td>
<td><code>com.oraclecloud.virtualnetwork.createpublicip</code></td>
</tr>
<tr>
<td>Delete Public IP</td>
<td><code>com.oraclecloud.virtualnetwork.deletepublicip</code></td>
</tr>
<tr>
<td>Update Public IP</td>
<td><code>com.oraclecloud.virtualnetwork.updatepublicip</code></td>
</tr>
</tbody>
</table>

**Public IP Example**

This is a reference event for a public IP:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createpublicip",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.publicip.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Route Table Event Types

These are the event types that route tables emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Route Table Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeroutetablecompartment</td>
</tr>
<tr>
<td>Create Route Table</td>
<td>com.oraclecloud.virtualnetwork.createroutetable</td>
</tr>
<tr>
<td>Delete Route Table</td>
<td>com.oraclecloud.virtualnetwork.deleteroutetable</td>
</tr>
<tr>
<td>Update Route Table</td>
<td>com.oraclecloud.virtualnetwork.updateroutetable</td>
</tr>
</tbody>
</table>

Route Table Example

This is a reference event for route tables:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createroutetable",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```
Security List Event Types

These are the event types that security lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Security List Compartment</td>
<td>com.oraclecloud.virtualnetwork.changesecuritylistcompartment</td>
</tr>
<tr>
<td>Create Security List</td>
<td>com.oraclecloud.virtualnetwork.createsecuritylist</td>
</tr>
<tr>
<td>Delete Security List</td>
<td>com.oraclecloud.virtualnetwork.deletesecuritylist</td>
</tr>
<tr>
<td>Update Security List</td>
<td>com.oraclecloud.virtualnetwork.updatesecuritylist</td>
</tr>
</tbody>
</table>

Security List Example

This is a reference event for security lists:

```json
{
   "eventType": "com.oraclecloud.virtualnetwork.createsecuritylist",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "virtualNetwork",
   "eventTime": "2019-08-12T17:51:42.789Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "ocid1.securitylist.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "eventID": "<unique_ID>",
      "extensions": {
         "compartmentId": "ocid1.compartment.oci..<unique_ID>"
      }
   }
}
```
## Service Gateway Event Types

These are the event types that service gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Service</td>
<td>com.oraclecloud.servicegateway.attachserviceid</td>
</tr>
<tr>
<td>Change Service Gateway Compartment</td>
<td>com.oraclecloud.servicegateway.changeservicegateway</td>
</tr>
<tr>
<td>Create Service Gateway</td>
<td>com.oraclecloud.servicegateway.createservicegateway</td>
</tr>
<tr>
<td>Delete Service Gateway End</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.end</td>
</tr>
<tr>
<td>Delete Service Gateway Start</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.begin</td>
</tr>
<tr>
<td>Detach Service</td>
<td>com.oraclecloud.servicegateway.detachserviceid</td>
</tr>
<tr>
<td>Update Service Gateway</td>
<td>com.oraclecloud.servicegateway.updateservicegateway</td>
</tr>
</tbody>
</table>

### Service Gateway Example

This is a reference event for service gateways:

```json
{
  "eventType": "com.oraclecloud.servicegateway.createservicegateway",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "servicegateway",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.servicegateway.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
Subnet Event Types

These are the event types that subnets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subnet</td>
<td>com.oraclecloud.virtualnetwork.createsubnet</td>
</tr>
<tr>
<td>Delete Subnet</td>
<td>com.oraclecloud.virtualnetwork.deletesubnet</td>
</tr>
<tr>
<td>Update Subnet</td>
<td>com.oraclecloud.virtualnetwork.updatesubnet</td>
</tr>
</tbody>
</table>

Subnet Example

This is a reference event for a subnet:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createsubnet",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.subnet.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
VCN Event Types

These are the event types that VCNs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VCN</td>
<td>com.oraclecloud.virtualnetwork.createvcn</td>
</tr>
<tr>
<td>Delete VCN</td>
<td>com.oraclecloud.virtualnetwork.deletevcn</td>
</tr>
<tr>
<td>Update VCN</td>
<td>com.oraclecloud.virtualnetwork.updatevcn</td>
</tr>
</tbody>
</table>

VCN Example

This is a reference event for VCNs:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createvcn",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci.<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.vcn.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```

Virtual Network Interface Card (VNIC) Event Types

These are the event types that VNICs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update VNIC</td>
<td>com.oraclecloud.virtualnetwork.updatevnic</td>
</tr>
</tbody>
</table>

VNIC Example

This is a reference event for a VNIC:

```json
{
}
```
VLAN Event Types

These are the event types that VLANs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VLAN</td>
<td>com.oraclecloud.virtualnetwork.createvlan</td>
</tr>
<tr>
<td>Update VLAN</td>
<td>com.oraclecloud.virtualnetwork.updatevlan</td>
</tr>
<tr>
<td>Delete VLAN</td>
<td>com.oraclecloud.virtualnetwork.deletevlan</td>
</tr>
</tbody>
</table>

VLAN Example

This is a reference event for a VLAN:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createvlan",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2020-04-16T17:44:31.116Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.vnic.oci.phx..<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance",
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
NoSQL Database Cloud

For details about events emitted by Oracle NoSQL Database Cloud, see Service Events.

Notifications

Notifications resources that emit events:

- Subscriptions Event Types on page 2514
- Topics Event Types on page 2515

Subscriptions Event Types

These are the event types that subscriptions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subscription</td>
<td>com.oraclecloud.notification.createsubscription</td>
</tr>
<tr>
<td>Delete Subscription</td>
<td>com.oraclecloud.notification.deletesubscription</td>
</tr>
<tr>
<td>Move Subscription</td>
<td>com.oraclecloud.notification.movesubscription</td>
</tr>
<tr>
<td>Resend Subscription Confirmation</td>
<td>com.oraclecloud.notification.resendsubscriptionconfirmation</td>
</tr>
<tr>
<td>Update Subscription</td>
<td>com.oraclecloud.notification.updatesubscription</td>
</tr>
</tbody>
</table>

Subscription Example

This is a reference event for subscriptions:

```json
{
    "eventType": "com.oraclecloud.notification.createsubscription",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "notification",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data":{
        "compartmentId": "ocid1.compartment.oc1.<unique_ID>",
        "compartmentName": "my_compartment",
```
Topics Event Types

These are the event types that topics emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Topic</td>
<td>com.oraclecloud.notification.createtopic</td>
</tr>
<tr>
<td>Delete Topic</td>
<td>com.oraclecloud.notification.deletetopic</td>
</tr>
<tr>
<td>Move Topic</td>
<td>com.oraclecloud.notification.movetopic</td>
</tr>
<tr>
<td>Update Topic</td>
<td>com.oraclecloud.notification.updateTopic</td>
</tr>
</tbody>
</table>

Topic Example

This is a reference event for topics:

```
{
    "eventType": "com.oraclecloud.notification.createtopic",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "notification",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data":{
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "my_compartment",
        "resourceName": "my_topic",
        "resourceId": "ocid1.onstopic.oc1..<unique_ID>",
        "availabilityDomain": "AD3"
    },
    "eventID": "<unique_ID>",
    "extensions":{
        "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Object Storage

Object Storage resources that emit events:

- [Buckets Event Types](#) on page 2516
- [Objects Event Types](#) on page 2516
**Buckets Event Types**

These are the event types that buckets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Bucket</td>
<td>com.oraclecloud.objectstorage.createbucket</td>
</tr>
<tr>
<td>Delete Bucket</td>
<td>com.oraclecloud.objectstorage.deletebucket</td>
</tr>
<tr>
<td>Update Bucket</td>
<td>com.oraclecloud.objectstorage.updatebucket</td>
</tr>
</tbody>
</table>

**Bucket Example**

This is an example event for buckets:

```json
{
   "cloudEventsVersion": "0.1",
   "eventID": "<unique_ID>",
   "eventType": "com.oraclecloud.objectstorage.createbucket",
   "source": "objectstorage",
   "eventTypeVersion": "2.0",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_bucket",
      "resourceId": "ocid1.compartment.oc1..<unique_ID>",
      "availabilityDomain": "all",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "additionalDetails": {
         "namespace": "example_namespace",
         "publicAccessType": "NoPublicAccess",
         "eTag": "f8ffbb6e9-f602-460f-a6c0-00b5abfa24c7"
      }
   }
}
```

**Objects Event Types**

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.
These are the event types that objects emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Object</td>
<td>com.oraclecloud.objectstorage.createobject</td>
</tr>
<tr>
<td>Delete Object</td>
<td>com.oraclecloud.objectstorage.deleteobject</td>
</tr>
<tr>
<td>Update Object</td>
<td>com.oraclecloud.objectstorage.updateobject</td>
</tr>
</tbody>
</table>

**Object Example**

This is an example event for objects:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.objectstorage.createobject",
    "source": "objectstorage",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T13:37:11Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "Example_Compartment",
        "resourceName": "v1/log/10.0.6.166",
        "resourceId": "",
        "availabilityDomain": "all",
        "additionalDetails": {
            "eTag": "8162db5b-50d7-4947-a576-4401798ed2fa",
            "namespace": "my_namespace",
            "archivalState": null,
            "bucketName": "my_bucket",
            "bucketId": "ocid1.bucket.oc1.<unique_ID>"
        }
    }
}
```

**Operations Insights**

Operations Insights resources that emit events:

- Database insights
# Database Insight Event Types

These are the event types that database insights emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingest SQL Text</td>
<td>com.oraclecloud.OperationsInsights.IngestSqlText</td>
</tr>
<tr>
<td>List SQL Searches</td>
<td>com.oraclecloud.OperationsInsights.ListSqlSearches</td>
</tr>
</tbody>
</table>
Database Insight Example 1: Read Event

Following is a reference read event for database insights:

```
{
    "eventType": "com.oraclecloud.OperationsInsights.SummarizeDatabaseInsightResourceCapacityTrend",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T00:05:46.370Z",
    "contentType": "application/json",
    "data":{
        "eventGroupingId": "<unique_ID>",
        "eventName": "SummarizeDatabaseInsightResourceCapacityTrend",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "resourceCapacityTrend",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeformTags": null,
        "definedTags": null
    }
}
```

Database Insight Example 2: Ingest Event

Following is a reference ingest event for database insights:

```
{
    "eventType": "com.oraclecloud.OperationsInsights.IngestSqlText",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T01:09:00.688Z",
    "contentType": "application/json",
    "data":{
        "eventGroupingId": "<unique_ID>",
        "eventName": "IngestSqlText",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "actions",
        "availabilityDomain": "AD1",

        "definedTags": null
    }
}
```

OS Management

For details about events emitted by OS Management, see Creating Automation with Events.

Resource Manager

Resource Manager resources that emit events:

- Job Event Types on page 2520
- Stack Event Types on page 2521
**Job Event Types**

These are the event types that jobs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cancel Job</td>
<td>com.oraclecloud.oracleresourcemanager.canceljob</td>
</tr>
<tr>
<td>Create Job Begin</td>
<td>com.oraclecloud.oracleresourcemanager.createjob</td>
</tr>
<tr>
<td>Create Job End</td>
<td>com.oraclecloud.oracleresourcemanager.createjob</td>
</tr>
<tr>
<td>Update Job</td>
<td>com.oraclecloud.oracleresourcemanager.updatejob</td>
</tr>
</tbody>
</table>

This is a reference event for jobs:

```json
{
    "eventType": "com.oraclecloud.oracleresourcemanager.updateJob",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OracleResourceManager",
    "eventTime": "2019-07-23T01:46:37.606Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "example_name",
        "resourceId": "ocid1.ormjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
Events

Stack Event Types

These are the event types that stacks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment Begin</td>
<td>com.oraclecloud.oraclemancresourcemanager.changestackcompartment.begin</td>
</tr>
<tr>
<td>Change Compartment End</td>
<td>com.oraclecloud.oraclemancresourcemanager.changestackcompartment.end</td>
</tr>
<tr>
<td>Create Stack</td>
<td>com.oraclecloud.oraclemancresourcemanager.createstack</td>
</tr>
<tr>
<td>Delete Stack</td>
<td>com.oraclecloud.oraclemancresourcemanager.deletestack</td>
</tr>
<tr>
<td>Update Stack</td>
<td>com.oraclecloud.oraclemancresourcemanager.updatestack</td>
</tr>
</tbody>
</table>

This is a reference event for stacks:

```json
{
"eventType": "com.oraclecloud.oraclemancresourcemanager.createstack",
"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "OracleResourceManager",
"eventTime": "2019-07-23T01:32:10.866Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_compartment",
  "resourceName": "example_name",
  "resourceId": "ocid1.ormstack.oc1.phx.<unique_ID>",
  "availabilityDomain": "availability_domain"
},
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
}
```

Vulnerability Scanning

For details about events emitted by Vulnerability Scanning, see Scanning Events.

WAF

WAF resources that emit events:

- Waas Policy Event Types on page 2522
- Address List Event Types on page 2523
- Custom Protection Rule Event Types on page 2524
- Certificate Event Types on page 2525
**Waas Policy Event Types**

These are the event types that Waas policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Waas Policy Compartment</td>
<td>com.oraclecloud.waf.changewaaspolicycompartment</td>
</tr>
<tr>
<td>Create Waas Policy Begin</td>
<td>com.oraclecloud.waf.createwaaspolicy.begin</td>
</tr>
<tr>
<td>Create Waas Policy End</td>
<td>com.oraclecloud.waf.createwaaspolicy.end</td>
</tr>
<tr>
<td>Delete Waas Policy Begin</td>
<td>com.oraclecloud.waf.deletewaaspolicy.begin</td>
</tr>
<tr>
<td>Delete Waas Policy End</td>
<td>com.oraclecloud.waf.deletewaaspolicy.end</td>
</tr>
<tr>
<td>Update Waas Policy Begin</td>
<td>com.oraclecloud.waf.updatewaaspolicy.begin</td>
</tr>
<tr>
<td>Update Waas Policy End</td>
<td>com.oraclecloud.waf.updatewaaspolicy.end</td>
</tr>
</tbody>
</table>

**Waas Policy Example**

This is an example event for a Waas policy:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updatewaaspolicy.begin",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_policy",
    "resourceId": "ocid1.waaspolicy.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "domain": "example.com"
    }
  }
}
```
Address List Event Types

These are the event types that address lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Address List Compartment</td>
<td>com.oraclecloud.waf.changeaddresslistcompartment</td>
</tr>
<tr>
<td>Create Address List</td>
<td>com.oraclecloud.waf.createaddresslist</td>
</tr>
<tr>
<td>Delete Address List</td>
<td>com.oraclecloud.waf.deleteaddresslist</td>
</tr>
<tr>
<td>Update Address List</td>
<td>com.oraclecloud.waf.updateaddresslist</td>
</tr>
</tbody>
</table>

Address List Example

This is an example event for address lists:

```json
{
   "cloudEventsVersion": "0.1",
   "eventID": "<unique_ID>",
   "eventType": "com.oraclecloud.waf.updateaddresslist",
   "source": "waf",
   "eventTypeVersion": "2.0",
   "eventTime": "2019-10-11T13:40:54.931962577Z",
   "contentType": "application/json",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_waas_address_list",
      "resourceId": "ocid1.waasaddresslist.oc1..<unique_ID>",
      "availabilityDomain": "all",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      }
   }
}
```
Custom Protection Rule Event Types

These are the event types that protection rules emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Custom Protection Rule Compartment</td>
<td>com.oraclecloud.waf.changecustomprotectionrulecompartment</td>
</tr>
<tr>
<td>Create Custom Protection Rule</td>
<td>com.oraclecloud.waf.createcustomprotectionrule</td>
</tr>
<tr>
<td>Delete Custom Protection Rule</td>
<td>com.oraclecloud.waf.deletecustomprotectionrule</td>
</tr>
<tr>
<td>Update Custom Protection Rule</td>
<td>com.oraclecloud.waf.updatecustomprotectionrule</td>
</tr>
<tr>
<td>Update Waas Policy Custom Protection Rules</td>
<td>com.oraclecloud.waf.updatewaaspolicycustomprotectionrule</td>
</tr>
</tbody>
</table>

Protection Rule Example

This is an example event for custom protection rules:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.waf.updatecustomprotectionrule",
    "source": "waf",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-10-11T13:40:54.931962577Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_waas_custom_protection_rule",
        "resourceId": "ocid1.waascustomprotectionrule.oc1..<unique_ID>",
        "availabilityDomain": "all",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```
Certificate Event Types
These are the event types that certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment</td>
<td>com.oraclecloud.waf.changecertificatecompartment</td>
</tr>
<tr>
<td>Create Certificate</td>
<td>com.oraclecloud.waf.createcertificate</td>
</tr>
<tr>
<td>Delete Certificate</td>
<td>com.oraclecloud.waf.deletecertificate</td>
</tr>
<tr>
<td>Update Certificate</td>
<td>com.oraclecloud.waf.updatecertificate</td>
</tr>
</tbody>
</table>

Certificate Example
This is an example event for certificates:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.waf.updatecertificate",
    "source": "waf",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-10-11T13:40:54.931962577Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_waas_certificate",
        "resourceId": "ocid1.waascertificate.oc1..<unique_ID>",
        "availabilityDomain": "all",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```

Events Metrics
You can monitor performance of your rules by using metrics, alarms, and notifications. This topic describes the metrics emitted by the metric namespace oci_cloudevents (the Events service).

Resources: rules. Also measures data for events, which are not resources.

Prerequisites
IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must
give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

### Overview of the Events Service Metrics

You create rules that specify which events should be delivered to other services for processing. This delivery creates the automation in your tenancy. A rule identifies an event pattern to match and specifies other services to deliver matching events to. Metrics help you measure the success of the rules you create (in terms of pattern matching and delivery) and the quality and scope of the emitted events in your tenancy. For more information, see Overview of Events on page 2382.

### Available Metrics: oci_cloudevents

The metrics listed in the following table are automatically available for rules you create. You do not need to enable monitoring to get these metrics.

Each metric includes one or more of the following dimensions:

- **RESOURCEID**
  - The OCID of the rule or compartment to which the metric applies.

- **EVENTTYPE**
  - The type of event emitted by a resource.

- **RESOURCEDISPLAYNAME**
  - The name of the rule.

- **ACTIONTYPE**
  - One or more of the following types of resources that receives an event from the Events service.
    - Notifications
    - Streaming
    - Functions

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PublishedEvents</td>
<td>Events Emitted</td>
<td>count</td>
<td>Total number of events emitted by resources in a compartment.</td>
<td>eventType, resourceId</td>
</tr>
<tr>
<td>MatchedEvents</td>
<td>Events Matched</td>
<td>count</td>
<td>If you view the default chart from a rule, this metric provides the total number of events matched for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of matched events for all the rules in a compartment.</td>
<td>resourceDisplayName, resourceId</td>
</tr>
</tbody>
</table>
### Using the Console

**To view default metric charts for a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose the **Compartment** that contains the rule you want to view, and then click the rule's name.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current rule.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**To view default metric charts for a compartment**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose the **Compartment** that contains the rules you want to monitor.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current compartment.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

### Using the API

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
This chapter explains how to create file systems, how to manage them, and how to mount them to write files.

**File Storage**

Use File Storage to create scalable, distributed, enterprise-grade network file systems. File Storage supports NFSv3 with NLM for full POSIX semantics, snapshots, capabilities, and data at-rest encryption.

### Prerequisites
- Create a VCN for your file system
- Configure VCN security rules for file storage
- Create a policy to let users manage file systems

### Encrypt Data
- Learn about encryption keys
- Create a policy to enable encryption keys
- Assign an encryption key to a file system
- Enable in-transit encryption

### Developer Tools
- File Storage API
- File Storage CLI
- SDKs and the CLI
- Cloud Shell

### Create and Access File Systems
- Create a file system and mount target
- Get a mount command sample
- Mount a file system from a Linux instance
- Mount a file system from a Windows instance

### Manage File Systems
- View file systems
- Create a new export for a file system
- View mount targets
- View file system metrics

### Troubleshooting
- Troubleshoot File Storage

### Community
- Oracle Cloud Infrastructure blog
- Cloud infrastructure community forum

---

Oracle Cloud Infrastructure User Guide
Overview of File Storage

Oracle Cloud Infrastructure File Storage service provides a durable, scalable, secure, enterprise-grade network file system. You can connect to a File Storage service file system from any bare metal, virtual machine, or container instance in your Virtual Cloud Network (VCN). You can also access a file system from outside the VCN using VCN peering, Oracle Cloud Infrastructure FastConnect, and Internet Protocol security (IPSec) virtual private network (VPN).

Large Compute clusters of thousands of instances can use the File Storage service for high-performance shared storage. Storage provisioning is fully managed and automatic as your use scales from a single byte to exabytes without upfront provisioning.

The File Storage service supports the Network File System version 3.0 (NFSv3) protocol. The service supports the Network Lock Manager (NLM) protocol for file locking functionality.

Oracle Cloud Infrastructure File Storage employs 5-way replicated storage, located in different fault domains, to provide redundancy for resilient data protection. Data is protected with erasure encoding.

The File Storage service uses the "eventual overwrite" method of data eradication. Files are created in the file system with a unique encryption key. When you delete a single file, its associated encryption key is eradicated, making the file inaccessible. When you delete an entire file system, the file system is marked as inaccessible. The service systematically traverses deleted files and file systems, frees all the used space, and eradicates all residual files.

Use the File Storage service when your application or workload includes big data and analytics, media processing, or content management, and you require Portable Operating System Interface (POSIX)-compliant file system access semantics and concurrently accessible storage. The File Storage service is designed to meet the needs of applications and users that need an enterprise file system across a wide range of use cases, including the following:

- **General Purpose File Storage**: Access to an unlimited pool of file systems to manage growth of structured and unstructured data.
- **Big Data and Analytics**: Run analytic workloads and use shared file systems to store persistent data.
- **Lift and Shift of Enterprise Applications**: Migrate existing Oracle applications that need NFS storage, such as Oracle E-Business Suite and PeopleSoft.
- **Databases and Transactional Applications**: Run test and development workloads with Oracle, MySQL, or other databases.
- **Backups, Business Continuity, and Disaster Recovery**: Host a secondary copy of relevant file systems from on premises to the cloud for backup and disaster recovery purposes.
- **MicroServices and Docker**: Deliver stateful persistence for containers. Easily scale as your container-based environments grow.

**Note:**

File Storage is designed to be used with 64-bit applications. For more information, see 32-Bit Application Stops Reading or Writing to a File System on page 2646.

**Tip:**

Watch a video introduction to the service and its capabilities.

File Storage Concepts

Using the File Storage service requires an understanding of the following concepts, including some that pertain to Oracle Cloud Infrastructure Networking:

**MOUNT TARGET**

An NFS endpoint that lives in a subnet of your choice and is highly available. The mount target provides the IP address or DNS name that is used in the mount command when connecting NFS clients to a file system.
File systems are exported (made available) through mount targets. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

Mount target limitations:

- Each mount target can accept up to 100,000 NFS client connections.
- If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 2551 for more information.
- By default, you can create two mount targets per account per availability domain. See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

See Managing Mount Targets on page 2589 for more information about working with this resource.

**EXPORT**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter,

- You can create as many exports in a mount target for different file systems as you wish.
- You can create as many exports in a mount target for a single file system as you wish.
- You can delete and re-create exports in a mount target as often as you need to.
- You can add export options to an export to control access to the file system.

For more information, see Managing Mount Targets on page 2589, and Working with NFS Export Options on page 2542.

**EXPORT SET**

Collection of one or more exports that control what file systems the mount target exports using NFSv3 protocol and how those file systems are found using the NFS mount protocol. Each mount target has an export set. Each file system associated with the mount target has at least one export in the export set.

**EXPORT PATH**

A path that is specified when an export is created. It uniquely identifies the file system within the mount target, letting you associate many file systems to a single mount target. This path is unrelated to any path within the file system itself, or the client mount point path.

The File Storage service adds an export that pairs the file system's Oracle Cloud Identifier (OCID) and path. See Paths in File Systems on page 2621 for more information.

**EXPORT OPTIONS**

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export. For more information, see Working with NFS Export Options on page 2542.

**VIRTUAL CLOUD NETWORK (VCN)**

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice. For more information about VCNs, see VCNs and Subnets on page 3693 in the Oracle Cloud Infrastructure Networking documentation.

You can set up a service gateway and give your VCN private access to the File Storage service. A service gateway can be used only by resources in the gateway's own VCN. Traffic to the service will not travel...
through the internet. When creating the service gateway, enable the service label called All <region>
Services in Oracle Services Network. It includes the File Storage service. Be sure to update route tables for
any subnets that need to access File Storage through the service gateway.

For more information and detailed instructions, see Setting Up a Service Gateway in the Console on page
4131

SUBNETS

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual
network interface cards (VNICs), which attach to instances. A subnet can span a region or exist in a single
availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other
subnets in the VCN. For each subnet, you specify the routing rules and security lists that apply to it. For
more information about subnets, see VCNs and Subnets on page 3693 in the Oracle Cloud Infrastructure
Networking documentation.

SECURITY RULES

Virtual firewall rules for your VCN. Your VCN comes with a default security list, and you can add more.
These security lists provide ingress and egress rules that specify the types of traffic allowed in and out of the
instances. You can choose whether a given rule is stateful or stateless. Security list rules must be set up so
that clients can connect to file system mount targets.

Network security groups (NSGs). Another method for applying security rules is to set them up in a network
security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all
VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

3718 for more information, examples, and scenarios about how these features interact in your network.
Networking Overview on page 3604 provides general information about networking. See Configuring VCN
Security Rules for File Storage on page 2536 for more specific information.

SNAPSHOTS

Snapshots provide a consistent, point-in-time view of your file system, and you can take as many snapshots
as you need. You pay only for the storage used by your data and metadata, including storage capacity
used by snapshots. Each snapshot reflects only data that changed from the previous snapshot. For more
information, see Managing Snapshots on page 2600.

Encryption

The File Storage service encrypts all file system and snapshot data at rest. By default all file systems are encrypted
using Oracle-managed encryption keys. You have the option to encrypt all of your file systems using the keys that
you own and manage using the Vault service.

Note:

Currently, only symmetric Advanced Encryption Standard (AES) keys are
supported for file system encryption.

For more information, see Overview of Vault on page 5006.

For information about how to use your own key for new file systems, see Creating File Systems on page 2557. See
To update the key for a file system on page 2588 for how to assign or change the key for an existing file system.

Data Transfers

FastConnect offers you the ability to accelerate data transfers. You can leverage the integration between FastConnect
and the File Storage service to perform initial data migration, workflow data transfers for large files, and disaster
recovery scenarios between two regions, among other things.
File Storage Space Allocation

The File Storage service allocates space in blocks of variable size in a way that is fine-tuned to minimize total customer cost and optimize performance for modern workloads. The minimum block size used is 8192 bytes. For example, if you create a 1-byte file, we allocate 8192 bytes. We use larger blocks to store larger files. To learn more about file system and snapshot usage, see File System Usage and Metering on page 2622.

How File Storage Permissions Work

File Storage service resources include file systems, mount targets, and export sets. The AUTH_UNIX style of authentication and permission checking is supported for remote NFS client requests. You use Oracle Cloud Infrastructure Identity and Access Management (IAM) policy language to define access to Oracle Cloud Infrastructure resources. You can consider exports and snapshots subsidiary resources of export sets and file systems, respectively. As such, they do not need their own permissions. Related resources include Oracle Cloud Infrastructure Compute instances and Oracle Cloud Infrastructure Networking virtual cloud networks (VCNs).

Oracle Cloud Infrastructure users require resource permissions to create, delete, and manage resources. Without the appropriate IAM permissions, you cannot export a file system through a mount target. Until a file system has been exported, Compute instances cannot mount it. For more information about creating an IAM policy, see Let users create, manage, and delete file systems on page 2813.

If you have successfully exported a file system on a subnet, then you use Networking security lists to control traffic to and from the subnet and, therefore, the mount target. Security lists act as a virtual firewall, allowing only the network traffic you specify to and from the IP addresses and port ranges configured in your ingress and egress rules. The security list you create for the subnet lets hosts send and receive packets and mount the file system. If you have firewalls on individual instances, use FastConnect, or use a virtual private network (VPN), the settings for those might also impact security at the networking layer. For more information about creating a security list for the File Storage service, see Creating File Systems on page 2557. See About Security on page 2534 for more information on how different types of security work together in your file system.

Regions and Availability Domains

You can use the File Storage service in all regions. For a list of supported regions, see Regions and Availability Domains on page 208.

When you create file systems and mount targets, you specify the availability domain they are created in. All file system data is then stored entirely within the availability domain the file system resides in. Within an availability domain, the File Storage service uses synchronous replication and high availability failover to keep your data safe and available.

You cannot move a file system to a different availability domain or region. However, you can take a snapshot of your data and use a tool such as rsync to copy your data to a different availability domain or region. To maximize performance for data protection operations, you can use the File Storage Parallel Tools suite. The Parallel File Tools suite provides parallel versions of tar, rm, and cp. See Managing Snapshots on page 2600 for more information on using snapshots to protect your data.

While it is possible to access mount targets from any availability domain in a region, for optimal performance, place File Storage resources in the same availability domain as the Compute instances that access them.

Subnets can be either AD-specific or regional. You can create File Storage resources in either type of subnet. Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet. For more information, see Overview of VCNs and Subnets on page 3694.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

The following File Storage resources emit events:
• File systems
• Snapshots
• Mount targets
• Exports
• Export sets

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle
Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource
Identifiers on page 225.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API.
Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see
Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:
• Google Chrome 69 or later
• Safari 12.1 or later
• Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all
interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users
can access which services, which resources, and the type of access. For example, the policies control who can create
new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more
information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of
the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that
your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which
compartment or compartments you should be using.

Limits on Your File Storage Components

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

To set compartment-specific limits on file systems or mount targets, administrators can use compartment quotas.

Additional Documentation Resources

The following Oracle Cloud Infrastructure File Storage service solution playbooks and white papers are available:

• Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle
  Cloud Infrastructure File Storage Service
  Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business
  Suite.
• Learn about deploying Oracle E-Business Suite on Oracle Cloud Infrastructure
  Learn how file storage is part of a multihost, secure, high-availability topology for Oracle E-Business Suite.
• Design a pilot-light disaster recovery (DR) topology
  Learn how to use file storage in your disaster recovery topology.
About Security

**Access Control**

The File Storage service uses four different layers of access control. Each layer has its own authorization entities and methods which are separate from the other layers.

**Tip:**

Watch a video about security in File Storage.

The **Oracle Cloud Infrastructure (OCI) policy** layer uses policies to control what users can do within Oracle Cloud Infrastructure, such as creating instances, a VCN and its security rules, mount targets, and file systems.

The **Network security** layer controls which instance IP addresses or CIDR blocks can connect to a host file system. It uses VCN security list rules to allow or deny traffic to the mount target, and therefore access to any associated file system.

The **NFS export option** layer is a method of applying access control per-file system export based on source IP address that bridges the Network Security layer and the NFS v.3 Unix Security layer.

The **NFS v.3 Unix security** layer controls what users can do on the instance, such as installing applications, creating directories, mounting external file systems by a local mount point, and reading and writing files.

</tbody>
</table>

**Oracle Cloud Infrastructure Identity and Access Management**

You can create users and groups in Oracle Cloud Infrastructure. Then, you can use policies to specify which users and groups can create, access, or modify resources such as file systems, mount targets, snapshots, and export options within. See [Overview of Oracle Cloud Infrastructure Identity and Access Management](#) on page 2788 to learn more about how to set up access.
**Network Security**

The network security layer allows you to use VCN network security groups (NSGs) and security rules to block the appropriate ports from specific IP addresses and CIDR blocks and restrict host access. However, it’s on an ‘all or nothing’ basis - the client either can or cannot access the mount target, and therefore all file systems associated with it. See [Ways to Secure Your Network](#) on page 3707 for general information about VCN security groups, security lists, and rules. See [Configuring VCN Security Rules for File Storage](#) on page 2536 for specific information about the security rules necessary for File Storage.

**NFS v.3 Unix security**

File Storage service supports the AUTH_UNIX style of authentication and permission checking for remote NFS client requests. When mounting file systems, we recommend that you use the `-nosuid` option. This option disables set-user-identifier or set-group-identifier bits. Remote users are prevented from gaining higher privileges using a `setuid` program. For more information, see [Mounting File Systems](#) on page 2564.

Remember that users in UNIX aren’t the same as users in Oracle Cloud Infrastructure - they’re not linked or associated in any way. The Oracle Cloud Infrastructure policy layer doesn’t govern anything that happens inside the file system, the UNIX security layer does. Conversely, the UNIX security layer doesn’t govern creating file systems or mount targets in Oracle Cloud Infrastructure.

File Storage does not support file level Access Control Lists (ACLs). Only `user`, `group`, and `world` permissions are supported. File Storage uses the NFSv3 protocol, which doesn’t include support for ACLs. `setfacl` fails on mounted file systems. `getfacl` returns only standard permissions.

### Note:

Some implementations might extend the NFSv3 protocol and add support for ACLs as part of a separate `rpc` program.

**SETFACL error example**

This example shows an example of a `setfacl` error:

```bash
[opc@example setfacl_testing]$ ls -ld test
drwxr--r--. 2 opc opc 0 Jul  2 10:31 test
[opc@example setfacl_testing]$ setfacl -m u:applmgr:r test
setfacl: test: Operation not supported
```

**NFS export options**

NFS export options are a method of applying access control at both the network security layer and the NFS v.3 Unix security layer. You can use NFS export options to limit access levels by IP addresses or CIDR blocks connecting to multiple file systems through exports of an associated mount target. Access can be restricted so that each client’s file system is inaccessible and invisible to the other, allowing for managed hosted environment security. Moreover, you can set NFS v.3 Unix security permissions for read-only, read/write, or root-squash for your file systems. See [Working with NFS Export Options](#) on page 2542 for more information.
Encryption

Within Oracle Cloud Infrastructure

All data is encrypted at rest. You can leave all encryption-related matters to Oracle, or you can choose to manage your own encryption using the Oracle Cloud Infrastructure Vault (KMS) service. You can use KMS to create master encryption keys and data encryption keys, rotate keys to generate new cryptographic material, enable or disable keys for use in cryptographic operations, assign keys to file systems, and use keys for encryption and decryption.

Note:
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 5006.

Between Instances and Mounted File Systems

In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v. 1.2 (Transport Layer Security) encryption.

In-transit encryption is enabled by installing a client package on your instance. The package creates an NFS endpoint, network namespace, and network interface. A forwarder process receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

For more information, see Using In-transit Encryption on page 2551.

Configuring VCN Security Rules for File Storage

Before you can mount a file system, you must configure security rules to allow traffic to the mount target's VNIC using specific protocols and ports. Security rules enable traffic for the following:

- Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility protocol
- Network File System (NFS) protocol
- Network File System (MOUNT) protocol
- Network Lock Manager (NLM) protocol

File Storage Security Rule Scenarios

There are three basic scenarios that require different security rules for File Storage:

Scenario A: Mount target and instance in the same subnet

In this scenario, the mount target that exports the file system is in the same subnet as the instance you want to mount the file system to.

- Stateful ingress from ALL ports in source CIDR block to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress from ALL ports in source CIDR block to UDP ports 111 and 2048.
- Stateful egress from TCP ALL ports to ports 111, 2048, 2049, and 2050 in destination CIDR block.
- Stateful egress from UDP ALL ports to port 111 in destination CIDR block.

Important:
Oracle recommends that NFS clients be limited to reserved ports. To do this, set the Source Port range to 1-1023. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options on page 2542.

Here's an example of the rules for Scenario A set up for a single subnet that contains both the mount target and the instance. In this example, both the mount target and the instance are in CIDR block 10.0.0.0/24:
Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to the resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2540 for an overview of these methods and instructions about how to use them to set up security rules.

Scenario B: Mount target and instance in different subnets

In this scenario, the mount target that exports the file system is in a different subnet than the instance you want to mount the file system to. Security rules must be configured for both the mount target and the instance either in a security list for each subnet, or a network security group (NSG) for each resource.

Set up the following the following security rules for the mount target. Specify the instance IP address or CIDR block as the source for ingress rules and the destination for egress rules:

- Stateful ingress from all ports in the source instance CIDR block to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress from all ports in the source instance CIDR block to UDP ports 111 and 2048.
- Stateful egress from TCP ports 111, 2048, 2049, and 2050 to all ports in the destination instance CIDR block.
- Stateful egress from UDP port 111 all ports in the destination instance CIDR block.

Important:

Oracle recommends that NFS clients be limited to reserved ports. To do this, set the Source Port range to 1-1023. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options on page 2542.

Next, set up the following security rules for the instance. Specify the mount target IP address or CIDR block as the source for ingress rules and the destination for egress rules:

- Stateful ingress from source mount target CIDR block TCP ports 111, 2048, 2049, and 2050 to all ports.
- Stateful ingress from source mount target CIDR block UDP port 111 to all ports.
- Stateful egress from all ports to destination mount target CIDR block TCP ports 111, 2048, 2049, and 2050.
- Stateful egress from all ports to destination mount target CIDR block UDP ports 111 and 2048.
Here's an example of the rules for Scenario B set up in security list rules for the instance and mount target. This example shows rules for specific source and destination CIDR blocks.

**Ingress** rules for the **mount target's** NSG or subnet security list. The `instance CIDR block 10.0.0.0/24` is the source:

Using a Security List

Security lists are associated with subnets. If you use security lists to set up your security rules, you need to set up the mount target rules in the mount target subnet, and the instance rules in the instance subnet. You can add the rules to the default security list for each subnet, or create new security lists.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target and instance to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2540 for an overview of these methods and instructions about how to use them to set up security rules.

Scenario C: Mount target and instance use in-transit encryption

In this scenario, in-transit encryption secures your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. See Using In-transit Encryption on page 2551 for more information.

You can limit the source or destination to the IP address or CIDR block of your choice. Alternatively, you can allow traffic from all sources or destinations.

Set up the following security rules for the mount target:

- Stateful ingress from ALL ports in the source CIDR block to TCP port 2051.
- Stateful egress from TCP port 2051 to ALL ports in the destination CIDR block.

Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.
Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2540 for an overview of these methods and instructions about how to use them to set up security rules.

Ways to Enable Security Rules for File Storage

The Networking service offers two virtual firewall features that both use security rules to control traffic at the packet level. The two features are:

- **Security lists:** The original virtual firewall feature from the Networking service. When you create a VCN, a default security list is also created. Add the required rules to the security list for the subnet that contains the mount target. (If you're setting up Scenario B: Mount target and instance in different subnets on page 2537, you have to add rules for both subnets.) See Setting Up Required Rules in a Security List on page 2541 for instructions.

- **Network security groups (NSGs):** A subsequent feature designed for application components that have different security postures. Create an NSG that contains the required rules, and then add the mount target to the NSG. Alternatively, you can add the required rules to a previously existing NSG, and add the mount target to the NSG. Each mount target can belong to up to five (5) NSGs. (If you're setting up Scenario B: Mount target and instance in different subnets on page 2537, you have to add both the mount target and instance to an NSG that contains the required security rules.) See Setting Up Required Rules in a Network Security Group (NSG) on page 2541 for instructions.

---

**Important:**

You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you choose to use both security lists and network security groups, the set of rules that applies to a given mount target VNIC is the combination of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

It doesn't matter which method you use to apply security rules to the mount target VNIC, as long as the ports for protocols necessary for File Storage are correctly configured in the rules applied.

See Security Rules on page 3710, Security Lists on page 3727, and Network Security Groups on page 3718 for more information, examples, and scenarios about how these features interact in your network. Networking Overview on page 3604 provides general information about networking. See About Security on page 2534 for information about how security rules work with other types of security in File Storage.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let network admins manage a cloud network on page 2807 covers management of all networking components, including security lists and NSGs. See the Policy Reference on page 2837 for more information.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.
Using the Console
Setting Up Required Rules in a Security List

You can add the required rules to a pre-existing security list associated with a subnet, such as the default security list that is created along with the VCN. See To create a security list on page 3730 for more information.

To add required rules to a security list

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. In the Scope section, select the compartment that contains the VCN the subnet is in.
3. Click the name of the VCN.
4. On the details page for the cloud network, in Resources, and then click Security Lists.
5. Click the name of the security list used by the subnet.
7. Click Add Ingress Rules.
   • Specify that it’s a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 3716). By default, rules are stateful unless you specify otherwise.
   • To allow traffic from the subnet of the cloud network, click Source Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   • Click IP Protocol, and then choose the protocol. For example, TCP.
   • In Source Port Range, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of All to allow traffic from any source port.
   • Click Destination Port Range, and then enter individual ports or a port range. For example, 2048-2050.
8. Click + Additional Ingress Rule to create more ingress rules.
9. When you're done, click Add Ingress Rules.
11. Click Add Egress Rules.
   • Specify that it’s a stateful rule by leaving the check box clear.
   • Click Destination Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   • Click IP Protocol, and then choose the protocol. For example, TCP.
   • In Source Port Range, and then enter individual ports or a port range. For example, 2048-2050.
   • In Destination Port Range, accept the default of All to allow traffic to any destination port.
12. Click + Additional Egress Rule to create more egress rules.
13. When you're done, click Add Egress Rules.

Setting Up Required Rules in a Network Security Group (NSG)

The general process for setting up NSGs that work with File Storage is:

1. Create an NSG with the required security rules. (Alternatively, you can add them to a previously existing NSG.)
2. Add the mount target (or more specifically, the mount target's VNIC) to the NSG. You can do this when you create the mount target, or you can update the mount target and add it to one or more NSGs that contain the required security rules.
3. If you're setting up Scenario B: Mount target and instance in different subnets on page 2537, you'll have to add both the mount target and instance to an NSG that contains the required security rules.

To create an NSG with the required security rules

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
5. Enter the following:
   • **Name**: A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   • **Create in Compartment**: The compartment where you want to create the network security group, if different from the compartment you're currently working in.
   • **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Next**.
7. Enter ingress rules.
   • Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 3716). By default, rules are stateful unless you specify otherwise.
   • In **Direction**, choose **Ingress**.
   • To allow traffic from the subnet of the cloud network, click **Source Type**, choose **CIDR**, and then enter the CIDR block for the subnet. For example, `10.0.0.0/24`.
   • Click **IP Protocol**, and then choose the protocol. For example, **TCP**.
   • In **Source Port Range**, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of **All** to allow traffic from any source port.
   • Click **Destination Port Range**, and then enter individual ports or a port range. For example, `2048-2050`.

8. Click **+ Another Rule** to create more ingress rules.
9. Enter egress rules.
   • Specify that it's a stateful rule by leaving the check box clear.
   • In **Direction**, choose **Egress**.
   • Click **Destination Type**, choose **CIDR**, and then enter the CIDR block for the subnet. For example, `10.0.0.0/24`.
   • Click **IP Protocol**, and then choose the protocol. For example, **TCP**.
   • In **Source Port Range**, and then enter individual ports or a port range. For example, `2048-2050`.
   • In **Destination Port Range**, accept the default of **All** to allow traffic to any destination port.

10. Click **+ Another Rule** to create more egress rules.
11. When you're done, click **Create**.

**To add a mount target to an NSG**
   • When creating a mount target along with a file system: See To create a file system on page 2557.
   • When creating only the mount target: See To create a mount target on page 2593.
   • For an existing mount target:
      1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
      2. In the **List Scope** section, select a compartment.
      3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount Target Details**.
      4. In the **Mount Target Information** tab, click the **Edit** link next to **Network Security Groups**.
      5. Select a **Compartment** and **NSG** from the list.
      6. Click **Save**.

**To add an instance to an NSG**

See To add or remove a resource from an NSG on page 3725 for instructions on how to add an instance to an NSG.

**Working with NFS Export Options**

This topic describes the basic features of NFS export options, and how to control client access to your file system.
Overview

NFS export options enable you to create more granular access control than is possible using just security list rules to limit VCN access. You can use NFS export options to specify access levels for IP addresses or CIDR blocks connecting to file systems through exports in a mount target. Access can be restricted so that each client’s file system is inaccessible and invisible to the other, providing better security controls in multi-tenant environments.

Using NFS export option access controls, you can limit clients’ ability to connect to the file system and view or write data. For example, if you want to allow clients to consume but not update resources in your file system, you can set access to Read Only. You can also reduce client root access to your file systems and map specified User IDs (UIDs) and Group IDs (GIDs) to an anonymous UID/GID of your choice. For more information about how NFS export options work with other security layers, see About Security on page 2534.

**Tip:**
Watch a video about working with NFS export options in File Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to manage NFS export options.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

See To create an export for a file system on page 2582 for more information.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

Each separate client IP address or CIDR block you want to define access for needs a separate export options entry in the export. For example, if you want to set options for NFS client IP addresses 10.0.0.6, 10.0.0.8, and 10.0.0.10, you need to create three separate entries, one for each IP address.

File Storage service considers the listed order of each export options entry for the export. During an NFS request by a client, File Storage service applies the first set of options that matches the client Source IP address. Only the first set is applied; the rest are ignored.

For example, consider the following two export options entries specifying access for an export:

Entry 1: Source: 10.0.0.0/16, Access: Read Only

Entry 2: Source: 10.0.0.8, Access: Read/Write

In this case, clients who connect to the export from IP address 10.0.0.8 have Read Only access. The request Source IP address is contained in the CIDR block specified in the first entry, and File Storage Service applies the options in the first match.
Important:

File systems can be associated with one or more exports, contained within one or more mount targets. If the client **source** IP address does not match any entry on the list for a single export, then that export is not visible to the client. However, the file system could be accessed through other exports on the same or other mount targets. **To completely deny client access to a file system, be sure that the client source IP address or CIDR block is not included in any export for any mount target associated with the file system.**

The following options can be set to control export access:

- **Source:** The IP address or CIDR block of a connecting NFS client.
- **Require Privileged Source Port (true/false):** This setting determines whether the NFS clients specified in **source** are required to connect from a privileged source port. Privileged ports are any port including 1-1023. On Unix-like systems, only the root user can open privileged ports. Setting this value to **true** disallows requests from unprivileged ports. The default for this setting is different depending on how the export is created. Creating an export without an explicit **ClientOption** array sets the **requirePrivilegedSourcePort** attribute of the client option to **false**. When you create a **ClientOption** array explicitly, **requirePrivilegedSourcePort** defaults to **true**.

For example, creating an export in the Console using the default selections sets **requirePrivilegedSourcePort** to **false**. Creating an export in the API along with a **ClientOption** array sets **requirePrivilegedSourcePort** to **true**.

Important:

When **Require Privileged Source Port** is set to **true**, you also have to follow these additional configuration steps:

1. When mounting the file system from a Unix-like system, include the **resvport** option in your mount command when mounting. For example:

   ```
   sudo mount -o resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```
   
   For more information, see **Mounting File Systems From Unix-Style Instances** on page 2567.

2. When mounting the file system from a Windows system, be sure the **UseReservedPorts** registry key value is set to 1.

   For more information, see **Mounting File Systems From Windows Instances** on page 2574.

- **Access (Read_Only, Read_Write):** This setting specifies the **source** NFS client access. If unspecified, defaults to **Read_Write**.
- **Identity Squash:** (**All**, **Root**, **None**): This setting determines whether the **source** clients accessing the file system have their User ID (UID) and Group ID (GID) remapped to **anonymousUid** and **anonymousGid**. If you choose **All**, all users and groups are remapped. If **Root**, only the root user UID/GID combination 0/0 is remapped. If **None**, no users are remapped. If unspecified, defaults to **None**.
- **anonymousUid:** This setting is used along with the **Identity Squash** option. When remapping users, you can use this setting to change the default anonymousUid of 65534 to any user ID of your choice.
- **anonymousGid:** This setting is used along with the **Identity Squash** option. When remapping groups, you can use this setting to change the default anonymousGid of 65534 to any group ID of your choice.
Typical Access Control Scenarios

When you create file system and export, the NFS export options for that file system are set to the following defaults, which allow full access for all NFS client source connections. These defaults must be changed if you want to restrict access:

- **Source:** 0.0.0.0/0 (All)
- **Require Privileged Source Port:** False
- **Access:** Read_Write
- **Identity Squash:** None

**Scenario A: Control Host Based Access**

Provide a managed hosted environment for two clients. The clients share a mount target, but each has their own file system, and cannot access each other’s data. For example:

- Client A, who is assigned to CIDR block 10.0.0.0/24, requires Read/Write access to file system A, but not file system B.
- Client B, who is assigned to CIDR block 10.1.1.0/24, requires Read/Write access to file system B, but not file system A.
- Client C, who is assigned to CIDR block 10.2.2.0/24, has no access of any kind to file system A or file system B.
- Both file systems A and B are associated to a single mount target, MT1. Each file system has an export contained in the export set of MT1.

Since Client A and Client B access the mount target from different CIDR blocks, you can set the client options for both file system exports to allow access to only a single CIDR block. Client C is denied access by not including its IP address or CIDR block in the NFS export options for any export of either file system.

**Console Example**

Set the export options for file system A to allow Read/Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image1)

Set the export options for file system B to allow Read/Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image2)
CLI Example

Set the export options for file system A to allow Read_Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```bash
oci fs export update --export-id <File_system_A_export_ID> --export-options '[{"source":"10.0.0.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"}]
```

Set the export options for file system B to allow Read_Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```bash
oci fs export update --export-id <File_system_B_export_ID> --export-options '[{"source":"10.1.1.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"}]
```

API Example

Set the export options for file system A to allow READ_WRITE access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```bash
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
            "source": "10.0.0.0/24",
            "requirePrivilegedSourcePort": true,
            "access": "READ_WRITE",
            "identitySquash": "NONE",
            "anonymousUid": 65534,
            "anonymousGid": 65534
        }
    ]
}
```

Set the export options for file system B to allow READ_WRITE access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```bash
PUT/<Current_API_Version>/exports/<File_System_B_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
            "source": "10.1.1.0/24",
            "requirePrivilegedSourcePort": true,
            "access": "READ_WRITE",
            "identitySquash": "NONE",
            "anonymousUid": 65534,
            "anonymousGid": 65534
        }
    ]
}
```

Scenario B: Limit the Ability to Write Data

Provide data to customers for consumption, but don’t allow them to update the data.
For example, you'd like to publish a set of resources in file system A for an application to consume, but not change. The application connects from IP address 10.0.0.8.

**Console Example**

Set the source IP address 10.0.0.8 to Read Only in the export for file system A:

<table>
<thead>
<tr>
<th>Source</th>
<th>Ports</th>
<th>Access</th>
<th>Squash</th>
<th>UID</th>
<th>GID</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.8</td>
<td>Privileged</td>
<td>Read Only</td>
<td>None</td>
<td>Not used</td>
<td>Not used</td>
</tr>
</tbody>
</table>

**CLI Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```
oci fs export update --export-id <File_System_A_export_OCID> --
export-options '[["source":"10.0.0.8","require-privileged-source-port":true,"access":"READ_ONLY","identitysquash":"NONE","anonymousuid":65534,"anonymousgid":65534}}'
```

**API Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID> Host: filestorage.us-phoenix-1.oraclecloud.com <authorization and other headers>
```

```
{
   "exportOptions": [
   {
       "source": "10.0.0.8",
       "requirePrivilegedSourcePort": true,
       "access": "READ_ONLY",
       "identitySquash": "NONE",
       "anonymousUid": 65534,
       "anonymousGid": 65534
   }
   ]
}
```

**Scenario C: Improve File System Security**

To increase security, you'd like to limit the root user's privileges when connecting to File System A. Use Identity Squash to remap root users to UID/GID 65534. In Unix-like systems, this UID/GID combination is reserved for 'nobody', a user with no system privileges.
Console Example

CLI Example

oci fs export update --export-id <File_System_A_export_OCID> --export-options '[]

API Example

PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>

Tip:
If you don't want a file system to be visible to any clients, you can set all of
the properties in the exportOptions array to empty values. For example,

Using the Console
To set export options for a file system

2. In the List Scope section, select a compartment. All of the file systems in the selected compartment are displayed.
3. Find the file system you want to set export options for, click the the Actions icon (three dots), and then click View File System Details.
4. In the **Exports** list, find the export you want to set export options in, click the the Actions icon (three dots), and then click **View Export Details**. If there is no export listed for the file system, you can create one. See To create an export for a file system on page 2582 for more information.

**Tip:**

To be sure you select the correct export, check the following:

- **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you’ve selected the export for the correct mount target.

5. Click **Edit Export Options**.

6. Make one or more of these changes:

   - Change an export option entry in the list.
   - Click **Another Option** to create a new export option entry.
   - Click the Actions icon (three dots) for an entry and move it up or down in the list.

7. When you're done, click **Update**.

**To view exports for a file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system in the list, click the Actions icon (three dots), and then click **View File System Details**.
4. Under **Resources**, click **Exports**.

**To view all exports in a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target in the list, click the Actions icon (three dots), and then click **View Details**.
4. Under **Resources**, click **Exports**.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

**To create an export**

Open a command prompt and run **oci fs export create** to create an export for a specified file system within a specified export set. This example creates an export along with its NFS export options.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path </pathname> --export-options '[["source":"10.0.0.0/16","requireprivilegedsourceport":"true","access":"READWRITE","identitysquash":"NONE","anonymousuid":"0","anonymousgid":"0"]]
```

**Important:**

Export Path Names

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For any two export resources associated with the same export set, the path sequence for the first export resource can’t contain the complete path element sequence of the second export sequence. Paths
can't end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes.

Examples:

Acceptable:
/example and /path
/example1 and /example2

Not Acceptable:
/example and /example/path
/ and /example
/example/
/example/path/..example1

To update export options

Open a command prompt and run `oci fs export update`. To update export options for a specified file system, use `--export-options`.

For example:

```
oci fs export update --export-id <export_OCID> --export-options '[["source":"<0.0.0.0/0>","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous_gid":"65534"]]
```

WARNING: Updates to export-options will replace any existing values. Are you sure you want to continue? [y/N]: y

Tip:

If you don't want a file system to be visible to any clients, you can set all of the properties in Client Options to empty values. For example,

```
oci fs export update --export-id <export_OCID> --export-options '[["source":"","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous_gid":"65534"]]
```

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id <target_compartment_id>
```

To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id <export_OCID>
```
Caution: When you delete an export, you can no longer mount the file system using the file path specified in the deleted export.

Using the API
- CreateExport
- UpdateExport
- ListExports
- GetExport
- DeleteExport

Using In-transit Encryption
In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. Together with other methods of security such as Oracle Cloud Infrastructure Vault (KMS) and File Storage's encryption-at-rest, in-transit encryption provides for end-to-end security.

- For general information about getting started with file systems, see Overview of File Storage on page 2529.
- For more information on the Vault service, see Overview of Vault on page 5006.
- For more information on securing your file system, see About Security on page 2534 and the Securing File Storage on page 4685 reference in the Security Guide.

How In-transit Encryption is Enabled
In-transit encryption doesn't require any updates to your file system's mount target or export configuration. To enable in-transit encryption, you install a package called oci-fss-utils on your instance. The oci-fss-utils package creates a network namespace and virtual network interface on your instance and provides a local NFS endpoint. The oci-fss-utils package also runs a forwarder process in the background called oci-fss-fowarder.

The network namespace isolates the forwarder process from your instance’s networking environment. The virtual network interface provides the forwarder process a unique IP address. The local NFS endpoint provides NFS connection capability.

The file system is mounted using a special command that initiates encryption. After the file system is mounted, the oci-fss-forwarder process connects the local NFS client to the NFS endpoint. The process then receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

Here are the general steps for setting up In-transit encryption:

1. Download the oci-fss-utils package. For instructions, see Task 1: Download the OCI-FSS-UTILS package on page 2552
2. Install the oci-fss-utils package on the instance. For instructions, see Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2553
3. Use the in-transit encryption command to mount the file system. For instructions, see Task 3: Mount the file system with the encryption command on page 2553

Limitations and Considerations
- In-transit encryption is only supported for instances running Oracle Enterprise Linux 7 or CentOS7 versions.
- The in-transit encryption installation package is distributed as an RPM for Oracle Linux and CentOS and can be downloaded at cloud-infrastructure-file-storage-downloads.html
- You must install the oci-fss-utils package on every instance that requires encrypted access to a mount target.
- The number of encrypted NFS/TLS connections for a single mount target is limited to 64. This limitation is caused by TLS memory requirements. Unlike NFS connections, TLS connections do not share memory buffers. So, once a TLS connection has been established, the allocated memory stays dedicated to it.
- DNS hostnames are not supported for mounting encrypted file systems with oci-fss-fowarder. Use the mount target IP address to mount encrypted file systems.
Important:

If you are not using the latest version of the oci-fss-utils package, you might experience SSL connection failures. SSL connection failures can cause NFSv3 operations to fail.

We recommend that you always upgrade to the latest version of the oci-fss-utils package as soon as it's available. See File Storage Release Notes for information about new RPM version releases.

Setting up In-transit Encryption

Prerequisites

- Add the following new rules to the security list for the mount target subnet. Alternatively, you can add the following rules to a Network Security Group (NSG) and then add the mount target to the NSG. For more information and instructions about adding security list rules for File Storage, see Configuring VCN Security Rules for File Storage on page 2536.
  - A stateful ingress rule allowing TCP traffic to a Destination Port Range of 2051.
  - A stateful egress rule allowing TCP traffic from a Source Port Range of 2051.

Important:

Standard (unencrypted) access to File Storage mount targets requires access to the following ports:

- Stateful ingress to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress to UDP ports 111 and 2048.
- Stateful egress from TCP ports 111, 2048, 2049, and 2050.
- Stateful egress from UDP port 111.

If you have previously set up rules for standard access, and you want to enforce encrypted access only, then you can disable the standard access ports.

Only the rules for TCP port 2051 are required for encrypted access.

Setup Tasks

Task 1: Download the OCI-FSS-UTILS package

Internet access is required to download the RPM installation package. If the destination instance doesn't have internet access, you can download the RPM to a staging instance on your network and then use the scp command to securely copy the RPM from the staging instance to the destination instance.

The scp command requires an SSH key pair to authenticate a remote user. If your instances are UNIX-style systems, you probably already have the ssh-keygen utility installed. To determine if it's installed, open a shell or terminal and type ssh-keygen on the command line. If it's not installed, you can obtain OpenSSH for UNIX from http://www.openssh.com/portable.html.

1. (Optional) Create a directory for the RPM installation package on the destination instance. For example:

    ```bash
    sudo mkdir -p /<rpm_directory_name>
    ```

2. Download the oci-fss-utils package from cloud-infrastructure-file-storage-downloads.html to the directory on the destination instance or to a staging instance on your network.

If you've downloaded the package directly to the destination instance, skip the next step and proceed directly to Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2553.

If you've downloaded the package to a staging instance, proceed to the next step in these instructions.
3. Open a terminal window on the staging instance, and use the `scp` command to securely copy the RPM from the staging instance to the destination instance. For example:

   ```
   scp -i <private_key> <path_to_.rpm> <username>@<destination-public-ip-address>:/<rpm_directory_name>
   ```

   After the RPM package is downloaded to the target instance, proceed to Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2553.

**Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS**

1. Open a terminal window on the destination instance.
2. Install the package using the following command:

   ```
   sudo yum localinstall oci-fss-utils-<version>.rpm
   ```

   The package creates a namespace called `ns1` in your instance, which contains a default network interface for ethernet traffic. A network interface pair is created for each mount target.

   After the package has finished installing, proceed to Task 3: Mount the file system with the encryption command on page 2553.

**Task 3: Mount the file system with the encryption command**

1. Open a terminal window in your instance.
2. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

   ```
   sudo mkdir -p /mnt/yourmountpoint
   ```

3. Mount the file system using the following command:

   ```
   sudo mount -t oci-fss 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```

   Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint`
with the path to the local mount point. The export path is the path to the file system (relative to the mount target IP address).

**Important:**

DNS hostnames are not currently supported for mounting file systems with the `mount -t oci-fss` command. You must use the mount target IP address.

Example output from the `mount -t oci-fss` command:

```
```

Each time you mount a file system using this command, a new `oci-fss` service is initiated with an incrementing sequence number between 2 and 255. For example, `oci-fss-2.service`, `oci-fss-3.service`, and so on.

**Tip:**

You can use the `resvport` option to restrict the client to using a specific reserved port. For example:

```
sudo mount -t oci-fss -o resvport=900 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Managing In-transit Encryption**

*To auto-mount a file system*

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a terminal window on the instance. Mount the file system as described in .
2. Open the `/etc/fstab` file for editing:

```
cd /etc
vi fstab
```

3. Add the following line to the fstab file:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-systemd.requires=oci-fss-init.service,defaults,nofail 0 0
```

Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with the path to the local mount point.

**Tip:**

You can use the `resvport` option to restrict the client to using a specific reserved port. For example:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-systemd.requires=oci-fss-init.service,defaults,nofail,resvport=900 0 0
```
To unmount a file system

When you unmount a file system, you must use another `oci-fss-utils` command to ensure that the associated local network namespace is removed:

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

   ```bash
sudo umount -t oci-fss /mnt/yourmountpoint
   ```

   Replace `yourmountpoint` with the path to the local mount point.

To uninstall the OCI-FSS-UTILS package

1. First, unmount all mounted file systems. For instructions, see To unmount a file system on page 2555.
2. Open a terminal window on the instance.
3. Type the following command to uninstall the `oci-fss` package:

   ```bash
   sudo yum remove oci-fss-utils
   ```

Troubleshooting

If you experience issues with in-transit encryption, try the following techniques:

*Verifying that you have all the security list rules set up correctly for the mount target subnet.*

In-transit encryption requires the following security list rules:

- A stateful ingress rule allowing TCP traffic to a Destination Port Range of 2051.
- A stateful egress rule allowing TCP traffic from a Source Port Range of 2051.

For more information and instructions, see Security Rules on page 3710.

*Verify that the oci-fss service is running for the mounted file system.*

If it is not, restart the service.

To verify the service is running

When you mount a file system using the `mount.oci-fss` command, it creates a systemd-managed service called `oci-fss<sequence_number>.service`. `<sequence_number>` is an incrementing value between 2-255. An `oci-fss` service is created for every file system mounted using the command. The exact name of the service is displayed as output when the file system is mounted.

For example:

```text
```

1. Open a terminal window on the instance.
2. Verify that the service is running using the following command:

   ```bash
   systemctl status oci-fss-<sequence_number>
   ```

To start the service

1. Open a terminal window on the instance.
2. Use the following command to start the service:

   ```bash
   systemctl start oci-fss-<sequence_number>
   ```
Verify that the namespace ns1 has been created and contains a network interface.

**To verify the network namespace**

1. Open a terminal window on the instance.
2. Use the following command to verify the namespace and see the network interface:

   ```
   sudo ip netns exec ns1 ip link list
   ```

   You should see output displaying all the ethernet devices within namespace ns1. For example:

   ```
   1: lo: <LOOPBACK> mtu 65536 qdisc noop state DOWN mode DEFAULT group default qlen 1000
   default qdisc noop state DOWN mode DEFAULT group default qlen 1000
   link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
   3: v-peer1@if4: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP mode DEFAULT group default qlen 1000
   link/ether be:5b:35:2d:e9:54 brd ff:ff:ff:ff:ff:ff link-netnsid 0
   ```

**Verify that IP forwarding is running on the instance.**

Installing `oci-fss-utils` automatically turns on IP forwarding. However, you may have other processes running on the instance that disable it.

**To verify that IP forwarding is running on the instance**

1. Open a terminal window on the instance.
2. Use the following command to view the status of IP forwarding:

   ```
   # sysctl net.ipv4.ip_forward
   net.ipv4.ip_forward = 1
   ```

   An output value of 1 means that IP forwarding is enabled. This value is read from the `/proc/sys/net/ipv4/ip_forward` file.

   If the output value is 0, then IP forwarding is not enabled for the instance. Enable IP forwarding by following the instructions in *To enable IP forwarding on the instance* on page 2556.

**To enable IP forwarding on the instance**

If IP forwarding is not currently enabled on the instance, you must enable it and make the change permanent.

1. Open a terminal window on the instance.
2. Type the following command to open the `/etc/sysctl.conf` file:

   ```
   sudo vi /etc/sysctl.conf
   ```

3. Remove the `#` to uncomment this line: `# net.ipv4.ip_forward=1`. If the value is 0, change it to 1.
4. Type :wq to save the file and exit the editor.

**Use the tcpdump utility to analyze traffic between the oci-fss service and the NFS client.**

**To obtain information using TCPDUMP**

1. Open a terminal window on the instance.
2. Type the following command:

   ```
   sudo ip netns exec ns1 tcpdump -i v-peer2 "port 2049"
   ```

**Use the journalctl command to view any messages that may have been logged by systemd regarding the service.**

**To obtain information from the SYSTEMD journal**

1. Open a terminal window on the instance.
2. Type the following command:

```
journalctl -f -u oci-fss-<version>
```

- `f` displays the most recent journal entries, and prints new entries as they are appended to the journal.
- `-u` specifies a specific `systemd` service unit. In this case, `oci-fss-<sequence_number>` is the specified unit. If no unit is specified, `journalctl` returns all `systemd` entries.

### Creating File Systems

You can create a shared file system in the cloud using the File Storage service. Network access to your file system is provided through a mount target. Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in one mount target for any instance to mount and use the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

### Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to create file systems. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 2837 for more information.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

### Prerequisites

Before you create a file system, you need:

- At least one Virtual Cloud Network (VCN) in a compartment. For more information, see VCNs and Subnets on page 3693.
- Correctly configured security rules for the file system mount target. Security rules can be created in the security list for the mount target subnet, or in a Network Security Group (NSG) that you add the mount target to. See Security Rules on page 3710 for information about how security rules work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security Rules for File Storage on page 2536 to set up security rules correctly for your file systems.

### Using the Console

**To create a file system**

2. In the left-hand navigation, in the List Scope section, under Compartment, select a compartment.
3. Click Create File System.

**Note:**

File systems are encrypted by default. You cannot turn off encryption.
4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.

- **File System Information:**
  - **Name:** File Storage service creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system. Avoid entering confidential information.
  - **Availability domain:** The first availability domain selected in the left panel list is used as default.
  - **Encryption:** File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

  **Note:**
  
  Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

  To use Vault for your encryption needs, select **Encrypt using customer-managed keys** check box. Then, select the **Vault compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master encryption key compartment** and **Master encryption key**. For more information about encryption, see **Overview of Vault** on page 5006.

  **Caution:**

  Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see **Backing Up Vaults and Keys** on page 5060.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Export Information**

  Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.

  - **Export Path:** The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

    **Important:**

    The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

    Acceptable:
    
    /example and /path
    /example and /example2
    
    Not Acceptable:
    
    /example and /example/path
    / and /example
Caution:
If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2621.

- **Use Secure Export Options:** Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options on page 2542 for more information.

Caution:
Leaving the "Use Secure Export Options" setting disabled allows unprivileged users to read and modify any file or directory on the target file system.

- **Mount Target Information:**

  File systems must be associated with a mount target to be mounted by an instance.

  If you have one or more previously created mount targets in the availability domain, the File Storage service automatically chooses the most recently created mount target in the list. If you don't have a mount target in the selected availability domain, the File Storage service creates one using the following defaults.

  - **Mount Target Name:** File Storage service creates a default mount target name using "Mount-YYYYMMDD-HHMM".
  - **Compartment:** The compartment you're currently working in.
  - **Virtual Cloud Network:** The first VCN listed in the current compartment is used as default.
  - **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list. Each mount target can belong to up to five (5) NSGs.

  Important:
  Rules for the NSG you select must be configured to allow traffic to the mount target’s VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2536.

  - **Subnet:** The most recently created subnet listed in the selected availability domain is used as default. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 3693.

5. If you want to accept the defaults for the mount target, click **Create. The file system is created with the information displayed.** If you want to choose another mount target or change the default information, click the **Edit Details** link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:

- **Select an Existing Mount Target**: Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

  **Tip:**
  If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:
  - Choose a different compartment.
  - Choose a different availability domain in the **File System Information** section.
  - Create a new mount target.

- **Create a New Mount Target**: Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

  **Important:**
  The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances that access them. For more information, see **Regions and Availability Domains** on page 2532.

- **Create in Compartment**: Specify the compartment you want to create the mount target in.

- **New Mount Target Name**: Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

  **Note:**
  The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment**: The compartment containing the cloud network (VCN) in which to create the mount target.

- **Virtual Cloud Network**: Select the cloud network (VCN) where you want to create the new mount target.

- **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

  **Important:**
  Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see **Configuring VCN Security Rules for File Storage** on page 2536.

- **Subnet Compartment**: Specify the compartment containing a subnet within the VCN to attach the mount target to.

- **Subnet**: Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see **VCNs and Subnets** on page 3693.

  **Caution:**
  Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation.
because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click Show Advanced Options to configure the mount target's advanced options.

- IP Address: You can specify an unused IP address in the subnet you selected for the mount target.
- Hostname: You can specify a hostname you want to assign to the mount target.

**Note:**

The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, myhostname.subnet123.dnslabel.oraclevcn.com.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 2589 for more information.

8. Click Create.

The File Storage service typically creates the file system and mount target within seconds. Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 2564 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To clone a file system**

Before you can clone a file system, at least one snapshot must exist for the file system. See To create a snapshot on page 2601 and Cloning File Systems on page 2604 for more information.

2. In the List Scope section, select a compartment.
3. Find the file system you want to clone, click the Actions icon (three dots), and then click View File System Details.
4. In the Snapshots list, find the snapshot you want to use as the source of the clone, click the Actions icon (three dots), and then click Clone.

The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the Create Clone page, specify the details about the clone that aren't inherited from the parent file system. You can choose to accept the provided system defaults, or change them by clicking Edit Details. For a detailed description of each file system property and its defaults, see File System Information.
6. Click Create.

Hydration begins immediately upon instantiation of the clone.

Cloned file systems are managed in the same way that any other file system is managed. See Managing File Systems on page 2579 for more information.

To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the Details page of the cloned file system. See To view file system details on page 2581.

You can mount and use the clone immediately for READ or WRITE operations after you create it. See Mounting File Systems on page 2564 for more information.
Using the command line interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

To create a file system

Open a command prompt and run `oci fs file-system create` to create a file system. For example:

```sh
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id>
```

Avoid entering confidential information.

The file system is created.

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key. For more information, see Overview of Vault on page 5006.

For example:

```sh
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id ocid1.key.oc1.phx.<unique_id>
```

To create a file system that is encrypted with a Key Management Key

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

**Note:**
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 5006.

**Caution:**
Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5060.

Open a command prompt and run `oci fs file-system create` to create a file system that is encrypted with a key management key.

```sh
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
```

For example:

```sh
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id ocid1.key.oc1.iad.<unique_id>
```

To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.
Caution:

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

To create an export

An export is a file system together with the path that can be used to mount it. Each export resource belongs to one export set.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "<pathname>"
```

Important:

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/..example1
```

Caution:

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.
To clone a file system

Before you can clone a file system, at least one snapshot must exist for the file system. See To create a snapshot on page 2601 and Cloning File Systems on page 2604 for more information.

To create a file system clone, use the file-system create command, and include the OCID of the file system snapshot you want to use as a source for the clone.

For example:

```
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "Clone_1" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.phx.<unique_id> --source-snapshot-id ocid1.snapshot.oc1..<unique_id>
```

For more information about clones, see Cloning File Systems on page 2604.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to create file systems:

- CreateFileSystem
- CreateMountTarget
- CreateExport

Mounting File Systems

Users of Unix-style operating systems and Windows Server 2012 R2 and later versions can connect to a file system and write files. Mount targets serve as file system network access points for file systems. After your mount target is assigned an IP address, you can use it together with the file system export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client. For Unix-style operating systems, you create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. Windows operating systems use a drive letter assignment instead of a mount point to represent root access.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2557 for more information.

Mounting File Systems From an Instance

Mounting File Systems From Unix-Style Instances on page 2567 (Including Oracle Linux DB instances)

Mounting File Systems From Windows Instances on page 2574
Obtaining Mount Command Samples

Mount command samples that include mount information for a specific mount target and file system are available in the Console. Samples are available for the following operating system images:

- Oracle Linux
- CentOS
- Debian
- Red Hat Linux
- Ubuntu

Here's an example of the information contained in a mount command sample. The file system name is used to create directory names:

If you specified a hostname for the mount target, the sample uses the FQDN in the commands. If you didn't specify a hostname, the sample uses the mount target IP address. Using a FQDN to mount your file system is optional; even if you specified a hostname, you can edit the command to use the IP address instead. If you use an FQDN to mount the file system, ensure that the FQDN correctly resolves to the mount target's IP address. For more information, see DNS in Your Virtual Cloud Network on page 3781.

Mount command samples mount the file system at the file system root directory. Mount command samples don't include subdirectory information for the file system. If you want to mount a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information on mounting subdirectories in Linux-type instances, see To mount a file system subdirectory (Linux). For more information on mounting subdirectories in Windows instances, see To mount a file system subdirectory (Windows).

Caution:

When mounting file systems, the following mount option combination is not supported by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). This combination can cause corruption of your data.
The following mount options or mount option combinations are not recommended for use with the File Storage service:

- soft when the file system is mounted with the read-only mount option (-o ro) and the timeo has been specified as less than 300 seconds. This combination can cause a profusion of I/O error responses.
- rsize, or wsize. These options cause issues with performance.

Note:
When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default. Some applications might require you to specify the nolock mount option. Refer to your application documentation for best practices regarding this mount option.

Required IAM Service Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to obtain mount commands.

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Using the Console
To get mount command samples
2. In the List Scope section, select a compartment.
   The Console displays a list of file systems that have already been created in the compartment, if any.
3. Find the file system you want to mount, click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Exports.
5. Find the export in the mount target you want to use to mount the file system, click the Actions icon (three dots), and then click Mount Commands.

Tip:
To be sure that you select the correct export, check the following:
- **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you’ve selected the export for the correct mount target.
6. In Image, choose the image of the Compute instance you want to mount the file system to.
7. Click the Copy link to copy the commands.

Next, mount the file system from a Unix-style or Windows instance.
Mounting File Systems From Unix-Style Instances

Users of Ubuntu and Linux operating systems can use the command line to connect to a file system and write files. Mount targets serve as network access points for file systems. After your mount target is assigned an IP address, you can use it together with the export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client and create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. You can mount to any directory within the file system.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2557 for more information.

Mounting File Systems

You can use the following instructions to construct your mount commands, or use the Console to get mount command samples that include all the information for a specific mount target and file system. For more information, see Obtaining Mount Command Samples on page 2565.

Mount command samples mount the file system at the file system root directory. Mount command samples don't include subdirectory information for the file system. If you want to mount your Linux-type instance at a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information, see To mount a file system subdirectory on page 2572.

Caution:

When mounting file systems, the following mount option combination is not supported by the File Storage service:

- soft when the file system is mounted with the read/write mount option (-o rw). This combination can cause corruption of your data.

The following mount options or mount option combinations are not recommended for use with the File Storage service:

- soft when the file system is mounted with the read-only mount option (-o ro) and the timeo has been specified as less than 300 seconds. This combination can cause a profusion of I/O error responses.
- rsize, or wsize. These options cause issues with performance.

Note:

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the nolock mount option. Refer to your application documentation for best practices regarding this mount option.

To mount a file system from Ubuntu or Debian

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or type the following:

   ```
   sudo apt-get install nfs-common
   ```

Oracle Cloud Infrastructure User Guide  2567
2. Create a mount point by copying and pasting the **Create Mount Point Command** from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```

3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See **To view details of a mount target** on page 2594 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to ‘root’. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See **Working with NFS Export Options** on page 2542 for more information.

4. View the file system.

```
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint

ls
```

See **Mount Command Fails** on page 2628 in **Troubleshooting Your File System** on page 2626 for more information about common issues you may encounter.

**To mount a file system from Linux, Red Hat, or CentOS**

1. Open a command window. Then, get the NFS client by copying and pasting the **Install Command** from the Console or typing the following:

```
sudo yum install nfs-utils
```
2. Create a mount point by copying and pasting the **Create Mount Point Command** from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```

3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**
IP address and export path information is available in the **Details** page of the mount target associated with your file system. See [To view details of a mount target](#) on page 2594 for more information.

**Caution:**
Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**
The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [Working with NFS Export Options](#) on page 2542 for more information.

4. View the file system.

```
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
ls
```

See [Mount Command Fails](#) on page 2628 in **Troubleshooting Your File System** on page 2626 for more information about common issues you may encounter. See if you want to mount a subdirectory of the file system.

**To mount a file system from a Database VM instance**

Database VM instances are built on Oracle Linux 6.8, unlike Oracle Linux Compute instances, which run on version 7.4. The NFS Utilities package is pre-installed on DB instances, but the Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility is disabled by default. Oracle Linux 6.8 does not have systemd, so DB instances are managed differently than OL compute instances. An Oracle DB instance comes with a set of iptables rules that excludes any non-database ports and need to be updated to allow mount target traffic.
1. SSH to the DB system.
   
   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Start the rpcbind service by typing the following:
   
   ```
   sudo service rpcbind start
   ```

3. Use the chkconfig command to enable starting rpcbind service at system startup.
   
   ```
   sudo chkconfig rpcbind on
   ```

4. Change the default configuration of iptables to include the mount target IP address and allow traffic by typing the following. Replace 10.x.x.x with the local subnet address assigned to the mount target for the file system. Save the new iptables entries.
   
   ```
   sudo iptables -A INPUT -p tcp -s 10.x.x.x -j ACCEPT
   ```
   
   ```
   sudo iptables -A OUTPUT -p tcp -s 10.x.x.x -j ACCEPT
   ```
   
   ```
   sudo service iptables save
   ```

5. Create a mount point by typing the following, replacing yourmountpoint with the local directory from which you want to access your file system.
   
   ```
   sudo mkdir -p /mnt/yourmountpoint
   ```

6. Mount the file system by copying and pasting the Mount Command from the Console or type the following:
   
   ```
   sudo mount -t nfs -o nosuid,resvport,tcp,vers=3 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```
   
   • Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
   • Replace fs-export-path with the export path you specified when associating the file system with the mount target.
   • Replace yourmountpoint with the path to the local mount point.

   **Tip:**

   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2594 for more information.

   **Caution:**

   Omitting the -o nosuid option may allow unprivileged users to escalate their permissions to 'root'. The nosuid option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

   **Note:**

   The -o resvport option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options on page 2542 for more information.

See Mount Command Fails on page 2628 in Troubleshooting Your File System on page 2626 for more information about common issues you may encounter.
To auto-mount a file system

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a command window. Then, mount the file system using the steps described in the previous section.
2. Type the following command to get the file system entry point:
   ```
   sudo cat /etc/mtab | grep -i nfs
   ```
3. Copy the file system entry point, and open the /etc/fstab file:
   ```
   cd /etc
   vi fstab
   ```
4. Add the following line to the fstab file:
   ```
   <file_system_ip_address>:<file_system_path_name> <your_local_mount_point>
   nfs defaults,nofail,nosuid,resvport 0 0
   ```

   **Caution:**
   Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

   **Important:**
   Be sure to add the `nofail` option to each entry. This option ensures that an unavailable file system does not cause the instance reboot process to fail.

   **Note:**
   The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options on page 2542 for more information.

5. Save the fstab file.

See Mount Command Fails on page 2628 in Troubleshooting Your File System on page 2626 for more information about common issues you may encounter.

Mounting File System Subdirectories

If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of /FileSystem1 and a directory structure like this:
The file system is exported from "MountTarget1" which has an IP address of 10.0.0.16.

The following command mounts directoryA to the instance mount point /mnt/mymountpoint:

```
sudo mount -o nosuid,resvport 10.0.0.16:/FileSystem1/rootdirectory/directoryA /mnt/mymountpoint
```

Neither directoryB or FileB would be accessible from the instance mount point.

**Caution:**
Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 2534.

**To mount a file system subdirectory**

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or typing the following:

   ```
   sudo yum install nfs-utils
   ```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing yourmountpoint with the local directory from which you want to access your file system.

   ```
   sudo mkdir -p /mnt/yourmountpoint
   ```
3. Mount the file system by copying and editing the **Mount Command** from the Console or type the following:

```bash
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path/directory-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `directory-path` with the path from the root directory to subdirectory you want to mount.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target on page 2594 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options on page 2542 for more information.

4. View the file system.

```bash
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
ls
```

**To unmount a file system**

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

```
sudo umount /mnt/yourmountpoint
```

Replace `yourmountpoint` with the path to the local mount point.

**Writing to File Systems**

When a file system is created, its root directory is owned by the `root` user. If you're connecting from an instance that uses a Linux or CentOS platform image, the default user is `opc`. If you're connecting from an instance that uses an Ubuntu platform image, the default user is `ubuntu`. These default users are not root users, so you can't initially write
a file or directory to a new file system with these users. Depending on your security requirements, there are several ways to proceed:

- Connect as the root user. Then, create files or directories in the new file system.
- Connect as the root user. Then, change the ownership or permissions of the file system root directory to allow other users (such as opc or ubuntu) to write to the file system.
- Connect as the root user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

Learn more about updating file and directory ownership and permissions.

- Connect as the default user. Then, use the sudo command to write or to change permissions or ownership of files or directories. The sudo command temporarily provides a regular user with root user permissions. Here's an example of using the sudo command to write to the file system:

  ```
  sudo touch /mnt/yourmountpoint/helloworld
  ```

Learn more about the sudo command.

For more information about accessing instances, see Connecting to an Instance on page 1083.

### Mounting File Systems From Windows Instances

Users of Windows Server 2012 R2 and later versions can mount a file system on any available drive letter using the mount target IP address and the file system export path.

The Windows NFS client must be installed on the instance from which you want to mount the file system.

**Caution:**

Installing the Windows NFS client may require a restart of your system.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using AnonymousGid and AnonymousUid. On brand new file systems, write permissions are only granted to the root user. The AnonymousGid and AnonymousUid identity values must be configured to allow write access.

**Caution:**

Updating the 'AnonymousGid' and 'AnonymousUid' values require registry changes to your system.

After you have installed the NFS client and correctly mapped user identities, you can mount the file system to any available drive letter using the command line or Map network drive. You can access your file system through the chosen drive letter to write files.

**Prerequisites**

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2557 for more information.

**Caution:**

When mounting file systems, the following mount option combination is not supported by the File Storage service:

- soft when the file system is mounted with the read/write mount option (-o rw). This combination can cause corruption of your data.
The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- **soft** when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than 300 seconds. **This combination can cause a profusion of I/O error responses.**
- **rsize**, or **wsize**. **These options cause issues with performance.**

**Note:**

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default. Some applications might require you to specify the **nolock** mount option. Refer to your application documentation for best practices regarding this mount option.

**Using Windows Command Prompt**

*To mount a file system from Windows Server Command Prompt*

If you are using Windows platform images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 4.

1. Open **Windows PowerShell** and run as **Administrator**:
   
   a. Go to **Start** and click the **Windows PowerShell** icon.
   
   b. In Windows PowerShell, type the following to run as Administrator:

   ```powershell
   Start-Process powershell -Verb runAs
   ```

   c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. In Administrator: PowerShell, get the NFS client by typing the following:

   ```powershell
   Install-WindowsFeature -Name NFS-Client
   Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousUid -Value 0
   Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousGid -Value 0
   Stop-Service -Name NfsClnt
   Restart-Service -Name NfsRdr
   Start-Service -Name NfsClnt
   ```

**Important:**

If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReservedPorts** registry key to **1**.

For example:

```powershell
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name UseReservedPorts -Value 1
```

For more information, see [Working with NFS Export Options](#) on page 2542.

Open a standard Command Prompt Window:

a. Click Start, then click Command Prompt.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NFS file systems mounted as Administrator are not available to standard users.</td>
</tr>
</tbody>
</table>

4. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

```
mount 10.x.x.x:/fs-export-path X:
```

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2594 for more information.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then &quot;/&quot; represents the full extent of the mount target. In that case, you must use a &quot;!/&quot; when mounting the file system. For example: mount 10.0.0.0:!/X:</td>
</tr>
</tbody>
</table>

5. Write a file to the file system by typing the following. Replace X with the drive letter you used in step 10 and helloworld with your file name.

```
X:
```

```
echo > helloworld.txt
```

6. Verify that you can view the file by typing the following.

```
dir
```

See Troubleshooting Windows NFS Connections on page 2647 for more information about common issues you might encounter.

**Using Windows File Explorer**

*To mount a file system from Windows Server File Explorer*

If you are using Windows platform images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 9.

1. Open Windows PowerShell and run as Administrator:

   a. Go to Start and click the Windows PowerShell icon.
   b. In Windows PowerShell, type the following to run as Administrator:

```
Start-Process powershell -Verb runAs
```
   c. In the User Account Control window, click Yes. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.
2. In Administrator: PowerShell, get the NFS client by typing the following:

   Install-WindowsFeature -Name NFS-Client

3. If necessary, restart your system.

4. Open the registry editor (regedit) to map the AnonymousGid and AnonymousUid to the root user.

   Caution:
   User identity mapping requires changes to your system registry.

   a. Click Windows Search.
   b. Enter regedit in the Search field and press Enter.
   c. Click Yes to allow changes to your device.
   d. Click HKEY_LOCAL_MACHINE. Then, browse to: \Software\Microsoft\ClientForNFS \CurrentVersion\Default.

5. Add a new DWORD32 registry entry for AnonymousGid:

   a. Click Edit, and select New DWORD (32 bit) Value.
   b. In the Name field, enter AnonymousGid. Leave the value at 0.

6. Repeat step 5 to add a second DWORD32 registry entry named AnonymousUid with a value of 0.

   Important:
   If you’ve set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the UseReserverdPorts registry key to 1.

   For more information, see Working with NFS Export Options on page 2542.

7. Open Windows Command Line (CMD) and run as Administrator:

   a. Go to Start and scroll down to Apps.
   b. In the Windows System section, press Ctrl+Shift and click Command Prompt.

8. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

   nfsadmin client stop
   nfsadmin client start

9. Open File Explorer and select This PC. In the Computer tab, select Map network drive.
10. Select the Drive letter that you want to assign to the file system.

11. In the Folder field, enter the following. Replace `10.x.x.x` with the local subnet IP address assigned to your mount target, and `fs-export-path` with the export path you specified when associating the file system with the mount target.

```
\10.x.x.x\fs-export-path
```

**Tip:**

IP address and export path information is available in the Details page of the mount target associated with your file system. See [To view details of a mount target](#) on page 2594 for more information.

**Important:**

The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "\" represents the full extent of the mount target. In that case, you must use a "!" when entering the file system folder path. For example: `\10.0.0.0\!`

12. Click the Finish button when complete.

See [Troubleshooting Windows NFS Connections](#) on page 2647 for more information about common issues you might encounter.

**Mounting File System Subdirectories**

If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of `/FileSystem1` and a directory structure like this:

```
(MountTarget1) 10.0.0.16: /FileSystem1
```

![Diagram of file system mounting](#)
The file system is exported from "MountTarget1" which has an IP address of 10.0.0.16.

The following command mounts directoryA to drive letter X:

```
mount 10.0.0.16:/rootdirectory/directoryA X:
```

Neither directoryB or FileB would be accessible from drive X.

**Caution:**

Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 2534.

To mount a file system subdirectory

1. Choose the method you want to use to mount the file system Using Windows Command Prompt on page 2575 or Using Windows File Explorer on page 2576.
2. Follow the instructions to install the NFS client and add the registry entries for AnonymousGid and AnonymousUid.
3. After the NFS client is installed and registry entries are added, both mounting methods describe how to enter the mount information for the file system. Depending on which method you use, edit the mounting information to append the subdirectory path to the export path:

   a. If you're Using Windows Command Prompt on page 2575, type the following command (step 4):
      
      ```
      • Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
      • Replace fs-export-path with the export path you specified when associating the file system with the mount target.
      • Replace directory-path with the path from the root directory to subdirectory you want to mount.
      
      mount 10.x.x.x:/fs-export-path/directory-path X:
      ```
   
   b. If you're Using Windows File Explorer on page 2576, enter the following in the Folder field of the drive letter you want to map the file system to (step 11):
      
      ```
      • Replace 10.x.x.x: with the local subnet IP address assigned to your mount target.
      • Replace fs-export-path with the export path you specified when associating the file system with the mount target.
      • Replace directory-path with the path from the root directory to subdirectory you want to mount.
      
      \10.x.x.x\fs-export-path\directory-path
      ```

**Managing File Systems**

In the File Storage service, file systems are associated with a single compartment. When you select a compartment, the Console displays all file systems in the compartment. You can also see exports and snapshots associated with each file system. If there are no file systems in the compartment, see Creating File Systems on page 2557 for instructions about creating one.

The compartment has policies that indicate what actions a user can take to manage file system. UNIX permissions control what actions a user can take on the files stored in the file system. See About Security on page 2534 for more information.

Actions you can take to manage a file system include:

- Viewing file system details
- Editing file system settings
- Viewing associated file system resources
- Creating an export for the file system
Deleting a file system

You can perform most administrative tasks for your file systems using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

To access a file system, it must have at least one export in one mount target. Next, mount the file system from an instance, and then you can create directories and read and write files. For more information about creating an export for a file system, see To create an export for a file system on page 2582 in this topic. For more information about accessing your file system, see Mounting File Systems.

Limitations and Considerations

Each tenancy in a region can have one CreateFileSystem or ChangeFilesystemCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to manage file systems.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Moving File Systems to a Different Compartment

You can move file systems from one compartment to another. When you move a file system to a new compartment, its associated snapshots move with it. After you move the file system to the new compartment, inherent policies apply immediately and affect access to the file system and snapshots through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments on page 3126.

Details About Your File System

The file system details page provides the following information about your file system:

FILE SYSTEM OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your file system's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 225.

Availability Domain

When you create a file system, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your file system's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains on page 208.
CREATED

The date and time that the file system was created.

COMPARTMENT

When you create a file system, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are only accessible to those groups that have been given permission by an administrator in your organization. You need your file system's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments on page 3126.

UTILIZATION

Metered size of the file system that gets updated hourly. If the file system is a clone, this value represents only the differentiated data unique to the clone. For more information, see File System Usage and Metering on page 2622.

HYDRATION

Indicates whether the file system is a clone currently copying metadata from its source. See Cloning File Systems on page 2604.

SOURCE SNAPSHOT

If the file system is a clone, a link is provided to the clone's source snapshot. If the source snapshot is deleted, the link is disabled. See Cloning File Systems on page 2604.

PARENT FILE SYSTEM

If the file system is a clone, a link is provided to the clone's parent file system. See Cloning File Systems on page 2604.

ROOT

Indicates whether the file system is the root of a clone tree. See Cloning File Systems on page 2604.

DESCENDANTS

Indicates whether the file system has been cloned. See Cloning File Systems on page 2604.

RESOURCES

Resources such as exports and snapshots that are associated with the file system are listed here. Click the resource type link to see a list of each individual resource. Each export in the list shows the file system's export path and mount target. You need the export path to mount a file system.

Using the Console

To view file system details

The File Storage service displays a list of file systems in each compartment.

2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click View File System Details.

To change the file system name

You can change the display name of the file system.

2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click View File System Details.
4. Click Rename.
5. Enter the new file system name. Avoid entering confidential information. Then click **Rename**.

**To create an export for a file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the file system you want to create an export for, and click **Create Export**.

**Note:**

File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. If you want to **accept the defaults** for the mount target, click **Create. The file system is created with the information displayed**. If you want to choose another mount target or change the default information, click the **Edit Details** link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:

   - **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the Mount Target from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

     **Tip:**

     If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

     - Choose a different compartment.
     - Create a new mount target.

   - **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

     **Important:**

     The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances.
that access them. For more information, see Regions and Availability Domains on page 2532.

- **Create in Compartment:** Specify the compartment you want to create the mount target in.
- **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

**Note:**

The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.
- **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

**Important:**

Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2536.

- **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 3693.

**Caution:**

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click Show Advanced Options to configure the mount target's advanced options.

- **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
- **Hostname:** You can specify a hostname you want to assign to the mount target.

**Note:**

The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, myhostname_subnet123.dnslabel.oraclevcn.com.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 2589 for more information.

8. Click Create.
Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 2564 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibenodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the Reported Size or Reported Inodes value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

| Important: |
| Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.** |

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. In **Exports**, click on the mount target name.
5. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in GiI) Edit** icon.
6. Enter the maximum free space in gibibytes or the maximum inodes in gibenodes you want the File Storage service to report.
7. Click the **Save** icon.

| Important: |
| **There can be a delay of up to 1 hour** when reporting file system usage, either in the console or by using the `df` command. For more information, see File System Usage and Metering on page 2622. |

**To manage tags for a file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags on page 239.

**To move a file system to a different compartment**

1. Open the Console,
2. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
3. In the **List Scope** section, select a compartment.
4. Find the file system in the list, click the the Actions icon (three dots), and then click **Change Compartment**.
5. Choose the destination compartment from the list.
6. Click **Change Compartment**.

The file system is moved immediately. Moving a file system doesn't affect mounted instances.

**To move a file system to a different subnet**

There might be situations where you need to move a file system to a different subnet. For example, since you can't change subnet size, you might need to move the file system to a larger or smaller subnet as your needs change.

1. Create the new subnet. See VCNs and Subnets on page 3693 for instructions.
2. Create a new mount target in the new subnet. See To create a mount target on page 2593 for instructions.

3. Create new export with the same export path in the new mount target to the file system. See To create an export for a file system on page 2582 for instructions.
   - Choose Select Existing Mount Target
   - Be sure that the export path for the new export is exactly the same as the export path for the original export. The original and new mount target can exist at the same time without issue.

4. Switch over the instance mount point to the new mount target. This can be done at any time convenient to your maintenance schedule:
   a. Stop any workload application processes running on the instance mount point.
   b. Unmount the file system. See To unmount a file system on page 2573 for instructions.
   c. Mount the file system using the new mount target, but the same mount point that was previously used.
      For example: If the file system was mounted with the original mount target like this:
      
      ```
      sudo mount 10.0.0.10:/my-export-path /mnt/MyMountPoint
      ```
      
      Then the new mount command would look like this:
      
      ```
      sudo mount 10.1.1.10:/my-export-path /mnt/MyMountPoint
      ```
      
      See Mounting File Systems on page 2564 for instructions.
   d. Update any system configuration files that use the old export path. For example, /etc/fstab.
   e. Start workload applications and verify that they can access the file system as expected.
   f. After testing and verification is complete, you can delete the original mount target and subnet.

To assign a key to a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5060.</td>
</tr>
</tbody>
</table>

Prerequisites:

- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 5006.
- Correctly set permissions that allow the File Storage service to use keys. For example:

  ```
  Allow service FssOciProd to use keys in compartment <compartment_name>
  ```

  For more information, see Common Policies on page 2806.

2. Under List Scope, in the Compartment list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. In Encryption Type, select Encrypt using customer-managed keys.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Save Changes**.

**To specify Oracle-managed keys for a file system**

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption. For more information, see **Overview of Vault** on page 5006.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to **Encryption Key**, click **Edit**.
5. In **Encryption Type**, select **Encrypt using Oracle-managed keys**.
6. When you are finished, click **Save Changes**.

**To delete a file system**

You can permanently delete a file system.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before you can delete the root file system of a clone tree, all of its descendants must first be deleted. See for more information.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you want to delete.
4. Click the Actions icon (three dots), and then click **View File System Details**.
5. Delete all of the file system's exports:
   - In **Exports**, select the check box for all exports listed, and then click **Delete**.
6. When all of the exports are deleted, click **Delete** to delete the file system.

The file system is deleted immediately, along with all of its snapshots.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see **Command Line Interface (CLI)** on page 5316.

**To list file systems**

Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment.

For example:

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id>
```

**To get a specific file system**

Open a command prompt and run `oci fs file-system get` to retrieve information about a specific file system.
For example:

```
oci fs file-system get --file-system-id <file_system_OCID>
```

**To update a file system**

Open a command prompt and run `oci fs file-system update` to update a specific file system's information.

For example:

```
oci fs file-system update --file-system-id <file_system_OCID> --display-name "<New File System Name>"
```

Avoid entering confidential information.

**To create an export for a file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/.. /example1
```

**Caution:**

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.
Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2621.

To set the file system reported free space
Some existing application installers perform a capacity check before running an installation process. Sometimes an installation fails because of too much available capacity. The File Storage service currently reports 8 exabytes of available capacity by default for each file system.

Customers can define how much free capacity is reported as available to the operating system.

Open a command prompt and type in the following command:

```
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

Important:
The maximum free space setting affects each export in the export set. Setting the maximum free space does not limit the amount of data you can store.

To move a file system to a different compartment

Open a command prompt and run

```
oci fs file-system change-file-system-compartment --file-system-id <file_system_OCID> --compartment-id <destination_compartment_OCID>
```

To update the key for a file system
File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

Note:
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

Caution:
Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5060.

Prerequisites:
- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 5006.
- Correctly set permissions that allow the File Storage service to use keys. For example:

```
Allow service FssOci1Prod to use keys in compartment <compartment_name>
```

Open a command prompt and run

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id <target_key_id>
```

To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption.

Open a command prompt and run `oci fs file-system update`. Leave the `--kms-key-id` value unspecified.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id ""
```

For example:

```
oci fs file-system update --file-system-id ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id ""
```

To delete a file system

You can delete a file system if no non-deleted export resources reference it. Deleting a file system also deletes all its snapshots.

Open a command prompt and run `oci fs file-system delete` to delete a file system.

For example:

```
oci fs file-system delete --file-system-id <file_system_OCID>
```

Caution:

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage file systems:

- ListFileSystems
- GetFileSystem
- UpdateFileSystem
- ChangeFileSystemCompartment
- DeleteFileSystem

Managing Mount Targets

This topic describes the basics of managing mount targets.

Overview

Actions you can take to manage a mount target include:
• Viewing mount target details
• Obtaining mount command samples
• Creating a new export and file system
• Editing exports and export options
• Change the reported size of exported file systems
• Deleting a mount target

You can perform most administrative tasks for your mount targets using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

Mount Target

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems. The mount target provides the IP address or DNS name that is used together with a unique export path to mount the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter:

• You can create as many exports in a mount target for different file systems as you wish.
• You can create as many exports in a mount target for a single file system as you wish.
• You can delete and re-create exports in a mount target as often as you need to.
• You can add export options to an export to control access to the file system.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

For more information, see Working with NFS Export Options on page 2542.

Limitations and Considerations

• Each availability domain is limited to two mount targets by default.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

• Each mount target can accept up to 100,000 NFS client connections. If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 2551 for more information.

• Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.
• Each mount target requires three internal IP addresses in the subnet to function:
  • Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
  • The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
  • The File Storage service doesn’t "reserve" the third IP address required for high availability failover.
  • Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
  • Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to manage mount targets. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 2837 for more information.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

**Moving Mount Targets to a Different Compartment**

You can move mount targets from one compartment to another. When you move a mount target to a new compartment, its associated export set and exports move with it. After you move the mount target to the new compartment, inherent policies apply immediately and affect access to the mount target, export set, and exports through the Console. Moving these resources doesn’t affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments on page 3126.

**Details About Your Mount Target**

The mount target details page provides the following information about your mount target:

**MOUNT TARGET OCID**

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your mount target's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support.

**CREATED**

The date and time that the mount target was created.

**Availability Domain**

When you create a mount target, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your mount target's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains on page 208.
COMPARTMENT
When you create a mount target, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are accessible only to those groups that have been given permission by an administrator in your organization. You need your mount target's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments on page 3126.

REPORTED SIZE (GiB)
The maximum capacity in gibibytes reported by the file systems exported through this mount target. The File Storage service currently reports 8589934592 gibibytes (GiB) of available capacity by default. If you are installing an application that requires a specific reported size, you can change the reported size. Typically, setting the size to 1024 GiB is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 2595 for more information.

REPORTED INODES (GiI)
The maximum capacity in gibiinodes reported by the file systems exported through this mount target. The File Storage service currently reports gibiinodes (GiI) of available inodes by default. If you are installing an application that requires specific reported inodes, you can change the reported inodes. Typically, setting the inodes to 1024 GiI is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 2595 for more information.

NETWORK SECURITY GROUPS
The network security groups that the mount target belongs to. Each mount target can belong to up to five (5) NSGs. See To add a mount target to a network security group on page 2596 for more information.

VIRTUAL CLOUD NETWORK
The VCN that contains the subnet where the mount target VNIC resides.

SUBNET
The subnet within the VCN where the mount target VNIC resides. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 3693.

IP ADDRESS
The IP address that was assigned to the mount target when it was created. You need your mount target's IP address to mount associated file systems.

HOSTNAME
The hostname that was assigned to the mount target, if any. For more information about hostnames, see DNS in Your Virtual Cloud Network on page 3781.

FULLY QUALIFIED DOMAIN NAME
The hostname together with the subnet domain name. For more information, see DNS in Your Virtual Cloud Network on page 3781. If you specify a hostname, you can use the FQDN to mount the file system.

EXPORT SET OCID
The OCID of the mount target's export set resource. Each mount target has one export set, which contains all of the exports for the mount target. You need your mount target's export set OCID when you perform export-related tasks in the Command Line Interface (CLI) or the API.

EXPORTS
All of the mount target's exports are listed here. The export path and name of each file system is also listed. You need the export path to mount a file system.
**Using the Console**

**To create a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
   
The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Click **Create Mount Target**.
4. Enter the required mount target information. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources:

   - **New Mount Target Name**: Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

     **Note:**
     The mount target name is different than the DNS hostname, which is specified in step 5.

   - **Virtual Cloud Network Compartment**: The compartment containing the cloud network (VCN) in which to create the mount target.

   - **Virtual Cloud Network**: Select the cloud network (VCN) where you want to create the new mount target.

   - **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

     **Important:**
     Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see **Configuring VCN Security Rules for File Storage** on page 2536.

   - **Subnet Compartment**: Specify the compartment containing a subnet within the VCN to attach the mount target to.

   - **Subnet**: Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see **VCNs and Subnets** on page 3693.

     **Caution:**
     Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

---

**Regions and Availability Domains** on page 2532.
5. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.
   - **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
   - **Hostname:** You can specify a hostname you want to assign to the mount target.

   **Note:**
   The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.
   For example, myhostname.subnet123.dnslabel.oraclevcn.com.
   Once created, the hostname may be changed in the mount target's Details page. See **Managing Mount Targets** on page 2589 for more information.

6. Click **Create**.

**To view details of a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
   
   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount Target Details**.

**To change the mount target name**

You can change the display name of the mount target.

   **Note:**
   Changing the display name doesn't affect mounting file systems exported through the mount target.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click **View Mount Target Details**.
4. Click **Rename**.
5. Enter the new mount target name. Avoid entering confidential information. Then click **Rename**.

**To create an export and a new file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in at least one mount target in order for **instances to mount the file system**. The following steps create an export and a new file system. If you want to create an export for an **existing** file system, see **To create an export for a file system** on page 2582.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the mount target you want to create an export for, and click **Create Export**.

   **Note:**
   File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. Click **Create**.
Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 2564 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

**Important:**

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount target Details**.
4. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in GiI) icon**.
5. Enter the maximum size in gibibytes or the maximum inodes in gibiinodes you want the File Storage service to report.
6. Click the **Save** icon.

**Important:**

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command. For more information, see File System Usage and Metering on page 2622.

**To delete an export**

**Note:**

Deleting an export does not impact the data stored in the associated file system. Deleting an export disconnects any instance that mounts the file system with the deleted export path. Mount targets that have no exports still count toward your service limit.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount target Details**.
4. In **Exports**, find the export you want to delete.
5. Click the Actions icon (three dots), and then click **Delete**.

**To manage tags for a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount Target Details**.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags on page 239.
To move a mount target to a different compartment

1. Open the Console,
2. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
3. In the List Scope section, select a compartment.
4. Find the mount target in the list, click the the Actions icon (three dots), and then click Change Compartment.
5. Choose the destination compartment from the list.
6. Click Change Compartment.

To add a mount target to a network security group

You can add the mount target to one or more Network Security Groups (NSGs). File storage requires specific rules to be configured for NSGs that are associated with mount targets. For more information, see Configuring VCN Security Rules for File Storage on page 2536.

1. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click View Mount Target Details.
4. In the Mount Target Information tab, click the Edit link next to Network Security Groups.
5. Select a Compartment and NSG from the list.
6. Click Save.

To delete a mount target

1. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you want to delete.
4. Click the Actions icon (three dots), and then click Delete.

Caution:
Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

Deleting a mount target has no effect on file system data or file system snapshots.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

Caution:
Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run oci fs mount-target create to create a mount target.
For example:

```bash
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

You can create a mount target that is added to a network security group (NSG).

For example:

```bash
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>" --nsg-ids '["<nsg_OCID_1>","<nsg_OCID_2>"]'
```

**To update a mount target**

Open a command prompt and run `oci fs mount-target update` to update a specific mount target's information or to add it to a network security group (NSG).

For example:

```bash
oci fs mount-target update --mount-target-id <mount_target_OCID> --display-name "<New Mount Target Name>" --nsg-ids '"["<nsg1_OCID>", "<nsg2_OCID>"]'
```

Avoid entering confidential information.

**To delete a mount target**

Open a command prompt and run `oci fs mount-target delete` to delete a mount target. Deleting a mount target also deletes the mount target's VNICs.

For example:

```bash
oci fs mount-target delete --mount-target-id <mount_target_OCID>
```

**Caution:**

Deleting a mount target can cause any clients that have mounted an associated file system to hang. Be sure to have all clients unmount the file systems before deleting the mount target.

**To list mount targets**

You cannot use the Console to list mount targets. Use the command line interface or the API from a host machine running a UNIX-style operating system.

Open a command prompt and run `oci fs mount-target list` to list all mount targets in a specified availability domain and compartment.

For example:

```bash
oci fs mount-target list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

**To get a specific mount target**

Open a command prompt and run `oci fs mount-target get` to retrieve information about a specific mount target.
For example:

```
oci fs mount-target get --mount-target-id <mount_target_OCID>
```

**To create an export**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "<pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

- Acceptable: `/example` and `/path`
- Acceptable: `/example` and `/example2`

- Not Acceptable: `/example` and `/example/path`
- Not Acceptable: `/example` and `/example/`
- Not Acceptable: `/example/path/../example1`

**Caution:**

If one file system associated to a mount target has `/` specified as an export path, you can't associate another file system with that mount target.

**Note:**

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2621.

**To list exports**

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.
For example:

```bash
oci fs export list --compartment-id <target_compartment_id>
```

**To get a specific export**

Open a command prompt and run `oci fs export get` to retrieve information about a specific export.

For example:

```bash
oci fs export get --export-id <export_OCID>
```

**To delete an export**

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```bash
oci fs export delete --export-id <export_OCID>
```

**Caution:**

When you delete an export, any file system referenced by the export is no longer accessible through the associated mount target.

**To list export sets**

Open a command prompt and run `oci fs export-set list` to list all export sets in a specified availability domain and compartment.

For example:

```bash
oci fs export-set list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

**To get a specific export set**

Open a command prompt and run `oci fs export-set get` to retrieve information about a specific export set.

For example:

```bash
oci fs export-set get --export-set-id <export_set_OCID>
```

**To update an export set**

Open a command prompt and run `oci fs export-set update` to update a specific export set's information.

For example:

```bash
oci fs export-set update --export-set-id <export_set_OCID> --display-name "<New Export Set Name>"
```

**To set the file system reported size**

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibanodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.
**Important:**

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

**Important:**

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command. For more information, see [File System Usage and Metering](#) on page 2622.

Open a command prompt and type in the following command:

```
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

**To move a mount target to a different compartment**

```
oci fs mount-target change-mount-target-compartment --mount-target-id <mount_target_OCID> --compartment-id <destination_compartment_OCID>
```

**Using the API**

- `CreateMountTarget`
- `UpdateMountTarget`
- `DeleteMountTarget`
- `GetMountTarget`
- `ListMountTargets`
- `ChangeMountTargetCompartment`
- `CreateExport`
- `DeleteExport`
- `GetExport`
- `ListExports`
- `UpdateExportSet`
- `GetExportSet`
- `ListExportSets`

**Managing Snapshots**

The File Storage service supports snapshots for data protection of your file system. Snapshots are a consistent, point-in-time view of your file systems. Snapshots are copy-on-write, and scoped to the entire file system. The File Storage service encrypts all file system and snapshot data at rest. You can take as many snapshots as you need.

Data usage is metered against differentiated snapshot data. If nothing has changed within the file system since the last snapshot was taken, the new snapshot does not consume more storage. For more information, see [File System Usage and Metering](#) on page 2622.

Snapshots are accessible under the root directory of the file system at `.snapshot/name`. When you use an NFSv3 client to perform operations such as `ls`, `du`, or `find` on the snapshot directory, the service automatically exports the directory. The client uses `nfs_d_automount()` to detect and mount the directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

For data protection, you can use a tool that supports NFSv3 to copy your data to a different availability domain, region, file system, object storage, or remote location.

For best performance, we recommend that you use the parallel `tar` (`partar`) and parallel copy (`parcp`) tools provided in the File Storage Parallel File Toolkit for this purpose. These tools work best with parallel workloads and
requests. The Parallel File Toolkit is available for Oracle Linux, Red Hat Enterprise Linux, and CentOS. You can use `rsync` or regular `tar` for other operating system types. See Installing the Parallel File Tools on page 2610 for more information.

**Tip:**
Watch a video about protecting data with snapshots in File Storage.

### Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems on page 2813 allows users to create and delete snapshots.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

### Details About Your Snapshot

The Details page provides the following information about your snapshot:

**SNAPSHOT OCID**

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your snapshot's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 225.

**CREATED**

The date and time that the snapshot was created.

**DESCENDANTS**

Indicates whether the this snapshot has been used to create a clone. See Cloning File Systems on page 2604.

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

### Using the Console

#### To create a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you want to take a snapshot of. Click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Snapshots.
5. Click Create Snapshot.
6. Fill out the required information:
   - **Name**: Enter a name for the snapshot. It must be unique among all other snapshots for this file system. The name can't be changed. Avoid entering confidential information.
7. Click Create Snapshot. The snapshot is accessible under the root directory of the file system at `.snapshot/name`. 
To view details of a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Snapshots.
5. In the Snapshots list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click View Snapshot Details.

To create a snapshot from a Unix-style instance

You can create a snapshot from an instance that you've mounted the file system to. Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

1. Connect to your instance and open a command window.
2. Navigate to your file system's hidden `.snapshot` directory. Type the following, replacing `yourmountpoint` with the name of the directory where you mounted the file system.
   
   ```bash
cd /mnt/yourmountpoint/.snapshot
   ```
3. Use the `mkdir` command to create a directory in the hidden `.snapshot` directory. The directory you create is the snapshot. Give the snapshot a name that will help you identify it. Avoid using confidential information in the snapshot name. For example:
   
   ```bash
   mkdir snapshot-Jan1
   ```
4. Use the `ls` command to verify that your snapshot has been created in the `.snapshot` directory.
   
   ```bash
   ls
   ```

To restore a snapshot

Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

You can restore a file within the snapshot, or an entire snapshot using the `cp` command. Use the `-r` option when restoring a snapshot that contains subdirectories.

For example:

```bash
cp -r .snapshot/snapshot_name/* destination_directory_name
```

Optionally, you can use `rsync`, `tar`, or another tool that supports NFSv3 to copy your data to another remote location. For optimal performance, use the Parallel File Tools.

For example:

```bash
parcp .snapshot/snapshot_name/* destination_directory_name
```

To manage tags for a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click View File System Details.
4. In Resources, click Snapshots.
5. In the Snapshots list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click View Snapshot Details.
6. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 239.
**To clone a file system from a snapshot**

Before you can clone a file system, at least one snapshot must exist for the file system. See To create a snapshot on page 2601 for more information.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you want to clone, click the Actions icon (three dots), and then click **View File System Details**.
4. In the **Snapshots** list, find the snapshot you want to use as the source of the clone, click the Actions icon (three dots), and then click **Clone**.

   The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the **Create Clone** page, specify the details about the clone that aren't inherited from the parent file system, such as name, export information, and mount target information. You can choose to accept the provided system defaults, or change them by clicking **Edit Details**. For a detailed description of each file system property and its defaults, see To create a file system on page 2557.

6. Click **Create**.

Hydration begins immediately upon instantiation of the clone.

Cloned file systems are managed in the same way that any other file system is managed. See Managing File Systems on page 2579 for more information.

To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the **Details** page of the cloned file system. See To view file system details on page 2581.

You can mount and use the clone immediately for READ or WRITE operations after you create it. See Mounting File Systems on page 2564 for more information.

**To delete a snapshot**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system with the snapshot you want to delete.
4. Click the Actions icon (three dots), and then click **View File System Details**.
5. In **Resources**, click **Snapshots**.
6. Find the snapshot you want to delete.
7. Click **Delete**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

**To create a snapshot**

You can create a snapshot of a file system. A snapshot is a point-in-time view of the file system. The snapshot is accessible at ./shapshot/name.

Open a command prompt and run `oci fs snapshot create` to create a snapshot of a file system.

For example:

```
oci fs snapshot create --file-system-id <file_system_OCID> --name "<January1>"
```
Avoid entering confidential information.

**To list snapshots**
Open a command prompt and run `oci fs snapshot create` to list all snapshots associated with a specific file system.
For example:

```
oci fs snapshot list --file-system-id <file_system_OCID>
```

**To get a specific snapshot**
Open a command prompt and run `oci fs snapshot get` to retrieve information about a specific snapshot.
For example:

```
oci fs snapshot get --snapshot-id <snapshot_OCID>
```

**To delete a snapshot**
Open a command prompt and run `oci fs snapshot delete` to delete a snapshot.
For example:

```
oci fs snapshot delete --snapshot-id <snapshot_OCID>
```

**Using the API**
- CreateSnapshot
- ListSnapshots
- GetSnapshot
- DeleteSnapshot
- CreateFileSystem (To create a file system clone, include the OCID of the file system snapshot you want to use as a source for the clone in the `sourceSnapshotId` parameter.)

If you have issues managing snapshots, see Troubleshooting Snapshot Management on page 2643.

**Cloning File Systems**
This topic describes how to create a clone of an existing file system.

**Overview**
A clone is a new file system that is created based on a snapshot of an existing file system. Snapshots preserve the state of the data of a file system at a particular point in time. If you take snapshots of a file system at regular intervals, you can create clones of the file system as it existed at multiple points in its lifetime.

A snapshot provides the initial blueprint for a clone. You can clone a parent file system, or you can clone a clone, as long as there's at least one snapshot available. At the point of creation, the data included in the clone is identical to the data in the snapshot. After creation, data changes in the clone aren't included in the original file system. Conversely, any data changes to the original file system aren't included in the clone. All file systems operate independently of each other, regardless of whether they are parent file systems, clones, or clones of clones.

Clones are space and time efficient because creating a clone doesn't replicate or move any data from the parent file system to the clone. Instead, the clone references the parent file system for any data they share. A file system that is a clone of a clone also references the original parent file system for any shared data.

When you create a clone, initially only the metadata incurs storage costs. Clone data usage is metered only against differentiated data. Data that the clone references from the parent file system isn't metered against the clone, just the parent. For more information, see File System Usage and Metering on page 2622.
**Note:**

Clones count against your tenancy's service limits the same way regular file systems do.

See [Service Limits](#) on page 243 for a list of applicable limits and instructions for requesting a limit increase.

You can use clones for testing, patching, and faster application provisioning. If failed testing or patching causes the data to become unrecoverable, create a new clone from the original file system snapshot, delete the old clone, and restart your operation.

**Cloning Concepts**

**PARENT FILE SYSTEM**

A parent file system is a file system that contains data referenced by one or many clones. When you create a clone, you must specify which file system snapshot is used as the blueprint for the clone directory hierarchy and file data. The file system that contains this snapshot is the initial parent of the clone. The clone continues to reference the parent file system for any data they share in common.

A clone’s parent file system can change after the clone is created. For example, if you delete a clone’s parent file system, the file system parent’s parent (the clone’s grandparent) becomes the clone’s new parent. The clone’s data references are transferred to the new parent.

**SOURCE SNAPSHOT**

The snapshot used as a blueprint to create a clone. A snapshot is a point-in-time reference of a file system. You can take as many snapshots of a file system as you like, as often as you like. A parent file system can have snapshots available for many points along its lifetime. You can create a clone of your file system as it exists today, or as it existed in the past, as long as snapshots were taken of the file system at those times. For more information, see [Managing Snapshots](#) on page 2600.

**FILE SYSTEM CLONE**

A clone is a new file system that is created based on a snapshot of existing file system. A clone automatically inherits the directory hierarchy and file data of the file system. All snapshots that exist in the parent file system are inherited by the clone, up to and including the snapshot that is used as the source of the clone. The `timeCreated` field of inherited snapshots are set to the time the clone operation was initiated. You can choose to keep or delete these snapshots.

File system properties such as compartment, tags, display name, keys, and mount target export information are not copied over from the parent. These properties must be specified manually. You can access the clone by creating an export for it and mounting it to an instance in the same manner as any other file system. See [To create an export for a file system](#) on page 2582 and [Mounting File Systems](#) on page 2564.

When a clone is created, it is assigned a unique OCID. A clone also contains the following information on its Details page to let you track its relationships to other file systems and snapshots:

- **Hydration**: Indicates whether the clone is currently copying metadata from the source.
- **Source snapshot**: A link to the snapshot used to create the clone.
- **Parent File System**: A link to the parent file system of the clone.
- **Root**: Indicates whether this file system is the root of a clone tree.
- **Descendants**: Indicates whether this file system has been cloned.

Cloned file systems are managed in the same way that any other file system is managed. See [Managing File Systems](#) on page 2579 for information on how view the clone's Details page, edit its properties, or delete the clone.
CLONE TREE

A clone tree is a group of clones that all descend from the same root file system. There is a transitive relationship between the root and the descendant clones. To delete the root of a clone tree, all its descendants must first be deleted.

In this diagram, B, C, D, E, F, G are all clones. A# B# C# D and A# B# E# F# G are all part of a clone tree. File system A is the root of this clone tree, and it is the parent of file system B.

BRANCH

A clone tree branch is a set of clones whose data diverges from a common ancestor in the clone tree. In the example above, C and D are one branch of the clone tree, and E, F, and G are a second branch of the clone tree.

Depth is a term used to describe how many clones are between one file system and another in a clone tree. In the example above, the depth from G to E is 2, and the depth from G to A is 4.

Size is a term used to describe how many clones descend from a single parent. In the example above, the size of the clone tree from clone A is 6, but the size of the clone tree from F is only 1.

HYDRATION

Hydration is the process of copying metadata from the source to the clone. Hydration is an asynchronous process that starts when the clone is created. The clone is immediately available on creation and can be used for regular operations while hydration is in progress. You can see whether a clone is still in the process of hydration by visiting its Details page. See To view file system details on page 2581.

Limitations and Considerations

Logical Organization

You can only create a clone in the same availability domain as its parent file system. See About Regions and Availability Domains on page 208 for more information.

Clone Hydration

Performance

Creating a clone is instantaneous and you can immediately access the clone for both READ and WRITE operations. However, there is a minor performance impact on both the parent and clone when accessing shared data while hydration is in progress. Performance impact is more significant on the clone than the parent. The duration of impact depends on the size of the source.

If the clone and parent are concurrently hydrating, hydration can affect the performance of the clone tree root. When creating clones, we recommend that you do not have more than 10 clones hydrating within a clone tree concurrently.

In this diagram, file system A is the root of the clone tree. File systems B, C, D, E, F, and G are all concurrently hydrating, so the performance of file system A might be impacted.
After hydration is complete, there is no further impact to the parent file system or clone tree root. You can see if hydration is in progress on a clone by viewing its Details page. See To view file system details on page 2581.

**Clone Tree Size and Depth**

The number of clones in a clone tree that can hydrate concurrently is limited based on the following two values:

- **Maximum Size: 10** This value represents the maximum allowed number of clones in a clone tree concurrently hydrating from a single parent file system.
- **Maximum Depth: 5** This value represents the maximum number of unhydrated clones on a clone tree branch between the clone you're creating and its last hydrated ancestor.

Exceeding these limits causes the cloning operation to fail. Wait until enough clones complete hydration, and then try the operation again.

**Deleting Resources**

**File Systems**

You can delete a file system *if it is not* the root of a clone tree. If a file system is the root of a clone tree, all descendant clones must first be deleted.

If a clone parent is deleted while any of its descendants are still hydrating, the parent remains in the DELETING state until hydration is complete. The metered space associated with the clone parent remains in use until all hydration is complete for all descendant clones. While a file system is still in a DELETING state, its parent, children, and siblings cannot be deleted. A file system in a DELETING state cannot be cloned. However, you can still clone its siblings or children.

After deletion is complete, the parent of the deleted file system becomes the new parent of the descendant clones.

**Source Snapshot**

You can delete the source snapshot of a clone. If the source snapshot is deleted while a clone of it is being hydrated, the source snapshot remains in the DELETING state until hydration is complete.

**Parent Snapshots**

A clone inherits all snapshots from the parent. If you delete a snapshot within a parent file system while hydration is in progress, the snapshot remains in the DELETING state until hydration is complete. After hydration is complete, you can delete any snapshot in the parent or clone file system at any time.

See instructions for deleting file systems in Managing File Systems on page 2579

See instructions for deleting snapshots in Managing Snapshots on page 2600.
**Metering and Billing**

A parent file system is metered for all the data shared with its descendant clones. A clone is metered for its metadata and incremental changes made to its data. When a clone is deleted, all blocks that are referenced solely by that clone are reclaimed. If another clone is hydrating from the deleted clone, the referenced blocks are reclaimed after hydration is complete.

If you delete a parent clone, any data blocks shared by descendant clones cannot be released. Allocated blocks referenced by descendant clones are transferred to the new clone parent (the clone parent's parent) for metering purposes. You are not metered more than once for data shared between multiple file systems. For more information, see File System Usage and Metering on page 2622.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: Cloning a file system uses the CreateFileSystem API operation and requires the FILE_SYSTEM_CLONE permission. The policy in Let users create, manage, and delete file systems on page 2813 allows users to clone file systems. See the Policy Reference on page 2837 for more information.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Using the Console**

**To clone a file system**

Before you can clone a file system, at least one snapshot must exist for the file system. See To create a snapshot on page 2601 for more information.

2. In the List Scope section, select a compartment.
3. Find the file system you want to clone, click the Actions icon (three dots), and then click View File System Details.
4. In the Snapshots list, find the snapshot you want to use as the source of the clone, click the Actions icon (three dots), and then click Clone.

The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the Create Clone page, specify the details about the clone that aren't inherited from the parent file system. You can choose to accept the provided system defaults, or change them by clicking Edit Details. For a detailed description of each file system property and its defaults, see File System Information.

6. Click Create.

Hydration begins immediately upon instantiation of the clone.

Cloned file systems are managed in the same way that any other file system is managed. See Managing File Systems on page 2579 for more information.

To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the Details page of the cloned file system. See To view file system details on page 2581.

**Next Steps:**

You can export, mount, and use the clone immediately for READ or WRITE operations after you create it. See To create an export for a file system on page 2582 and Mounting File Systems on page 2564 for more information.
Using the Command Line Interface (CLI)

To create a file system clone

To create a file system clone, use the `file-system create` command, and include the OCID of the file system snapshot you want to use as a source for the clone.

For example:

```bash
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "Clone_1" --compartment-id ocid1.compartment.oc1..<unique_id> --source-snapshot-id ocid1.snapshot.oc1..<unique_id>
```

To find all clones created from a specific source snapshot or parent file system

Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment. Include either `--source-snapshot-id` or `--parent-file-system-id`.

An example using `--source-snapshot-id`.

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --source-snapshot-id <snapshot_id>
```

An example using `--parent-file-system-id`.

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --parent-file-system-id <parent_filesystem_id>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to create file system clones:

- CreateFileSystem
- CreateMountTarget
- CreateExport

To create a cloned file system instead of a new file system, the `CreateFileSystem` operation requires the `sourceSnapshotId` parameter. For example:

```json
POST /20171215/fileSystems
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "availabilityDomain": "pWEh:PHX-AD-2",
  "compartmentId": "ocid1.compartment.oc1..<unique_id>" ,
  "displayName": "Clone_1",
  "freeformTags": {},
  "definedTags": {},
  "kmsKeyId": "ocid1.key.oc1..<unique_ID>",
  "sourceSnapshotId": "ocid1.snapshot.oc1..<unique_ID>
}
```

If you have issues managing clones, see Troubleshooting File System Clones on page 2636.
Using File Storage Parallel Tools

The Parallel File Tools suite provides parallel versions of `tar`, `rm`, and `cp`. These tools can run requests on large file systems in parallel, maximizing performance for data protection operations.

The toolkit includes:

- `partar`: Use this command to create and extract tarballs in parallel.
- `parrm`: You can use this command to recursively remove a directory in parallel.
- `parcp`: Use this command to recursively copy a directory in parallel.

Installing the Parallel File Tools

The tool suite is distributed as an RPM for Oracle Linux, Red Hat Enterprise Linux, and CentOS.

To install Parallel File Tools on Linux

To install Parallel File Tools on an Oracle Linux instance:
1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo yum install -y fss-parallel-tools
   ```

To install Parallel File Tools on CentOS and Red Hat 6.x

To install Parallel File Tools on CentOS and Red Hat 6.x:
1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol6 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
   sudo yum --enablerepo=ol6_developer install fss-parallel-tools
   ```

To install Parallel File Tools on CentOS and Red Hat 7.x

1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol7 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
   sudo yum --enablerepo=ol7_developer install fss-parallel-tools
   ```

Using the Tools - Simple Examples

Here are some simple examples of how the different tools are commonly used in Oracle Cloud Infrastructure File Storage.

To copy all files and folders from one directory to another

In this example, `parcp` is used to copy the contents of one folder to another. The `-P` option is used to set the number of parallel threads you want to use.

```bash
$ parcp -P 16 /source/folder /destination/folder
```
To create a .TAR archive of a directory

The following command will create a .tar archive of the contents of the specified directory, and store it as a tarball in the directory. In the example below, the name of the directory that is being used to create the tarball is example.

```
$partar pcf example.tar example -P 16
```

You can also create a tarball and send it to a different directory. In the example below, the directory being used to create the tarball is example. The tarball is being created in the /test directory.

```
$partar pcf example.tar example -P 16 -C /test
```

Using the Tools - Advanced Examples

Here are some examples of how the different tools are used in more advanced scenarios.

To copy selected files or folders into a .TAR archive and exclude others

You can specify which files and folders are included when you create a .tar archive using partar. Let's say you have a directory that looks like this:

```
opc@example sourcedir]$ ls -l
total 180
-rw-r-----  1 opc opc          0 Apr 15 02:55 example2020-04-15_02-55-33_217107549.error
-rw-r-----  1 opc opc         10 Apr 15 03:18 example2020-04-15_02-55-33_217107549.log
-rw-rw-r--  1 opc opc         12 Apr 15 03:18 example2020-04-15_03-18-13_267771997.error
-rw-rw-r--  1 opc opc         10 Apr 15 03:18 example2020-04-15_03-18-13_267771997.log
-rw-rw-r--  1 opc opc         37 Nov 30  2017 File1.txt
-rw-rw-r--  1 opc opc         15 Dec  1  2017 File2.txt
-rw-rw-r--  1 opc opc         39 Nov 30  2017 File3.txt
-rw-rw-r--  1 opc opc         57 Dec  1  2017 File4.txt
```

The following command creates a .tar archive that:

- Excludes all .log and .error files.
- Names the .tar archive mytar
- Sends the .tar ball from /sourcedir to /mnt/destinationdir
- Extracts the .tar archive

```
[opc@example sourcedir]$ partar cf - mytar '*.log*' --exclude '*.err*' |
partar xf - -C /mnt/destinationdir
```

Performing ls -l on /mnt/destinationdir/mytar shows that only the desired files have been copied.

```
[opc@example mytar]$ ls -l
total 148
-rwrxr-x-x  1 opc opc         37 Nov 30 2017 File1.txt
-rwrxr-x-x  1 opc opc         15 Dec  1  2017 File2.txt
-rwrxr-x-x  1 opc opc         39 Nov 30  2017 File3.txt
-rwrxr-x-x  1 opc opc         57 Dec  1  2017 File4.txt
```
To copy selected files or folders from one directory to another

You can specify which files and folders are included when you use `parcp` to copy from one directory to another. Let's say you have a directory that looks like this:

```
[opc@example sourcedir]$ ls -l
```
```
total 180
-rw-r-----.  1 opc opc          0 Apr 15 02:55
 example2020-04-15_02-55-33_217107549.error
-rw-r-----.  1 opc opc         10 Apr 15 03:18
 example2020-04-15_02-55-33_217107549.log
-rw-r--r--.  1 opc opc         12 Apr 15 03:18
 example2020-04-15-03-18-13_267771997.error
-rw-r--r--.  1 opc opc         10 Apr 15 03:18
 example2020-04-15-03-18-13_267771997.log
-rwxr-xr-x.  1 opc opc         37 Nov 30  2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30  2017 File3.txt
-rwxr-xr-x.  1 opc opc         57 Dec  1  2017 File4.txt
```

First, create a `.txt` file containing a list of files you want to exclude. In this example, it's `/home/opc/list.txt`.

The following command copies the contents from `sourcedir` to `/mnt/destinationdir` and:

- Excludes `File4.txt` and the `.log` and `.err` files, as listed in `/home/opc/list.txt`.

```
[opc@example ~]$ cat /home/opc/list.txt
File4.txt
*.log*
*.err*

[opc@example ~]$ date; time sudo parcp --exclude-from=/home/opc/list.txt -P 16 --restore /sourcedir /mnt/destinationdir;
date Mon Jun  1 15:58:30 GMT 2020
real 9m55.820s
user 0m3.602s
sys 1m5.441s

Mon Jun  1 16:08:25 GMT 2020
```

Performing `ls -l` on `/mnt/destinationdir` shows that only the desired files have been copied.

```
[opc@example destinationdir]$ ls -l
```
```
total 91
-rwxr-xr-x.  1 opc opc         37 Nov 30  2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30  2017 File3.txt
```

To use PARCP as an effective alternative for RSYNC in parallel

The `--restore` option in `parcp` is similar to using the `-a -r -x` and `-H` options in `rsync`. (See `rsync(1) - Linux Man Page`.) The `-P` option is used to set the number of parallel threads you want to use.

The `restore` option includes the following behavior:

- Recurse into directories
- Stop at file system boundaries
• Preserve hard links, symlinks, permissions, modification times, group, owners, and special files such as named sockets and fifo files

```bash
$parcp -P 16 --restore /source/folder/ /destination/folder/
```

You can use `parcp` with the `--restore` and `--delete` options to sync files between a source and target folder. This is a good substitute for using `rsync` in parallel. As files are added or removed from the source directory, you can run this command at regular intervals to add or remove the same files from the destination directory. You can automate syncing by using this command option in a cron job.

```bash
sudo parcp -P 32 --restore --delete /source/folder/ /destination/folder/
```

### File System Metrics

You can monitor the health, capacity, and performance of your file systems and mount targets by using `metrics`, `alarms`, and `notifications`.

This topic describes the metrics emitted by the metric namespace `oci_filestorage` (the File Storage service).

#### Overview of Metrics for `oci_filestorage`

File Storage service metrics help you measure operations and throughput related to file systems and mount targets. The available metrics help you determine quickly if your file system is accessible, how much data is flowing through its associated mount target, and if operations are producing unexpected errors. You can get visibility into your workload IOPs and latency, and set up alarms to receive notifications if tolerance thresholds are exceeded.

File Storage metrics include these resources:

- **File system**: A high-performance shared storage entity made available to a network by an associated mount target.
- **Mount target**: An NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems.

Metrics provided for file systems can be filtered or grouped by their associated mount target.

#### Raw Data Point Frequency

For every 1-minute interval, the File Storage service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, 1-hour (60-minute), and 1-day intervals. Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the `1h` or `1d` interval values are supported. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

- The mean for each 5-minute interval is calculated over 5 raw data points.
- The mean for each 60-minute interval is calculated over 60 raw data points.

#### Required IAM Policy

To monitor resources, you must be given the required type of access in a `policy` written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which `compartment` you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

#### Available Metrics: `oci_filestorage`

The metrics listed in the following table are automatically available for any file system or mount target. You do not need to enable monitoring on the resource to get these metrics.
You also can use the Monitoring service to create custom queries. Each metric includes one or more of the following dimensions:

**RESOURCEID**

The *OCID* of the file system or mount target.

**MOUNTTARGETID**

The *OCID* of the mount target exporting an associated file system.

**THROUGHPUT**

The type of request throughput:

- ReadThroughput
- WriteThroughput

**SIZE**

The request size range:

- 0–8 KiB
- 8–64 KiB
- 64 KiB – 1 MiB

**HEALTHITEM**

The type of health rate item:

- SuccessRate
- ErrorRate

</tbody>
</table>

### Tips for Working with File Storage Metrics

You can use the tables below to help interpret the data you see in File Storage metric charts. You can familiarize yourself with the typical metrics emitted by the File Storage service using the chart defaults.
## File System Charts

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults....</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Read Throughput/ Write Throughput** | The read or write throughput of your file system in bytes per second. Read/write throughput is averaged across all mount targets that export the file system. Only the default **mean** statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• y-axis - bytes per second | • Ensure that your workloads have sufficient read/write bandwidth for maximum performance.  
• Identify which file systems have the highest and lowest throughput.  
• Receive notifications when read or write throughput is above or below tolerance, so you can take action. |
| **Read Requests/ Write Requests** | Read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0-8 KiB  
• 8-64 KiB  
• 64 KiB - 1 MiB  
Only the default **mean** statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size  
• y-axis - bytes per second | • See which file systems might have lower performance than expected.  
• Measure impact of operation size on file system and workload performance.  
• Identify and monitor file systems whose workloads are consistently receiving larger read or write requests and compare performance over time.  
• Receive notifications when operation bytes per second for a larger group size is too high. |
<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| **Read Latency/Write Latency** | Average latency of read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB – 1 MiB  
These charts don't report zero latency, or periods when there are no read/write operations happening. Information is presented in the charts as individual data points. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which file systems might have lower performance than expected due to operation latency.  
• Measure impact of operation latency on file system and workload performance.  
• Troubleshoot possible network or application issues that might increase file system latency.  
• Receive notifications when operation latency exceeds tolerance, so you can take action. |
| **Metadata Latency** | Average latency of read or write metadata operation requests processed by your file systems in bytes per second. CREATE, GETATTR, SETATTR, and REMOVE operations are shown.  
Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB – 1 MiB | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which metadata operations requested by your workload have the highest and lowest latency.  
• Measure impact of metadata operation latency on file system and workload performance.  
• Receive notifications when a metadata operation exceeds tolerance.  
• Troubleshoot your application workloads. |
| **Metadata IOPs** | IOPs per second of read or write metadata operation requests processed by your file systems. CREATE, GETATTR, SETATTR, and REMOVE operations are shown.  
| • Statistic - rate  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: operation  
• y-axis - bytes per second | | • See which metadata operations requested by your workload have the highest and lowest IOPs.  
• Identify specific operations that might consistently have higher or lower IOPs.  
• Receive notifications when IOPs for a metadata operation are below tolerance.  
• Troubleshoot your application workloads. |
### File Storage

This chart shows this information using these defaults that you can use to...

<table>
<thead>
<tr>
<th><strong>Usage</strong></th>
<th>The total space utilization for each file system per hour. The data in this chart is presented differently than the utilization value shown in the Details tab of the file system:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• File system utilization is displayed in GiB. This chart displays GB.</td>
</tr>
<tr>
<td></td>
<td>• File system utilization is captured once every hour. This chart captures one data point every minute.</td>
</tr>
<tr>
<td></td>
<td>• There may be temporary discrepancies between the file system utilization value and the Usage chart. For example, if the usage for a file system briefly spikes during the file system's hourly update, the utilization value may temporarily appear higher than expected when compared to the Usage chart.</td>
</tr>
<tr>
<td><strong>Usage</strong></td>
<td>• Statistic - mean</td>
</tr>
<tr>
<td></td>
<td>• Interval - 1 hour</td>
</tr>
<tr>
<td></td>
<td>• Time range - 1 day</td>
</tr>
<tr>
<td></td>
<td>• See what the total space utilization is for all of your file systems.</td>
</tr>
<tr>
<td></td>
<td>• Identify which of your file systems are consuming the most and least space.</td>
</tr>
<tr>
<td></td>
<td>• Identify which of your file systems are incurring the most and least cost.</td>
</tr>
<tr>
<td></td>
<td>• Use in conjunction with the information in File System Usage and Metering on page 2622 and receive notifications when usage is not within expectations.</td>
</tr>
</tbody>
</table>

### Mount Target Charts

This chart shows this information using these defaults that you can use to...

<table>
<thead>
<tr>
<th><strong>Read Throughput/Write Throughput</strong></th>
<th>The read or write throughput of your mount target in bytes per second. Read/write throughput is averaged across all file systems exported by the mount target. Only the default mean statistic is meaningful.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Read Throughput/Write Throughput</strong></td>
<td>• Statistic - mean</td>
</tr>
<tr>
<td></td>
<td>• Interval - 1 minute</td>
</tr>
<tr>
<td></td>
<td>• Time range - 3 hours</td>
</tr>
<tr>
<td></td>
<td>• y-axis - bytes per second</td>
</tr>
<tr>
<td></td>
<td>• Ensure that your workloads have sufficient read/write bandwidth for maximum performance.</td>
</tr>
<tr>
<td></td>
<td>• Identify which mount targets have the highest and lowest throughput.</td>
</tr>
<tr>
<td></td>
<td>• Receive notifications when read or write throughput is below tolerance, so you can take action.</td>
</tr>
<tr>
<td>This chart...</td>
<td>shows this information...</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------</td>
</tr>
</tbody>
</table>
| Connections  | The number of active connections for each mount target. Typically, one connection represents one NFS client. | • Statistic - sum  
• Interval - 1 minute  
• Time range - 3 hours | • See how many active connections each mount target has.  
• Measure impact of high connection count on file system and workload performance.  
• Decide if additional mount targets are required for your workload. |
| Health       | The percentage of requests processed successfully by the mount target. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours | • See which mount targets have the highest and lowest percentage of successfully processed requests.  
• Identify mount targets that are not performing well and troubleshoot possible causes.  
• Receive notifications when mount target health drops below tolerance, so you can take action. |

**Using the Console**

**To view default metric charts for a single file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. Click the file system to view its details.
3. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 3458. For information about notifications for alarms, see **Notifications Overview** on page 4248.

**To view default metric charts for a single mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. Click the mount target to view its details.
3. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 3458. For information about notifications for alarms, see **Notifications Overview** on page 4248.

**To view default metric charts for multiple file systems and mount targets**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the file storage resource you're interested in.
3. For Metric Namespace, select **oci_filestorage**.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Paths in File Systems**

The File Storage service uses three kinds of paths:

1. **Export Paths** are part of the information contained in an export that makes a file system available through a mount target. The export path uniquely identifies the file system within the mount target, letting you associate up to 100 file systems behind a single mount target. The export path is used by an instance to mount (logically attach to) the file system. This path is unrelated to any path within the file system or the client instance. It exists solely as a way to distinguish one file system from another within a single mount target.

In this mount command example, `10.0.0.6` is the mount target IP address. `/FileSystem1` is the unique export path that was specified when the file system was associated with a mount target during creation.

```
sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
```
Caution:
If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

See Managing Mount Targets on page 2589 for more information about mount targets and exports.

2. **Mount Point Paths** are paths within a client instance to a locally accessible directory to which the remote file system is mounted.

In this mount command example, `/mnt/mountpointA` is the path to the directory on the client instance on which the external file system is mounted.

```
sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
```

See Mounting File Systems on page 2564 for more information.

3. **File System Paths** are paths to directories within the file system, and contain the contents of the file system. When the file system is mounted, you can create any directory structure within it you like. Snapshots of the file system can be accessed using the file system path, under the file system's root directory at `.snapshot/name`.

The following example shows the path to a snapshot called 'January 1' when navigating from the instance:

```
/mountpointA/.snapshot/January1
```

**File System Usage and Metering**

This topic describes how usage and metering are calculated for your file systems, to help you understand and manage your service costs. This topic also describes different ways to see your file system, clone, and snapshot utilization and the differences in reporting that can occur depending on which method you use.

**Overview**

File Storage service provisioning is fully managed and automatic as your utilization scales. For more information, see Space Allocation on page 2622.

Here are the methods you can use to view your file system, clone, and snapshot usage:

- The File Storage service reports metered file system utilization and updates hourly. The metered file system utilization comes from the `meteredBytes` value in the API, and represents the authoritative utilization value that is used to count your service cost. You can access the reported utilization for each of your file systems using the Console, the Command Line Interface (CLI), or the API. For more information, see the following section File System Metered Utilization on page 2623.

- The File Storage service supports Network File System (NFS) protocol, so you can use the `df` or `du` command from your instance command line tool to see usage for mounted file systems. However, the usage reported by `du` can differ from both the `meteredBytes` value and the `df` value. For more information, see Using DF and DU Commands on page 2624.

**Space Allocation**

The File Storage service allocates space in blocks of variable size in a way that minimizes total customer cost and optimizes performance. Other storage systems might allocate blocks differently than Oracle Cloud Infrastructure File Storage. If you copy files from another storage device to your Oracle Cloud Infrastructure file system, you might see minor differences when you compare the physical file size before and after copying.
**Metering and Service Cost**

This section describes aspects of file system usage and how they affect your overall service costs.

**File System Metered Utilization**

The File Storage service reports metered utilization size for each file system. The metered utilization size is updated on an hourly cycle. You can see the metered **Utilization** size in the Console on the **Details** page of the file system. This value comes from the File Storage service API `meteredBytes` property which is the total number of bytes consumed by the file system. If the file system is a clone of another file system, the clone is only metered for the differentiated data unique to the clone.

The `meteredBytes` value is updated asynchronously with respect to updates to the file system. Your usage charges are calculated based on the `meteredBytes` value.

You can also use the CLI or API to obtain this information. See [Managing File Systems](#) on page 2579 for instructions about how to view your file system utilization.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you add or remove files from your file system, it can take the File Storage service up to one hour to report the change in metered size.</td>
</tr>
</tbody>
</table>

**Snapshot Metered Utilization**

A snapshot is a point-in-time view of your file system. Snapshots initially consume no additional usage in the file system, because they reference the original data instead of duplicating it, limiting usage cost. A snapshot doesn't change which blocks it references after it's taken.

Snapshot data usage is metered against differentiated data only. If nothing has changed within the file system since the last snapshot was taken, a new snapshot does not consume more storage. The metered size of snapshots is included in the reported `meteredBytes` value of the file system it belongs to.

For example:

1. Let's say you create a file system called "MyFileSystem" and add "File1". The new file system now contains 1 GB including metadata. After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service is 1 GB.
2. Next, you create a snapshot of "MyFileSystem" named "Snapshot1". After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service remains at 1 GB, because there's no differentiated data yet.
3. You then overwrite the first 0.5 GB of "File1". Now, "MyFileSystem" has a file that is different than the version previously captured in "Snapshot1". The `meteredBytes` value is 1.5 GB, because the differentiated data between the live file system and the snapshot is 0.5 GB.
   \[
   1 \text{ GB (snapshot)} + 0.5 \text{ GB (differentiated data)} = 1.5 \text{ GB}
   \]
4. If you then delete "File1", "MyFileSystem" now has a `meteredBytes` value of 1 GB, which represents just the usage for "Snapshot1".
5. Finally, delete "Snapshot1". Deleting the snapshot removes its references to the file data. Provided no other snapshots reference the file data, the space is relinquished and utilization returns to zero.

**Clone Metered Utilization**

The initial metered cost of a file system clone is based on its metadata only, because clones reference the parent file system's data instead of duplicating it.

A clone's parent file system is metered for all the data shared with its descendant clones. A clone is metered for all its metadata and incremental changes made to its data. When a clone is deleted, all blocks that are referenced solely by that clone are reclaimed. If another clone is hydrating from the deleted clone, the referenced metadata blocks are reclaimed after hydration is complete.
If you delete a parent clone, any data blocks shared by descendant clones cannot be released. Allocated blocks referenced by descendant clones are transferred to the new clone parent (the parent's parent) for metering purposes. You are not metered more than once for data shared between multiple file systems.

For example:

1. Let's say you create a clone of "FileSystemA" called "Clone1". At the time of creation, and before any data is altered:
   • "FileSystemA" (parent) is metered for its data and metadata.
   • "Clone1" is metered only for its metadata.
2. Then, you create a new 1GB file in "Clone1" called "File1":
   • "FileSystemA" (parent) is metered for the data it shares with "Clone1" (clone).
   • "Clone1" is metered for its metadata plus the 1GB of changed data incurred by "File1".
3. FileSystemA's parent is "OriginalRoot". It is the root of the clone tree. Let's say you delete "FileSystemA":
   • "OriginalRoot" becomes the new parent of "Clone1".
   • "OriginalRoot" is metered for the data it shares with "Clone1".
   • "Clone1" is metered for its metadata plus the 1GB of changed data incurred by "File1".

Metadata Metered Utilization

Files in the file system require space to be allocated for metadata. 512 bytes are required for each directory entry, and 8192 bytes are required for each symlink. Multiple hardlinks to a file create multiple directory entries for the file, and increases the metadata utilization. This utilization is included in the meteredBytes value of the file system it belongs to.

Using DF and DU Commands

You can use df or du commands from your instance command-line application to view usage information about your file system. To use these commands to view file system usage, the file system must first be mounted to the instance. See Mounting File Systems on page 2564 for instructions on mounting your file system.

How the Commands Work

- df provides the amount of storage metered for your file system. Results are returned quickly, but can be up to 1 hour out of date.
- du provides the storage used by a directory hierarchy. The du command walks the directory tree, and if your hierarchy is large, it can take a long time to run and return results.

How Results can Differ

DF and DU report snapshot and clone utilization differently

A snapshot is a point-in-time view of a file system. Snapshots reference unchanged file system data instead of duplicating it. The file system blocks that the snapshot references don't count towards the snapshot utilization. Only differentiated data increases the snapshot utilization.

The same behavior is true for file system clones. Clones reference the data they share with their parent file system. The file system blocks that the clone references don't count toward the clone's utilization. Only differentiated data increases clone utilization.

- The df command retrieves information provided by the File Storage service using the NFS FSSTAT call. The NFS FSSTAT call accounts correctly for the way that snapshots and clones reference file system data. Only utilization caused by differentiated data is reported.
- The du command descends the file system tree and uses each file's size attribute to total up the space used. When you create a snapshot or a clone, it copies the original size attribute for each file. So, if you run the du command, the snapshot reports the file system's size at the time the snapshot was taken not necessarily the snapshot's actual
current utilization. Clones initially report the parent file system's size at the time the source snapshot was taken. When changes are made to clone data, du begins to report new size attributes for updated files only.

For example,

1. Let's say you create file system called "MyFileSystem". You then add a 1 GB file called "FileA" to the file system. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

2. You then create "Snapshot1". The snapshot is placed in the / snapshot folder of MyFileSystem. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

   • df reports 0 GB for Snapshot1 because the data hasn't changed yet, so there is no space allocated for differentiated data.
   • du reports 1 GB for Snapshot1 because it reports the copied file size attribute of FileA, which is 1 GB.

3. You then use "Snapshot1" to create a clone called "Clone1". Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Clone1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
</tbody>
</table>

   • df reports 0 GB for Clone1 because the data hasn't changed yet, so there is no space allocated for differentiated data.
   • du reports 1 GB for Clone1 because it reports the copied file size attribute of FileA, which is 1 GB.

4. You add a 1 GB file called "FileB" to the cloned file system. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Clone1</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>FileB</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

   • df reports 1 GB for Clone1 for the differentiated data added in FileB.
   • du reports 2 GB for Clone1 because it reports the sum of the copied file size attributes of FileA and FileB.
Important:

Charges are calculated using the `meteredBytes` value. The utilization size reported by `du` can be much larger than `meteredBytes` value. `df` reports the same value as `meteredBytes`, so you can use it to accurately view the file system size.

**DF and DU count hard links differently**

- `df` counts each file only once.
- `du` may count files with hard links more than once.

**DF and DU count symlinks and metadata differently**

- `df` reports the utilization of bytes required by File Storage for metadata and symlinks, even on empty files.
- `du` reports empty files as using zero bytes. It doesn't accurately report the bytes being used by File Storage for metadata and symlinks.

**Troubleshooting Your File System**

These topics cover some common issues you may run into and how to address them.

**File System Setup**

- Mount Command Fails
- Mount Target Creation Fails on page 2630
- Mount Target is in a Failed State on page 2640
- Write to File System Fails on page 2630
- File Storage CREATE API Operations Fail on page 2628
- Creating a File System With an Assigned Key Fails on page 2627

**File System Management**

- Showmount Command Fails on page 2635
- Symbolic Links (Symlinks) Produce Errors on page 2635
- Removing File Locks from a Host that is No Longer Available on page 2634
- Cannot Delete VCN - Mount Target VNIC Still Attached
- Metadata Operations Are Very Slow or Fail on page 2633
- 409 Error Occurs When Creating or Moving a File System or Mount Target on page 2636
- Mount Fails With USE -NOLOCK Error After Instance Reboot on page 2631
- Cannot Unmount a File System: Device is Busy on page 2632
- DF Operation Reports File System as 100% Used (0% Free) on page 2632
- Mounted File System No Longer Accessible on page 2634
- RSYNC is Slow When Copying Files on page 2635
- Deleted Snapshots Still Appear in DF Output on page 2643

**File System Clones**

- Cloning a File System Fails on page 2638
- Cloning a File System Doesn't Replicate File System Data on page 2637
- File System Clones Aren't Visible on page 2638
- Cannot Delete a File System on page 2637
Mount Target Management

- Cannot Delete VCN- Mount Target VNIC Still Attached on page 2639
- Mount Target is in a Failed State on page 2640
- Checking Network Connectivity for a Mount Target With RPCINFO on page 2641

Snapshot Management

- Deleted Snapshots Still Appear in DF Output on page 2643
- Removing Snapshots With RM -RF Fails on page 2643

Applications and File Storage

- Application Installation Fails Due to Too Much or Too Little Available Capacity on page 2645
- Application Performance is Not as Expected on page 2645
- Apache Webserver Fails on page 2644
- Oracle E-Business Suite Concurrent Processing is Slow on page 2646
- Access to File System is Denied Due to Stale File Handle on page 2644
- Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service
- 32-Bit Application Stops Reading or Writing to a File System on page 2646

Windows NFS Connections

- Create and Write to File System Fails using Windows NFS on page 2648
- Mounted Drive is Not Visible in File Explorer on page 2651
- Mounting from File Explorer Fails With "An Unexpected Error Occurred." on page 2652
- File Copy or Delete is Stuck at 99% on page 2652
- Transferring Data From a Windows SMB Share to a File System on page 2652
- Accessing a Mounted File System is Slow or Fails After a Few Seconds on page 2653

Troubleshooting File System Setup

Here are some issues you may run into when you set up your file system.

- Creating a File System With an Assigned Key Fails on page 2627
- File Storage CREATE API Operations Fail on page 2628
- Mount Command Fails
- Mount Target Creation Fails on page 2630
- Write to File System Fails on page 2630

Creating a File System With an Assigned Key Fails

How to resolve problems creating a file system with an assigned Oracle Cloud Infrastructure Vault key.

**Symptom:** Creating a file system with an assigned Oracle Cloud Infrastructure Vault key fails with the following exception:

```
com.oracle.bmc.model.BmcException: (401, NotAuthenticated, false) The required information to complete authentication was not provided or was incorrect.
```

**Cause:** The File Storage service requires authorization to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to the service in the first place. Authorization is provided to the service and users using specific IAM policies.
Solution:

1. Create a policy in the tenancy to let a user group delegate key usage in a compartment. For example:

   Allow group FileWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'

2. Assign the user who is creating the file system to the group.

3. Create a policy in the tenancy to let the File Storage service use the key. For example:

   Allow service FssOc1Prod to use keys in compartment ABC where target.key.id = '<key_OCID>'

For more information, see Assigning Keys on page 5026.

File Storage CREATE API Operations Fail

Symptom: API resource create operations such as createFileSystem fail to create resources.

Cause: High volume can cause API calls to fail. If you haven't specified retry in your request, the operation isn't tried again, and the resource isn't created.

Solution: Retry the API operation. Use the opc-retry-token header in the create resource request. For example:

   POST /20171215/fileSystems
   Host: filestorage.us-phoenix-1.oraclecloud.com
   opc-retry-token: 239787fs987
   <authorization and other headers>
   {
     "availabilityDomain" : "pWEh:PHX-AD-2",
     "compartmentId" : "ocid1.compartment.oc1..<unique_ID>",
     "displayName" : "media-files-1"
   }

See REST APIs on page 5528 for more information.

Mount Command Fails

This topic troubleshoots issues with file system mount commands.

Symptom: Mount command fails.

Cause 1: Network security rules are incorrectly set up or missing

Solution 1: Verify that the network security rules are set up according to the instructions found in Configuring VCN Security Rules for File Storage on page 2536.

Cause 2: There is an issue with the peering configuration of the network between the instance and the file system

Examples of network peering include:

- Remote Peering: Same tenancy, different region
- Local Peering: Same-region, cross-tenancy
- On-premises network to Oracle Cloud Infrastructure

Solution 2: Verify that your network peering elements are correctly configured to allow traffic. Some example of elements that restrict traffic are:

- Route table source and destination
- Firewall rules

You can confirm that your connection issue is caused by your peering network configuration by verifying that you can mount the file system from an instance within the same VCN or subnet. For more information, see Networking Overview on page 3604.

Cause 3: There is no export option specified for the export you're using in the mount command.
Solution 3: There must be at least one export option in the export you use to mount the file system. See Working with NFS Export Options on page 2542 for more information.

Symptom: Mount command fails with an error such as:

```bash
_mount.nfs: mount point <mount_point> does not exist
```

or

```bash
_mount.nfs: mounting <MountTarget>:<ExportPath> failed, reason given by server: No such file or directory
```

Cause: The information in the mount command is incorrect or there's a typo in it.

Solution: Verify the information in your mount command is correct:

- Verify that the mount point directory exists. If not, create it.
- Verify that there's no typo in the mount point in the mount command.
- Verify that the export path in the mount command doesn't contain a typo, and the spelling and case is the same as in the export.

More Information:

If there's a typo in the mount point, the system reports that the mount point doesn't exist.

If there's a typo or a case mismatch in the export path, the system reports that the path doesn't exist.

The export path is specified when you create an export for the file system in a mount target. It uniquely identifies the file system within the mount target, letting you associate multiple file systems to a single mount target. The export path is appended to the mount target IP address, and used to mount the file system.

```bash
sudo mount 10.0.0.6:/example/path /mnt/mountpointA
```

In this example, 10.0.0.6: is the mount target IP address, and /example/path is the export path. /mnt/mountpointA is the path to the directory on the client instance on which the external file system is mounted.

Tip:

You can find all the export paths for a file system in the Exports list shown in its Details page, together with associated mount target information.

- You can obtain the correct export path by copying mount commands directly from the file system export. These commands minimize the chance of a typing error. See To get mount command samples on page 2566 for more information.
- If one file system associated with a mount target uses an export path of '/', it will prevent you from associating more file systems with that mount target. No two file systems associated with the same mount target can have an export path that contains a complete path of the other.

See Paths in File Systems on page 2621 for more information.

Symptom: Mounting a file system using an FQDN in the mount command fails, but mounting with an IP address succeeds.

Cause: If the mount target has a hostname specified, the File Storage service creates an FQDN for it and includes it in the mount command sample for the file system. Be sure that the FQDN correctly resolves to the mount target's IP address. For more information about DNS resolution, see DNS in Your Virtual Cloud Network on page 3781.

Symptom: Mount command fails. The dmsg operation displays the following message: 2249184.121077]

Redirecting File System Framework Version 0.10 <www.redirfs.org> with TrendMicro Patch 1.2779.e4268f8

Cause: TrendMicro Deep Security Agent has mount hooks that can interfere with NFS.
Solution: Stop the ds_agent by running the following command:

/etc/init.d/ds_agent stop

Mount Target Creation Fails

Mount target creation can fail for various reasons:

- **You've exceeded your mount target limit.**

  Each availability domain is limited to two mount targets by default. If you create both a file system and a mount target at the same time, it is possible for the file system to be successfully created but the mount target creation to fail because of this limitation.

  This limitation can be avoided by reusing a previously created mount target for new file systems. You can reuse a single mount target to make as many file systems available on the network as you wish.

  - To reuse a mount target when creating a new file system, select **Select an Existing Mount Target**. The workflow creates a new export for the file system in the existing mount target of your choice.
  
  - To reuse a mount target for an existing file system, you must manually create a new export for the file system in the mount target. For more information, see **To create an export for a file system** on page 2582.

  See **Service Limits** on page 243 for a list of applicable limits and instructions for requesting a limit increase.

- **There aren't enough available IP addresses in your subnet.**

  Each mount target requires three internal IP addresses in the subnet to function:

  - Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
  
  - The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
  
  - The File Storage service doesn't "reserve" the third IP address required for high availability failover.
  
  - Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
  
  - Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

Write to File System Fails

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Linux-style instances:

- Mount the file system. Follow the procedure found in **Mounting File Systems From Unix-Style Instances** on page 2567.
- Set up security rules to work with File Storage. Follow the procedure found in **Configuring VCN Security Rules for File Storage** on page 2536

**Symptom 1:** Writing to a file system from a mounted instance fails.

For example, open a terminal window on the instance and use the `touch` command to write a 'helloworld' file:

```
touch /mnt/yourmountpoint/helloworld
```

The write operation fails with the error:

```
touch: cannot touch '/mnt/yourmountpoint/helloworld': Permission denied
```

**Cause:** When a file system is created, the *root* user owns the root directory. If you're connecting from an instance that uses a Linux or CentOS platform image, the default user is *opc*. The default user is *ubuntu* when you connect from an
instance that uses an Ubuntu platform image. These default users are not root users, so you can't initially write a file or directory to a new file system with these users.

**Solution:** You can implement one of the following solutions:

- Connect as the *root* user. Then, create files or directories in the new file system.
- Connect as the *root* user. Then, change the ownership or permissions of the file system root directory to allow other users (such as opc or ubuntu) to write to the file system.
- Connect as the *root* user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

**Learn more about updating file and directory ownership and permissions.**

- Connect as the default user. Then, use the `sudo` command to write or to change permissions or ownership of files or directories. The `sudo` command temporarily provides a regular user with *root* user permissions. Here's an example of using the `sudo` command to write to the file system:

  ```bash
  sudo touch /mnt/yourmountpoint/helloworld
  ```

  **Learn more about the `sudo` command.**

For more information about accessing instances, see [Connecting to an Instance](#) on page 1083.

**Troubleshooting File System Management**

Here are some issues you may run into while managing your file system.

- [Showmount Command Fails](#) on page 2635
- [Symbolic Links (Symlinks) Produce Errors](#) on page 2635
- [Removing File Locks from a Host that is No Longer Available](#) on page 2634
- [Cannot Delete VCN - Mount Target VNIC Still Attached](#)
- [409 Error Occurs When Creating or Moving a File System or Mount Target](#) on page 2636
- [Metadata Operations Are Very Slow or Fail](#) on page 2633
- [Mount Fails With USE -NOLOCK Error After Instance Reboot](#) on page 2631
- [Cannot Unmount a File System: Device is Busy](#) on page 2632
- [DF Operation Reports File System as 100% Used (0% Free)](#) on page 2634
- [Mounted File System No Longer Accessible](#) on page 2634
- [RSYNC is Slow When Copying Files](#) on page 2635
- [Deleted Snapshots Still Appear in DF Output](#) on page 2643

**Mount Fails With USE -NOLOCK Error After Instance Reboot**

**Symptom:** Cannot re-mount a file system after rebooting the instance. Manual re-mount fails with `use -nolock` error.

**Cause:** The NFS client services aren't running on the instance.

**More Information:** The `rpcbind` and `nfslock` services don't automatically start at reboot by default.

**Solution:**

1. Add the file system to the instance `/etc/fstab` file, so the file system is automatically remounted after reboot.
   a. See [To auto-mount a file system](#) on page 2571 for instructions.
2. Set the `rpcbind` and `nfslock` services to start automatically on every reboot.
   a. Use the following commands to start the `rpcbind` and `nfslock` services:

   ```bash
   $service rpcbind start
   ```
Cannot Unmount a File System: Device is Busy

**Symptom:** Unmounting (`umount`) fails with a message: `device is busy`. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
device is busy
```

**Cause 1:** You're attempting to run the `umount` command from within the mountpoint directory.

**Solution 1:** Move to a directory outside the file system mount point, and retry the `umount` command.

**Cause 2:** An abrupt disconnect from the file system's mount target occurred.

**More Information:** An NFS message similar to the example below is displayed:

```
parrm: B cannot remove '/mnt/directory/.nfs <unique_id>':
Device or resource busy
```

**Solution 2:**

1. Use the `fuser` or `lsof` operation to find the process that has locked the file and note its ID.

   See [lsof(8)- Linux Man Page](https://linux.die.net/man/8/lsof) for information about how to use `lsof`.

   See [fuser(1)- Linux Man Page](https://linux.die.net/man/1/fuser) for information about how to use `fuser`.

2. After you've identified the process that has locked the file, stop the process using the `kill` command. For example:

   ```
   kill <process_id>
   ```

   See [kill(1)- Linux Man Page](https://linux.die.net/man/1/kill) for more information.

3. Retry the `umount` command.

DF Operation Reports File System as 100% Used (0% Free)

**Symptom:** Running the `df` command on a mounted file system unexpectedly reports zero available space (100% used, 0% free), rather than a realistic value.

**Cause:** The mount target that exports the file system has its `Reported Size` value set incorrectly.

**Solution:** Reset the mount target's `Reported Size (GiB)` to the default value of 8589934592 GiB. For instructions, see [To set the file system reported size](https://docs.oracle.com/en/cloud/oracle/cloud/filestorage/service/index.html#GUID-0EDB388F-2756-4898-B67B-AD80E04CA801) on page 2595.

**Important:** Changing the `Reported Size` in the mount target affects all file systems exported through the mount target.

File System Resources Aren't Visible in the Console

Learn about why a file system resource might not be visible to you.

**Symptom:** You create a resource, but can't view it after it's created.
Cause: You don't have permission to work in the compartment that the resource resides in. Resources in a compartment that you don't have access to aren't visible to you.

When you create a resource, you can specify the compartment you want to create it in. The resource doesn't have to be in the same compartment as related file system resources. Another user might move the resource from one compartment (that you have access to) to another (that you don't).

Solution 1: Create the resource in a compartment you have permission to work in.

Solution 2: Obtain permission to work in the compartment that the resource resides in. For information about setting up user access, see Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

Metadata Operations Are Very Slow or Fail

Symptom: Metadata operations such as ls -l, du, or find are very slow.

Causes:
1. ls, find, and du are sequential operations. They create NFS readdir and readdirplus requests proportional to the number of entries in the directory. The service has high response latency on readdir and readdirplus requests. The severity of this performance issue can vary because of the directory size, number of files, or how busy the file system is.
2. If a client performs an ls -l operation while another client is writing to the file system, an issue with READDIRPLUS can cause looping behavior on the client instance.

Solutions for Cause 1:
- Use ls -ld or stat instead of ls -l. These operations are much quicker on large directories than ls -l. For example:

```
[opc@instance01 dd]$ time ls -l|wc -l
401425
real 0m39.786s
user 0m4.389s
sys 0m5.403s
[opc@instance01 dd]$ time ls -ld
drwxrwxr-x. 4 opc opc 401424 Apr 17 14:18 .
real 0m0.009s
user 0m0.001s
sys 0m0.003s
[opc@instance01 dd]$ time stat .|grep Size
Size: 401424 Blocks: 785 IO Block: 32768 directory
real 0m0.010s
user 0m0.002s
sys 0m0.003s
[opc@instance01 dd]$
```

- Redistribute your files to sub-directories instead of storing a large volume of files in a single directory.

Solutions for Cause 2:
- Disable the READDIRPLUS NFS operation on the instance:
  1. Open a terminal window on the instance.
  2. Unmount the file system with the umount command. For example:

```
sudo umount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

  3. Remount the file system, and include the -o noradirplus option to disable READDIRPLUS. For example:

```
sudo mount -o noradirplus 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```
• Apply a Linux kernel patch:

A Linux kernel patch is available that addresses this issue. The patch is available to install with Oracle Ksplice on Oracle Linux 7.x instances only. Oracle Ksplice lets you apply important security updates and other critical kernel updates without a reboot. The patch addressing this behavior was made available on April 17th, 2020.

Oracle Ksplice must be installed on the instance. After you install Ksplice, you can install available Ksplice patches.

See Installing and Running Oracle Ksplice on page 987 for instructions.

After you install the patch, you can verify the effective kernel version. Ksplice uptrack doesn't change the output of the uname command. uname continues to reflect the version of the kernel the instance was booted into.

Instead, use uptrack-uname to see what effective kernel your instance is running. uptrack-uname has the same format as uname and supports the common uname flags, including -r and -a

For example:

```
$ uptrack-uname -r
4.14.35-1902.302.2.el7uek.x86_64
```

Mounted File System No Longer Accessible

Symptom: A file system that was previously mounted and available is no longer accessible.

Cause: The file system's mount target or export was deleted.

More Information: File systems are made available to the network using an associated mount target. An export controls how NFS clients access the file systems when they connect to the mount target. A file system needs at least one export in an associated mount target to be available for mounting. Deleting a mount target or an export of a file system makes the file system unavailable.

Even if the file system is exported through multiple mount targets, any instance that uses the deleted mount target or export information to mount the file system loses access. See Managing Mount Targets on page 2589.

Solution: Re-create the mount target and a new export for the file system.

1. Follow these instructions to re-create the mount target and export: To create an export for a file system on page 2582.
2. If the mount target still exists, choose Select an Existing Mount Target. If the mount target has been deleted, choose Create a New Mount Target.
3. If you're re-creating the mount target, you can re-use the same name, IP address, and hostname information as the old mount target. Click on Advanced Options to set the IP address and hostname.

Removing File Locks from a Host that is No Longer Available

The File Storage service supports the removal of file locks from any file system. To request the removal of file locks on a file system:

1. Go to My Oracle Support and sign in.
   If you are not signed in directly to Oracle Cloud Support, click Switch to Cloud Support at the top of the page.
2. Click Create Service Request.
3. Select the following from the displayed menus:
   • Service Type: Select Oracle Cloud Infrastructure from the list.
   • Service Name: Select the appropriate option for your organization.
   • Problem Type: FSS File System Lock Removal Request.
4. Enter your contact information.
5. Enter a **Description**, and then enter the following required fields specific to your issue. For most Oracle Cloud Infrastructure issues you need to include the OCID (Oracle Cloud Identifier) for each resource you need help with. See [Locating Oracle Cloud Infrastructure IDs](#) on page 152 for instructions on locating these.

- Tenancy OCID
- File System OCID
- Mount Target OCID
- Host IP Address

For help with any of the general fields in the service request or for information on managing your service requests, click **Help** at the top of the Oracle Cloud Support page.

### RSYNC is Slow When Copying Files

**Symptom:** `rsync` runs very slowly against a file system.

**Cause:** `rsync` is a serial operation, so it is slow when copying a large file system, especially if snapshots are included in the process.

**Solution:** Use one of the following alternatives:

- GNU Parallel to run `rsync` in parallel. For example:

  ```
  time find /mnt/MyFileSystem -mindepth 1 -maxdepth 1 | parallel -P100 rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --exclude=.snapshot --ignore-errors --progress --log-file=$HOME/rsync/logs/test.log1 --quiet -e ssh () root@10.0.3.6:/mnt/rsync_target
  ```

  For more information, see [GNU Parallel - GNU Project](#).

- File Storage Parallel Tools
  
  For more information and examples, see [Using File Storage Parallel Tools](#) on page 2610.

- The `find` command in combination with the `xargs` option. For example:

  ```
  find $(source_dir) -mindepth 1 -maxdepth 1 | xargs -P 24 -I {} rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --log-file=<logfile_path> -quiet -e ssh () <destination_user>@<destination_instance>:<destination_dir>
  ```

  See [find(1)- Linux Man Page](#) and [xargs(1)- Linux Man Page](#) for more information.

### Showmount Command Fails

The File Storage service supports the `showmount -e` command. You can use the `showmount -e` command to show a list of NFS exports available from a specific mount target IP address.

For example, `$ showmount -e 10.0.0.0`

To enable the command, you must create a security list rule in the subnet containing the mount target. The rule must be a **stateful ingress** rule for **UDP** traffic with a **Destination Port Range** of 111.

Click here for instructions about [Configuring VCN Security Rules for File Storage](#) on page 2536.

For more information about this command, see the [Linux manual page about showmount](#).

**Important:**

Only `showmount -e` is supported. No other options are supported, and the `-e` option must be included.

### Symbolic Links (Symlinks) Produce Errors

The File Storage service fully supports the use of symbolic links. However, symbolic links are interpreted by the client and symlinks that point outside of the mounted File Storage system may be interpreted differently by each client and lead to unexpected results, such as broken links or pointing to the wrong file. Symbolic link targets that
work on one client might be broken on another due to differences in file system layout or because clients mounted the file system using different mount targets.

Snapshots can also break symbolic links that point to a target outside the file system’s root directory. This is because when you create a snapshot of a file system, it becomes available as a subdirectory of the .snapshot directory.

To minimize these potential issues, use a relative path as the target path when creating a symbolic link to a file in the network file system. Also, ensure that relative paths do not point to a target path outside the File Storage service root directory except when the target is on the local machine. If you must use a symbolic link that points to a target path outside the file system, use an absolute path starting with the client’s root directory.

For example:

- Pointing to "/user/bin/example" works.
- Pointing to "/yourmountpoint/..." does not work.
- Pointing to "/home/user/yourmountpoint/..." does not work.

409 Error Occurs When Creating or Moving a File System or Mount Target

**Symptom:** When creating or moving a file system or mount target from one compartment to another, you encounter a 409 error. For example:

```
oci.exceptions.ServiceError: {'opc-request-id': '<OCP REQUEST ID>', 'code': 'Conflict', 'message': 'Another filesystem is currently being provisioned, try again later', 'status': 409}
```

**Cause:** There are constraints that limit the number of concurrent operations that a tenancy can perform on file system and mount target resources in a region:

- Each tenancy in a region can have 1 CreateFileSystem or ChangeFilesystemCompartment operation in progress at a time.
- Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment operation in progress at a time.

**Solution:** Retry the operation, either manually or programmatically. The default retry strategy for the OCI SDK is to not retry 409 conflicts, so create a custom retry strategy that retries on 409.

For more information, see 409 error occurs when creating or moving a file system or mount target in Known Issues. For more information about retry strategies, see SDK Behaviors - Retries.

Several examples of building a custom retry strategy are provided at https://github.com/oracle/oci-python-sdk/blob/master/examples/retries.py.

Operations on a File System Fail With Error: 37: No Locks Available

Troubleshoot operations failure on a file system that produces Error: 37: No locks available.

**Symptom:** Operations on the file system sometimes fail with Linux-x86_64 Error: 37: No locks available.

**Cause:** The rpc-statd service and lockd daemon are not running on the client.

**Solution:** Enable and start the rpc-statd service to initialize the lockd service:

1. Open a terminal window on the instance and use the following commands to enable the rpc-statd service:

```
$sudo systemctl status rpc-statd
$sudo systemctl enable rpc-statd
$sudo systemctl start rpc-statd
$sudo systemctl status rpc-statd
```

Troubleshooting File System Clones

A list of troubleshooting topics about cloning file systems.
Cannot Delete a File System
Troubleshoot issues deleting a file system.

Symptom: Deleting a file system fails.

Cause 1: The file system has exports in one or more mount targets. Before you can delete a file system, all of its exports must first be deleted.

Solution 1: Delete all of the file system's exports, then delete the file system. See To delete a file system on page 2586 for instructions.

Cause 2: The file system is the root of a clone tree. Before you can delete the root of a clone tree, all of its descendant clones must first be deleted.

Solution 2: Locate and delete all of the file system's descendant clones:

1. Visit the file system Details page and note down the file system OCID. See To view file system details on page 2581.
2. Use the Command Line Interface (CLI) to list all of the file system's clones. Use the following command, and replace `<parent_filesystem_id>` with the file system OCID you obtained in step 1. For more information about using the CLI, see Command Line Interface (CLI) on page 5316.

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --parent-filesystem-id <parent_filesystem_id>
```

3. Delete all of the file systems in the resulting output list.
4. Delete the parent file system.

You can also use the API to locate all of the file systems with a specified parent. For more information, see ListFileSystems.

Cause 3: Clones or siblings of the file system are currently being deleted.

Solution 3: Wait until the clones or siblings have all finished deleting, and then try again.

Cause 4: The file system is currently being cloned.

Solution 4: Wait until the clone operation succeeds, and then try again.

For general information, see Cloning File Systems on page 2604 and Managing File Systems on page 2579.

Cloning a File System Doesn't Replicate File System Data
Find out why cloning is not suitable for data replication of file systems for data protection purposes, and what to do instead.

Problem: You want to use the cloning feature to replicate a file system in another location in Oracle Cloud Infrastructure for data protection purposes.

More information: File system clones are not a data protection or replication solution. There are two reasons for this:

- Clones can only be created in the same availability domain as the parent file system. You can't specify a target location for a file system clone.
- Creating a clone doesn't replicate or move any data from the parent to the clone. Instead, the clone references the parent file system for any data they share.

Solution: You can use File Storage Parallel Tools to copy or sync your file system data between locations.

The toolkit includes:

- **partar**: Use this command to create and extract tarballs in parallel.
• **parrm:** You can use this command to recursively remove a directory in parallel.
• **parcp:** Use this command to recursively copy a directory in parallel.

See [Using File Storage Parallel Tools](#) on page 2610 for installation instructions and example commands for common data protection operations.

**Cloning a File System Fails**
Troubleshoot problems creating a clone.

**Symptom 1:** Cloning a file system fails with the following error:

"The cloning operation failed because the clone tree has reached the maximum number of clones (10) allowed to concurrently hydrate from a single specified parent. Wait until one or more clones of this parent finish hydrating, and then try again."

**Cause 1:** The clone tree has reached the maximum size of unhydrated clones descending from the parent you're cloning. See [Cloning Concepts](#) on page 2605 for a diagram and examples. See [Limitations and Considerations](#) on page 2606 for an example of how this value relates to hydrating clones.

Clone tree size can fluctuate while hydration is in progress, causing the cloning operation to fail. For example:

Let's say a root file system (File System A) has two child clones currently hydrating from it. (Clone 1 and Clone 2). Clone 1 has 10 children currently hydrating from it, which is the maximum allowed clone tree size for Clone 1.

If you delete Clone 1, File System A becomes the new parent of the 10 child clones currently hydrating, in addition to Clone 2. Deleting Clone 1 causes File System A to immediately reach the maximum clone tree size of 11.

If you then try to clone File System A, the operation fails because File System A has reached the maximum allowed clone tree size.

**Solution 1:** Wait until at least one of the parent's descendant clones has finished hydrating, and then try the operation again.

**Symptom 2:** Cloning a file system fails with the following error:

"The cloning operation failed because the clone tree branch has reached the maximum number of unhydrated clones (5) between the clone and a hydrated ancestor. Wait until a closer ancestor of the clone finishes hydrating, and then try again."

**Cause 2:** There are too many clones currently hydrating in the clone tree branch between the closest fully hydrated ancestor and the clone you're creating. This attribute is also called clone tree depth. See [Cloning Concepts](#) on page 2605 for a diagram and examples. See [Limitations and Considerations](#) on page 2606 for an example of how this value relates to hydrating clones.

**Solution 2:** Wait until at least one closer ancestor of the clone has completed hydrating, and then try the operation again.

**Symptom 3:** Cloning a file system fails with no specific error.

**Cause 3:** The file system you're attempting to clone is currently in a DELETING state.

**Solution 3:** You can't create a clone from a parent file system that's currently being deleted. Clone a child or sibling of the file system instead.

For general information, see [Cloning File Systems](#) on page 2604.

**File System Clones Aren't Visible**
Learn about why your clones may not be visible in the Console.

**Symptom:** You use a file system snapshot to create a clone, but can't view the clone after it's created.

**Cause:** You don't have permission to work in the compartment that the clone resides in. Resources in a compartment that you don't have access to aren't visible to you.

When you create a clone, you can specify the compartment you want to create it in. The clone doesn't have to be in the same compartment as the parent file system. Another user might move the clone from one compartment (that you have access to) to another (that you don't).
**File Storage**

**Solution 1:** Create the clone in a compartment you have permission to work in.

**Solution 2:** Obtain permission to work in the compartment that the clone resides in. For information about setting up user access, see Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

For general information, see Cloning File Systems on page 2604.

**Troubleshooting Mount Target Management**

Troubleshooting topics about mount target management.

- Cannot Delete VCN- Mount Target VNIC Still Attached on page 2639
- Mount Target is in a Failed State on page 2640
- Checking Network Connectivity for a Mount Target With RPCINFO on page 2641

**Cannot Delete VCN- Mount Target VNIC Still Attached**

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for the file systems that it exports. Each mount target has a VNIC to enable network access. Mount target VNICs that remain in a VCN must be deleted before you can delete the VCN.

Deleting a mount target also deletes all of the exports of associated file systems that exist in its export set. Data in the file systems is not affected, but the file systems are no longer available through the deleted mount target. You can create new exports for the file system in a different mount target and subnet.

For more information, see Managing Mount Targets on page 2589.

**To resolve this issue using the Console**

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

   ocid1.mounttarget.ocl.phx.examplemounttargetid

2. Note the Compartment and Subnet information of the VCN you want to delete, and to assist navigation and choosing the correct mount target to delete.

3. Delete the mount target using the following steps:

   a. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
   b. In the List Scope section, select a compartment.
   c. Find the mount target you want to delete.
   d. Click the Actions icon (three dots), and then click Delete.

   **Caution:**

   Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

   **Tip:**

   In the Console, the mount target OCID can be seen in the mount target details page in the Mount Target Information tab. See Managing Mount Targets on page 2589 for more information about how to view the mount target details page. Be sure the mount target OCID seen on the details page matches the mount target OCID provided by the VCN delete process error message.

4. Delete the VCN.
To resolve this issue using the API

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier mounttarget. For example:

```
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

2. Delete the mount target using the following steps:

   a. Use `DeleteMountTarget` to delete the mount target. For example:

```
DELETE /20171215/mountTargets/
ocid1.mounttarget.oc1.phx.examplemounttargetid
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
```

   b. You can use `GetMountTarget` to verify that the mount target has been deleted. For example:

```
GET /20171215/mountTargets/
ocid1.mounttarget.oc1.phx.examplemounttargetid?
compartmentId=<compartmentId>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
```

   The API should return Status 404 Not Found.

To resolve this issue using the CLI

For general information about using the CLI, see Command Line Interface (CLI) on page 5316.

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier mounttarget. For example:

```
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

2. Delete the mount target using the following steps:

   a. Use `oci fs mount-target delete` to delete the mount target. For example:

```
oci fs mount-target delete --mount-target-id
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

   b. You can use `oci fs export get` to verify that the mount target has been deleted. For example:

```
oci fs export get --export-id
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

   The CLI should return a message indicating the mount target is not found. For example:

```
{
   "code": "NotAuthorizedOrNotFound",
   "message": "Authorization failed or requested resource not found.",
   "opc-request-id": "<requestID>",
   "status": 404
}
```

If you still can't delete the VCN, be sure there are no other resources remaining in the VCN that might prevent it. For more information, see Subnet or VCN Deletion on page 4227.

Mount Target is in a Failed State

**Symptom:** A mount target reports a Failed state. File systems are not accessible using the mount target’s IP address.

**Possible Cause:** There are insufficient unallocated IP addresses in the subnet. The mount target cannot fail over successfully.
Each mount target requires three internal IP addresses in the subnet to function:

- Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
- The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
- The File Storage service doesn't "reserve" the third IP address required for high availability failover.
- Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
- Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

**Solution:**

1. Delete the failed mount target.
   
   To delete a mount target on page 2596

2. Export the file system through an active mount target. You can create a replacement mount target and then create an export for the file system, or create an export for the file system in a pre-existing mount target.
   
   - You can use the same export paths for the associated file systems as the previous mount target. However, the export path must be unique for each file system within the mount target.
   - If you create a replacement mount target, you can use the same IP address as the previous mount target, if available. Be sure to explicitly specify the desired IP address when you create the mount target.

   To create a mount target on page 2593

   To create an export for a file system on page 2582

3. If necessary, mount the file systems again.
   
   Mounting File Systems on page 2564

   **Note:**

   If a replacement mount target uses *exactly the same* IP address and export paths as previously existed in the deleted mount target, mounted instances reconnect automatically.

4. To prevent a recurrence of this issue, ensure that sufficient unallocated IP addresses remain available in the subnet.

**Checking Network Connectivity for a Mount Target With RPCINFO**

Use the RPCINFO utility to check that your mount target is connected to the network on all required ports.

The `rpcinfo` utility is a program that retrieves a list of all the remote procedure call (RPC) services currently running, their names and descriptions, and the ports they are using. You can use the `rpcinfo` utility to verify that a mount target is connected to the network on all required ports.

Mount targets require connectivity to the following ports and protocols:

- TCP connectivity to ports 111, 2048, 2049, and 2050
- UDP connectivity to ports 111 and 2048

**Installing the RPCINFO Utility**

The utility must be installed on an instance that has network access to the mount target IP address.

Windows Server 2012 R2 and later versions come with `rpcinfo` already installed.

For other operating systems, such as Linux, CentOS, or Ubuntu, open a terminal and run the `.rpcinfo` command to verify that the utility is installed. If the command isn't recognized, use the following commands to install the utility.

**To install RPCINFO on Linux or CentOS**

To install rpcinfo on an Oracle Linux or CentOS instance:
1. Open a terminal window on the instance.
2. Type the following command:

   ```
   yum install rpcbind
   ```

**To install RPCINFO on Ubuntu**

To install rpcinfo on an Ubuntu instance:

1. Open a terminal window on the instance.
2. Type the following command:

   ```
   apt-get install rpcbind
   ```

**Using the RPCINFO Utility**

1. Identify the IP address of the mount target. You can obtain it from the details page of the mount target. See [To view details of a mount target](#) on page 2594.
2. Open a terminal on the instance, and type the following command to retrieve information about the mount target. Replace `mount_target_IP_address` with the mount target IP address:

   ```
   $ rpcinfo -p <mount_target_IP_address>
   ```

For example, if your mount target IP address is `10.0.0.7`, your command and its output would look like this:

```
$ rpcinfo -p 10.0.0.7

<table>
<thead>
<tr>
<th>program</th>
<th>vers</th>
<th>proto</th>
<th>port</th>
<th>service</th>
</tr>
</thead>
<tbody>
<tr>
<td>100021</td>
<td>4</td>
<td>tcp</td>
<td>2050</td>
<td>nlockmgr</td>
</tr>
<tr>
<td>100000</td>
<td>2</td>
<td>udp</td>
<td>111</td>
<td>portmapper</td>
</tr>
<tr>
<td>100000</td>
<td>3</td>

<td>111</td>
<td>portmapper</td>
</tr>
<tr>
<td>100003</td>
<td>3</td>
<td>tcp</td>
<td>2049</td>
<td>nfs</td>
</tr>
<tr>
<td>100005</td>
<td>1</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>1</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>2</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>2</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>3</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>3</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
</tbody>
</table>
```

3. For each program listed, use the following commands to make an RPC call to report whether a response was received:
   - Make an RPC call using UDP (-u)
     ```
     $ rpcinfo -u <mount_target_IP_address> <program_number>
     ```
   - Make an RPC call using TCP (-t)
     ```
     $ rpcinfo -t <mount_target_IP_address> <program_number>
     ```

If the RPC call is successful, the output should look like this example:

```
$ rpcinfo -u 10.0.0.7 100005

program 100005 version 1 ready and waiting
program 100005 version 2 ready and waiting
program 100005 version 3 ready and waiting
```
For more information on the *rpcinfo* utility, see [rpcinfo(8)-Linux Man Page](#) and [Windows RPCINFO Documentation](#).

**Troubleshooting Snapshot Management**

Troubleshooting topics about snapshot management.

- [Deleted Snapshots Still Appear in DF Output](#) on page 2643
- [Removing Snapshots With RM -RF Fails](#) on page 2643

**Deleted Snapshots Still Appear in DF Output**

Resolve an issue where deleted snapshots still appear in DF output with "stale file handle".

**Symptom:** Previously deleted snapshots still appear in `df` output with the message *stale file handle*.

**Cause:** When you use an NFSv3 client to perform operations such as `ls`, `du`, or `find` on the snapshot directory, the service automatically exports the directory. The client uses `nfs_d_automount()` to detect and mount the directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

If you then delete the snapshot, the mount becomes disconnected. The client still holds an active reference to the snapshot, but can no longer access the snapshot itself, so it reports *stale file handle*.

**Solution:** Manually unmount the snapshot. This might require using the `-f` flag in the `umount` command. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Note:**

If the unmount command fails with the message *device busy*, see [Cannot Unmount a File System: Device is Busy](#) on page 2632 for a solution to this problem.

**Removing Snapshots With RM -RF Fails**

**Symptom:** Using the `rm -rf .snapshot/<snapshot_folder>` operation to delete a snapshot from a mounted file system fails.

**Cause:** Snapshots are read-only and can't be deleted by running `rm -rf .snapshot/<snapshot_folder>` from a client instance. Snapshots must be deleted using the console, CLI, or API.

**Solution:** Use one of these methods to delete the snapshot:

- Use the Console
- Use the CLI
- Use the API

**Troubleshooting Applications**

Here are some issues you might run into when installing applications that use your file system.

- [Application Installation Fails Due to Too Much or Too Little Available Capacity](#) on page 2645
- [Application Performance is Not as Expected](#) on page 2645
- [Apache Webserver Fails](#) on page 2644
- [Oracle E-Business Suite Concurrent Processing is Slow](#) on page 2646
- [Access to File System is Denied Due to Stale File Handle](#) on page 2644
- [Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service](#)

Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business Suite.

- [32-Bit Application Stops Reading or Writing to a File System](#) on page 2646
**Access to File System is Denied Due to Stale File Handle**

Symptom: Access to a file system fails with a message: `stale file handle`. For example:

```bash
[root@example]# /mnt/MyFileSystem
[root@example]# ls -l
ls: cannot access dbclient: Stale file handle
```

Cause: This issue happens when an application opens or creates a file, deletes and closes it, and then attempts to access or delete the same file again.

**Solution 1:** Restart the application.

**Solution 2:** If Solution 1 doesn't solve the issue, unmount and re-mount the file system. This might require using the `-f` flag in the `umount` command. For example:

```bash
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
sudo mount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Note:**

If the `umount` command fails with the message `device busy`, see `Cannot Unmount a File System: Device is Busy` on page 2632 for a solution to this problem.

**Solution 3:** If the first two solutions don't solve the issue, reboot the instance.

**Apache Webserver Fails**

**Symptom 1:** When Apache webserver is installed on a File Storage file system, login to the web page fails and the Apache `error_log` contains messages like the following:

```
Permission denied: [client IP:port] AH00529: <FSS_mount_point>/public/.htaccess pcfg_openfile: unable to check htaccess file, ensure it is readable and that <FSS_mount_point>/public is executable

Permission denied: [client IP:port] AH00035: access to /index.php denied (filesystem path '\<FSS_mount_point>/public/index.php') because search permissions are missing on a component of the path
```

**Additional Information:**

Permission checks show sufficient read and execute access on the directory and the files. Providing full access (777 permission) to the file storage mount point for testing purposes also fails.

**Caution:**

The '777' permission is used strictly for testing purposes, and might compromise your security policy. **Be sure to revert your file system mount point permissions to their previous state after testing is complete.**

**Cause:** By default, the Apache webserver installation expects a local drive. You need to explicitly direct the installation to NFS.

**Solution:** Enable NFS compatibility for Apache.

Open a terminal on the instance and run:

```
$ sudo setsebool httpd_use_nfs on
```
Application Installation Fails Due to Too Much or Too Little Available Capacity

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the Reported Size or Reported Inodes value in the export set of the file system's mount target.

Important:

Changing the Reported Size or Reported Inodes for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store.

If your application installation is failing because of too little available space, you can expand the reported available free space. If your application installation is failing because of too much reported available free space, you can reduce it. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important:

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the df command.

To set the file system reported size on page 2595 in the Console
To set the file system reported size on page 2599 in the CLI
To set the reported free space in the API

You can use the UpdateExportSet operation to update the MaxFsStatBytes.

See REST APIs on page 5528 for more information.

Application Performance is Not as Expected

Several factors can impact application performance:

• Available bandwidth

We recommend that you use bare metal Compute instances because instance bandwidth scales with the number of oCPU’s. Bare metal Compute instances provide the greatest bandwidth. Virtual machines (VMs) are bandwidth limited based on the number of CPUs consumed. Single oCPU VM Compute instances provide the least bandwidth.

• Latency

Subnets can be either AD-specific or regional. The type of subnet you choose to create your File Storage resources in can affect latency. You can create File Storage resources in either type of subnet.

Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet.

For more information, see VCNs and Subnets on page 3693.

Tip:

If you want to verify that your instance and mount target are in the same availability domain, you can view the availability domain for any mount target in its Details page, in the Mount Target Information tab:
A file system is always in the same subnet as its associated mount target.

You can also view the availability domain for any instance in its Details page, in the Instance Information tab:

- **Mount options**
  By not providing explicit values for mount options such as rsize and wsize, the client and server can negotiate the window size for read and write operations that provide the best performance.

**Oracle E-Business Suite Concurrent Processing is Slow**

**Symptom:** On an Oracle E-business Suite system that uses a shared application tier file system, EBS concurrent processing is slow.

**Cause:** The APPLLDM environment variable is referenced by AutoConfig and used to control the placement of concurrent processing logs. The placement of these files can have performance implications.

**Solution:** Set APPLLDM to a value other than single, so that there are multiple log and output directories instead of one large directory. See Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service for instructions.

**32-Bit Application Stops Reading or Writing to a File System**

**Troubleshoot 32-bit application read/write failure on a file system.**

**Symptom:** After a period of functioning correctly, a 32-bit application suddenly stops reading or writing to a file system. The read/write operations fail with an error such as:

```
Applications fail to install on FSS mount point: "Value too large for defined data type" - OCI FSS/Mount Target Resources (Doc ID 2672465.1)
```

**Cause:** The 32-bit application cannot consume larger file IDs. The File Storage service is designed to work with 64-bit applications, so the file IDs generated by File Storage become too large for legacy applications to consume.
More Information:

- If the application uses a signed 32-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 2147483647 \((2^{31}-1)\).
- If the application uses an unsigned 32-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 4294967295 \((2^{32}-1)\).
- If the application uses a signed 64-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 9223372036854775807 \((2^{63}-1)\).

To check the size of new file IDs being generated, open a terminal on a connected instance, and run the following command:

```bash
  touch <File_Storage_mount_point>/test; ls -i <File_Storage_mount_point>/test
```

Solution 1: Upgrade your application to a 64-bit version.

Solution 2: Create a new file system to use with your legacy 32-bit application.

More Information: Removing files from the original file system does not reset the file ID generation back to 0, so you must create a new file system to start again with small file IDs. Remember that after a certain amount of time, file IDs will become too large for the 32-bit application.

**Note:**

Solution 2 isn't applicable in all cases, depending on the nature of the application and the files it produces. For example, if you are performing a data refresh that copies files from a production file system to a non-production file system, this option would work. However, for applications with organically growing file systems, this option may not work.

Solution 3: Set the kernel parameter `enable_ino64=0`.

More Information: Setting `nfs.enable_ino64=0` instructs the NFS client to return 32-bit inode numbers for `readdir()` and `stat()` system calls (instead of the full 64-bit inode numbers).

**Important:**

This solution requires an instance reboot.

1. Open a terminal window on the instance as the root user and type the following command to verify the current `nfs.enable_ino64=0` setting.

   ```bash
   #  cat /sys/module/nfs/parameters/enable_ino64
   ``

   The system should return `Y`, indicating that 64-bit inodes are enabled.

2. Run the following command to set `nfs.enable_ino64=0`.

   ```bash
   echo "options nfs enable_ino64=0" > /etc/modprobe.d/nfs.conf
   ``

3. Reboot the instance.

4. Verify that the setting is updated using the following command:

   ```bash
   #  cat /sys/module/nfs/parameters/enable_ino64
   ``

   The system should return `N`, indicating that 64-bit inodes are disabled and returned to 32-bit.

5. Verify that the file system is mounted to the instance, or mount the file system. See Mounting File Systems on page 2564.

**Troubleshooting Windows NFS Connections**

Here are some issues you may run into with Windows NFS Connections to your file system.
Create and Write to File System Fails using Windows NFS

Important:

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2574.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2536.

Symptom: After installing Windows NFS client, you can successfully mount the file system from Windows, but any attempt to create or update a file in the file system fails.

Cause 1: Registry entries that map the AnonymousGid and AnonymousUid to the root user are missing or in the wrong place.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using AnonymousGid and AnonymousUid. On brand new file systems, write permissions are only granted to the root user.

Solution: Verify that the correct registry entries are located in HKEY_LOCAL_MACHINE\Software\Microsoft\ClientForNFS\CurrentVersion\Default. If not, add the AnonymousGid and AnonymousUid registry entries to map them to the root user, and then remount the file system with the new user privileges.

Tip:

You can verify the AnonymousGid and AnonymousUid are correctly set for a mounted file system by opening a Windows Command Line (CMD) window and typing the mount command without any arguments. A list of all mounted file systems and their properties is shown. The AnonymousGid (GID) and AnonymousUid (UID) values should appear as 0.

For example:

```
C:\>mount
Local    Remote
Properties

X:    \10.0.1.0\FileSystem
UID=0, GID=0
rsize=1048576, wsize=1048576
mount=soft, timeout=0.8
retry=1, locking=yes
fileaccess=755, lang=ANSI
casesensitive=no
```
sec=sys

If they appear as −2, they have not been correctly set. Proceed to the instructions below.

To map the AnonymousGid and AnonymousUid to the root user

1. In the Windows Command Line (CMD) window, unmount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

   umount 10.x.x.x:/fs-export-path X:

   Tip:
   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2594 for more information.

2. Open the registry editor (regedit):
   - Click Windows Search.
   - Enter regedit in the Search field and press Enter.
   - Click Yes to allow changes to your device.
3. Click HKEY_LOCAL_MACHINE, Then, browse to: Software\Microsoft\ClientForNFS \CurrentVersion\Default.
4. Add a new DWORD32 registry entry for AnonymousGid:
   - Click Edit, and select New DWORD (32 bit) Value.
   - In the Name field, enter AnonymousGid. Leave the value at 0.
5. Repeat step 3 to add a second DWORD32 registry entry named AnonymousUid with a value of 0.
6. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl+Shift and click Command Prompt.
7. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

    nfsadmin client stop

    nfsadmin client start

8. Close the Administrator: Windows Command Prompt (CMD) window. Open a standard Command Prompt Window:

   • Click Start, then click Command Prompt.

   **Important:**

   NFS file systems mounted as Administrator are not available to standard users.

9. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

    mount 10.x.x.x:/fs-export-path X:

**Cause 2:** A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

**Solution:** Unmount the file system and then remount the file system using a standard Command Prompt. (CMD)

*To remount a file system with a standard Command Prompt (CMD)*

1. Open Windows Command Line (CMD) and run as Administrator:

   • Go to Start and scroll down to Apps.
   • In the Windows System section, press Ctrl+Shift and click Command Prompt.

2. In the Administrator: Windows Command Line (CMD) window, unmount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

    umount 10.x.x.x:/fs-export-path X:

4. Open a standard Command Prompt Window:

   • Click Start, then click Command Prompt.

5. In the standard Command Line (CMD) window, mount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

    mount 10.x.x.x:/fs-export-path X:
Mounted Drive is Not Visible in File Explorer

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in [Mounting File Systems From Windows Instances](#) on page 2574.
- Set up security rules to work with File Storage. Follow the procedure found in [Configuring VCN Security Rules for File Storage](#) on page 2536.

**Symptom:** After installing Windows NFS client, you can successfully mount the file system from Windows, but the file system drive is not visible in File Explorer.

**Cause:** A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

**Solution:** Unmount the file system and then remount the file system using a standard Command Prompt. (CMD) See [To remount a file system with a standard Command Prompt (CMD)](#) on page 2650.

Mounted Drive is Not Visible in PowerShell

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in [Mounting File Systems From Windows Instances](#) on page 2574.
- Set up security rules to work with File Storage. Follow the procedure found in [Configuring VCN Security Rules for File Storage](#) on page 2536.

**Symptom:** After installing Windows NFS client, you can successfully mount the file system from either Windows File Explorer or the Command Prompt (CMD) using `mount` or `net use` commands. However, the file system drive is not visible in PowerShell.

**Cause:** A known issue exists where drives mapped from outside PowerShell aren't visible from within PowerShell.

**Solution:** Unmount the file system and remount the file system within PowerShell, using options to make it visible in File Explorer and in the CMD application.

**To unmount a file system using the CMD prompt**

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl+Shift and click Command Prompt.
2. In the Administrator: Windows Command Line (CMD) window, unmount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

   ```
   unmount 10.x.x.x:/fs-export-path X:
   ```

   **Tip:**

   IP address and export path information is available in the Details page of the mount target associated with your file system. See [To view details of a mount target](#) on page 2594 for more information.

To map a drive in PowerShell and make it visible

You can map a drive in PowerShell and then use options to make it visible from File Explorer and the Windows Command Line (CMD).

1. Open Windows PowerShell and run as Administrator:
   a. Go to Start and click the Windows PowerShell icon.
   b. In Windows PowerShell, type the following to run as Administrator:

   ```bash
   Start-Process powershell -Verb runAs
   ```
   c. In the User Account Control window, click Yes. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. Type the following cmdlet. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to:

   ```bash
   New-PSDrive X -PsProvider FileSystem -Root \10.x.x.x:fs-export-path -Persist
   ```

Mounting from File Explorer Fails With "An Unexpected Error Occurred."

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:</td>
</tr>
<tr>
<td>• Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2574.</td>
</tr>
<tr>
<td>• Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2536</td>
</tr>
</tbody>
</table>

Symptom: The IP address and export path are correctly represented in the Folder field. When you click Finish, the system attempts to connect to the file system, but fails with an error: “The mapped network drive could not be created because the following error has occurred: An unexpected error occurred.”

Solution 1: Reboot the instance, and mount the file system again using File Explorer.

Solution 2: Mount the file system using the Command Prompt.

File Copy or Delete is Stuck at 99%

Troubleshoot an issue where a Windows mounted file system cannot complete a copy or delete operation.

Symptom: When you try to copy or delete a file in a file system mounted on a Windows instance, the process gets stuck at 99%.

Cause: By default, a Windows instance tries to access a mounted file system using Server Message Block (SMB) ports 139 and 445. Since File Storage file systems use an NFS mount, the process fails.

Solution: Reorder the network provider list to place Nfsnp first. Follow the steps in To change the network provider order on Windows 2012+ on page 2654.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reordering of the network provider list requires a system restart.</td>
</tr>
</tbody>
</table>

Transferring Data From a Windows SMB Share to a File System

Mount the Windows SMB share as a CIFS share and use a copy tool such as PARCP or FPSYNC to transfer data.

This topic describes how to transfer data from a Windows Server Message Block (SMB) share to a File Storage file system. Since the SMB protocol and the NFS protocol used by File Storage are not compatible, an instance that can mount both the NFS file system and the SMB share is used to create a bridge between them.
1. Identify or create a Linux instance in Oracle Cloud Infrastructure that has network access to both the File Storage file system and the Windows SMB share.

2. Open a terminal on the instance.

3. Type the following to install the CIFS utility and verify that it is installed:

   ```
   $sudo yum install -y cifs-utils
   $rpm -qa|grep cifs
   ```

4. Mount the Windows SMB share as a Common Internet File System (CIFS) share:

   a. Create a mount point directory. For example,
   
   ```
   sudo mkdir /mnt/win_share
   ```

   b. Mount the CIFS share:
   
   ```
   sudo mount -t cifs -o username=<win_share_user> //<win_IP_address/
   hostname>/<share_name> /mnt/<win_share_dir>
   ```

   For example:
   
   ```
   $sudo mount -t cifs -o username=opc //win2012/c /mnt/win_share
   ```

5. Use the parcp utility from the File Storage Paralell Tools suite or fpsync to copy the files from the CIFS share to the mounted file system. For installation information about parcp, see Using File Storage Parallel Tools on page 2610. For information about fpsync, visit fpsyncManual Page.

   For example:
   
   ```
   parcp -P 32 /mnt/win_share /mnt/MyFilesystem
   ```

   ```
   fpsync -v -n 8 -f 101 -o "-lptgoD -v --numeric-ids -e ssh" /mnt/
   win_share /mnt/MyFilesystem
   ```

Accessing a Mounted File System is Slow or Fails After a Few Seconds

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:</td>
</tr>
<tr>
<td>• Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2574.</td>
</tr>
<tr>
<td>• Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2536</td>
</tr>
</tbody>
</table>

**Symptom 1**: Accessing a mounted file system with File Explorer or Universal Naming Convention (UNC) path or Command Prompt/Powershell is significantly delayed or fails. The effect is intermittent.

**Symptom 2**: Mount fails using Windows NFS connection with "Network Error 53 "Network path not found".

**Cause**: By default, Windows network providers have higher priority than the client for NFS network provider. Initially, the delay as Windows tries each provider in the default order is significant. Subsequent attempts may be faster because the mount information is cached. After the cache times out, the delay increases again. The native Windows file system client called Distributed File System (DFS) is also given default priority over NFS client, increasing the delay.

**Solution**: Change the network provider order and disable the DFS client so that the client for NFS Network provider is tried first.

For reference, see:

• Support for UNC Naming and MUP
• Modify the protocol bindings and network provider order
• MUP and DFS Interactions

To change the network provider order on Windows 2012+
1. Click Windows Search.
2. Enter regedit in the Search field and press Enter.
3. Click Yes to allow changes to your device.
4. Click HKEY_LOCAL_MACHINE.
5. Browse to: System\CurrentControlSet\Control\NetworkProvider\Order
6. Change the Network Provider order from default to Nfsnp,RDPNP,LanmanWorkstation:
   a. Right-click ProviderOrder, and select Modify.
   b. In the Value Data field, enter Nfsnp,RDPNP,LanmanWorkstation. If there are any further items that exist in this field on your instance, enter them after LanmanWorkstation.
   c. Click OK.
7. Restart the instance.

To disable the DFS Client on Windows 2012+
1. Click Windows Search.
2. Enter regedit in the Search field and press Enter.
3. Click Yes to allow changes to your device.
4. Click HKEY_LOCAL_MACHINE.
5. Browse to: System\CurrentControlSet\Services\Mup.
6. Add a new DWORD32 registry entry for DisableDfs:
   a. Click Edit, and select New DWORD (32 bit) Value.
   b. In the Name field, enter DisableDfs.
   c. Right-click DisableDFS, and select Modify.
   d. In the Value Data field, enter 1.
   e. Click OK.
7. Restart the instance.

Get Started with File Systems

File Storage is a fully managed, network-attached storage that offers high scalability, high durability, high availability and high security for your data in every availability domain. File Storage protects your data by maintaining multiple replicas locally along with the encryption and the ability to take frequent snapshots. File Storage supports NFS version 3 along with NLM for the locking mechanism to provide POSIX semantics.
File Storage

Features

Scalability
Oracle Cloud Infrastructure File Storage service provides the reliability and consistency of traditional NFS and offers enterprise-grade file systems that can scale up in the cloud without any upfront provisioning. Start with a file system that contains only a few kilobytes of data and scale up to 8 exabytes of data based on your needs.

Availability and durability
Data is replicated for durability within each availability domain in a highly available infrastructure that implements industry-leading data protection techniques and best practices.

Data protection
File Storage encrypts your data and maintains multiple replicas locally along with the ability to take frequent snapshots.

Built-in security
File Storage uses encryption-at-rest for newly created file systems, with unique Oracle-provided encryption keys for each file system. You also have the option to encrypt all of your file systems using the keys that you own, managed by the Vault service. Additionally, File Storage provides the option for configuring encryption in transit for all data and metadata. Data encryption in transit uses Transport Layer Security (TLS) v.1.2 to encrypt data sent between your clients and your file systems.

Functions

This chapter explains how to create, deploy, and invoke functions using Oracle Functions.

Functions is a serverless platform that enables you to create, run, and scale business logic without managing any infrastructure.

What's new

Sample Functions
- Sample functions on GitHub
- Try Developer tutorials

Invoke Functions
- Invoke functions
- Invoke functions from other services

Integrate Functions
- Integrate with other products
- Access file systems
- Pass parameters

Developer Tools
- Functions API
- OCI CLI for Functions
- Terraform
- SDKs and the CLI

Observe Functions
- Function logs
- Function tracing
- Function metrics
- Troubleshooting

Control access
- Control access to functions
- Container permissions
- Private network access

Functions and Fn Project
- Upgrade Fn Project CLI
- Manage FDKs and languages
- Differences between Functions and Fn Project

Support

Overview of Functions

Oracle Functions is a fully managed, multi-tenant, highly scalable, on-demand, Functions-as-a-Service platform. It is built on enterprise-grade Oracle Cloud Infrastructure and powered by the Fn Project open source engine. Use Oracle Functions (sometimes abbreviated to just Functions) when you want to focus on writing code to meet business needs.

The serverless and elastic architecture of Oracle Functions means there's no infrastructure administration or software administration for you to perform. You don't provision or maintain compute instances, and operating system software patches and upgrades are applied automatically. Oracle Functions simply ensures your app is highly-available, scalable, secure, and monitored. With Oracle Functions, you can write code in Java, Python, Node, Go, and Ruby (and for advanced use cases, bring your own Dockerfile, and Graal VM). You can then deploy your code, call it directly or trigger it in response to events, and get billed only for the resources consumed during the execution.

Oracle Functions is based on Fn Project. Fn Project is an open source, container native, serverless platform that can be run anywhere - any cloud or on-premises. Fn Project is easy to use, extensible, and performant. You can download and install the open source distribution of Fn Project, develop and test a function locally, and then use the same tooling to deploy that function to Oracle Functions.

You can access Oracle Functions using the Console, a CLI, and a REST API. You can invoke the functions you deploy to Oracle Functions using the CLI or by making signed HTTP requests.

Oracle Functions is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality. See Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

To get set up and running quickly with Oracle Functions, see the Functions QuickStart Guides on page 2663. A number of related Developer Tutorials are also available.

Important:
Advance Notice of Mandatory Requirement to Upgrade the Fn Project CLI, April 2021
If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you will have to upgrade the Fn Project CLI on or before 1st May, 2021. For more information see Upgrading the Fn Project CLI on page 2714.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the REST API, see REST APIs on page 5528.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

The following Oracle Functions resources emit events:

- applications
- functions
You can also have events in other services invoke functions in Oracle Functions. See Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services on page 2700.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up *groups*, *compartments*, and *policies* that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Oracle Functions Capabilities and Limits**

The number of functions and applications you can create in a region is controlled by Oracle Functions service limits (see Functions Limits on page 258). The default service limits vary according to your payment method. If you need more capacity, you can submit a request to increase the default service limits (see Requesting a Service Limit Increase on page 245).

The maximum amount of data you can send to a function (the function's request payload) is 6MB. The maximum amount of data a function can return in response to a request (the function's response payload) is 6MB. These limits are fixed and cannot be changed.

Some other Oracle Functions capabilities and limits are also fixed. However, there are also a number that you can change. See Changing Default Memory and Timeout Settings on page 2695.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more information about policies for Oracle Functions, see:

- Creating Policies to Control Access to Network and Function-Related Resources on page 2766
- Details for Functions on page 2967

**Oracle Functions Concepts**

This topic describes key concepts you need to understand when using Oracle Functions.

**Functions Developers**

Oracle Cloud Infrastructure users who use Oracle Functions to create and deploy functions are referred to as 'functions developers'. To use Oracle Functions, functions developers must have Oracle Cloud Infrastructure user accounts. Their user accounts must belong to groups to which appropriate policies grant access to function-related resources.
See Creating Groups and Users to use with Oracle Functions, if they don't exist already on page 2764.

Applications
In Oracle Functions, an application is:
• a logical grouping of functions
• a way to allocate and configure resources for all functions in the application
• a common context to store configuration variables that are available to all functions in the application
• a way to ensure function runtime isolation

When you define an application in Oracle Functions, you specify the subnets in which to run the functions in the application. You also specify whether to enable logging for the functions in the application.

When functions from different applications are invoked simultaneously, Oracle Functions ensures these function executions are isolated from each other.

Best practice is to group multiple functions in a single application for better efficiency and performance.

Oracle Functions shows applications and their functions in the Console.
See Creating Applications on page 2682.

Functions
In Oracle Functions, functions are:
• small but powerful blocks of code that generally do one simple thing
• grouped into applications
• stored as Docker images in a specified Docker registry
• invoked in response to a CLI command or signed HTTP request

When you deploy a function to Oracle Functions using the Fn Project CLI, the function is built as a Docker image and pushed to a specified Docker registry.

A definition of the function is stored as metadata in the Oracle Functions server. The definition describes how the function is to be executed and includes:
• the Docker image to pull when the function is invoked
• the maximum length of time the function is allowed to execute for
• the maximum amount of memory the function is allowed to consume

Oracle Functions shows functions, and the applications into which they are grouped, in the Console.
See Creating, Deploying, and Invoking a Helloworld Function on page 2680.

Invocations
In Oracle Functions, a function's code is run (or executed) when the function is called (or invoked). You can invoke a function that you've deployed to Oracle Functions from:
• The Fn Project CLI.
• The Oracle Cloud Infrastructure SDKs.
• Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
• Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions pulls the function's Docker image from the specified Docker registry, runs it as a Docker container, and executes the function. If there are subsequent requests to the same function, Oracle Functions directs those requests to the same container. After a period being idle, the Docker container is removed.

Oracle Functions shows information about function invocations in metric charts.
See Invoking Functions on page 2696.
**Triggers**

A trigger is the result of an action elsewhere in the system, that sends a request to invoke a function in Oracle Functions. For example, an event in the Events service might cause a trigger to send a request to Oracle Functions to invoke a function. Alternatively, a trigger might send regular requests to invoke a function on a defined, time-based schedule.

A function might not be associated with any triggers, or it can be associated with one or multiple triggers.

**How Oracle Functions Works**

This topic describes how Oracle Functions works when you deploy a function, and when you invoke a function.

**What Happens When You Deploy a Function to Oracle Functions?**

When you have written the code for a function and it's ready to deploy, you can use a single Fn Project CLI command to perform all the deploy operations in sequence:

- building a Docker image from the function
- providing a definition of the function in a func.yaml file that includes:
  - the maximum length of time the function is allowed to execute for
  - the maximum amount of memory the function is allowed to consume
- pushing the image to the specified Docker registry
- uploading function metadata (including the memory and time restrictions, and a link to the image in the Docker registry) to the Fn Server
- adding the function to the list of functions shown in the Console

The above process of deploying a function to Oracle Functions is shown in the diagram.

**What Happens When You Invoke a Function?**

You can invoke a function that you've deployed to Oracle Functions from:

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
• Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions first verifies the request with the IAM service. Assuming the request passes authentication and authorization checks, Oracle Functions then passes the request to the Fn Server, which uses the function definition to:

• identify the Docker image of the function to pull from the Docker registry
• execute the function by running the function’s image as a container on an instance in a subnet associated with the application to which the function belongs

When the function is executing inside the container, the function can read from and write to other resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services. You can specify the maximum length of time the function is allowed to execute by setting a timeout in the func.yaml file or in the Console.

Oracle Functions stores the function’s logs in Oracle Cloud Infrastructure or in an external logging destination.

When the function has finished executing and after a period being idle, the Docker container is removed. If Oracle Functions receives another call to the same function before the container is removed, the second request is routed to the same running container. If Oracle Functions receives a call to a function that is currently executing inside a running container, Oracle Functions scales horizontally to serve both incoming requests and a second Docker container is started.

Oracle Functions shows information about function invocations in metric charts.

The above process of invoking a function is shown in the diagram.

---

**Oracle Functions Resiliency, Availability, Concurrency, and Scalability**

**Resiliency and Availability**

Resiliency and availability refers to the ability of a system to continue operating, despite the failure or sub-optimal performance of some of its components.

In the case of Oracle Functions:

• The control plane is a set of components that manages function definitions.
The data plane is a set of components that executes functions in response to invocation requests. For resiliency and high availability, both the control plane and data plane components are distributed across different availability domains and fault domains in a region. If one of the domains ceases to be available, the components in the remaining domains take over to ensure that function definition management and execution are not disrupted.

When functions are invoked, they run in the subnets specified for the application to which the functions belong. For resiliency and high availability, best practice is to specify a regional subnet for an application (or alternatively, multiple AD-specific subnets in different availability domains). If an availability domain specified for an application ceases to be available, Oracle Functions runs functions in an alternative availability domain.

Concurrency and Scalability

Concurrency refers to the ability of a system to run multiple operations in parallel using shared resources. Scalability refers to the ability of the system to scale capacity (both up and down) to meet demand.

In the case of Functions, when a function is invoked for the first time, the function’s image is run as a container on an instance in a subnet associated with the application to which the function belongs. When the function is executing inside the container, the function can read from and write to other shared resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services.

If Oracle Functions receives multiple calls to a function that is currently executing inside a running container, Oracle Functions automatically and seamlessly scales horizontally to serve all the incoming requests. Oracle Functions starts multiple Docker containers, up to the limit specified for your tenancy. The default limit is 60 GB of RAM reserved for function execution per availability domain, although you can request an increase to this limit. Provided the limit is not exceeded, there is no difference in response time (latency) between functions executing on the different containers.

When functions from different applications are invoked simultaneously, Oracle Functions ensures these function executions are isolated from each other.

Different Options for Function Development Environments

When setting up your Oracle Functions development environment, you have different options:

- **Option 1: Setting up Cloud Shell. (Recommended)** For users trying out Oracle Functions for the first time, this is the recommended way to get started quickly. By copying and pasting a few commands from the Console into the Cloud Shell window, you can set up an Oracle Functions development environment in just a few minutes.

  This option enables you to experiment creating, deploying, and invoking new functions. You can also explore Oracle Functions using the samples on Git Hub (see Oracle Functions Samples).

  Use the Functions QuickStart on Cloud Shell on page 2663 if you want to set up Cloud Shell as your Oracle Functions development environment.

- **Option 2: Setting up a local machine.** For most users (especially Mac and Linux users), this will be the way to work with Oracle Functions. If you set up a local machine, you’ll have to specify --provider oracle when you create a new Fn Project CLI context.

  This option enables Oracle Functions to perform authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

  Use the Functions QuickStart on Local Host on page 2668 if you want to set up a local machine as your Oracle Functions development environment.

- **Option 3: Setting up an Oracle Cloud Infrastructure compute instance.** For some users, this will be more convenient than setting up a local machine. If you set up an Oracle Cloud Infrastructure compute instance, you’ll have to specify --provider oracle-ip when you create a new Fn Project CLI context.

  This option enables Oracle Functions to perform authentication and authorization using instance OCIDs, dynamic groups, and policies granting permissions to those dynamic groups. This approach removes the requirement for
functions to manage private keys. Note that to set up an Oracle Functions development environment on an Oracle Cloud Infrastructure compute instance, you must:

- have permission to create dynamic groups
- create a new dynamic group that includes the compute instance's OCID
- create a policy to give the new dynamic group access to function resources, network resources, and Oracle Cloud Infrastructure Registry
- specify `--provider oracle-ip` when you create a new Fn Project CLI context

Use the Functions QuickStart on an OCI Compute Instance on page 2674 if you want to set up an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment.

Functions QuickStart Guides

Use these QuickStart Guides to get set up and running quickly with Oracle Functions:

- Functions QuickStart on Cloud Shell on page 2663 (recommended)
- Functions QuickStart on Local Host on page 2668
- Functions QuickStart on an OCI Compute Instance on page 2674

If you're not sure which QuickStart Guide to use, see Different Options for Function Development Environments on page 2662.

Functions QuickStart on Cloud Shell

A. Set up your tenancy
   1. Create groups and users

If suitable users and groups don't exist already:

1. Sign in to the Console as a tenancy administrator.
3. Create a new group by clicking Groups and then Create Group.
4. Create a new user by clicking Users and then Create User.
5. Add a user to a group by clicking Groups, then the name of the group, and then Add User to Group.

See Configuration Notes for more information.

2. Create compartment

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments.
3. Click Create Compartment.

See Configuration Notes for more information.

3. Create VCN and subnets

If a suitable VCN in which to create network resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click Start VCN Wizard to create a new VCN.
4. In the Start VCN Wizard dialog box, select VCN with Internet Connectivity and click Start VCN Wizard.
5. Enter a name for the new VCN, click Next, and then click Create to create the VCN along with the related network resources.

See Configuration Notes for more information.

4. Create policy for group and service

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
3. Click Create Policy, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select Functions from the list of Policy use cases, and base the policy on the policy template Let users create, deploy, and manage functions and applications using Cloud Shell.

The policy template includes the following policy statements:

- Allow group <group-name> to use cloud-shell in tenancy
- Allow group <group-name> to manage repos in tenancy
- Allow group <group-name> to read objectstorage-namespaces in tenancy
- Allow group <group-name> to manage logging-family in tenancy
- Allow group <group-name> to read metrics in tenancy
- Allow group <group-name> to manage functions-family in tenancy
- Allow group <group-name> to use virtual-network-family in tenancy
- Allow group <group-name> to use apm-domains in tenancy
- Allow service faas to use apm-domains in tenancy

If necessary, you can restrict these policy statements by compartment.

See Configuration Notes for more information.
B. Create application
1. Create your first application

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions.

4. **Click Create Application.**

5. Specify:
   - helloworld-app as the name for the new application. You'll deploy your first function in this application, and specify this application when invoking the function.
   - The VCN and subnet in which to run the function.

6. **Click Create.**

See detailed instructions for more information.

C. Set up your Cloud Shell dev environment
1. Display the Getting Started page and the Cloud Shell window

On the Applications page in the Console:

1. Click the helloworld-app application you just created to display the application details page.

2. **Click the Getting Started link, and then click Cloud Shell Setup.**

   **Tip:** The Getting Started page now displays commands tailored specifically for you. You copy and paste these commands to configure your Cloud Shell environment for functions development.

3. **Click Launch Cloud Shell to display the Cloud Shell terminal window.**

2. Set up Fn Project CLI context

   Copy and paste commands from the Getting Started page into the Cloud Shell terminal window to configure your environment, as follows:

   1. Find the name of the pre-created Fn Project context for the current region in which you created the application:

      ```
      fn list context
      ```

      At least two Fn Project contexts are returned, a default context and a context for the current region (for example, named us-phoenix-1).

   2. Set the Fn Project context to use the region context:

      ```
      fn use context <region-context>
      ```

      where `<region-context>` is the context for the current region. For example:

      ```
      fn use context us-phoenix-1
      ```
3. Configure the Fn Project context with the OCID of the current compartment that will own deployed functions:

```
fn update context oracle.compartment-id <compartment-ocid>
```

For example:

```
fn update context oracle.compartment-id
ocid1.compartment.oc1..aaaaaaaarvdfa72n...
```

4. Configure the Fn Project context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

```
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

where `<repo-name>` is a name of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store containers for the function. For example:

```
fn update context registry phx.ocir.io/ansh81vrulzp/acme-repo
```

See Configuration Notes for more information.

### 3. Generate auth token

On the Getting Started page in the Console:

1. Click Generate an Auth Token to display the Auth Tokens page, and click Generate Token.

2. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed (for example, 6aN...6MqX).

3. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.

4. Close the Generate Token dialog.

See Configuration Notes for more information.

### 4. Log in to Registry

On the Getting Started page in the Console:

1. Copy the following command:

```
docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
```

For example:

```
docker login -u 'ansh81vrulzp/jdoe@acme.com' phx.ocir.io
```

If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

```
docker login -u 'ansh81vrulzp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
```

2. In the terminal window, paste the command you just copied and run it.
3. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

You're now ready to start creating, deploying, and invoking functions.

See Configuration Notes for more information.

D. Create, deploy, and invoke your function

1. Create your first function

In the terminal window:

1. Create a helloworld java function by entering:

   ```
   fn init --runtime java hello-java
   ```

   A directory called hello-java is created, containing:

   - a function definition file called func.yaml
   - a /src directory containing source files and directories for the helloworld function
   - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

   Java is just one of several supported languages.

   See detailed instructions for more information.

2. Deploy your first function

In the terminal window:

1. Change directory to the hello-java directory created in the previous step:

   ```
   cd hello-java
   ```

2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

   ```
   fn -v deploy --app helloworld-app
   ```

3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking Functions (under Resources on the details page for the helloworld-app application) and noting that the hello-java function now appears.

   See detailed instructions for more information.

3. Invoke your first function

In the terminal window:

1. Invoke the hello-java function by entering:

   ```
   fn invoke helloworld-app hello-java
   ```

   The 'Hello world!' message is displayed.

2. Invoke the hello-java function with the parameter 'John' by entering:

   ```
   echo -n 'John' | fn invoke helloworld-app hello-java
   ```

   The 'Hello John!' message is displayed.

Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

See detailed instructions for more information.
Functions

4. Next steps

Now that you've created, deployed, and invoked a function, learn how to:

• view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see Storing and Viewing Function Logs on page 2724)
• explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
• invoke a function using SDKs (see Using SDKs to Invoke Functions on page 2698)

You're done!

Functions QuickStart on Local Host

A. Set up your tenancy
   1. Create groups and users

If suitable users and groups don't exist already:

1. Sign in to the Console as a tenancy administrator.
3. Create a new group by clicking Groups and then Create Group.

4. Create a new user by clicking Users and then Create User.
5. Add a user to a group by clicking Groups, then the name of the group, and then Add User to Group.

See Configuration Notes for more information.

2. Create compartment

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments.
3. Click Create Compartment.

See Configuration Notes for more information.

3. Create VCN and subnets

If a suitable VCN in which to create network resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click Start VCN Wizard to create a new VCN.
4. In the Start VCN Wizard dialog box, select VCN with Internet Connectivity and click Start VCN Wizard.

5. Enter a name for the new VCN, click Next, and then click Create to create the VCN along with the related network resources.

See Configuration Notes for more information.

4. Create policy for group and service

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
3. Click Create Policy, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select Functions from the list of Policy use cases, and base the policy on the policy template Let users create, deploy, and manage functions and applications using Cloud Shell.

The policy template includes the following policy statements:

- Allow group <group-name> to use cloud-shell in tenancy
- Allow group <group-name> to manage repos in tenancy
- Allow group <group-name> to read objectstorage-namespaces in tenancy
- Allow group <group-name> to manage logging-family in tenancy
- Allow group <group-name> to read metrics in tenancy
- Allow group <group-name> to manage functions-family in tenancy
- Allow group <group-name> to use virtual-network-family in tenancy
- Allow group <group-name> to use apm-domains in tenancy
- Allow service faas to use apm-domains in tenancy

If necessary, you can restrict these policy statements by compartment.

See Configuration Notes for more information.

B. Create application

1. Create your first application

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions.
4. Click Create Application.
5. Specify:
   • `helloworld-app` as the name for the new application. You'll deploy your first function in this application, and
     specify this application when invoking the function.
   • The VCN and subnet in which to run the function.

6. Click **Create**.

See detailed instructions for more information.

**C. Set up your local host dev environment**

1. **Install and start Docker**

   In a terminal window in your development environment:

   1. Confirm that Docker is installed by entering:

      ```bash
      docker version
      ```

      If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding. See the Docker documentation for your platform (for Oracle Linux, see here).

      Assuming Docker is installed, go to the Prerequisites section of the Fn Project home page on GitHub and confirm that the installed version of Docker is at least the minimum version specified there. If not, re-install Docker before proceeding.

   2. Launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

      ```bash
      docker run hello-world
      ```

      If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation.

   See Configuration Notes for more information.

2. **Set up API signing key and OCI profile**

   1. Sign in to the Console as a functions developer.
   2. Open the **Profile** menu ( ), and click **User Settings**.
   3. Under **Resources**, click **API Keys**, and then click **Add API Key**.
   4. Select **Generate API Key Pair** in the **Add API Key** dialog.
   5. Click **Download Private Key** and save the private key file (as a .pem file) in the `~/.oci` directory. (If the `~/.oci` directory doesn't already exist, create it now).
   6. Click **Add** to add the new API signing key to your user settings.

      The **Configuration File Preview** dialog is displayed, containing a configuration file snippet with basic authentication information for a profile named `DEFAULT` (including the fingerprint of the API signing key you just created).

   7. Copy the configuration file snippet shown in the text box, and close the **Configuration File Preview** dialog.
   8. In a text editor, open the `~/.oci/config` file and paste the snippet into the file. (If the `~/.oci/config` file doesn't already exist, create it now).
9. In the text editor, change the profile in the snippet you've just pasted, as follows:
   - Change the name of the profile from [DEFAULT] to a name of your choosing (for example, [functions-developer-profile]). Note that the ~/.oci/config file cannot contain two profiles with the same name.
   - Change the value of the key_file parameter of the profile to specify the path of the private key file (the .pem file) you downloaded earlier.

10. In the text editor, save the changes you've made to the ~/.oci/config file, and close the text editor.

11. In a terminal window, change permissions on the private key file (the .pem file) to ensure that only you can read it, by entering:

    chmod go-rwx ~/.oci/<private-key-file-name>.pem

See Configuration Notes for more information about setting up an API signing key and creating a profile.

3. Install Fn Project CLI

In a terminal window in your development environment:

1. Install the Fn Project CLI using the appropriate instructions below for your environment:
   - Linux or MacOS: Enter:
     curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
   - MacOS using Homebrew: Enter:
     brew update && brew install fn
   - Windows: Follow the Install Fn Client instructions on GitHub.
   - Linux, MacOS, or Windows: Download and run the binary from the Fn Project Releases page on GitHub.

2. Confirm that the Fn Project CLI has been installed by entering:

    fn version

See Configuration Notes for more information.

4. Set up Fn Project CLI context provider --oracle

In a terminal window in your development environment:

1. Create a new Fn Project CLI context by entering:

    fn create context <my-context> --provider oracle

   Note that you specify --provider oracle to enable authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

2. Specify that the Fn Project CLI is to use the new context by entering:

    fn use context <my-context>

3. Configure the new Fn Project CLI context with the name of the OCI profile you've created for use with Oracle Functions (for example, [functions-developer-profile]), by entering:

    fn update context oracle.profile <profile-name>

See Configuration Notes for more information.

5. Complete Fn Project CLI context configuration

In a terminal window in your development environment:
1. Configure the new Fn Project CLI context with the OCID of the compartment you want to own deployed functions

```
fn update context oracle.compartment-id <compartment-ocid>
```

2. Configure the new context with the api-url endpoint to use when calling the OCI API by entering:

```
fn update context api-url <api-endpoint>
```

where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format `https://functions.<region-identifier>.oci.oraclecloud.com`. For example:

```
fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
```

3. Configure the Fn Project CLI context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

```
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

where `<repo-name>` is a name of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store containers for the function. For example:

```
fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo
```

See Configuration Notes for more information.

6. Generate auth token

1. Sign in to the Console as a functions developer.
2. Open the User menu and go to User Settings. On the Auth Tokens page, click Generate Token.
3. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed.
4. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
5. Close the Generate Token dialog.

See Configuration Notes for more information.

7. Log in to Registry

On the Getting Started page in the Console:

1. Copy the following command:

```
docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
```

For example:

```
docker login -u 'ansh81vru1zp/jdoe@acme.com' phx.ocir.io
```

If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

```
docker login -u 'ansh81vru1zp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
```

2. In the terminal window, paste the command you just copied and run it.
3. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

You're now ready to start creating, deploying, and invoking functions.

See Configuration Notes for more information.

D. Create, deploy, and invoke your function
1. Create your first function

In the terminal window:

1. Create a helloworld java function by entering:

   ```
   fn init --runtime java hello-java
   ```

   A directory called hello-java is created, containing:
   - a function definition file called func.yaml
   - a /src directory containing source files and directories for the helloworld function
   - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

   Java is just one of several supported languages.

   See detailed instructions for more information.

2. Deploy your first function

In the terminal window:

1. Change directory to the hello-java directory created in the previous step:

   ```
   cd hello-java
   ```

2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

   ```
   fn -v deploy --app helloworld-app
   ```

3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking Functions (under Resources on the details page for the helloworld-app application) and noting that the hello-java function now appears.

   See detailed instructions for more information.

3. Invoke your first function

In the terminal window:

1. Invoke the hello-java function by entering:

   ```
   fn invoke helloworld-app hello-java
   ```

   The 'Hello world!' message is displayed.

2. Invoke the hello-java function with the parameter 'John' by entering:

   ```
   echo -n 'John' | fn invoke helloworld-app hello-java
   ```

   The 'Hello John!' message is displayed.

Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

See detailed instructions for more information.
4. Next steps

Now that you've created, deployed, and invoked a function, learn how to:

- view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see Storing and Viewing Function Logs on page 2724)
- explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
- invoke a function using SDKs (see Using SDKs to Invoke Functions on page 2698)

You're done!

Functions QuickStart on an OCI Compute Instance

A. Set up your tenancy

1. Create groups and users

If suitable users and groups don't exist already:

1. Sign in to the Console as a tenancy administrator.
3. Create a new group by clicking Groups and then Create Group.
4. Create a new user by clicking Users and then Create User.
5. Add a user to a group by clicking Groups, then the name of the group, and then Add User to Group.

See Configuration Notes for more information.

2. Create compartment

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments.
3. Click Create Compartment.

See Configuration Notes for more information.

3. Create VCN and subnets

If a suitable VCN in which to create network resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click Start VCN Wizard to create a new VCN.
4. In the Start VCN Wizard dialog box, select VCN with Internet Connectivity and click Start VCN Wizard.

5. Enter a name for the new VCN, click Next, and then click Create to create the VCN along with the related network resources.

See Configuration Notes for more information.

4. Create policy for group and service

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
3. Click Create Policy, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select Functions from the list of Policy use cases, and base the policy on the policy template Let users create, deploy, and manage functions and applications using Cloud Shell.

The policy template includes the following policy statements:

- Allow group <group-name> to use cloud-shell in tenancy
- Allow group <group-name> to manage repos in tenancy
- Allow group <group-name> to read objectstorage-namespaces in tenancy
- Allow group <group-name> to manage logging-family in tenancy
- Allow group <group-name> to read metrics in tenancy
- Allow group <group-name> to manage functions-family in tenancy
- Allow group <group-name> to use virtual-network-family in tenancy
- Allow group <group-name> to use apm-domains in tenancy
- Allow service faas to use apm-domains in tenancy

If necessary, you can restrict these policy statements by compartment.

See Configuration Notes for more information.

B. Create application

1. Create your first application

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions.
4. Click Create Application.
5. Specify:
   • helloworld-app as the name for the new application. You'll deploy your first function in this application, and specify this application when invoking the function.
   • The VCN and subnet in which to run the function.
6. Click Create.

See detailed instructions for more information.

**C. Set up an OCI compute instance**

1. **Create instance and obtain OCID**

   1. Sign in to the Console as a tenancy administrator.
   2. Open the navigation menu and click Compute. Under Compute, click Instances.
   3. Select the compartment in which to create network resources and Oracle Functions resources.
   4. If a suitable compute instance doesn't exist in the compartment already, click Create Instance and:
      • select the compartment, VCN, and subnets for use with Oracle Functions
      • specify that a public IP address is to be assigned to the new compute instance
      • select the file that contains the SSH key to access the new compute instance
   5. On the Instance Details page, copy the OCID and public IP address of the compute instance to use as the development environment.

See documentation for more information.

2. **Create a dynamic group**

Create a new dynamic group to include the compute instance:

   2. Create a new dynamic group.
   3. Enter a rule that includes the compute instance's OCID:

```
ANY {instance.id = '<instance-ocid>'}
```

See documentation for more information.

3. **Create policy for dynamic group**

Create a policy to give the new dynamic group access to function resources, network resources, and Oracle Cloud Infrastructure Registry:

   2. Click Create Policy and use the Policy Builder's manual editor to create a new policy with the following policy statements:
      • Allow dynamic-group <dynamic-group-name> to manage functions-family in compartment <compartment-name>
      • Allow dynamic-group <dynamic-group-name> to use virtual-network-family in compartment <compartment-name>
      • Allow dynamic-group <dynamic-group-name> to read repos in tenancy

See documentation for more information.

**D. Set up your OCI compute instance dev environment**

1. **Install and start Docker**

In a terminal window in your development environment:
1. Confirm that Docker is installed by entering:

    docker version

If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding. See the Docker documentation for your platform (for Oracle Linux, see here).

Assuming Docker is installed, go to the Prerequisites section of the Fn Project home page on GitHub and confirm that the installed version of Docker is at least the minimum version specified there. If not, re-install Docker before proceeding.

2. Launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

    docker run hello-world

If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation.

See Configuration Notes for more information.

2. Install Fn Project CLI

In a terminal window in your development environment:

1. Install the Fn Project CLI using the appropriate instructions below for your environment:
   - Linux or MacOS: Enter:
     
     ```bash
     curl -LSt https://raw.githubusercontent.com/fnproject/cli/master/install | sh
     ```
   - MacOS using Homebrew: Enter:
     
     ```bash
     brew update && brew install fn
     ```
   - Windows: Follow the Install Fn Client instructions on GitHub.
   - Linux, MacOS, or Windows: Download and run the binary from the Fn Project Releases page on GitHub.

2. Confirm that the Fn Project CLI has been installed by entering:

    fn version

See Configuration Notes for more information.

3. Set up Fn Project CLI context provider --oracle-ip

In a terminal window in your development environment:

1. Create a new Fn Project CLI context by entering:

    ```bash
    fn create context <my-context> --provider oracle-ip
    ```

    Note that you specify --provider oracle-ip to enable authentication and authorization using instance OCIDs, dynamic groups, and policies granting permissions to those dynamic groups.

2. Specify that the Fn Project CLI is to use the new context by entering:

    ```bash
    fn use context <my-context>
    ```

See Configuration Notes for more information.

4. Complete Fn Project CLI context configuration

In a terminal window in your development environment:
1. Configure the new Fn Project CLI context with the OCID of the compartment you want to own deployed functions

   `fn update context oracle.compartment-id <compartment-ocid>`

2. Configure the new context with the api-url endpoint to use when calling the OCI API by entering:

   `fn update context api-url <api-endpoint>`

   where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format `https://functions.<region-identifier>.oci.oraclecloud.com`. For example:

   `fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com`

3. Configure the Fn Project CLI context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

   `fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name>`

   where `<repo-name>` is a name of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store containers for the function. For example:

   `fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo`

See Configuration Notes for more information.

5. **Generate auth token**

   1. Sign in to the Console as a functions developer.
   2. Open the User menu and go to User Settings. On the Auth Tokens page, click Generate Token.
   3. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed.
   4. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
   5. Close the Generate Token dialog.

   See Configuration Notes for more information.

6. **Log in to Registry**

   In a terminal window in your development environment:

   1. Enter the following command:

   ```sh
   docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
   ```

   For example:

   ```sh
   docker login -u 'ansh81vru1zp/jdoe@acme.com' phx.ocir.io
   ```

   If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

   ```sh
   docker login -u 'ansh81vru1zp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
   ```

   2. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

   You're now ready to start creating, deploying, and invoking functions.
See **Configuration Notes** for more information.

**E. Create, deploy, and invoke your function**

1. **Create your first function**

   In the terminal window:

   1. Create a helloworld java function by entering:

      ```
      fn init --runtime java hello-java
      ```

      A directory called hello-java is created, containing:

      - a function definition file called func.yaml
      - a /src directory containing source files and directories for the helloworld function
      - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

      Java is just one of several supported languages.

      See [detailed instructions](#) for more information.

2. **Deploy your first function**

   In the terminal window:

   1. Change directory to the hello-java directory created in the previous step:

      ```
      cd hello-java
      ```

   2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

      ```
      fn -v deploy --app helloworld-app
      ```

   3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking **Functions** under **Resources** on the details page for the helloworld-app application and noting that the hello-java function now appears.

      See [detailed instructions](#) for more information.

3. **Invoke your first function**

   In the terminal window:

   1. Invoke the hello-java function by entering:

      ```
      fn invoke helloworld-app hello-java
      ```

      The 'Hello world!' message is displayed.

   2. Invoke the hello-java function with the parameter 'John' by entering:

      ```
      echo -n 'John' | fn invoke helloworld-app hello-java
      ```

      The 'Hello John!' message is displayed.

   Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

   See [detailed instructions](#) for more information.

4. **Next steps**

   Now that you've created, deployed, and invoked a function, learn how to:
   - view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see [Storing and Viewing Function Logs](#) on page 2724)
Functions

- explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
- invoke a function using SDKs (see Using SDKs to Invoke Functions on page 2698)

You're done!

Preparing for Functions

Before you can deploy functions to Oracle Functions, you have to perform the tasks described in the Functions QuickStart Guides on page 2663 to configure:

- Your Oracle Cloud Infrastructure tenancy for function development.
  
  When your tenancy is configured, you will have access, via a suitable policy and user account, to a compartment that has a VCN with at least one public subnet (and an internet gateway) or at least one private subnet (and a service gateway). For more information about these network components, see Networking on page 3604.

- Your client environment for functions development.
  
  When your client environment is configured, you will have access to the Fn Project CLI, and a Docker registry in which to store images (this documentation assumes you will be using Oracle Cloud Infrastructure Registry as your Docker registry and provides instructions accordingly).

Use the Functions QuickStart Guides on page 2663 to complete these configuration tasks.

For additional information about the configuration tasks, see Appendix: Configuration Notes for Oracle Functions on page 2764.

Availability by Region

Oracle Functions is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 208. Refer to that topic to see region identifiers, region keys, and availability domain names.

Creating Functions

Read about how to create functions and applications with Oracle Functions:

- Creating, Deploying, and Invoking a Helloworld Function on page 2680
- Creating Applications on page 2682
- Creating and Deploying Functions on page 2684
- Using Custom Dockerfiles on page 2685
- Creating Functions from Existing Docker Images on page 2687

Creating, Deploying, and Invoking a Helloworld Function

You can start off using Oracle Functions by using Fn Project CLI commands to:

- create a simple helloworld function written in java
- push the image to the Docker registry that's configured for Oracle Functions
- deploy the function to an application in Oracle Functions
- invoke the function

Tip:

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2751).

To get started with Oracle Functions:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2663.
2. Sign in to the Console as a functions developer.
3. Use the Console to create a new application in Oracle Functions:
   a. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
   b. Select the region you intend to use for Oracle Functions. Oracle recommends that you use the same region as the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
   c. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   The **Applications** page shows the applications already defined in the compartment.

   d. Click **Create Application** and specify:
      - The name for the new application as helloworld-app.
      - The VCN and subnet (or subnets, up to a maximum of three) in which to run the function. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that subnets are in the same region as the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   e. Click **Create**.

4. Log in to your development environment as a functions developer.

5. In a terminal window, create a helloworld java function by entering:

   ```sh
   fn init --runtime java helloworld-func
   ```

   A directory called helloworld-func is created, containing:
   - A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
   - A /src directory containing source files and directories for the helloworld function (including /src/main/java/com/example/fn/HelloFunction.java).
   - A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

6. Change directory to the newly created helloworld-func directory.

7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called helloworld-func, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app:

   ```sh
   fn -v deploy --app helloworld-app
   ```

   The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 2713).
8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the helloworld-func image has been pushed to Oracle Cloud Infrastructure Registry successfully:

   a. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Container Registry**.

   b. Choose the registry's region.

      You see all the repositories in the registry to which you have access. The image you pushed is in a new repository with a name constructed from:

      - the repository name in the address of the Docker registry in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770)
      - the name of the helloworld-func image

      For example, the new repository might be called *acme-repo/helloworld-func*.

   c. Click the name of the new repository. You see details of the helloworld-func image that's been pushed to Oracle Cloud Infrastructure Registry.

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.

   b. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

      The **Applications** page shows that an application called helloworld-app has been created.

   c. Click the helloworld-app application to see the functions within it.

      The **Functions** page shows that the helloworld-func function has been deployed to Oracle Functions.

10. In a terminal window, invoke the helloworld-func function by entering:

    ```
    fn invoke helloworld-app helloworld-func
    ```

    The 'Hello World!' message is displayed.

Congratulations! You've successfully created and deployed your first function to Oracle Functions!

**Creating Applications**

You can create applications in Oracle Functions in readiness for deploying functions. An application need not contain any functions.

You can create applications using the Console, the Fn Project CLI, and the API.

For more information about applications, see Applications on page 2659.

**Using the Console**

To create a new application in Oracle Functions using the Console:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2663.
2. Sign in to the Console as a functions developer.
3. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
4. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
5. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   The **Applications** page shows the applications already defined in the compartment.
6. Click Create Application and specify:

   - A name for the new application (for example, acmeapp). Avoid entering confidential information.
   - The VCN and subnet (or subnets, up to a maximum of three) in which to run functions. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that the subnets are in the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

7. Click Create.

   The new application appears in the list of applications.

Using Fn Project CLI Commands

To create a new application in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new application by entering:

   ```
   fn create app <app-name> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:

   - `<app-name>` is the name of the new application. Avoid entering confidential information.
   - `<subnet-ocid>` is the OCID of the subnet (or subnets, up to a maximum of three) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, specify multiple subnets (enclose each OCID in double quotes separated by commas, in the format '"<subnet-ocid>","<subnet-ocid>"'). Oracle recommends that the subnets are in the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   For example:

   ```
   fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
   ```

   An application is created in Oracle Functions, in the tenancy and region implied by the subnet OCID and belonging to the compartment specified in the Fn Project CLI context file.

3. Verify that the new application has been created by entering:

   ```
   fn list apps
   ```

   For example:

   ```
   $ fn list apps
   acmeapp
   ```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage applications:

- CreateApplication
- DeleteApplication
Creating and Deploying Functions

You use Fn Project CLI commands to create and deploy functions to Oracle Functions.

Tip:
If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2751).

Using Fn Project CLI Commands

To create and deploy a function to Oracle Functions using Fn Project CLI commands:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2663.
2. If the application to which you want to add the function doesn't yet exist in Oracle Functions, create it now using the Fn Project CLI or the Console. For example, you might create a new application called acmeapp. See Creating Applications on page 2682.
3. Log in to your development environment as a functions developer.
4. In a terminal window, change directory to the directory containing the function code.
5. Initialize the function by entering:

   ```
   fn init --runtime <runtime-language> <function-name>
   ```

   where:

   - `<runtime-language>` is one of the supported runtime languages (currently go, java, node, python, and ruby are supported)
   - `<function-name>` is the name to use as the function name. If you don't specify a function name, the name of the current directory (in lower case) is used. Avoid entering confidential information.

   For example:

   ```
   fn init --runtime java acme-func
   ```

   A directory is created with the function name you specified, containing:

   - A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
   - A /src directory containing source files and directories.
   - A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

   Note that depending on the runtime language you specify, the `fn init` command might create an /example directory containing code for a helloworld application. As a matter of good practice, you'll probably want to delete the /example directory.

6. Change directory to the newly created directory.
7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image, push the image to the specified Docker registry, and deploy the function to Oracle Functions:

```
fn -v deploy --app <app-name>
```

where `<app-name>` is the name of the application in Oracle Functions to which you want to add the function. For example:

```
fn -v deploy --app acmeapp
```

The `--v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 2713).

Note that you can build, push, and deploy the function using separate Fn Project commands, instead of the single `fn deploy` command.

8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the image has been pushed to Oracle Cloud Infrastructure Registry successfully:
   
   a. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Container Registry**.
   
   b. Choose the registry's region.

   You see all the repositories in the registry to which you have access. The image you pushed is in a new private repository with a name constructed from:

   - the repository name in the address of the Docker registry in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770)
   - the name of the image you pushed

   For example, the new repository might be called `acme-repo/acme-func`.

   c. Click the name of the new repository. You see details of the image that's been pushed to Oracle Cloud Infrastructure Registry.

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.

   b. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   The **Applications** page shows the applications in the compartment, including the one you specified in the `fn deploy` command.

   c. Click the name of the application you specified in the `fn deploy` command to see the functions within it.

   The **Functions** page shows that the function has been deployed to Oracle Functions.

### Using Custom Dockerfiles

When you build or deploy a function with Oracle Functions, a Docker image is created and pushed to a Docker registry. As with any Docker image, the instructions to build the image are contained in a Dockerfile.

If the function is written in one of the languages supported by an Fn Project FDK (Functions Development Kit), Oracle Functions uses the `runtime: build_image: and run_image:` settings in a `func.yaml` file to determine the language (and therefore the build-time and run-time dependencies) to include in the Docker image. If you use the `fn init` command to initialize the function, a `func.yaml` file is created for you. For example, a `func.yaml` might look like:

```
schema_version: 20180708
name: hello-java
version: 0.0.1
runtime: java
build_image: fnproject/fn-java-fdk-build:jdk11-1.0.116
```
When you build or deploy the function, Oracle Functions uses the settings in the `func.yaml` file to create a temporary Dockerfile containing the instructions from which to build the Docker image. For example, a temporary Dockerfile is shown below.

```
FROM fnproject/fn-java-fdk-build:jdk11-1.0.116 as build-stage
WORKDIR /function
ENV MAVEN_OPTS -Dhttp.proxyHost= -Dhttp.proxyPort= -Dhttps.proxyHost= -Dhttps.proxyPort= -Dhttp.nonProxyHosts= -Dmaven.repo.local=/usr/share/maven/ref/repository
ADD pom.xml /function/pom.xml
ADD src /function/src
RUN ["mvn", "package"]
FROM fnproject/fn-java-fdk:jre11-1.0.116
WORKDIR /function
COPY --from=build-stage /function/target/*.jar /function/app/
CMD ["com.example.fn.HelloFunction::handleRequest"]
```

Having created the Docker image, Oracle Functions deletes the temporary Dockerfile.

If you want more control over the Docker image that is created, you can modify the Dockerfile that Oracle Functions creates. Alternatively, you can create your own Dockerfile entirely from scratch. In both cases, the Dockerfile is referred to as a 'custom Dockerfile'. This workflow is sometimes referred to as Bring-Your-Own-Dockerfile, or BYOD.

When you build or deploy the function, Oracle Functions uses the instructions in the custom Dockerfile to build the Docker image.

To have Oracle Functions use a custom Dockerfile when building a Docker image:

1. Make a copy of the Dockerfile you want to use as a custom Dockerfile.
2. Save the new file to the directory containing the `func.yaml` file.
3. Give the new file the name `Dockerfile`.
   
   Note that you must name the file `Dockerfile`.
4. Open the file named `Dockerfile` in an editor of your choice.

For example, the `Dockerfile` file might contain the following lines to install the Oracle Instant Client from an `oraclelinux:7-slim` base image:

```
FROM oraclelinux:7-slim

RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 & & \ 
ymvn-config-manager --disable el7_developer_EPEL & & \ 
yum -y install oracle-instantclient19.3-basiclite nodejs & & \ 
rm -rf /var/cache/yum

WORKDIR /function
ADD . /function/
RUN npm install

CMD exec node func.js
```

5. Include the following lines in the file named `Dockerfile` (as described in Permissions Granted to Containers Running Functions on page 2712):

```
groupadd --gid 1000 fn & & 
```
adduser --uid 1000 --gid fn fn

For example:

FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && \
    yum-config-manager --disable ol7_developer_EPEL && \
    yum -y install oracle-instantclient19.3-basiclite nodejs && \
    rm -rf /var/cache/yum && \
    groupadd --gid 1000 fn && \
    adduser --uid 1000 --gid fn fn

WORKDIR /function
ADD . /function/
RUN npm install

CMD exec node func.js

6. Save the file named Dockerfile. You can now use the Dockerfile file as a custom Dockerfile.
7. In the func.yaml file, change the value of the runtime: parameter to runtime: docker.

   For example, if the func.yaml file contains runtime: java, change it to runtime: docker.
8. Use the fn build or fn deploy commands to build or deploy the function.

Oracle Functions uses the instructions in the custom Dockerfile (the file named Dockerfile) to build the Docker image for the function, and push it to the Docker registry.

Creating Functions from Existing Docker Images

You can create a new function definition in the Oracle Functions server in different ways:

• Using the Console or the Fn Project CLI command fn create function to create a new function based on an existing Docker image that has already been pushed to the Docker registry (as described in this topic).
• Using the single Fn Project CLI command fn deploy to build a new Docker image, push the image to the Docker registry, and create a new function based on the image in one step (as described in Creating and Deploying Functions on page 2684).
• Using the API (see CreateFunction).

When using the Console or the fn create function command to create a new function based on an existing Docker image, you specify function metadata to store in the Oracle Functions server. For example, the maximum length of time the function is allowed to execute for.

The existing image on which you base a new function must be suitable for use with Oracle Functions. Typically, to build and push a suitable image, you or somebody else will use Fn Project CLI commands and/or Docker CLI commands. For example, having written your function code and a func.yaml file containing function metadata (perhaps based on the template helloworld function and func.yaml created using fn init), you can:

• Use fn build to build a new Docker image from the function.
• Use docker push to push the image to the Docker registry.

With the image in the Docker registry, you can then use the Console to create a function based on the image, as described in this topic.

Using the Console

To use the Console to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

The Applications page shows the applications defined in the compartment.

5. Click the name of the application in which you want to create the new function.

6. Click Create Function and specify:
   - **Name:** A name for the new function. Avoid entering confidential information.
   - **Image:** The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version.
   - **Memory:** The maximum amount of memory the function can use during execution.
   - **Timeout:** The maximum amount of time the function will be allowed to run for.
   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click Create to create the new function in the Oracle Functions server.

The new function is shown in the Console, in the list of functions in the application you selected.

### Using Fn Project CLI Commands

To use the Fn Project CLI to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new function by entering:

   ```bash
   fn create function <app-name> <function-name> <image-name>
   ```

   where:
   - `<app-name>` is the name of an existing application in which to create the new function.
   - `<function-name>` is the name of the new function you want to create. Avoid entering confidential information.
   - `<image-name>` is the name of the existing image in the Docker registry on which to base the new function.

   For example:

   ```bash
   fn create function acmeapp acme-func phx.ocir.io/ansh81vrlzp/acme-repo/acme-func:0.0.3
   ```

   A new function is created in Oracle Functions, based on the existing image and with the name you specified.

3. Verify that the new function has been created by entering:

   ```bash
   fn list functions <app-name>
   ```

   For example:

   ```bash
   $ fn list functions acme-app
   NAME       IMAGE
   acme-func  phx.ocir.io/ansh81vrlzp/acme-repo/acme-func:0.0.3
   ```
Using the API
For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage functions:

- CreateFunction
- DeleteFunction
- GetFunction
- UpdateFunction

Managing Functions
Read about how to manage functions and applications with Oracle Functions:

- Viewing Functions and Applications on page 2689
- Updating Functions on page 2691
- Deleting Applications and Functions on page 2694
- Changing Default Memory and Timeout Settings on page 2695

Viewing Functions and Applications
Having deployed functions to Oracle Functions, you'll typically want to view the functions you've deployed, along with other functions in the same application and different applications. For example, you might want to see:

- all the applications in a compartment
- details of the image for a given function

You can view applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console
To view details of applications and functions deployed to Oracle Functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
4. Select the compartment containing the applications and functions that you want to see information about.
   
   The Applications page shows all the applications in the compartment you selected.
5. Click the name of an application to see the functions within it.
   
   The Functions page shows details for all the functions within the application you selected, including:
     - the Docker image created for each function
     - when the function was last updated
6. Click the name of a function on the Functions page to see additional information about that function, including the values of timeout and memory configuration parameters.

Using Fn Project CLI Commands
To view details of applications and functions deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. If you want to see details about applications, in a terminal window:

- Enter the following command to see a simple list of applications:

  ```
  fn list apps
  ```

  For example:

  ```
  $ fn list apps
  acme-app
  ```

- Enter the following command to see more detail about a particular application:

  ```
  fn inspect app <app-name>
  ```

  For example:

  ```
  $ fn inspect app acme-app
  {
    "annotations": {
      "oracle.com/oci/appCode": "fht7ns4mn2q",
      "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq",
      "oracle.com/oci/subnetIds": [
        "ocid1.subnet.oc1.phx.aaaaaaaao..."
      ],
      "oracle.com/oci/tenantId": "ocid1.tenancy.oc1..aaaaaaaap...keq"
    },
    "created_at": "2018-07-13T17:54:34.000Z",
    "id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
    "name": "acme-app",
    "updated_at": "2018-07-13T17:54:34.000Z"
  }
  ```

3. If you want to see details about functions, in a terminal window:

- Enter the following command to see a simple list of functions in a particular application:

  ```
  fn list functions <app-name>
  ```

  For example:

  ```
  $ fn list functions acme-app
  NAME            IMAGE
  acme-func       phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3
  acme-func-dev   phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-dev:0.0.7
  acme-func-test  phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-test:0.0.6
  ```

- Enter the following command to see more detail about a particular function:

  ```
  fn inspect function <app-name> <function-name>
  ```

  For example:

  ```
  $ fn inspect function acme-app acme-func
  {
    "annotations": {
  ```
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to see details about applications and functions:

- ListApplications
- ListFunctions

Updating Functions

Having previously created a function definition in the Oracle Functions server, you can change some, but not all, of the function's properties. For example, you can change the maximum length of time a function is allowed to execute for, but you cannot change the function's name.

You can change the Docker image on which a function is based. If you do want to change the image, the replacement image must be suitable for use with Oracle Functions, and must have already been pushed to the Docker registry. With the replacement image in the Docker registry, you can then update a function's definition so that it is based on the replacement image, as described in this topic. If the replacement image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2693.

You can update functions using the Console, the Fn Project CLI, and the API.

Using the Console to update an existing function

To use the Console to update an existing function in the Oracle Functions server:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

   The Applications page shows the applications defined in the compartment.
5. Click the name of the application containing the existing function that you want to update.
6. Click the name of the function that you want to update.
7. Click **Edit** and update some or all of the following properties:
   - **Image:** The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version. If the image has the same name and tag as the image on which the function was originally based, see [Notes About Image Digests](#) on page 2693.
   - **Memory:** The maximum amount of memory the function can use during execution.
   - **Timeout:** The maximum amount of time the function will be allowed to run for.

8. Click **Save** to update the function in the Oracle Functions server.

The function's updated properties are shown in the Console.

### Using Fn Project CLI Commands

To use the Fn Project CLI to update an existing function in the Oracle Functions server:

1. Log in to your development environment as a functions developer.
2. In a terminal window, update properties of an existing function by entering:

   ```
   fn update function <app-name> <function-name> --image <image-name> --
   <property> <value>
   ```

   where:
   - `<app-name>` is the name of an existing application containing the existing function.
   - `<function-name>` is the name of the existing function you want to update.
   - `--image <image-name>` (optionally) is the name of an existing image in the Docker registry that you now want to base the function on, instead of the previously specified image. If the image has the same name and tag as the image on which the function was originally based, see [Notes About Image Digests](#) on page 2693.
   - `--<property> <value>` (optionally) is the property you want to update, and the new value you want it to have. Enter `fn update function --help` to see a list of properties and valid values.

   For example:

   ```
   fn update function acmeapp acme-func --image phx.ocir.io/ansh81vrulzp/
   acme-repo/acme-func:0.0.4 --timeout 60
   fn update function acmeapp acme-func --memory 256
   ```

   The properties of the existing function are updated with the values you specified.

3. Verify that the function has been updated by entering:

   ```
   fn inspect function <app-name> <function-name>
   ```

   For example:

   ```
   fn inspect function acme-app acme-func
   ```

   Output:

   ```
   
   "annotations": {
     "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/
   ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke",
     "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaawaaaaaaw__nyq"
   },
   "app_id": "ocid1.fnapp.oc1.phx.aaaaaaaaafaaaaaaf_____r3ca",
   ```
Functions

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the UpdateFunction API operation to update functions.

Notes About Image Digests

Images in a Docker registry are identified by repository, name, and a tag. In addition, Docker gives each version of an image a unique alphanumeric digest. When pushing an updated Docker image, it's recommended best practice to give the updated image a new tag to identify it, rather than reusing an existing tag. However, even if you push an updated image and give it the same name and tag as an earlier version, the newly pushed version will have a different digest to the earlier version.

When you create a function with Oracle Functions, you specify the name and tag of a particular version of an image on which to base the function. To avoid later inconsistencies, Oracle Functions also records the unique digest of that particular version of the image.

By default, if you push an updated version of an image to the Docker registry with the same name and tag as the original version of the image on which a function is based, Oracle Functions continues to use the original digest to pull the original version of the image. This might be the behavior you require. However, if you want Oracle Functions to pull the later version of the image, you can explicitly change the digest that Oracle Functions uses to identify which version of the image to pull in one of the following ways:

- Use the fn update function command and specify the original name and tag of the version of the image on which you want the function to be based. For example:

  `fn update function acmeapp acme-func --image phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.4 --annotation oracle.com/oci/imageDigest=""`

  Oracle Functions will update the digest recorded for the image on which the function is based to be the digest of the image in the Docker registry that has the name and tag you specify.

- Use the fn update function command and specify the digest of the version of the image on which you want the function to be based. For example:

  `fn update function acmeapp acme-func --annotation oracle.com/oci/imageDigest="sha256:8af7cb8d7______c498c0"`

  Oracle Functions will update the digest recorded for the image on which the function is based to be the digest you specify.

- Use the Console and click Edit Function on the Function Information tab, re-select the original name and tag of the version of the image on which the function is currently based, and click Save Changes. Oracle Functions will update the digest recorded for the image on which the function is based.

- Use the Oracle Cloud Infrastructure API or an Oracle Cloud Infrastructure SDK (for more information, see REST APIs on page 5528 and Software Development Kits and Command Line Interface on page 5351).
Deleting Applications and Functions

You can delete applications and functions in Oracle Functions that you or other functions developers have created, provided you have been granted the necessary permission (FN_APP_DELETE or FN_FUNCTION_DELETE as appropriate).

Note the following:

• Deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 4443).
• Deleting applications and functions is permanent. You cannot undelete an application or function that you've deleted.
• Deleting a function does not necessarily enable you to immediately delete the subnet and VCN in which the function runs. Expect to wait up to five minutes after the function was last invoked before you can delete the associated network resources.

You can delete applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

When using the Console to delete applications and functions, note that:

• when you delete an application, all of its functions are also deleted
• you're always prompted to confirm deletion because you cannot undelete an application or function later

To delete applications and functions in Oracle Functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

The Applications page shows the applications defined in the compartment.

5. To delete an application, and all of its functions:
   a. Click the name of the application you want to delete.
   b. On the Application Detail page, click Delete and confirm you want to delete the application as follows:
      • If the application does not have functions within it, click Delete to confirm that you want to delete the application.
      • If the application does have functions within it, you are shown a list of the functions in the application. To delete the application, enter DELETE <APPLICATION-NAME> in the text box, and click Delete.

   Note that deleting an application and all of its functions does not delete the Docker images on which the functions are based. To delete the images, you have to delete them explicitly (see Deleting and Undeleting an Image on page 4443).

6. To delete a function:
   a. Click the name of the application containing the function you want to delete.
   b. On the Application Detail page, click the name of the function you want to delete.
   c. On the Function Detail page, click Delete and confirm you want to delete the function.

   Note that deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 4443).

Using Fn Project CLI Commands

When using the Fn Project CLI to delete applications and functions, note that you cannot delete an application if it contains functions (you must delete the functions first).
To delete applications and functions in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. To delete an application:
   a. In a terminal window, enter:

   ```
   fn delete app <app-name>
   ```

   where `<app-name>` is the name of the application to delete.

   For example:

   ```
   fn delete app acmeapp
   ```

   b. Verify that the application has been deleted by entering:

   ```
   fn list apps
   ```

3. To delete a function:
   a. In a terminal window, enter:

   ```
   fn delete function <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function you want to delete.
   - `<function-name>` is the name of the function you want to delete.

   For example:

   ```
   fn delete function acmeapp acme-func
   ```

   b. Verify that the function has been deleted by entering:

   ```
   fn list functions <app-name>
   ```

   For example:

   ```
   fn list functions acmeapp
   ```

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to delete applications and functions:

- `DeleteApplication`
- `DeleteFunction`

Changing Default Memory and Timeout Settings

You can change several aspects of Oracle Functions default behavior using configuration parameters and environment variables.

Depending on the parameter, you can override a default value by specifying an alternative value in the following ways (note the order of precedence):

- by adding an entry to the `func.yaml` file (which overrides default values)
- by explicitly setting an environment variable (which overrides values set in the `func.yaml` file)
• by including a command option when you invoke the function using the Fn Project CLI (which overrides values set in environment variables or in the func.yaml file)

The following table indicates the parameters you can set, the default value, and where the default value can be overridden.

<table>
<thead>
<tr>
<th>Parameter Description</th>
<th>Default Value</th>
<th>Units</th>
<th>func.yaml Parameter</th>
<th>Environment Variable</th>
<th>Fn CLI option</th>
<th>Notes</th>
</tr>
</thead>
</table>
| Maximum time a function will be allowed to run | 30            | Seconds  | timeout             | n/a                   | n/a           | Maximum value: 300  
Best practice is to specify a timeout that is close to that likely to be required, rather than significantly more. |
| Maximum memory threshold for a function        | 128           | MB       | memory              | FN_MEMORY             | n/a           | One of:  
• 128  
• 256  
• 512  
• 1024  
If this limit is exceeded during execution, the function is stopped and an error message is logged. |

For more information about the above parameters, and other configuration parameters, see Func files in the Fn Project documentation.

Invoking Functions

Read about how to invoke functions with Oracle Functions:

• Invoking Functions on page 2696
• Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services on page 2700

Invoking Functions

You can invoke a function that you've deployed to Oracle Functions in different ways:

• Using the Fn Project CLI.
• Using the Oracle Cloud Infrastructure CLI.
• Using the Oracle Cloud Infrastructure SDKs.
• Making a signed HTTP request to the function's invoke endpoint. Every function has an invoke endpoint.

Each of the above invokes the function via requests to the API. Any request to the API must be authenticated by including a signature and the OCID of the compartment to which the function belongs in the request header. Such
a request is referred to as a 'signed' request. The signature includes Oracle Cloud Infrastructure credentials in an encrypted form.

If you use the Fn Project CLI or the Oracle Cloud Infrastructure CLI to invoke a function, authentication is handled for you. See Using the Fn Project CLI to Invoke Functions on page 2697 and Using the Oracle Cloud Infrastructure CLI to Invoke Functions on page 2698.

If you use an Oracle Cloud Infrastructure SDK to invoke a function, you can use the SDK to handle authentication. See Using SDKs to Invoke Functions on page 2698.

If you make a signed HTTP request to a function's invoke endpoint, you'll have to handle authentication yourself by including a signature and the OCID of the compartment to which the function belongs in the request header. You can do this in different ways:

- Using the Oracle Cloud Infrastructure CLI raw-request command. See Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command) on page 2699.
- Writing code to programmatically sign requests. For information about the required credentials and how to sign the requests, see Request Signatures on page 5546.

Tip:
If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 2751).

Using the Fn Project CLI to Invoke Functions

To invoke a function deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   fn invoke <app-name> <function-name>
   ```

   where:

   - `<app-name>` is the name of the application containing the function you want to invoke
   - `<function-name>` is the name of the function you want to invoke

   For example:

   ```
   fn invoke helloworld-app helloworld-func
   ```

   Output:

   Hello World!

   Tip:
   If you want to pass arguments and values to a function, prefix the fn invoke command with `echo -n '"<argument>"=<value>"' |`.

   If the function is expecting the argument and value as JSON, use a valid JSON format. For example:

   ```
   echo -n '"name":"John"' | fn invoke helloworld-app helloworld-func
   ```

   Output:

   Hello John!
Using the Oracle Cloud Infrastructure CLI to Invoke Functions

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the Oracle Cloud Infrastructure CLI will facilitate Oracle Cloud Infrastructure authentication. For information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 5316.

These instructions assume:

• you have already installed and configured the Oracle Cloud Infrastructure CLI
• you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function using the Oracle Cloud Infrastructure CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

```bash
oci fn function invoke <function-ocid> --file "<output-filepath>" --body "<request-parameters>"
```

where:

• `<function-ocid>` is the OCID of the function you want to invoke. To find out a function's OCID, use the `fn inspect` command to see the value of the function's `id` property (see Viewing Functions and Applications on page 2689).
• `<output-filepath>` is the path and name of a file to write the response to. To write the response to stdout, specify `--file "-"`
• `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. For example, `--body '{"name":"John"}'`. Note that you must include `--body ""` in the request, even if there are no request parameters to pass.

For example:

```bash
oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body ""
```

Output:

```
Hello World !
```

```bash
oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body '{"name":"John"}'
```

Output:

```
Hello John !
```

Using SDKs to Invoke Functions

If you're writing a program to invoke a function in a language for which an Oracle Cloud Infrastructure SDK exists, Oracle recommends you use that SDK to send API requests to invoke the function. Among other things, the SDK will facilitate Oracle Cloud Infrastructure authentication.

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the InvokeFunction API operation to invoke functions.

Obtaining a Function's Invoke Endpoint

When invoking a function using the Oracle Cloud Infrastructure CLI raw-request command, you have to specify the function's invoke endpoint.
To obtain a function's invoke endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   fn inspect function <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function for which you want to obtain the invoke endpoint
   - `<function-name>` is the name of the function for which you want to obtain the invoke endpoint

   For example:

   ```
   fn inspect function helloworld-app helloworld-func
   ```

   Output:

   ```
   {
     "annotations": {
       "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke",
       ...
     }
   }
   ```

   The function's invoke endpoint is the value of "fnproject.io/fn/invokeEndpoint". For example, "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke" (abbreviated for readability).

**Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command)**

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the CLI will facilitate Oracle Cloud Infrastructure authentication. For more information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 5316.

These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using the Oracle Cloud Infrastructure CLI `raw-request` command:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint on page 2698).

   For example, "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke" (abbreviated for readability).
3. Use the Oracle Cloud Infrastructure CLI `raw-request` command to invoke the function by sending a signed POST request to the function’s invoke endpoint by entering:

```bash
oci raw-request --http-method POST --target-uri <invoke-endpoint> --request-body "<request-parameters>"
```

where:
- `<invoke-endpoint>` is the endpoint you obtained in the earlier step.
- `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. Note that you must include `--request-body ""` in the request, even if there are no request parameters to pass.

For example:

- ```bash
  ```
  Output:
  ```
  Hello World !
  ```

- ```bash
  ```
  Output:
  ```
  Hello John !
  ```

4. If a passphrase was provided to encrypt the API signing key, enter the passphrase when prompted.

**Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services**

You can invoke functions in Oracle Functions from other Oracle Cloud Infrastructure services. Typically, you'll want an event in another service to trigger a request to invoke a function defined in Oracle Functions.

This functionality is currently available in:

- The Events service. For more information, see [Functions](#) on page 2485 in [Services that Produce Events](#) on page 2414.
- The Notifications service. For more information, see [Notifications Overview](#) on page 4248. For a scenario, see [Scenario A: Automatically Resize VMs](#) on page 4264.
- The API Gateway service. For more information, see [Adding a Function in Oracle Functions as an API Gateway Back End](#) on page 509.
- The Oracle Integration service, using the OCI Signature Version 1 security policy. For more information, see [Configure Oracle Integration to Call Oracle Cloud Infrastructure Functions with the REST Adapter](#) in Using the REST Adapter with Oracle Integration.
- The Service Connector Hub service. You can invoke a function to process data (as the task in a service connector), or to act on the processed data (as the target in a service connector). For more information, see [Service Connector Hub](#) on page 4752. For a scenario, see [Scenario: Send Log Data to an Autonomous Database](#) on page 4772.
- The Streaming service (via Service Connector Hub). You can synchronously invoke a function to consume and process data from partitions in a stream (as the task in a service connector). For more information, see [Streaming](#) on page 4858 and [Service Connector Hub](#) on page 4752.
Integrating Functions

Read about how to integrate Oracle Functions with other systems:

- Integrating Oracle Functions with Other Oracle Products on page 2701
- Accessing File Systems from Running Functions on page 2706
- Passing Custom Configuration Parameters to Functions on page 2707

Integrating Oracle Functions with Other Oracle Products

You can integrate functions you've deployed to Oracle Functions with other Oracle products, as described in the following topics:

- Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 2701
- Connecting to Oracle Autonomous Database Instances from Running Functions on page 2706

Accessing Other Oracle Cloud Infrastructure Resources from Running Functions

When a function you've deployed to Oracle Functions is running, it can access other Oracle Cloud Infrastructure resources. For example:

- You might want a function to get a list of VCNs from the Networking service.
- You might want a function to read data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.

To enable a function to access another Oracle Cloud Infrastructure resource, you have to include the function in a dynamic group, and then create a policy to grant the dynamic group access to that resource. For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups on page 3118.

Having set up the policy and the dynamic group, you can then include a call to a 'resource principal provider' in your function code. The resource principal provider uses a resource provider session token (RPST) that enables the function to authenticate itself with other Oracle Cloud Infrastructure services. The token is only valid for the resources to which the dynamic group has been granted access.

Note also that the token is cached for 15 minutes. So if you change the policy or the dynamic group, you will have to wait for 15 minutes to see the effect of your changes.

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

Using the Console

To enable a running function to access other Oracle Cloud Infrastructure resources:
1. Log in to the Console and create a new dynamic group:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Dynamic Groups**.
   b. Follow the instructions in To create a dynamic group on page 3119, and give the dynamic group a name (for example, `acme-func-dyn-grp`).
   c. When specifying a rule for the dynamic group, consider the following examples:
      - If you want all functions in a compartment to be able to access a resource, enter a rule similar to the following that adds all functions in the compartment with the specified compartment OCID to the dynamic group:
        \[
        \text{ALL } \{\text{resource.type} = 'fnfunc', \text{resource.compartment.id} = 'ocid1.compartment.oc1..aaaaaaaa23______smwa'\}
        \]
      - If you want a specific function to be able to access a resource, enter a rule similar to the following that adds the function with the specified OCID to the dynamic group:
        \[
        \text{resource.id} = 'ocid1.fnfunc.oc1.iad.aaaaaaaaacq______dnya'
        \]
      - If you want all functions with a specific defined tag to be able to access a resource, enter a rule similar to the following that adds all functions with the defined tag to the dynamic group:
        \[
        \text{ALL } \{\text{resource.type} = 'fnfunc', \text{tag.department.operations.value} = '45'\}
        \]
      Note that free-form tags are not supported. For more information about tagging, see Resource Tags on page 239.
   d. Click **Create Dynamic Group**.

   Having created a dynamic group that includes the function, you can now create a policy to give the dynamic group access to the required Oracle Cloud Infrastructure resource.

2. Create a new policy:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
   b. Follow the instructions in To create a policy on page 3147, and give the policy a name (for example, `acme-func-dyn-grp-policy`).
   c. When specifying a policy statement, consider the following examples:
      - If you want functions in the `acme-func-dyn-grp` to be able to get a list of all the VCNs in the tenancy, enter a rule similar to the following:
        \[
        \text{allow dynamic-group acme-func-dyn-grp to inspect vcns in tenancy}
        \]
      - If you want functions in the `acme-func-dyn-grp` to be able to read and write to a particular Object Storage bucket, enter a rule similar to the following:
        \[
        \text{allow dynamic-group acme-func-dyn-grp to manage objects}
        \text{in compartment acme-storage-compartment where all}
        \text{target.bucket.name='acme-functions-bucket'}
        \]
      - If you want functions in the `acme-func-dyn-grp` to be able to read and write to all resources in a compartment, enter a rule similar to the following:
        \[
        \text{allow dynamic-group acme-func-dyn-grp to manage all-resources in}
        \text{compartment acme-storage-compartment}
        \]
   d. Click **Create** to create the new policy.
3. Include a resource principal provider in the function code to enable the function to authenticate with other Oracle Cloud Infrastructure services. See:

- **Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the Networking Service** on page 2703
- **Example: Adding a Custom Resource Principal Provider to a Function** on page 2703

**Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the Networking Service**

Having added a function to a dynamic group, and created a policy that allows the dynamic group to list the VCNs in the tenancy, you could include code similar to the following example to get a list of VCNs from the Networking service. This example uses the Oracle resource principal provider to extract credentials from the RPST token.

```python
import io
import json
from fdk import response
import oci

def handler(ctx, data: io.BytesIO=None):
    signer = oci.auth.signers.get_resource_principals_signer()
    resp = do(signer)
    return response.Response(ctx,
        response_data=json.dumps(resp),
        headers={"Content-Type": "application/json"} )

def do(signer):
    # List VCNs -----------------------------------------
    client = oci.core.VirtualNetworkClient({}, signer=signer)
    try:
        vcns = client.list_vcns(signer.compartment_id)
        vcns = [[v.id, v.display_name] for v in vcns.data]
    except Exception as e:
        vcns = str(e)
    return {"vcns": vcns, }
```

**Example: Adding a Custom Resource Principal Provider to a Function**

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

The container in which a function executes includes a directory tree that holds Oracle Cloud Infrastructure compatible credentials, specifically:

- A resource principal session token (RPST) in a file named `rpst`. The RPST token is formatted as a JWT token, and includes claims that identify the function's host tenancy and compartment.
- A private key for use in making requests to Oracle Cloud Infrastructure services on behalf of the function, in a file named `private.pem`.

The following environment variables are set inside the container in which the function executes:

- **OCI_RESOURCE_PRINCIPAL_VERSION**, containing the value `2.2`.
- **OCI_RESOURCE_PRINCIPAL_RPST**, containing the absolute path to the `rpst` file (including the filename).
- **OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM**, containing the absolute path to the `private.pem` file (including the filename).
- **OCI_RESOURCE_PRINCIPAL_REGION**, containing the region identifier in which the function is deployed (for example, `us-phoenix-1`).
To enable a function to access another Oracle Cloud Infrastructure service, add code to the function so that it can authenticate itself with the other resource:

1. Add code that loads the RPST token from the path in the `OCI_RESOURCE_PRINCIPAL_RPST` environment variable.
2. Add code that loads the private key from the path in the `OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM` environment variable.
3. Add code that uses the RPST token and the private key to create an Oracle Cloud Infrastructure request signature (see Request Signatures on page 5546).
4. Add code that constructs the request to the other Oracle Cloud Infrastructure resource.

If necessary, you can identify:

- The endpoints of other Oracle Cloud Infrastructure services in the same (local) region as the function, using the region identifier in the `OCI_RESOURCE_PRINCIPAL_REGION` environment variable.
- The function's host tenancy and compartment, using the `res_tenant` and `res_compartment` claims in the RPST token.

For example, the sample Python function below includes a custom resource principal provider that extracts credentials from the RPST token. It then submits a GET request to the IAM API's `getTenancy` operation to return the OCID of the function's tenancy.

```python
#!/usr/bin/env python3
import base64
import email.utils
import hashlib
import httpsig_cffi.sign
import json
import logging
import os.path
import re
import requests.auth
import urllib.parse

LOG = logging.getLogger(__name__)

# The following class is derived from the Python section in https://docs.cloud.oracle.com/iaas/Content/API/Concepts/signingrequests.htm

class SignedRequestAuth(requests.auth.AuthBase):
    """A requests auth instance that can be reused across requests""
    generic_headers = [
        "date",
        "(request-target)",
        "host"
    ]
    body_headers = [
        "content-length",
        "content-type",
        "x-content-sha256",
    ]
    required_headers = {
        "get": generic_headers,
        "head": generic_headers,
        "delete": generic_headers,
        "put": generic_headers + body_headers,
        "post": generic_headers + body_headers,
    }
```
def __init__(self, key_id, private_key):
    # Build a httpsig_cffi.requests_auth.HTTPSignatureAuth for each
    # HTTP method's required headers
    self.signers = {}
    for method, headers in self.required_headers.items():
        signer = httpsig_cffi.sign.HeaderSigner(
            key_id=key_id, secret=private_key,

tenancies/{}/".format(region, claims['res_tenant']), auth=rp_auth)
print(response.json())

Connecting to Oracle Autonomous Database Instances from Running Functions
You can deploy a function to Oracle Functions that connects to Oracle Autonomous Database instances.

Note that an Oracle Autonomous Database instance can be protected by an access control list (ACL). If the ACL is enabled, only those IP addresses and VCNs explicitly added to the ACL are allowed to connect to the database.

If you want a function running in a private subnet to connect to an Oracle Autonomous Database instance that has ACL enabled, edit the database's access control list and add the VCN.

If you want a function running in a public subnet to connect to an Oracle Autonomous Database instance that has ACL enabled:

1. Remove the default route rule that routes all outgoing internet traffic through the VCN's internet gateway.
2. Add a NAT gateway to the VCN.
3. Configure the subnet's route table with a rule that sends all outgoing internet traffic to the NAT gateway, and configure the subnet's security lists to allow internet traffic.
4. Review the NAT gateway's properties to obtain its public IP address.
5. Edit the database's access control list and add the NAT gateway's public IP address.

For more information about Oracle Autonomous Databases and ACLs, see Access Control Lists (ACLs) for Databases on Shared Exadata Infrastructure on page 1676.

Accessing File Systems from Running Functions
A function you've deployed to Oracle Functions can access the file system of the container in which it's running as follows:

- the function can read files from all directories
- the function can write files to the /tmp directory

For example, you might want a function to download an Excel file and then read its contents. To meet this requirement, you might create a function that writes the file to the /tmp directory in the container's filesystem, and then subsequently reads the file.
When writing files to the /tmp directory, the /tmp directory is generally always writable. However, the maximum allowable size of the /tmp directory depends on the maximum memory threshold specified for the function:

<table>
<thead>
<tr>
<th>Maximum memory threshold for the function (MB)</th>
<th>Maximum allowed size of /tmp (MB)</th>
<th>Maximum allowed number of files (inodes) in /tmp</th>
</tr>
</thead>
<tbody>
<tr>
<td>128MB</td>
<td>32MB</td>
<td>1024</td>
</tr>
<tr>
<td>256MB</td>
<td>64MB</td>
<td>2048</td>
</tr>
<tr>
<td>512MB</td>
<td>128MB</td>
<td>4096</td>
</tr>
<tr>
<td>1024MB</td>
<td>256MB</td>
<td>8192</td>
</tr>
</tbody>
</table>

Note that the /tmp directory might be shared by successive invocations of the function. A file written by an earlier invocation of a function could still exist when the function is invoked a second time. It is your responsibility to delete any files to avoid unexpected behavior.

### Passing Custom Configuration Parameters to Functions

The code in functions you deploy to Oracle Functions will typically require values for different parameters. Some pre-defined parameters are available to your functions as environment variables. But you’ll often want your functions to use parameters that you’ve defined yourself. For example, you might create a function that reads from and writes to a database. The function will require a database connect string, comprising a username, password, and hostname. You’ll probably want to define username, password, and hostname as parameters that are passed to the function when it’s invoked.

To pass user-defined parameters to a function deployed in Oracle Functions, you create key-value pairs known as custom configuration parameters. You can create custom configuration parameters that are:

- application-wide, meaning they are passed to every function in an application
- function-specific, meaning they are passed to the particular function for which they are defined (function-specific parameters override application-wide parameters with the same name)

To create custom configuration parameters, you can use:

- the config: section of a function's func.yaml file, to define function-specific custom configuration parameters
- the Console and the Fn Project CLI, to define both application-wide and function-specific custom configuration parameters

Oracle Functions combines all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

### Using the Console

To specify custom configuration parameters to pass to functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that’s specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

The Applications page shows the applications defined in the compartment.
5. Click the name of the application containing functions to which you want to pass custom configuration parameters:
   • To pass one or more custom configuration parameters to every function in the application, click Configuration to see the Configuration section for the application.
   • To pass one or more custom configuration parameters to a particular function, click the function's name to see the Configuration section for the function.

6. In the Configuration section, specify details for the first custom configuration parameter:
   • Key: The name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number. For example, username
   • Value: A value for the custom configuration parameter. The value must only contain printable unicode characters. For example, jdoe

7. Click the plus button to save the new custom configuration parameter.

Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb. You cannot save the new custom configuration parameter if the size of the serially-encoded configuration object would be greater than 4Kb.

8. (Optional) Enter additional custom configuration parameters as required.

Using Fn Project CLI Commands

To specify custom configuration parameters to pass to functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer and open a terminal window.
2. To specify one or more custom configuration parameters to pass to every function in an existing application, enter:

```
fn config app <app-name> <key> <value>
```

where:
   • `<app-name>` is the name of the application containing the functions to which you want to pass the custom configuration parameter.
   • `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
   • `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```
fn config app acmeapp username jdoe
```

Note the following:
   • You can also define application-wide custom configuration parameters when you create a new application using the `fn create app` command.
   • Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.
3. To specify one or more custom configuration parameters to pass to a particular function, enter:

```bash
fn config function <app-name> <function-name> <key> <value>
```

where:
- `<app-name>` is the name of the application containing the function to which you want to pass the custom configuration parameter.
- `<function-name>` is the name of the function to which to pass the custom configuration parameter.
- `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
- `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```bash
fn config function acmeapp acme-func username jdoe
```

Note the following:
- You can also define function-specific custom configuration parameters when you create a new function using the `fn create function` command.
- Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to define custom configuration parameters:

- CreateFunction
- UpdateFunction
- CreateApplication
- UpdateApplication

**Samples, Playbooks, Architectures, and Tutorials**

Refer to other resources to learn more about using Oracle Functions:

- Sample Functions on page 2709
- Solution Playbooks on page 2710
- Reference Architectures on page 2710
- Developer Tutorials on page 2710

**Sample Functions**

When you set up your development environment for Oracle Functions, simple helloworld functions are included by default. These sample functions enable you to get up and running quickly with Oracle Functions.

In addition, a number of how-to's, patterns, use cases, and other samples are available in the Oracle Functions samples repository on GitHub. These include:

- examples of how to interact with other Oracle Cloud Infrastructure services
- examples of how to optimally connect to databases
- examples of how to use Cloud Events to trigger functions
- use cases for IT Governance, Data Processing, SaaS Application Extensions, and more
Solution Playbooks

Solution playbooks are targeted, cross-product explanations and architectures showing how to handle or implement a specific scenario on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Extend SaaS Applications with a Cloud Native Approach

The Extend SaaS Applications with a Cloud Native Approach solution playbook shows how to design a SaaS extension for Oracle Fusion Applications Cloud Service using a Cloud Native approach.

In this high-level design, Oracle Functions serves as the back-end implementation of a REST API, secured by Oracle Identity Cloud Service. Authentication is handled by Oracle Cloud Infrastructure API Gateway.

Reference Architectures

Reference architectures are architectures, configurations, and best practices for deploying on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Automate Loading Data to a Data Warehouse Using a Serverless Application

The Automate Loading Data to a Data Warehouse Using a Serverless Application reference architecture shows how to use a serverless function to automate the process of extracting data from files generated by various databases or applications and loading the data into a data warehouse for analysis.

In this architecture, the Events service is triggered when zipped CSV files are uploaded to a specific bucket in Oracle Cloud Infrastructure Object Storage. The emitted event invokes a function in Oracle Functions, which extracts the data from the uploaded files and loads the data into an Oracle Autonomous Data Warehouse instance. After the data is loaded to the data warehouse, the processed CSV files are moved to a different bucket in Object Storage.

Developer Tutorials

Developer Tutorials show you how to complete development-related tasks with step-by-step instructions. Developer Tutorials for Oracle Functions are available in the Oracle Cloud Infrastructure documentation.

Controlling Access

Read about access control with Oracle Functions:

- Controlling Access to Invoke and Manage Functions on page 2710
- Permissions Granted to Containers Running Functions on page 2712
- Oracle Functions Support for Private Network Access on page 2713

Controlling Access to Invoke and Manage Functions

When configuring a tenancy for function development, you specify the following identity policy statement (as described in Policy Statements to Give Oracle Functions Users Access to Function-Related Resources on page 2766):

Allow group <group-name> to manage functions-family in compartment <compartment-name>

This identity policy enables authenticated users in the specified group to manage (that is, create, update, and delete) functions and applications in the named compartment, and also enables those users to invoke functions in the compartment. This policy typically meets the requirements of functions developers developing and testing multiple functions in your organization.

However, this identity policy might be too permissive to meet your security requirements to control the invocation and management of functions in production environments. For example, in a production environment you might
want to prevent users from invoking functions completely, or restrict users to invoking just functions in a specific application, or to invoking just a particular function.

To control the functions that users in a group can invoke and manage, set up identity policies:

1. To control the functions that a user can invoke and manage, confirm that they are not in a group that has been given the manage functions-family permission.

2. If you want to enable users in a group to create, update, and delete applications and functions in a compartment, but to be unable to invoke functions, enter the following policy statements:

   ```
   Allow group <group-name> to manage fn-app in compartment <compartment-name>
   
   Allow group <group-name> to manage fn-function in compartment <compartment-name>
   ```

3. If you want to allow invocations of particular functions only, or invocations of functions in particular applications only, include the appropriate function and application OCIDs in suitable policy statements. For example:

   - To enable users to invoke all the functions in a specific application, enter a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id = '<application-OCID>'
     ```

   - To enable users to invoke one specific function, enter a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id = '<function-OCID>'
     ```

   - To enable users to invoke all the functions in all applications except for functions in one specific application, enter a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id ! = '<application-OCID>'
     ```

   - To enable users to invoke all the functions in a compartment except for one specific function, enter a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id ! = '<function-OCID>'
     ```

   - To enable users to invoke two specific functions, enter a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.function.id='<function-OCID>'}
     ```

   - To enable users to invoke one specific function along with all the functions in a specific application, a policy statement in the following format:
     ```
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.app.id='<application-OCID>'}
     ```
4. If you want to allow function invocation and management requests only from particular IP addresses:
   
a. Create a network source to specify the allowed IP addresses, if a suitable network source doesn't exist already (see Managing Network Sources on page 3123).

b. Add a policy statement to enable only those IP addresses in the network source to invoke or manage functions. For example:

   • To only allow function invocation requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
     
     Allow group <group-name> to use fn-invocation in compartment <compartment-name> where request.networkSource.name='corpnet'

   • To only allow function management requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
     
     Allow group <group-name> to manage functions-family in compartment <compartment-name> where request.networkSource.name='corpnet'

Permissions Granted to Containers Running Functions

When a function you've deployed to Oracle Functions is invoked, it runs inside a container. The operations that a container can perform are determined by the user ID (UID) and group ID (GID) specified when the container is started. If a UID or GID is not specified, the container runs processes as the root user, with all the default capabilities enabled.

When starting a container to run a function, Oracle Functions always specifies a user named 'fn' with a UID of 1000, and a group name 'fn' with a GID of 1000. No privileges are granted to UID 1000 and GID 1000, so the container (and the function running inside it) does not acquire the default capabilities listed in the Docker documentation. In addition, the container is prevented from gaining privileges.

As a result, do not create and deploy functions that:

• depend on capabilities that are unavailable
• depend on privilege elevation (for example, su, sudo or setuid)

If you are using your own Dockerfile, include the following lines:

```bash
  groupadd --gid 1000 fn && 
  adduser --uid 1000 --gid fn fn
```

For example:

```bash
FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && 
    yum-config-manager --disable ol7_developer_EPEL && 
    yum -y install oracle-instantclient19.3-basiclite nodejs && 
    rm -rf /var/cache/yum && 
    groupadd --gid 1000 fn && 
    adduser --uid 1000 --gid fn fn
WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js
```
Note that if you do not include the `groupadd` and `adduser` lines in the above example Dockerfile, you will see the following error message:

```
 cx_Oracle.DatabaseError: ORA-12560: TNS:protocol adapter error
```

**Oracle Functions Support for Private Network Access**

Oracle Functions supports private communication between a function in a VCN and other Oracle Cloud Infrastructure resources and supported services in the Oracle Services Network without the traffic going over the internet. You can:

- enable a function in the VCN to access other resources and services
- enable other resources and services to invoke functions in the VCN

To provide such private access:

- create and deploy functions in private subnets
- add a service gateway to the VCN

For more information, see Access to Oracle Services: Service Gateway on page 4127.

**Functions and Fn Project**

Read about how to use Oracle Functions together with Fn Project:

- Using the Fn Project CLI with Oracle Functions on page 2713
- Upgrading the Fn Project CLI on page 2714
- Differences between Oracle Functions and Fn Project on page 2716

**Using the Fn Project CLI with Oracle Functions**

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions.

To enable you to use the Fn Project CLI with Oracle Functions, you perform a number of preparatory tasks. See Functions QuickStart Guides on page 2663 and Client Environment Configuration Notes for Oracle Functions on page 2768.

Most Fn Project CLI commands have a similar syntax:

```
 fn [global options] <command> [command options] [subcommands] [arguments]
```

For example, to:

- list all the available applications, use the command:

  ```
  fn list apps
  ```

- create an application, use a command like:

  ```
  fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaaacnh..."]'
  ```

- invoke a function, use a command like:

  ```
  fn invoke helloworld-app helloworld-func
  ```

- change the profile that the Fn Project CLI uses for its context, use a command like:

  ```
  fn update context oracle.profile john-oci-profile
  ```

To see a complete list of Fn Project CLI commands, you can:
• Log in to your development environment as a functions developer and enter `fn --help` or `fn -h` in a terminal window.

• In a web browser, go to the Fn Project CLI documentation.

To see detailed information about individual Fn Project CLI commands, you can:

• Log in to your development environment as a functions developer and enter `fn <command> [subcommand] --help` or `fn <command> [subcommand] -h` in a terminal window. For example:

  fn create --help
  fn update app -h

• In a web browser, go to the Fn Project CLI documentation and select the command from the list.

From time to time, new versions of the Fn Project CLI are released. See Upgrading the Fn Project CLI on page 2714.

**Upgrading the Fn Project CLI**

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions. For more information about the Fn Project CLI, see Using the Fn Project CLI with Oracle Functions on page 2713.

From time to time, new versions of the Fn Project CLI are released. To:

• See which version of the Fn Project CLI is currently installed and whether it is the most recent version, log in to your development environment as a functions developer and enter `fn version` in a terminal window. The Fn Project CLI version number is displayed. If a more recent version of the Fn Project CLI is available, the number of the latest available version is also displayed.

• Upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI. See Functions QuickStart Guides on page 2663 and Installing the Fn Project CLI on page 2770.

**Advance Notice of Mandatory Requirement to Upgrade the Fn Project CLI, April 2021**

If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you must upgrade the Fn Project CLI on or before 1st May, 2021. After this date, the initialize, build, and deploy commands might start failing with errors.

By 1st May, 2021:

• The Fn Project Java FDK libraries will no longer be available from the current Jfrog Bintray repository. The Fn Project Java FDK libraries are moving to the new Maven Central repository.
• New versions of the Fn Project Python FDK libraries will have been released.

Both of these changes require you to upgrade the Fn Project CLI to version 0.6.6 (or later).

**Steps to upgrade to Fn Project CLI version 0.6.6 (or later)**

1. In a terminal window in your development environment, confirm that the Fn Project CLI has been installed by entering:

```
fn --version
```

If the version shown is not version 0.6.6 (or later), complete the following steps to upgrade the Fn Project CLI.
2. Upgrade to the latest version of the Fn Project CLI in one of the following ways:
   - In a Linux or MacOS environment, enter:
     
     ```
     curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
     ```
     
     If prompted for a password, enter the superuser's password.
   - In a MacOS environment using Homebrew, enter:
     
     ```
     brew update && brew install fn
     ```
     
     For more detailed instructions, see the README.md file in the fnproject/cli repository on GitHub.
   - In all environments, download and install the latest binary from the Releases page.

3. In a terminal window, confirm that Fn Project CLI version 0.6.6 (or later) has been installed by entering:

   ```
   fn --version
   ```

**General FAQs**

**How does this affect me?**

If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you must upgrade the Fn Project CLI on or before 1st May, 2021. After this date, the initialize, build, and deploy commands might start failing with errors.

**Are there any required actions I need to take?**

Yes. Oracle has released a new version of the Fn Project CLI. Follow the steps to upgrade the Fn Project CLI promptly. See Steps to upgrade to Fn Project CLI version 0.6.6 (or later) on page 2714.

**What if I don't upgrade by 1st May, 2021?**

If you do not upgrade the Fn Project CLI by 1st May, 2021, the initialize, build, and deploy commands might start failing with errors. You can fix the errors by upgrading the Fn Project CLI. However, we strongly recommend you upgrade the Fn Project CLI before 1st May, 2021 to avoid any disruption.

**Can I do anything to work around or avoid this change?**

No. Upgrading the Fn Project CLI promptly is the recommended solution.

**I am using the Fn Project CLI pre-installed with Cloud Shell. Do I need to upgrade the Fn Project CLI myself?**

No. If you are using the Fn Project CLI bundled in Cloud Shell, Oracle will automatically upgrade the Fn Project CLI for you before 1st May, 2021.

**I am using the Fn Project CLI pre-installed with Visual Builder Studio (previously Developer Cloud). Do I need to upgrade the Fn Project CLI myself?**

No. If you are using the Fn Project CLI bundled with Visual Builder Studio (previously Developer Cloud), Oracle will automatically upgrade the Fn Project CLI for you before 1st May, 2021.

**Will the functions that I have already deployed stop working after 1st May, 2021?**

No. Any functions you have already deployed will continue to work. However, if you need to change the functions and redeploy them, you have to use the latest Fn Project CLI.
Java Function FAQs

I have functions written in Java. What changes, if any, do I need to make?

If you have existing Java functions, you have to:

- Upgrade the Fn Project CLI to version 0.6.6 (or later). See Steps to upgrade to Fn Project CLI version 0.6.6 (or later) on page 2714.
- Remove the definition of the `fn-release-repo` Jfrog Bintray repository from each function's pom.xml file. In the example below, remove everything between the `<repositories>` and `</repositories>` tags, including the tags themselves:

```xml
<repositories>
  <repository>
    <id>fn-release-repo</id>
    <url>https://dl.bintray.com/fnproject/fnproject</url>
    <releases>
      <enabled>true</enabled>
    </releases>
    <snapshots>
      <enabled>false</enabled>
    </snapshots>
  </repository>
</repositories>
```

By upgrading the Fn Project CLI and removing the definition of the `fn-release-repo` Jfrog Bintray repository, you ensure that subsequent build and deploy operations use the Maven Central repository instead of the Jfrog Bintray repository.

Python Function FAQs

When I run `fn init --help` using the new CLI, I don't see Python 3.7.1 and Python 3.8.5 anymore. Why not?

Python 3.7.1 has been replaced by Python 3.7, and Python 3.8.5 has been replaced by Python 3.8. This change ensures you get the latest patch version each time you build a function image using the `fn build` or `fn deploy` commands.

I have functions written in Python 3.7.1 or Python 3.8.5. What changes should I make to use the latest Python 3.7 or Python 3.8 patch versions?

Make the following change in each function's `func.yaml` file and redeploy the function:

- replace `runtime: python3.7.1` with `runtime: python3.7`
- replace `runtime: python3.8.5` with `runtime: python3.8`

Other Language FAQs

My functions use Node.js, Golang, Ruby, or my own Dockefile. I do not use Java or Python. Do I need to upgrade the Fn Project CLI?

Yes. We strongly recommend you upgrade the Fn Project CLI before 1st May, 2021.

Differences between Oracle Functions and Fn Project

In general, Oracle Functions and Fn Project are very similar. However there are some differences, as detailed below.

Differences in Authentication When Making API Calls

When you use the Oracle Cloud Infrastructure API with Oracle Functions, in the request header you have to provide:

- the OCID of the compartment to which the function belongs
• Oracle Cloud Infrastructure authentication details

**Differences When Invoking Functions**

To invoke a function deployed to Oracle Functions, you have to explicitly specify an Oracle Cloud Infrastructure endpoint (unless you're using the Fn Project CLI).

For example, https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke.

You can obtain the appropriate endpoint by making a call to the API, either directly or by using the Fn Project CLI command:

```
fn inspect function <app-name> <function-name>
```

**Additional Context Configuration Parameters in Oracle Functions**

As well as supporting Fn Project context configuration parameters, Oracle Functions also has some additional parameters, as shown in the following table.

<table>
<thead>
<tr>
<th>Additional Parameter</th>
<th>Set in</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>provider</strong></td>
<td>A context configuration .yaml file in ~/.fn/contexts</td>
<td>oracle</td>
<td>Enables Oracle Functions rather than Fn Project functionality. When provider is set to oracle, the following parameters are valid:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• oracle.compartment-id</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• oracle.profile</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>See Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770.</td>
</tr>
<tr>
<td><strong>oracle.compartment-id</strong></td>
<td>A context configuration .yaml file in ~/.fn/contexts</td>
<td>&lt;compartment - ocid&gt;</td>
<td>Specifies the OCID of the Oracle Cloud Infrastructure compartment that owns function-related resources.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>See Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770.</td>
</tr>
<tr>
<td><strong>oracle.profile</strong></td>
<td>A context configuration .yaml file in ~/.fn/contexts</td>
<td>&lt;profile-name&gt;</td>
<td>Specifies which profile to use from the ~/.oci/config file. If not set, the profile named default is used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>See Setting the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2772</td>
</tr>
</tbody>
</table>
**Use of Annotations**

When you're creating and viewing Oracle Functions resources using the Fn Project CLI, annotations enable you to identify and specify associated Oracle Cloud Infrastructure resources.

For example:

- When you're using the Fn Project CLI to create a new application, you use the `--annotation` parameter to specify the OCID of the subnet in which to run the function.
- When you're using the Fn Project CLI to view the properties of a function, the `annotations` element shows the OCID of the compartment that owns the function.

Note that unlike other configuration parameters and environment variables, annotation values cannot be passed as arguments to running Docker containers.

**Function Runtimes**

Read about managing Function Development Kits (FDKs) and supported language versions:

- [Function Development Kits (FDKs)](page 2718)
- [Languages Supported by Oracle Functions](page 2724)

**Function Development Kits (FDKs)**

Oracle Functions uses Fn Project Function Development Kits (FDKs) to support popular languages - Java, Node.js, Python, Go, and Ruby. An FDK is a set of helper libraries that handle system internals (such as protocols, parsing input and output, and logic for function containers). Each language FDK consists of three components:

- A build-time base image, containing language-specific libraries and tools to build executable functions.
- A runtime base image, to provide a language-specific runtime environment in which to run executable functions.
- An FDK library (in the case of Java, the FDK library is included in the build-time and runtime base images).

FDKs are specific to particular versions of a given language. Oracle regularly publishes new FDK build-time and runtime base images for supported languages (for example, to issue a patch, or to support a newly released version of the language). In the case of Java, an FDK update always includes all three components (the build-time and runtime base images, as well as the FDK library). In the case of other languages, an FDK update might include one or more of the components.

When you first create a function using the Fn Project CLI `fn init` command, you specify the language in which the function's source code is written using the `--runtime` command option. As well as specifying a language, you can optionally specify a version of the language. If you don't specify the language version, the Fn Project CLI assumes you want to use the most recent version of the language FDK that's available. The Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`. The Fn Project CLI also adds values for the `build_image:` and `run_image:` parameters in the `func.yaml` file according to the `--runtime` command option you specify, as follows:

- If you specify simply a language as the value of the `--runtime` command option, the Fn Project CLI adds the most recent versions of that language's FDK build-time and runtime base images as values for the `build_image:` and `run_image:` parameters. For example, if you enter `fn init --runtime python helloworld-func` and Python 3.8 is the most recent version available, the Fn Project CLI adds the following:

  ```yaml
  runtime: python
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- If you specify both a language and a version as the value of the `--runtime` command option, the Fn Project CLI adds the corresponding version of the language's FDK build-time and runtime base images as values for the `build_image:` and `run_image:` parameters. For example, if you enter `fn init --runtime python3.7 helloworld-func`, the Fn Project CLI adds the following:

  ```yaml
  runtime: python3.7
  build_image: fnproject/python:3.7-dev
  ```
When you build a function using `fn build` or `fn deploy`, the Fn Project CLI creates a Docker image (and in the case of `fn deploy`, pushes the image to a Docker registry). The Docker image contains the function’s runtime dependencies. If the function is written in a language for which an FDK is available, the Fn Project CLI:

- Uses the build-time base image specified by the `build_image:` parameter to build an executable version of the function, and includes the executable function in the Docker image.
- Includes the runtime base image specified by the `run_image:` parameter in the Docker image, to provide the runtime environment in which to run the executable function.

The Fn Project CLI uses cached versions of the FDK’s build-time and runtime base images, if these are available. If cached versions of the base images are not available, the Fn Project CLI pulls the language FDK’s build-time and runtime base images from Docker Hub.

Note that if a new version of a language FDK is released, the values for the `build_image:` and `run_image:` parameters in an existing function’s `func.yaml` file are not automatically updated. The initial versions of the language FDK’s build-time and runtime base images that were previously specified as values for the `build_image:` and `run_image:` parameters when the function was created are still used to build the function executable, and to provide the runtime environment. Using the initial values of the `build_image:` and `run_image:` parameters helps to ensure the function code remains compatible with the language FDK’s build-time and runtime base images.

If you want to re-build an existing function with a different language version, and include a different runtime in the function’s Docker image, change the values of the `build_image:` and `run_image:` parameters in the function’s `func.yaml` file to reference a different version of the language FDK. For consistency and to avoid confusion, update the value of the `runtime:` parameter to correspond to the `--runtime` command option for the version of the language FDK. In the case of Java functions, you also have to change the FDK version in the function’s `pom.xml` file.

**Examples**

The examples in this section assume you are using Fn Project CLI version 0.6.7 (and later), and that Python 3.8 is the most recent version of Python supported by the Python FDK.

**Example 1: Create a new function with Python 3.8 using Fn Project CLI version 0.6.7 (or later)**

If you want to create a new function with Python 3.8, run either of the following commands:

```bash
fn init --runtime python helloworld-func
fn init --runtime python3.8 helloworld-func
```

In the case of `fn init --runtime python helloworld-func`, the Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function’s `func.yaml`, and adds the most recent version numbers of the Python FDK’s build-time and runtime base images as values for the `build_image:` and `run_image:` parameters:

```yaml
runtime: python
build_image: fnproject/python:3.8-dev
run_image: fnproject/python:3.8
```

In the case of `fn init --runtime python3.8 helloworld-func`, the Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function’s `func.yaml`, and adds the Python 3.8 FDK’s build-time and runtime base images as values for the `build_image:` and `run_image:` parameters:

```yaml
runtime: python3.8
build_image: fnproject/python:3.8-dev
run_image: fnproject/python:3.8
```
From now on, when you build the function, the Fn Project CLI continues to use those initial versions of the build-time and runtime base images to build the function executable, and to provide the runtime environment.

**Example 2: Create a new function with Python 3.7 using Fn Project CLI version 0.6.7 (or later)**

If you want to create a new function with Python 3.7, run the following command:

```bashn init --runtime python3.7 helloworld-func
```

The Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`, and adds the version of the Python FDK's build-time and runtime base images that are appropriate for Python 3.7 as values for the `build_image:` and `run_image:` parameters, as shown:

```yaml
runtime: python3.7
build_image: fnproject/python:3.7-dev
run_image: fnproject/python:3.7
```

From now on, when you build the function, the Fn Project CLI continues to use those initial Python 3.7 versions of the build-time and runtime base images to build the function executable, and to provide the runtime environment.

**Example 3: Rebuild an existing function with Python 3.6 using Fn Project CLI version 0.6.7 (or later)**

If you want to rebuild an existing function that was initially built with Python 3.6 (using Fn Project CLI version 0.6.7), and you want to continue to build it with Python 3.6, run the following command:

```bashn build helloworld-func
```

The `build_image:` and `run_image:` parameters in the `func.yaml` file were originally set to versions of the Python FDK's build-time and runtime base images appropriate for Python 3.6. When you build the function, the Fn Project CLI continues to use the same Python 3.6 build-time and runtime base images to build the function executable, and to provide the runtime environment.

**Example 4: Rebuild an existing Python 3.6 function with Python 3.8 using Fn Project CLI version 0.6.7 (or later)**

If you want to rebuild an existing function that was initially built with Python 3.6 (using Fn Project CLI version 0.6.7), and you now want to build it with Python 3.8:

- Change the values of the `build_image:` and `run_image:` parameters in the function's `func.yaml` to reference the latest FDK version for Python 3.8 (see [How to find out the latest FDK build-time and runtime base image versions for a particular supported language version](#) on page 2722):

  ```yaml
  runtime: python3.6
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- For consistency and to avoid confusion, update the value of the `runtime:` parameter to correspond to the `--runtime` command option for Python 3.8.

  ```yaml
  runtime: python3.8
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- Run the following command:

  ```bash
  fn build helloworld-func
  ```

The Fn Project CLI uses the versions of the Python FDK's build-time and runtime base images specified by the `build_image:` and `run_image:` parameters in the `func.yaml` file to build the function executable, and to provide
the runtime environment. From now on, when you build the function, the Fn Project CLI uses those versions of the build-time and runtime base images.

**Behavior in Earlier Versions of the Fn Project CLI (prior to version 0.6.7)**

Using versions of the Fn Project CLI prior to version 0.6.7, every time you built or rebuilt a function written in a language supported by an FDK (with the exception of Java, see below), the Fn Project CLI used cached versions of the language FDK's build-time and runtime base images, if these were available. If cached versions of the base images were not available, the Fn Project CLI pulled the most recent versions of the base images from Docker Hub. As a result, you could not be certain that the function code was compatible with the language FDK's build-time base image used to build the function executable, or with the runtime base image used to provide the runtime environment.

You can continue to build existing functions exactly as before, by not explicitly specifying the version of the language FDK when you build a function. The Fn Project CLI will continue to use cached versions of the FDK's build-time and runtime base images (if available), or pull the most recent versions of the base images from Docker Hub (if cached images are not available).

Starting with Fn Project CLI version 0.6.7:

- If you explicitly specify the version of the language FDK when you create a function, the Fn Project CLI adds that version as the value of the `build_image:` and `run_image:` parameters in the function's `func.yaml` file.
- If you build or deploy a function and the function's `func.yaml` file does not already contain `build_image:` and `run_image:` parameters because it was created with an earlier Fn Project CLI version, the Fn Project CLI adds the parameters to the `func.yaml` file. The values of the `build_image:` and `run_image:` parameters record the versions of the FDK build-time and runtime base images that the Fn Project CLI is currently using. Unless you explicitly specify a different version when you re-build the function later, the Fn Project CLI continues to use the FDK version specified by the `build_image:` and `run_image:` parameters.

Note that in the case of Java functions, previous versions of the Fn Project CLI did add the `runtime:`, `build_image:`, and `run_image:` parameters to `func.yaml` files, to help ensure the function code remained compatible with the Java FDK's build-time and runtime base images.

If you want to re-build an existing function with a different language version, and include a different runtime in the function's Docker image, change the values of the `build_image:` and `run_image:` parameters in the function's `func.yaml` file to reference a different version of the language FDK. For consistency and to avoid confusion, update the value of the `runtime:` parameter to correspond to the `--runtime` command option for the version of the language FDK. In the case of Java functions, you also have to change the FDK version in the function's `pom.xml` file.

**How to find out the language versions supported by FDKs**

To find out the versions of languages supported by FDKs (Java, Node.js, Python, Go, and Ruby):

1. If it hasn't already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 2714.
2. In a terminal window, enter:

   ```bash
   fn init --help | grep runtime
   ```

   For example:

   ```bash
   fn init --help | grep runtime
   --runtime value Choose an existing runtime - go, go1.15, java, javav11, java8, kotlin, node, node11, node14, python, python3.6, python3.7, python3.8, ruby, ruby2.7
   ```

   In the above example, you can see that different FDKs support two versions of Java, three versions of Python, and one version each of Node.js, Go, and Ruby. For more details about the supported versions, see Languages Supported by Oracle Functions on page 2724.
Functions

**How to find out the version of the FDK build-time and runtime base images used for an existing function**

To find out the version of the FDK build-time and runtime base images that the Fn Project CLI is currently using to build the function executable, and to provide the runtime environment:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 2714.
2. In a terminal window, change to the directory containing the function code.
3. Use the `fn build` or `fn deploy` commands to build or deploy the function.

   The `build_image:` and `run_image:` parameters are added to the function’s `func.yaml` file, if they aren’t already present. The parameter values show the version of the FDK build-time and runtime base images that the Fn Project CLI is currently using to build the function executable, and to provide the runtime environment.

**How to find out the default FDK build-time and runtime base image versions for a given language**

To find out the default FDK build-time and runtime base image versions that the Fn Project CLI is currently using to build function executables, and to provide the runtime environment, for functions written in a given language:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 2714.
2. In a terminal window, create a new helloworld function by entering:

   ```bash
   fn init --runtime <language> hello-func
   ```

   where `<language>` is the particular language you’re interested in (one of `java`, `python`, `node`, `ruby`, or `go`). For example:

   ```bash
   fn init --runtime java hello-func
   ```

3. Change to the `/hello-func` directory created for the new function, and open the `func.yaml` file in a text editor.

   The default FDK build-time and runtime base image versions for the language you specified are shown as values of the `build_image:` and `run_image:` parameters.

**How to find out the latest FDK build-time and runtime base image versions for a particular supported language version**

To find out the latest FDK build-time and runtime base image versions that the Fn Project CLI is currently using to build executables, and to provide the runtime environment, for functions in a particular version of a given language:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 2714.
2. To see the supported language versions available, run:

   ```bash
   fn init --help | grep runtime
   ```

   For example:

   ```bash
   fn init --help | grep runtime
   ```

   ```bash
   --runtime value Choose an existing runtime - go, go1.15, java, java11, java8, kotlin, node, node11, node14, python, python3.6, python3.7, python3.8, ruby, ruby2.7
   ```

   Note the valid values of the `--runtime` command option for the particular language you’re interested in, which include the numbers of supported versions. For example, `java11`, `java8`, `python3.8`, `python3.7`, `python3.6`, `node14`, `node11`, `ruby2.7`, `go1.15`. 

Oracle Cloud Infrastructure User Guide 2722
3. In a terminal window, create a new helloworld function by entering:

```
fn init --runtime <language-version> hello-func
```

where `<language-version>` is the particular language and version you're interested in.

For example:

```
fn init --runtime java8 hello-func
```

4. Change to the `/hello-func` directory created for the new function, and open the `func.yaml` file in a text editor.

The latest supported FDK build-time and runtime base image versions for the language version you specified are shown as values of the `build_image:` and `run_image:` parameters.

**How to upgrade an existing function to use the latest FDK build-time and runtime base image version for a supported language**

To upgrade an existing function so that the Fn Project CLI uses the latest FDK build-time and runtime base image versions for a supported language to build the function executable, and to provide the runtime environment:

1. If it hasn't already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 2714.

2. In a terminal window, change to the directory containing the function code and open the `func.yaml` file in a text editor.

   The `build_image:` and `run_image:` parameters show the FDK build-time and runtime base image versions currently being used by the Fn Project CLI to build the function executable, and to provide the runtime environment. For example:

   ```
   build_image: fnproject/fn-java-fdk-build:jdk11-1.0.105
   run_image: fnproject/fn-java-fdk:jre11-1.0.105
   ```

   If the `build_image:` and `run_image:` parameters are not present in the `func.yaml` file, use the `fn build` or `fn deploy` commands to build the function. Doing so will add the `build_image:` and `run_image:` parameters to the `func.yaml` file, set to the FDK build image and runtime image versions currently being used by the Fn Project CLI.

3. Find out the FDK build-time image and runtime base image versions for the version of the language you want the Fn Project CLI to use (see How to find out the latest FDK build-time and runtime base image versions for a particular supported language version on page 2722).

4. Open the `func.yaml` file in a text editor (if it's not already open), and update it as follows:

   a. Change the values of the `build_image:` and `run_image:` parameters to the FDK build-time and runtime base image versions you identified in the previous step.

      For example, you might change:

      ```
      build_image: fnproject/fn-java-fdk-build:jdk11-1.0.105
      run_image: fnproject/fn-java-fdk:jre11-1.0.105
      ```

      to

      ```
      build_image: fnproject/fn-java-fdk-build:jdk11-1.0.130
      run_image: fnproject/fn-java-fdk:jre11-1.0.130
      ```

   b. For consistency and to avoid confusion, change the value of the `runtime:` parameter to correspond to the `--runtime` command option for the version of the language. For example:
5. For Java functions only, open the pom.xml file in a text editor and update the `<fdk.version>` element to correspond to the version specified in the func.yaml.
   
   For example, you might change `<fdk.version>1.0.105</fdk.version>` to `<fdk.version>1.0.130</fdk.version>`.

6. Deploy the function again and test it to confirm that the function code is compatible with the new FDK build-time and runtime base image versions that the Fn Project CLI is now using to build the function executable, and to provide the runtime environment.

Languages Supported by Oracle Functions

Function Development Kits (FDKs) are specific to particular versions of a given language. FDK updates are regularly published for supported languages (for example, to issue a patch, or to support a newly released version of the language).

Existing functions built using old FDK base images will continue to work. However, Oracle recommends you upgrade functions to a supported language version wherever possible.

The following table shows:

- **FDK Language**: The languages for which FDKs are currently available.
- **Default**: The default language version for an FDK (usually the latest language version).
- **Supported**: The language versions for which FDK updates are regularly published.
- **Deprecated**: Language versions for which FDK updates are no longer published.

<table>

Observing Functions

Read about how to view function logs and use function tracing with Oracle Functions:

- Storing and Viewing Function Logs on page 2724
- Distributed Tracing for Functions on page 2727
- Function Metrics on page 2747

Storing and Viewing Function Logs

When a function is invoked, you'll typically want to access the function's logs for troubleshooting. The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs. See Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging on page 2725. For more information about the contents of function logs, see Details for Functions on page 3388.

Alternatively, there might be occasions when you want to send function logs to an external logging destination like Papertrail. To send logs to an external logging destination instead of the Oracle Cloud Infrastructure Logging service, you use the Fn Project CLI to specify a syslog URL. See Using Fn Project CLI Commands to Specify a syslog URL on page 2725.

Note that to store and view logs for a function, the function must include print statements. For example:

- For node.js: `console.log('Entering Hello Node.js function');`
- For java: `System.err.println("Entering Java Hello World Function");`
- For go: `fmt.Println("Entering Hello Go function")`
Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging

To enable and view function logs in the Oracle Cloud Infrastructure Logging service:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region and compartment containing the application with functions for which you want to create, enable, and view logs.

   The Applications page shows all the applications in the compartment you selected.
4. Select the application with functions for which you want to create, enable, and view logs.
5. To create and enable a new function log in the Oracle Cloud Infrastructure Logging service:
   a. Under Resources, click Logs, click the Actions icon (three dots), and then click Enable Log and specify:
      • Compartment: The compartment in which to create the new log. By default, the current compartment.
      • Log Group: The log group in which to create the new log. Select an existing log group, or select:
         • Auto-create a default log group to create a default log group with a default name (DEFAULT_GROUP), if one doesn't exist already.
         • Create a new log group to create a new log group with a name and description that you provide.
      • Log Name: The name of the new log. By default, <application-name>_invoke.
      • Log Retention: The length of time to retain log data.
   b. Click Enable Log to create the new log (and the new log group, if you specified one).

   For more information, see Enabling Logging for a Resource on page 3363.
6. To enable an existing function log, under Resources, click Logs, click the Actions icon (three dots), and then click Enable Log.
7. To view the data in an existing function log, under Resources, click Logs, and then click the name of the log you want to view in the Log Name column.

   The log opens in the log group's Log Details page, enabling you to sort and filter log data by time.

Using Fn Project CLI Commands to Specify a syslog URL

The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs.

Alternatively, you can send function logs to an external logging destination like Papertrail instead by using the Fn Project CLI to specify a syslog URL. Note that to use an external logging destination, you must have set up a VCN with public subnets and an internet gateway (see Creating the VCN and Subnets to Use with Oracle Functions, if they don't exist already on page 2765).

To send function logs to an external logging destination by setting the syslog URL:

1. Log in to your development environment as a functions developer.
2. To create a new application and specify that all functions in the application send their logs to an external logging destination, enter:

   ```
   fn create app <app-name> --syslog-url <logging-service-url> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:
   • <app-name> is the name of the new application. Avoid entering confidential information.
   • <logging-service-url> is the syslog URL to which to send logs.
   • <subnet-ocid> is the OCID of the public subnet (or subnets, up to a maximum of six) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets (enclose each OCID in double quotes separated by commas, in the format ' ["<subnet-ocid>", "<subnet-ocid>" ] '). Oracle recommends that the public subnets
are in the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

For example:

```bash
fn create app acmeapp --syslog-url tcp://my.papertrail.com:4242 --
annotation oracle.com/oci/
subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
```

Note that if you subsequently set up Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.

3. To update an existing application and specify that all functions in the application send their logs to an external logging destination, enter:

```bash
fn update app <app-name> --syslog-url <logging-service-url>
```

where:

- `<app-name>` is the name of the application to update
- `<logging-service-url>` is the syslog URL to which to send logs

For example:

```bash
fn update app acmeapp --syslog-url tcp://my.papertrail.com:4242
```

4. To update an existing application and remove the external logging destination specified for the syslog URL, enter:

```bash
fn update app <app-name> --syslog-url ''
```

where:

- `<app-name>` is the name of the application to update

For example:

```bash
fn update app acmeapp --syslog-url ''
```

**Previously Supported Logging Options**

In earlier Oracle Functions releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could specify where Oracle Functions stores a function's logs by setting up a 'logging policy' for the application containing the function. Previously, you could use the Console to set up a logging policy to:

- Store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage by selecting the **OCI Logging** option.

To view function logs in a storage bucket, the group to which you belong must have been granted access with the following identity policy statements:

- Allow group `<group-name>` to manage object-family in compartment `<compartment-name>`
- Allow group `<group-name>` to read objectstorage-namespaces in compartment `<compartment-name>` (Usually created when configuring your tenancy for function development. See Policy Statements to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories on page 2766.)

- Store logs by sending them to an external logging destination like Papertrail by selecting the **Syslog URL** option.

For an existing application where you have previously already set up a logging policy, the above functionality is still supported and the existing logging policy is applied. However, note the following:

- You cannot use the Console to set up a new logging policy or edit an existing logging policy.
If the existing logging policy specified storing function logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage:

- The ability to store logs in Object Storage will be deprecated in a future release.
- Oracle recommends you switch to storing logs using Oracle Cloud Infrastructure Logging.
- If you do switch to using Oracle Cloud Infrastructure Logging to store logs, you cannot revert to storing the logs in Object Storage.
- Logs stored in Object Storage will continue to exist (with each log name including the OCID of the associated function, as before).

If the existing logging policy specified a syslog URL:

- If you switch to using Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.
- If you want to change the syslog URL in the existing logging policy, you have to use the Fn Project CLI to change it.

### Distributed Tracing for Functions

When a function is invoked but doesn't run or perform as expected, you need to investigate the issue at a detailed level. The distributed tracing feature observes the function's execution as it moves through the different components of the system. You can trace and instrument standalone functions to debug execution and performance issues. You can also use function tracing to debug issues with complete serverless applications comprising multiple functions and services, such as:

- a function calling another function
- a function calling other services such as the Object Storage service
- a function that serves as a backend for an API gateway deployed in the API Gateway service
- a function triggered in response to an event by the Events service, Notifications service, or Service Connector Hub

The Oracle Functions tracing capabilities are provided by the Oracle Cloud Infrastructure Application Performance Monitoring service. Features in Application Performance Monitoring (APM) enable you to identify and troubleshoot failures and latency issues in the functions you create and deploy.

In the Application Performance Monitoring service:

- An APM domain contains the systems monitored by Application Performance Monitoring. An APM domain is an instance of a collector of trace and span data which stores, aggregates, displays, and visualizes the data.
- A trace is the complete flow of a request as it passes through all the components of a distributed system in a given time period. It consists of an entire tree of spans all related to the same single overall request flow.
- A span is an operation or a logical unit of work with a name, start time, and duration, within a trace. A span is a time segment associated with the duration of a unit of work within the overall request flow.

The Application Performance Monitoring Trace Explorer enables you to visualize the entire request flow and explore trace and span details for diagnostics. You can view and monitor slow traces and traces with errors. To isolate and identify trace issues, you can drill down into specific spans, such as page loads, AJAX calls, and service requests. For more information about the Application Performance Monitoring service, see Application Performance Monitoring.

To enable tracing for a function, you must:

1. Set up a policy to give the Oracle Functions service permission to access APM domains, if the policy does not exist already (see Policy Statements to Give Oracle Functions Users and the Oracle Functions Service Access to Tracing Resources on page 2767).
2. Set up an APM domain.
3. Enable tracing for the Functions application and select the APM domain you created.
4. Enable tracing for one or more functions.

When you enable tracing for a function, Oracle Functions automatically generates a "default function invocation span." The default span captures information about the function's execution context including the overall time taken to process the request and return a response to the caller. In addition to the default function invocation span, you can
add code to functions to define custom spans. Use custom spans to capture more function-specific information to help with debugging. For example, you might define custom spans to capture the start and end of specific units of work. For example, units of work could include getting the database password from the Vault, opening a database connection, and retrieving records from the database.

Four variables have been added to the Oracle Functions context that provide helpful tracing information. These variables include:

- **FN_APP_NAME**: The function application name.
- **FN_FN_NAME**: The function name.
- **OCI_TRACE_COLLECTOR_URL**: The APM domain URL with data key.
- **OCI_TRACING_ENABLED**: Is tracing enabled?
  - When retrieved from environment variables, returns 0 or 1.
  - When retrieved from the function context, returns `true` or `false` as appropriate for the language used.

### Required IAM Policy for Enabling Tracing

Before you can enable tracing, the group to which you belong must have permission to access existing APM domains or to create APM domains. In addition, Oracle Functions must have permission to access APM domains. See Policy Statements to Give Oracle Functions Users and the Oracle Functions Service Access to Tracing Resources on page 2767.

### Using the Console to Enable Tracing and View Function Traces

A couple of steps are required to enable tracing and to view function traces for the Oracle Cloud Infrastructure Application Performance Monitoring (APM) service. First, enable tracing for the application containing the function. Then, enable tracing for one or more functions. You can then view function traces in the APM Trace Explorer.

### Using the Console to Enable Tracing

To enable tracing, follow these steps.

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region and compartment containing the Functions application.

   The Applications page shows all the applications in the compartment you selected.

4. Select the Functions application for which you want to enable tracing.
5. To enable tracing for the application:
   a. Under Resources, click Traces.
   b. Select the Trace Enabled option and specify:
      - **Compartment**: The compartment in which to create the trace. By default, the current compartment.
      - **APM Domain**: The APM domain (defined in the Application Performance Monitoring service) in which to create the trace. To use an existing APM Domain, select an existing APM domain from the list. Or, to create a new APM domain, click APM Domain. For more information about APM domains, see Getting Started with Application Performance Monitoring.

   **Note:**

   The APM Domain needs to have both public and private data keys for function tracing to work. If the keys do not exist, you can create them through the console interface.

   c. Click Enable Trace to enable tracing for the application.

Having enabled tracing for the Functions application, you can now enable tracing for one or more functions in the application.
6. To enable tracing for specific functions in the application:
   a. Under Resources, click Functions.
   b. Select the Enable Trace option beside one or more function(s) for which you want to enable tracing.

   The Enable Trace option is only shown if you have previously enabled tracing for the application. Note the following:
   • If the Enable Trace option is not shown, you must enable tracing for the application. If you haven't already enabled tracing for the application, see the previous step.
   • If you previously enabled tracing for the application but later disabled it, an Enable application tracing link is shown. Click the Enable application tracing link to re-enable tracing for the application (see the previous step). Having re-enabled tracing for the application, you can then enable tracing for specific functions.

When you have enabled tracing for the application and one or more functions, you can view function traces.

**Using the Console to View Function Traces**

To view the traces for functions that have tracing enabled:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region and compartment containing the Functions application with functions for which you want to view function traces.

   The Applications page shows all the applications in the compartment you selected.
4. Select the application containing the functions for which you want to view traces.
5. To see traces for functions:
   a. To see traces for all the functions that have tracing enabled in the application:
      1. Under Resources, click Traces.
      2. Click the name of the trace.

         | Note: |
         | A trace name is only shown if you have already enabled tracing for the application. |

   b. To see the trace for a specific function that has tracing enabled:
      1. Under Resources, click Functions.
      2. Click the Actions icon (three dots) beside the function, and then click View Trace.

         | Note: |
         | The View Trace option is only shown if you have already enabled tracing for the function. |

   The traces for the functions you selected are shown in the APM Trace Explorer. By default, a trace is shown for the default function invocation span, and any custom spans defined for the function.

6. In the APM Trace Explorer:
   a. Click a trace to see the spans for that trace.
   b. Click a span to see the details captured for that span.

   For more information about using the APM Trace Explorer, see Use Trace Explorer.

**Tracing a Chain of Functions**

By default, function tracing provides a trace for an entire function invocation. However, often with modern cloud applications, you need to chain function invocations. OCI Functions tracing provides the ability trace the execution of
a function invoked by another function. This ability means you can examine the execution of each function in a chain of calls in a single tree of spans in APM trace explorer.

To trace a chain of functions, you need to propagate the X-B3 headers X-B3-TraceId, X-B3-SpanId, X-B3-ParentSpanId, and X-B3-Sampled in the function invocation request from your function code.

After the function has run, the trace data from your functions is collected and available in APM Trace Explorer. For more information about using the APM Trace Explorer, see Use Trace Explorer.

**Tracing a Chain of Functions with Python**

Here's an example of how you can trace a chain of functions. If you want to try this example, you need to create two sample functions. Follow these steps to set up your functions.

1. Create your tracing Python function: `fn init --runtime python <your-function-name-1>`
2. Create your "Hello World!" Python function: `fn init --runtime python <your-function-name-2>`
3. Deploy both functions: `fn -v deploy --app <app-name>`
4. Get the second functions OCID and invoke endpoint: `fn inspect function your-app-name your-function-name-2`
5. Create JSON file to pass the required information into the first function. For example, your `test.json` file might look like this:

```json
{
   "function_ocid": "ocid1.fnfunc.oc1.iad.aaaaaaaxxxxxxxxxxx",
   "function_endpoint": "https://xxxxxxxxx.us-ashburn-1.functions.oci.oraclecloud.com",
   "function_body": "",
   "__comment": "Alternatively, you can set function_body to { "name": "Oracle" }"
}
```

6. When the first function is invoked, you can pass the second functions information using `test.json`: `fn invoke <app-name> <your-function-name-1> < test.json`

Now you are ready to update the first function with the required code updates.

**Configure Packages**

Update your `requirements.txt` file to include the following packages:

```bash
fdk
oci
```

Save the file.

**Update your Function Code to Propagate the X-B3 Headers**

The Python function calls the `handler` function and passes in the JSON information from the invoke command. The `handler` function is broken into several small blocks to simplicity. The complete source file is provided at the bottom of this section.

**Load the JSON Data**

In this first part, the JSON data is loaded from the function invocation.
import io
import json
import logging
import oci
from fdk import response

def handler(ctx, data: io.BytesIO=None):
    app_name = ctx.AppName()
    func_name = ctx.FnName()
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler")

    try:
        body = json.loads(data.getvalue())
        function_endpoint = body.get("function_endpoint")
        function_ocid = body.get("function_ocid")
        function_body = body.get("function_body")
    except (Exception) as ex:
        print('ERROR: Missing key in payload', ex, flush=True)
        raise

Create Invoke Client and Gather Header Information

Create the Functions invoke client using the OCI Python SDK and Functions resource principals. Then, retrieve the `tracing_context` and extract the required information to create the HTTP headers.

```python
signer = oci.auth.signers.get_resource_principals_signer()
client = oci.functions.FunctionsInvokeClient(config={}, signer=signer,
service_endpoint=function_endpoint)

# Zipkin X-B3- header propagation
#
tracing_context = ctx.TracingContext()
trace_id = tracing_context.trace_id()
span_id = tracing_context.span_id()
parent_span_id = tracing_context.parent_span_id()
is_sampled = tracing_context.is_sampled()
```

Propagate the X-B3 Headers

The OCI Python SDK lets you set custom headers. Use this technique to pass the X-B3 headers in to the second function invocation. Header information is passed for `trace_id`, `span_id`, `parent_span_id`, and `is_sampled`. Finally, the second function is invoked with `client` and the response is passed to this function's response.

```python
# if tracing is enabled, is_sampled will be true in the tracing context
if is_sampled:
    # To propagate headers in the OCI SDK in the request to the next function,
    # add the X-B3- headers in the request. This header will be included in ALL
    # subsequent calls made.
    if trace_id is not None:
        client.base_client.session.headers["X-B3-TraceId"] = trace_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | trace_id: " + trace_id)
```
if span_id is not None:
    client.base_client.session.headers['X-B3-SpanId'] = span_id
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | span_id: " + span_id)
if parent_span_id is not None:
    client.base_client.session.headers['X-B3-ParentSpanId'] = parent_span_id
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | parent_span_id: " + parent_span_id)
    client.base_client.session.headers['X-B3-Sampled'] = str(int(is_sampled))
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | is_sampled: " + str(int(is_sampled))")
else:
    # function.trace is DISABLED
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | function tracing is DISABLED")

    resp = client.invoke_function(function_id=function_ocid,
    invoke_function_body=function_body)
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | Response: " + resp.data.text)
    return response.Response(
        ctx,
        response_data=resp.data.text,
        headers={"Content-Type": "application/json"})

Review Complete Function Source Code

Here is the complete source code for the sample Python function.

#
# oci-invoke-function-python version 2.0.

# Licensed under the Universal Permissive License v 1.0 as shown at https://oss.oracle.com/licenses/upl.
#
import io
import json
import logging
import oci
from fdk import response
def handler(ctx, data: io.BytesIO=None):
    app_name = ctx.AppName()
    func_name = ctx.FnName()
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler")
    try:
        body = json.loads(data.getvalue())
        function_endpoint = body.get("function_endpoint")
        function_ocid = body.get("function_ocid")
        function_body = body.get("function_body")
    except (Exception) as ex:
        print('ERROR: Missing key in payload', ex, flush=True)
Functions

```python
raise

signer = oci.auth.signers.get_resource_principals_signer()
client = oci.functions.FunctionsInvokeClient(config={}, signer=signer,
service_endpoint=function_endpoint)

# Zipkin X-B3- header propagation
# tracing_context = ctx.TracingContext()
trace_id = tracing_context.trace_id()
span_id = tracing_context.span_id()
parent_span_id = tracing_context.parent_span_id()
is_sampled = tracing_context.is_sampled()

# if tracing is enabled, is_sampled will be true in the tracing context
if is_sampled:
    # To propagate headers in the OCI SDK in the request to the next
    # function,
    # add the X-B3- headers in the request. This header will be included
    in ALL
    # subsequent calls made.
    if trace_id is not None:
        client.base_client.session.headers['X-B3-TraceId'] = trace_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | trace_id: " + trace_id)
    if span_id is not None:
        client.base_client.session.headers['X-B3-SpanId'] = span_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | span_id: " + span_id)
    if parent_span_id is not None:
        client.base_client.session.headers['X-B3-ParentSpanId'] = parent_span_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | parent_span_id: " + parent_span_id)
        client.base_client.session.headers['X-B3-Sampled'] = str(int(is_sampled))
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | is_sampled: " + str(int(is_sampled)))
else:
    # function.trace is DISABLED
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | function tracing is DISABLED")

resp = client.invoke_function(function_id=function_ocid,
invoke_function_body=function_body)
logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | Response: " + resp.data.text)

return response.Response(
    ctx,
    response_data=resp.data.text,
    headers={"Content-Type": "application/json"})
```

Adding Custom Spans to Functions

With function tracing enabled, the default function invocation span provides a trace for the entire function invocation. The default span can provide good information, but when investigating your code you might want to dig deeper. Custom spans are added directly to your code and allow you to define spans for a method or a block of code. The resulting data provides a better picture of your function as it runs.
Before you can use custom spans, you must enable tracing for your application and functions using the Oracle Cloud Infrastructure Application Performance Monitoring (APM) service. To set up tracing, you must:

1. Set up a policy to give the Oracle Functions service permission to access APM domains, if the policy does not exist already (see Policy Statements to Give Oracle Functions Users and the Oracle Functions Service Access to Tracing Resources on page 2767).
2. Set up an APM domain.
3. Enable tracing for the Functions application and select the APM domain you created.
4. Enable tracing for one or more functions.

These steps have already been covered. However, a couple more things are required for custom spans:

- Select a distributed tracing client library, for example Zipkin.
- Add client libraries to your function dependencies.
- In your function code, use the `OCI_TRACING_ENABLED` function context variable to check if tracing is enabled.
- In your function code, use the `OCI_TRACE_COLLECTOR_URL` function context variable to send your custom spans to your APM domain.
- Add instrumentation to your function code.

**Note:**
To use custom spans, you must have the following minimum versions of the Fn Project FDKs:
- Java FDK: 1.0.129
- Python FDK: 0.1.22
- Node FDK: 0.0.20

### Adding Custom Spans to Java Functions

Here's an example of how to use Zipkin to add custom spans to your Java function. If you want to try this example, you can create a Java "Hello World!" function and add custom span code. To create a sample function:

- Create a Java function: `fn init --runtime java apm-fn-java`
- For simplicity, remove the src/test directory.

#### Configure Maven

Add the following dependencies to the `<dependencies>` section of your Maven `pom.xml` file.

```xml
<dependency>
    <groupId>io.zipkin.reporter2</groupId>
    <artifactId>zipkin-sender-urlconnection</artifactId>
    <version>2.16.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.reporter2</groupId>
    <artifactId>zipkin-reporter-brave</artifactId>
    <version>2.16.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.brave</groupId>
    <artifactId>brave</artifactId>
    <version>5.13.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.brave</groupId>
    <artifactId>brave-core</artifactId>
    <version>4.13.6</version>
</dependency>
```
Save the file.

**The HandleRequest Method**

Observations about the method follow the `handleRequest` source code.

```java
package com.example.fn;
import brave.Span;
import brave.Tracer;
import brave.Tracing;
import brave.propagation.*;
import brave.sampler.Sampler;
import com.fnproject.fn.api.tracing.TracingContext;
import com.github.kristofa.brave.IdConversion;
import zipkin2.reporter.Sender;
import zipkin2.reporter.brave.AsyncZipkinSpanHandler;
import zipkin2.reporter.urlconnection.URLConnectionSender;

public class HelloFunction {
    Sender sender;
    AsyncZipkinSpanHandler zipkinSpanHandler;
    Tracing tracing;
    Tracer tracer;
    String apmUrl;
    TraceContext traceContext;

    public String handleRequest(String input, TracingContext tracingContext)
    {
        try {
            initializeZipkin(tracingContext);
            // Start a new trace or a span within an existing trace
            // representing an operation
            Span span =
                tracer.newChild(traceContext).name("MainHandle").start();
            System.out.println("Inside Java Hello World function");
            try (Tracer.SpanInScope ws = tracer.withSpanInScope(span)) {
                method1();
                method2();
                method3();
                } catch (RuntimeException | Error e) {
                    span.error(e); // Unless you handle exceptions, you might
                    not know the operation failed!
                    throw e;
                } finally {
                    span.finish(); // note the scope is independent of the span.
                    Always finish a span.
                    tracing.close();
                    zipkinSpanHandler.flush();
                }
            } catch (Exception e) {
                return e.getMessage();
            }
            return "Hello, AppName " + tracingContext.getAppName() + " :: fnName " + tracingContext.getFunctionName();
        }
    
    • The `TracingContext` object passes in all the APM-related information needed to make
connections to the APM service.
```
- The `initializeZipkin` method is called which updates the `tracingContext` and creates a `tracer` object which is used to set up custom spans.
- A span is created for the parent custom span. Then three methods are called in the scope of the parent span.
- Notice in the `finally` block all the tracing objects are closed out.

**The `initializeZipkin` Method**

Observations about the `initializeZipkin` method follow the source code.

```java
public void initializeZipkin(TracingContext tracingContext) throws Exception {
    System.out.println("Initializing the variables");
    apmUrl = tracingContext.getTraceCollectorURL();
    sender = URLConnectionSender.create(apmUrl);
    zipkinSpanHandler = AsyncZipkinSpanHandler.create(sender);
    tracing = Tracing.newBuilder()
        .localServiceName(tracingContext.getServiceName())
        .sampler(Sampler.NEVER_SAMPLE)
        .addSpanHandler(zipkinSpanHandler)
        .build();
    tracer = tracing.tracer();
    tracing.setNoop(!tracingContext.isTracingEnabled());
    traceContext = TraceContext.newBuilder()
        .traceId(IdConversion.convertToLong(tracingContext.getTraceId()))
        .spanId(IdConversion.convertToLong(tracingContext.getSpanId()))
        .sampled(tracingContext.isSampled()).build();
}
```

- The `traceContext` is passed in to create all the objects used to create custom spans.
- The `apmURL` is retrieved from the `getTraceCollectorURL()` method. The URL is the endpoint to the APM domain and is used to create the `tracer` object which builds the custom spans.
- A builder takes the `zipkinSpanHandler` and the service name to create a `tracer` object. This `tracer` object is used to create custom spans.

**Creating Custom Spans**

With the `tracer` object initialized, custom spans can be created.

```java
public void method1() {
    System.out.println("Inside Method1 function");
    TraceContext traceContext = tracing.currentTraceContext().get();
    Span span = tracer.newChild(traceContext).name("Method1").start();
    try {
        Thread.sleep(200);
    } catch (InterruptedException e) {
        e.printStackTrace();
    } finally {
        span.finish();
    }
}
```

- The `method1` method creates a custom span named "Method1."
Review Complete Function Source Code

Here is the complete source code for the sample Java tracing function.

```java
package com.example.fn;
import brave.Span;
import brave.Tracer;
import brave.Tracing;
import brave.propagation.*;
import brave.sampler.Sampler;
import com.fnproject.fn.api.tracing.TracingContext;
import com.github.kristofa.brave.IdConversion;
import zipkin2.reporter.Sender;
import zipkin2.reporter.brave.AsyncZipkinSpanHandler;
import zipkin2.reporter.urlconnection.URLConnectionSender;

public class HelloFunction {
    Sender sender;
    AsyncZipkinSpanHandler zipkinSpanHandler;
    Tracing tracing;
    Tracer tracer;
    String apmUrl;
    TraceContext traceContext;
    public void initializeZipkin(TracingContext tracingContext) throws Exception {
        System.out.println("Initializing the variables");
        apmUrl = tracingContext.getTraceCollectorURL();
        sender = URLConnectionSender.create(apmUrl);
        zipkinSpanHandler = AsyncZipkinSpanHandler.create(sender);
        tracing = Tracing.newBuilder()
                .localServiceName(tracingContext.getServiceName())
                .sampler(Sampler.NEVER_SAMPLE)
                .addSpanHandler(zipkinSpanHandler)
                .build();
        tracer = tracing.tracer();
        tracing.setNoop(!tracingContext.isTracingEnabled());
        traceContext = TraceContext.newBuilder()
                .traceId(IdConversion.convertToLong(tracingContext.getTraceId()))
                .spanId(IdConversion.convertToLong(tracingContext.getSpanId()))
                .sampled(tracingContext.isSampled()).build();
    }

    public String handleRequest(String input, TracingContext tracingContext) {
        try {
            initializeZipkin(tracingContext);
            // Start a new trace or a span within an existing trace
            // representing an operation
            Span span =
                    tracer.newChild(traceContext).name("MainHandle").start();
            System.out.println("Inside Java Hello World function");
            try (Tracer.SpanInScope ws = tracer.withSpanInScope(span)) {
                method1();
                method2();
                method3();
            } catch (RuntimeException | Error e) {
                span.error(e); // Unless you handle exceptions, you might not know the operation failed!
                throw e;
            }
        } finally {
            // Clean up resources
            tracing.stop();
            zipkinSpanHandler.flush();
            sender.shutdown();
        }
        return "Hello World!";
    }
}
```

Adding Custom Spans to Python Functions

Here's an example of how to use Zipkin to add custom spans to your Python function. If you want to try this example, you can create a Python "Hello World!" function and add custom span code. To create a sample function:

- Create a Python function: `fn init --runtime python apm-fn-python`
Configure Packages

Update your requirements.txt file to include the following packages:

```python
def handler(ctx, data: io.BytesIO = None):
    try:
        body = json.loads(data.getvalue())
        name = body.get("name")
        except (Exception, ValueError) as ex:
            logging.getLogger().info('error parsing json payload: ' + str(ex))
            logging.getLogger().info("Inside Python Hello World function")
            time.sleep(0.005)
    return response.Response(
        ctx, response_data=json.dumps(
            {"message": "Hello {0}".format(name)}),
            headers={"Content-Type": "application/json"}
    )
```

Save the file.

Creating Handler Class and Parent Custom Span

The Python function calls the handler function and passes in the function context to create custom spans.

- The `tracing_context` is passed from the function context and contains all the information needed to create and configure custom spans.

  - The `with zipkin_span` statement is used to create spans.
  - The information in `tracing_context` is used to get the `service_name`, call the `transport_handler`, and set the `zipkin_attrs`.
  - A custom span name is specified just by setting `span_name`.
  - Tracing attributes required for Zipkin are retrieved from the tracing context: `tracing_context.zipkin_attrs()`.

  - If tracing is not enabled, the tracing context is an empty object. With an empty tracing context, the `is_sampled` flag is set to `None` and `py_zipkin` does not emit spans.
• With the custom span setup, the main block runs boilerplate "Hello World!" code. With the only exception, a call to the example function.

The transport_handler Function

The transport_handler function communicates with the APM domain with messages about span execution.

```python
# transport handler, needed by py_zipkin
def transport_handler(encoded_span, tracing_context):
    return requests.post(
        tracing_context.trace_collector_url(),
        data=encoded_span,
        headers={"Content-Type": "application/json"},
    )
```

• The trace_collector_url is returned from the function context. This URL provides the communication endpoint for your custom spans to the APM domain.

Creating a Custom Span in Example Function

The example function demonstrates the creation of a custom span.

```python
def example(ctx):
    with zipkin_span(
        service_name=ctx.TracingContext().service_name(),
        span_name="Get ADB Password from OCI Vault",
        binary_annotations=ctx.TracingContext().annotations()
    ) as example_span_context:
        try:
            logging.getLogger().debug("Get ADB Password from OCI Vault")
            time.sleep(0.005)
            # throwing an exception to show how to add error messages to spans
            raise Exception('Request failed')
        except (Exception, ValueError) as error:
            example_span_context.update_binary_annotations(
                {"Error": True, "errorMessage": str(error)}
            )
        else:
            FakeResponse = namedtuple("FakeResponse", "status, message")
            fakeResponse = FakeResponse(200, "OK")
            # how to update the span dimensions/annotations
            example_span_context.update_binary_annotations(
                {"responseCode": fakeResponse.status,
                "responseMessage": fakeResponse.message
            }
        )
```

• The with zipkin_span statement is used to identify the custom span and give it a name.
• The example_span_context block raises an exception and returns an error message.

Review Complete Function Source Code

Here is the complete source code for the sample Python tracing function.

```python
import io
import json
import logging
```
from fdk import response

import requests
import time
from py_zipkin import Encoding
from py_zipkin.zipkin import zipkin_span
from collections import namedtuple

# transport handler, needed by py_zipkin
def transport_handler(encoded_span, tracing_context):
    return requests.post(
        tracing_context.trace_collector_url(),
        data=encoded_span,
        headers={"Content-Type": "application/json"},
    )

def handler(ctx, data: io.BytesIO = None):
    tracing_context = ctx.TracingContext()
    with zipkin_span(
        service_name=tracing_context.service_name(),
        span_name="Customer Code",
        transport_handler=(
            lambda encoded_span: transport_handler(
                encoded_span, tracing_context
            )
        ),
        zipkin attrs=tracing_context.zipkin_attrs(),
        encoding=Encoding.V2_JSON,
        binary annotations=tracing_context.annotations()
    ):
        name = "World"
        try:
            body = json.loads(data.getvalue())
            name = body.get("name")
        except (Exception, ValueError) as ex:
            logging.getLogger().info('error parsing json payload: ' + str(ex))
            logging.getLogger().info("Inside Python Hello World function")
            time.sleep(0.005)
            example(ctx)
        return response.Response(
            ctx, response_data=json.dumps(
                {"message": "Hello {0}".format(name)}
            ),
            headers={"Content-Type": "application/json"}
        )

def example(ctx):
    with zipkin_span(
        service_name=ctx.TracingContext().service_name(),
        span_name="Get ADB Password from OCI Vault",
        binary annotations=ctx.TracingContext().annotations()
    ) as example_span_context:
        try:
            logging.getLogger().debug("Get ADB Password from OCI Vault")
            time.sleep(0.005)
            # throwing an exception to show how to add error messages to
            raise Exception('Request failed')
        except (Exception, ValueError) as error:
            example_span_context.update_binary_annotations("error: \

Functions

```javascript
{"Error": true, "errorMessage": str(error)}
else:
FakeResponse = namedtuple("FakeResponse", "status, message")
fakeResponse = FakeResponse(200, "OK")
# how to update the span dimensions/annotations
example_span_context.update_binary_annotations(
    {
        "responseCode": fakeResponse.status,
        "responseMessage": fakeResponse.message
    }
)
```

### Adding Custom Spans to Node Functions

Here's an example of how to use Zipkin to add custom spans to your Node.js function. If you want to try this example, you can create a Node "Hello World!" function and add custom span code. To create a sample function:

- Create a Node function: `fn init --runtime node apm-fn-node`

### Configure Node Dependencies

Update your `package.json` file to include the following packages:

```json
{
    "name": "apm-tracing-node-fdk-simple-trace-final",
    "version": "1.0.0",
    "description": "Example APM tracing function",
    "main": "func.js",
    "author": "",
    "license": "Apache-2.0",
    "dependencies": {
        "@fnproject/fdk": ">=0.0.13",
        "node-fetch": "^2.6.1",
        "zipkin": "^0.22.0",
        "zipkin-transport-http": "^0.22.0"
    }
}
```

Save the file.

### Update Handle Method

Key observations about the `fdk.handle` method follow the source code.

```javascript
// ZipkinJS core components.
const {
    ExplicitContext,
    Annotation,
    Tracer,
    TraceId,
    BatchRecorder,
    jsonEncoder,
    sampler,
    option
} = require('zipkin');

// An HTTP transport for dispatching Zipkin traces.
const (HttpLogger) = require('zipkin-transport-http');
```
Functions

```javascript
fdk.handle(async function(input, ctx){
  tracer = createOCITracer(ctx);

  var result;
  // Start a new 'scoped' server handling span.
  await tracer.scoped(async function () {
    // Fetch some resource
    result = await tracer.local('fetchResource', () => {
      return fetchResource();
    });
    // Perform some processing
    result = await tracer.local('processResource', () => {
      return someComputation(result);
    });
    // Update some resource
    result = await tracer.local('updateResource', () => {
      return updateResource(result);
    });
    await flush();
  });
  return result;
})
```

- The `tracer` is created and then used to create a parent custom span. Then child spans are created for the `fetchResource`, `processResource`, and `updateResource` functions.

**Reviewing the createOCITracer Function**

Key observations about the function follow the source code.

```javascript
/**
 * Creates a basic Zipkin Tracer using values from context of the function
 * invocation.
 *
 * @param {*} ctx The function invocation context.
 * @returns A configured Tracer for automatically tracing calls.
 */
function createOCITracer (ctx) {
  // An OCI APM configured Tracer
  // The configured OCI APM endpoint is available in the function
  // invocation context.
  const tracingCxt = ctx.tracingContext
  const tracer = new Tracer({
    ctxImpl: new ExplicitContext(),
    recorder: new BatchRecorder({
      logger: new HttpLogger({
        // The configured OCI APM endpoint is available in the function
        // invocation context.
        endpoint: tracingCxt.traceCollectorUrl,
        jsonEncoder: jsonEncoder.JSON_V2
      })
    }),
    // APM Dimensions that should be included in all traces can be
    // configured directly on Tracer.
    defaultTags: createOCITags(ctx),
    // A custom sampling strategy can be defined.
    sampler: createOCISampler(ctx),
    localServiceName: tracingCxt.serviceName,
  })
```
supportsJoin: true,
    traceId128Bit: true
})

// The initial function invocation trace identifiers can be added directly.
// If this is not defined a default TraceId is created.
const traceId = createOCITraceId(tracer, ctx)
tracer.setId(traceId)
return tracer

- The function context (ctx) is passed to this function which provides the information required to connect to the APM domain. If you follow the function calls, you can see how the tracing IDs and fields are built.

**Review Complete Function Source Code**

Here is the complete source code for the sample Node tracing function.

```javascript
const fdk = require('@fnproject/fdk')

// ZipkinJS core components.
const {
    ExplicitContext,
    Tracer,
    TraceId,
    BatchRecorder,
    jsonEncoder,
    sampler,
    option
} = require('zipkin')

// An HTTP transport for dispatching Zipkin traces.
const { HttpLogger } = require('zipkin-transport-http')

fdk.handle(async function (input, ctx) {
    var tracer = createOCITracer(ctx)

    var result
    // Start a new 'scoped' server handling span.
    await tracer.scoped(async function () {
        // Fetch some resource
        result = await tracer.local('fetchResource', () => {
            return fetchResource()
        })
        // Perform some processing
        result = await tracer.local('processResource', () => {
            return someComputation(result)
        })
        // Update some resource
        result = await tracer.local('updateResource', () => {
            return updateResource(result)
        })
        await flush()
    })

    return result
})
```
// App Simulation Functions
//
/**
 * Simulate fetching some required resource. This could be another OCI service
 * or an external call.
 * @returns A Promise with the success or failure of the operation.
 */
function fetchResource () {
  return simulate(1000, { fetchResource: 'OK' })
}

/**
 * Simulate some work. This could be another OCI service.
 * @returns A Promise with the success or failure of the operation.
 */
async function someComputation (toReturn) {
  var i
  for (i = 0; i < 5; i++) {
    await simulate(1000)
  }
  toReturn.processResource = 'OK'
  return toReturn
}

/**
 * Simulate updating some resource. This could be another OCI service or an
 * external call.
 * @returns A Promise with the success or failure of the operation.
 */
async function updateResource (toReturn) {
  await simulate(500)
  toReturn.updateResource = 'OK'
  return toReturn
}

/**
 * A helper function to simulate an operation that takes a specified amount
 * of time.
 * @param {*} ms The simulated time for the activity in milliseconds.
 * @returns A promise that resolves when the simulated activity
 * finishes.
 */
function simulate (ms, result) {
  return new Promise(resolve => setTimeout(resolve, ms, result))
}

/**
 * Functions service may freeze or terminate the container on completion.
 * This function gives extra time to allow the runtime to flush any pending
traces.
 * See: https://github.com/openzipkin/zipkin-js/issues/507
 * @returns A Promise to await on.
 */
function flush () {
  return new Promise(resolve => setTimeout(resolve, 1000))
}
// OpenZipkin ZipkinJS Utility Functions

/**
 * Creates a basic Zipkin Tracer using values from context of the function
 * invocation.
 *
 * @param {*} ctx The function invocation context.
 * @returns       A configured Tracer for automatically tracing calls.
 */
function createOCITracer (ctx) {
  // An OCI APM configured Tracer
  
  const tracingCxt = ctx.tracingContext
  const tracer = new Tracer({
    ctxImpl: new ExplicitContext(),
    recorder: new BatchRecorder({
      logger: new HttpLogger({
        // The configured OCI APM endpoint is available in the function
        // invocation context.
        endpoint: tracingCxt.traceCollectorUrl,
        jsonEncoder: jsonEncoder.JSON_V2
      })
    }),
    // APM Dimensions that should be included in all traces can be
    // configured
    defaultTags: createOCITags(ctx),
    sampler: createOCISampler(ctx),
    localServiceName: tracingCxt.serviceName,
    supportsJoin: true,
    traceId128Bit: true
  })
  
  // The initial function invocation trace identifiers can be added
  // directly on Tracer.
  defaultTags: createOCITags(ctx),
  // A custom sampling strategy can be defined.
  sampler: createOCISampler(ctx),
  localServiceName: tracingCxt.serviceName,
  supportsJoin: true,
  traceId128Bit: true
}

// If this is not defined a default TraceId is created.
const traceId = createOCITraceId(tracer, ctx)
tracer.setId(traceId)
return tracer

/**
 * A ZipkinJS 'TraceId' can be created directly from the function invocation
 * context.
 *
 * @param {*} ctx The function invocation context.
 * @returns       A ZipkinJS 'TraceId' created from the invocation context.
 */
function createOCITraceId (tracer, ctx) {
  const tracingCxt = ctx.tracingContext
  if (tracingCxt.traceId && tracingCxt.spanId) {
    return new TraceId({
      traceId: tracingCxt.traceId,
      spanId: tracingCxt.spanId,
      sampled: new option.Some(tracingCxt.sampled),
      debug: new option.Some(tracingCxt.debug),
      shared: false
    })
  }
  else {
    return 
  }
}
/**
 * A ZipkinJS 'TraceId' can be created directly from the function invocation context.
 * This configuration will automatically add the function meta-data as APM dimensions to each trace. Function environment variable and other dimensions could also be added.
 * @param {*} ctx The function invocation context.
 * @returns       A map of key-value pairs, that will be added as APM dimensions to the traces.
 */
function createOCITags (ctx) {
    return {
        appID: ctx.appID,
        appName: ctx.appName,
        fnID: ctx.fnID,
        fnName: ctx.fnName
    }
}

/**
 * A ZipkinJS 'Sampler' can be created directly from the function invocation context.
 * This configuration will only create a trace if the function is configured for tracing.
 * @param {*} ctx The function invocation context.
 * @returns       A ZipkinJS 'TraceId' created from the invocation context.
 */
function createOCISampler (ctx) {
    return new sampler.Sampler((traceId) => ctx.tracingContext.isEnabled)
}

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to enable and disable tracing for applications and the functions they contain:

- CreateApplication
- UpdateApplication
- CreateFunction
- UpdateFunction

**Function Metrics**

You can monitor the health, capacity, and performance of functions you've deployed to Oracle Functions by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_faas (the Oracle Functions service).
Overview of the Oracle Functions Service Metrics

Oracle Functions monitors function execution, and collects and reports metrics such as:

- The number of times a function is invoked.
- The length of time a function runs for.
- The number of times a function failed.
- The number of requests to invoke a function that returned a '429 Too Many Requests' error in the response (known as 'throttled function invocations').

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

For more information about the policy statement required to access metrics emitted by Oracle Functions, see Policy Statements to Give Oracle Functions Users Access to Function-Related Resources on page 2766.

Available Metrics: oci_faa

The metrics listed in the following tables are automatically available for any functions you create. You do not need to enable monitoring on the resource to get these metrics.

Oracle Functions metrics include the following dimensions:

APPLICATIONID

The OCID of the application containing functions.

RESOURCEID

The OCID of the function.

RESPONSETYPE

The response when a function is invoked (one of Success, Error, or Throttled).

<table>

<td>Total number of function responses.</td>
<td>applicationId resourceId responseType</td>
</tr>
</tbody>
</table>

### Using the Console

**To view default metric charts for a single function**

1. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
3. Select the compartment containing the application with functions for which you want to view metrics.
   
   The Applications page shows all the applications in the compartment you selected.

4. Click the name of the application containing the function for which you want to view metrics.
5. Click the name of the function for which you want to view metrics.

   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci.faas on page 2748.

   For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

### Not seeing the function metrics data you expect?

If you don't see the metrics data for a function that you expect, see the following possible causes and resolutions.

<table>

<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missing functions: A function I invoked is missing from the Invocations chart.</td>
<td>The chart range (time period or x-axis window) does not cover the time of invocation.</td>
<td>Adjust the chart range or time period as necessary.</td>
</tr>
<tr>
<td>Gaps in metrics data: The chart line is discontinuous. I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>No metrics data exist in the times indicated by the gaps.</td>
<td>Smooth out the display by increasing the chart interval to see if gaps are removed.</td>
</tr>
<tr>
<td>Problem</td>
<td>Possible Cause</td>
<td>Resolution</td>
</tr>
<tr>
<td>---------</td>
<td>---------------</td>
<td>------------</td>
</tr>
<tr>
<td>Empty charts: The Errors and Throttles charts never show data.</td>
<td>No metrics data exists for these charts in the specified chart range. No errors have occurred, and no requests have been throttled. Empty Errors and Throttles charts are expected.</td>
<td>Not applicable.</td>
</tr>
</tbody>
</table>

**Throttles data: The Throttles chart shows data. What should I do?**

Data in the Throttles chart indicates at least one request to invoke a function returned a '429 Too Many Requests' error in the response. Submit the throttled invocation requests. Submit future invocation requests less frequently.

---

*To view default metric charts for all functions in an application*

1. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
3. Select the compartment containing the application for which you want to view function metrics.
   - The **Applications** page shows all the applications in the compartment you selected.
4. Click the name of the application for which you want to view function metrics.
5. Under **Resources**, click **Metrics**.
   - The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas on page 2748.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

*To view default metric charts for all the functions in all the applications in a compartment*

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).
3. Select the compartment containing the applications for which you want to view function metrics.
4. For **Metric Namespace**, select **oci_faas**.
   - The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace. For more information about the emitted metrics, see Available Metrics: oci_faas on page 2748.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.
**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Troubleshooting Oracle Functions**

This topic covers common issues related to Oracle Functions and how to address them.

Use the following techniques to find out more about an error or issue:

- **Use tracing to observe function execution**: If a function doesn't run or perform as expected when you invoke it, you can use tracing to debug execution and performance issues. To use tracing, you have to enable tracing for the application containing the function, and then enable tracing for one or more functions. You can then view function traces in the APM Trace Explorer. For more information, see Distributed Tracing for Functions on page 2727.

- **Use function logs to review function invocation information**: The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs. Note that to store and view logs for a function, the function must include print statements. For more information, see Storing and Viewing Function Logs on page 2724.

- **Use DEBUG=1 to see details about requests and responses sent to and from the Oracle Functions service**: If you encounter an unexpected error when using an Fn Project CLI command, you can see more details about the HTTP requests and responses sent to and from the Oracle Functions service. Start the command with the string DEBUG=1 and run the command again. For example:

  ```
  $ DEBUG=1 fn invoke helloworld-app helloworld-func
  ```

  Note that DEBUG=1 must appear before the command, and that DEBUG must be in upper case.

  If you engage with Oracle Support and raise a support ticket, you can attach the output to the ticket.

  Note also that if you have set up a local machine as your Oracle Functions development environment (specifying --provider oracle in the Fn Project CLI context), you must set the environment variable OCI_GO_SDK_DEBUG=v as well as starting the command with DEBUG=1.

The issues in this topic are organized in the following broad categories:

- Setting up and running Oracle Functions on page 2751
- Creating applications and functions on page 2752
- Deploying applications and functions on page 2752
- Invoking functions on page 2752
- Miscellaneous on page 2754

**Setting up and running Oracle Functions**

<table>

</tbody>
</table>

**Issues setting up and running Oracle Functions**

You might encounter these issues when setting up and running Oracle Functions.

**Running Fn Project CLI commands returns a 401 error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that the credentials specified for your current profile in the ~/.oci/config file are authenticating you correctly:

```bash
$ fn list apps
Fn: [GET /apps][401] ListApps default &{Fields: Message:Not authenticated}
```

For example:

- Does user specify the OCID of your Oracle Cloud Infrastructure user account?
- Does fingerprint specify the fingerprint of the public API key value uploaded to the Console?
- Does key_file specify the full path to the private key file?

See [Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File](#) on page 2768. Also see [API Errors](#) on page 5532.

**Running Fn Project CLI commands returns a 404 error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that you are authorized to access function-related and network resources:

```bash
$ fn list apps
Fn: [GET /apps][404] ListApps default &{Fields: Message:Resource is not authorized or not found}
```

For example:

- Does oracle.compartment-id in your current context correctly specify the OCID of the compartment that owns deployed functions?
- Have policies been set up correctly to give group access to function-related and network resources?
If you are using a local machine as your Oracle Functions development environment, has your user account been included correctly in the group to which access to function-related and network resources has been granted?

If you are using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, has the compute instance's OCID been included correctly in the dynamic group that has been granted access to Oracle Cloud Infrastructure Registry?

Has a policy been set up to give Oracle Functions access to network resources?

See Different Options for Function Development Environments on page 2662, Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770, and Creating Policies to Control Access to Network and Function-Related Resources on page 2766. Also see API Errors on page 5532.

**Running Fn Project CLI commands returns an X509: decryption password incorrect error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that the pass_phrase specified for your current profile in the ~/.oci/config file is correct:

```
$ fn list apps
Fn: x509: decryption password incorrect
```

See Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768.

**Performing Docker-related operations with the Fn Project CLI displays an "Error response from daemon... unknown: Unauthorized" message**

To enable the Fn Project CLI to access the Docker registry specified in the Fn Project CLI context, the local Docker client (the Docker daemon on Linux) in your development environment must be logged in to that Docker registry. If the Docker client is not logged in to the Docker registry, you see a message similar to the following:

```
Error response from daemon: Get https://phx.ocir.io/v2/: unknown: Unauthorized
```

Follow the instructions in Logging in to Oracle Cloud Infrastructure Registry on page 2774 to log the Docker client in to the appropriate Oracle Cloud Infrastructure Registry, an Oracle-managed Docker registry available in a number of different regions.

**Running an Fn Project CLI command displays an "Fn: asn1:structure error: tags don't match" message**

When running an Fn Project CLI command, you might see a message similar to the following:

```
Fn: as1: structure error: tags don't match (16 vs {class:1 tag:15 length:112 isCompound: true}) (optional: false explicit: false application: false private: false defaultValue: <nil> tag: <nil> stringType: 0 timeType: 0 set: false omitEmpty: false) pkcs1PrivateKey @2
```

This message indicates a problem with the format of the private key. Double-check the private key is PEM-encoded by opening the private key file in the ~/.oci directory and confirming that the private key starts with BEGIN RSA PRIVATE KEY. For more information about generating keys, see Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2768.

**Running fn version shows that a more recent version of the Fn Project CLI is available**

If you see a message similar to the following when you enter the fn version command, a more recent version of the Fn Project CLI is available:

```
$ fn version
Client version: 0.5.33 is not latest: 0.5.34
Server version: ?
```
To upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in Installing the Fn Project CLI on page 2770.

**Issues creating applications and functions**

You might encounter these issues when creating applications and functions with Oracle Functions.

**Creating a new application displays an error message in the New Application dialog**

If you've already reached the limit for the number of applications in your tenancy, you might see a message similar to the following in the New Application dialog when trying to create a new application:

```
Unable to create your app, please try again.
```

Double-check how many applications already exist in your tenancy. Compare that with the number of applications you're allowed to create. See Oracle Functions Capabilities and Limits on page 2658.

If you've exceeded the number of applications allowed in your tenancy, consider:

- Deleting unwanted applications (see Deleting Applications and Functions on page 2694).
- Requesting an increase to the application limit (see Service Limits on page 243 for instructions).

**Issues deploying applications and functions**

You might encounter these issues when deploying applications and functions with Oracle Functions.

**Deploying an application returns an "unauthorized: incorrect username or password" message**

When deploying an application, you might see a message similar to the following:

```
$ fn -v deploy --app acme-app
Deploying go-app to app: acme-app
Bumped to version 0.0.2
Building image phx.ocir.io/ansh81vru1zp/acme-repo/go-app:0.0.2
FN_REGISTRY: phx.ocir.io/ansh81vru1zp/acme-repo
Current Context: acme-functions-compartment
Sending build context to Docker daemon 5.12kB
Step 1/10 : FROM fnproject/go:dev as build-stage
Get https://registry-1.docker.io/v2/fnproject/go/manifests/dev:
  unauthorized: incorrect username or password
```

The message indicates an unnecessary and unsuccessful attempt to log in to Docker Hub. To resolve this situation, log out from Docker using the following command:

```
docker logout
```

Having logged out from Docker, re-run the command to deploy the application.

**Deploying a function returns an "error running docker push, are you logged into docker?" message**

If you see a message similar to the following when deploying a function, double-check that your development environment doesn't have the FN_REGISTRY environment variable set to your Docker username:

```
The push refers to repository [docker.io. ...  
:  
:  
:  
: denied: requested access to the resource is denied
Fn: error running docker push, are you logged into docker?: exit status 1
See fn <command> --help’ for more information.
```
If you have used the open source Fn Project platform, you might have followed instructions in the Fn Project documentation to set the FN_REGISTRY environment variable to your Docker username to enable interaction with the official Docker registry (docker.io).

The FN_REGISTRY environment variable overrides the value of the registry option in your Fn Project CLI context.

To use the Fn Project CLI with Oracle Functions, do one of the following:

- Unset the FN_REGISTRY environment variable.
- Override the FN_REGISTRY environment variable using the `--registry` global option whenever you enter an Fn Project CLI command that interacts with Oracle Cloud Infrastructure Registry.

**Deploying a function returns a ListTriggers message and a 500 error**

When deploying a function that you've previously created using an earlier version of the Fn Project CLI, you might see a message similar to the following:

```
Fn: [GET /triggers][500] ListTriggers default &{Fields: Message:Internal server error}
```

This message indicates that the function's func.yaml file contains one or more HTTP trigger definitions. Oracle Functions does not currently support HTTP triggers. To deploy the function, remove the `triggers:` section from the func.yaml file.

To avoid creating new func.yaml files containing trigger definitions, follow the instructions in Installing the Fn Project CLI on page 2770 to upgrade the Fn Project CLI to the most recent version.

**Deploying a function returns an "Image does not exist or you do not have access to use it" message**

When deploying a function using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, you might see a message similar to the following:

```
Fn: Image phx.ocir.io/ansh81vrulzp/acme-repo/helloworld-func:0.0.2 does not exist or you do not have access to use it.
```

This message indicates that the compute instance does not have access to Oracle Cloud Infrastructure Registry.

Double-check that a policy statement (similar to the one below) exists in the tenancy's root compartment to allow a dynamic group that includes the compute instance's OCID to access Oracle Cloud Infrastructure Registry:

```
Allow dynamic-group <dynamic-group-name> to read repos in tenancy
```

For more information about using an Oracle Cloud Infrastructure compute instance as your development environment, see Different Options for Function Development Environments on page 2662.

**Deploying a function to Oracle Functions returns "Fn: Missing subnets annotation" message**

When you deploy a function to Oracle Functions, you might see the following message:

```
$ fn deploy --app joes-helloworld-app
Deploying helloworld-func to app: joes-helloworld-app
... Fn: Missing subnets annotation
```

If you see the Fn: Missing subnets annotation message, confirm that you entered the correct application name. For example:

- the application might not be in the compartment currently specified by the Fn Project CLI context
- the application might have existed previously, but has subsequently been deleted
Functions

Issues invoking functions
You might encounter these issues when invoking functions deployed to Oracle Functions.
Invoking a function returns an FunctionInvokeRequestContentTooLarge message and a 413 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeRequestContentTooLarge","message":"Request content
too large"}
Fn: Error invoking function. status: 413 message: Request content too large
The message indicates the content of the request to Oracle Functions exceeds the maximum allowed size of 6 MB.
If you see this error, double-check that the content of the request does not exceed the maximum allowed size.
Invoking a function returns a TooManyRequests message and a 429 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"TooManyRequests","message":"User-rate limit exceeded"}
Fn: Error invoking function. status: 429 message: User-rate limit exceeded
The message indicates that Oracle Functions is already handling the maximum number of requests allowed for your
tenancy, and cannot accept another request.
If you see this error, wait a few minutes before invoking the function again. Alternatively, or if the problem persists,
Contact Us to increase the total memory for concurrent function execution.
Invoking a function returns a Function failed message and a 502 error
If there is a problem with a function's code, you will see the following error when you invoke the function:
Fn: Error invoking function. status: 502 message: Function failed
To investigate the issue with the function's code, check the logs output by the function. The Oracle Cloud
Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function
logs. Note that to store and view logs for a function, the function must include print statements. For more information,
see Storing and Viewing Function Logs on page 2724.
Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error
Oracle Functions enables you to send a function's logs to an external logging destination (like Papertrail) by setting a
syslog URL for the application. See Storing and Viewing Function Logs on page 2724.
If the syslog URL is invalid or unreachable, you will see the following error when you invoke the function:
{"code":"FunctionInvokeSyslogUnavailable","message":"Syslog endpoint
unavailable"}
Fn: Error invoking function. status: 502 message: Syslog endpoint
unavailable
To confirm that the external logging destination's URL is the cause of the error:
1. Update the application to unset the syslog URL using the Fn Project CLI. For example, by entering:
fn update app helloworld-app --syslog-url ''
2. Deploy the function you want to run. See Creating and Deploying Functions on page 2684.
3. Invoke the function. See Invoking Functions on page 2696.
If the function runs successfully, the external logging destination's URL is not reachable from the subnet in which the
function is running. Double-check that:

Oracle Cloud Infrastructure User Guide

2758


Functions

•
•
•

The external logging destination's URL is valid.
The external logging destination's URL is publicly accessible.
The subnet in which the function is running has outbound access to the public internet.

Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error
When you invoke a function, Oracle Functions pulls the corresponding image from Oracle Cloud Infrastructure
Registry using the VCN and subnets specified for the application.
If Oracle Functions is unable to pull the image, the following message is returned when you invoke a function:
{"code":"FunctionInvokeImageNotAvailable","message":"Failed to pull function
image"}
Fn: Error invoking function. status: 502 message: Failed to pull function
image

Possible solutions:
•
•
•

Double-check that the image specified for the function still exists in the specified location in Oracle Cloud
Infrastructure Registry.
Double-check that Oracle Cloud Infrastructure is available (this message is returned if Oracle Cloud Infrastructure
is unexpectedly unavailable).
Double-check that the VCN includes an internet gateway or service gateway. For Oracle Functions to be able
to access Oracle Cloud Infrastructure Registry to pull an image, the VCN must include an internet gateway or a
service gateway, as follows:
•

•

If public subnets were specified for the application, the VCN must also include an internet gateway. A route
table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set
to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure
Registry (for example, with its Destination Type property set to Service, its Destination Service property
set to All <region> services In Oracle Services Network, and its IP Protocol property set
to All).
If private subnets were specified for the application, the VCN must also include a service gateway. The
service gateway must be set up to allow access to All <region> Services In Oracle Services
Network. A route table must include a route rule that targets the service gateway, with its Destination
Service property set to All <region> Services In Oracle Services Network. A security
list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example,
with its Destination Type property set to Service, its Destination Service property set to All <region>
services In Oracle Services Network, and its IP Protocol property set to All).

If an internet gateway or service gateway has not been defined for the VCN already, define one now.
Invoking a function returns a FunctionInvokeSubnetOutOfIPs message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeSubnetOutOfIPs","message":"subnet
ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs"}
Fn: Error invoking function. status: 502 message: subnet
ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs
If you see this error, double-check that each subnet in the VCN has at least the required minimum number of free IP
addresses specified in Creating the VCN and Subnets to Use with Oracle Functions, if they don't exist already on page
2765.

Oracle Cloud Infrastructure User Guide

2759


Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a subnet issue)

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```json
{
  "code": "FunctionInvokeSubnetNotAvailable",
  "message": "subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it"
}
Fn: Error invoking function. status: 502 message: subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it
```

If you see this error, double-check that the subnet specified for the application still exists.

Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a DHCP Options issue)

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```json
{
  "code": "FunctionInvokeSubnetNotAvailable",
  "message": "dhcp options ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it"
}
Fn: Error invoking function. status: 502 message: dhcp options ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it
```

If you see this error, double-check that the set of DHCP Options in the VCN specified for the application still exists.

Invoking a function returns a FunctionInvokeResponseBodyTooLarge message and a 502 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```json
{
  "code": "FunctionInvokeResponseBodyTooLarge",
  "message": "function response body too large"
}
Fn: Error invoking function. status: 502 message: function response body too large
```

The message indicates that the response returned by executing the function exceeds the maximum size allowed of 6 MB.

If you see this error, review the function code and reduce the size of responses that the function returns.

Invoking a function returns a FunctionInvokeResponseHeaderTooLarge message and a 502 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```json
{
  "code": "FunctionInvokeResponseHeaderTooLarge",
  "message": "function response header too large"
}
Fn: Error invoking function. status: 502 message: function response header too large
```

The message indicates that the response header returned by executing the function exceeds the maximum size allowed.

If you see this error, review the function code and reduce the number and/or size of any custom headers that the function returns.

Invoking a function returns a FunctionInvokeExecutionError message and a 502 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```json
{
  "code": "FunctionInvokeExecutionError",
  "message": "error receiving function response"
}
```
Functions

Fn: Error invoking function. status: 502 message: error receiving function
response
The message indicates that the response from executing the function returns an error.
If you see this error unexpectedly, review the function code to understand the conditions in which the function does
not execute successfully.
Invoking a function returns a FunctionInvokeExecutionFailed message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeExecutionFailed","message":"function failed"}
Fn: Error invoking function. status: 502 message: function failed
The message indicates that an error was detected during function execution, which was most likely caused by a bug in
the function code.
If you see this error, review the function code and fix any bugs you find.
Invoking a function returns a FunctionInvokeInvalidResponse message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeInvalidResponse","message":"invalid function
response"}
Fn: Error invoking function. status: 502 message: invalid function response
The message indicates that invoking the function returns an invalid HTTP response code (neither a function failure
nor a timeout).
If you see this error, review the function code and fix any bugs you find.
Invoking a function returns a FunctionInvokeServiceUnavailable message and a 503 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeServiceUnavailable","message":"Timed out - server too
busy"}
Fn: Error invoking function. status: 503 message: Timed out - server too
busy
The message indicates that Oracle Functions is currently unable to handle the request, possibly because of insufficient
capacity.
If you see this error, invoke the function again.
Invoking a function returns a FunctionInvokeContainerInitFail error message, a 504 error, and a
'ModuleNotFoundError: No module named 'contextvars'' log message
When you invoke a Python 3.6 function that you've deployed to Oracle Functions, you might see the following error
message:
{"code":"FunctionInvokeContainerInitFail","message":"Container failed to
initialize, please ensure you are using the latest fdk and check the logs"}
Fn: Error invoking function. status: 504 message: Container failed to
initialize, please ensure you are using the latest fdk and check the logs
If you see this error, check the function's logs. If you see a "ModuleNotFoundError: No module named
'contextvars' message in the function's logs:

Oracle Cloud Infrastructure User Guide

2761


1. Add the following line to the function's requirements.txt file:

   \[\text{fdk}\geq0.1.21\]

2. Re-deploy the function to Oracle Functions.
3. Invoke the function again.

**Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out' messages, and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function execution is subject to a maximum memory threshold. If this limit is exceeded, function execution stops and the following error message is returned:

   \[\{\text{"code":"FunctionInvokeContainerInitFail","message":"Container failed to initialize, please ensure you are using the latest fdk and check the logs"}\}\]

   Fn: Error invoking function. status: 504 message: Container failed to initialize, please ensure you are using the latest fdk and check the logs

If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see Changing Default Memory and Timeout Settings on page 2695).

For example, to set a function's maximum memory threshold to 256MB, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and select **256** from the **Memory (in MBs)** drop-down list.
- Add the following line to the function's func.yaml file. This will set the maximum memory threshold to 256MB whenever the function is invoked:

   \[\text{memory: 256}\]

   Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you enter the `fn init --runtime python <function-name>` command to create the helloworld function, the line `memory: 256` is added to the func.yaml file automatically.

**Invoking a function returns a FunctionInvokeTimeout message and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function is only allowed to run for a certain amount of time. If this time limit is exceeded, function execution stops and the following error message is returned:

   \[\{\text{"code":"FunctionInvokeTimeout","message":"Timed out"}\}\]

   Fn: Error invoking function. status: 504 message: Timed out

If you see this error, increase the maximum time a function is allowed to run for. For example, to set the maximum time to 120 seconds, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and enter **120** in the **Timeout** field.
- Add the following line to the function's func.yaml file. This will set the maximum time limit to 120 seconds whenever the function is invoked:

   \[\text{timeout: 120}\]

   Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.
You might also see this error message when a function running in a public subnet is unable to connect to an Oracle Autonomous Database instance that has access control lists (ACLs) enabled. If this is the case, see Connecting to Oracle Autonomous Database Instances from Running Functions on page 2706 for more information about:

- Configuring the subnet to send all outgoing internet traffic to a NAT gateway, and to allow internet traffic.
- Adding the NAT gateway's public IP address to the database's access control list.

**Invoking a function returns a FunctionInvokeContainerInitTimeout message and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function's image is pulled from the Docker registry and run inside a container. Depending on the function's dependencies, the container might take a long time to start. If the container takes too long to start, you might see the following error message:

```json
{"code": "FunctionInvokeContainerInitTimeout", "message": "Container initialization timed out, please ensure you are using the latest fdk and check the logs"}

Fn: Error invoking function. status: 504 message: Container initialization timed out, please ensure you are using the latest fdk and check the logs
```

If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see Changing Default Memory and Timeout Settings on page 2695).

For example, to set a function's maximum memory threshold to 256MB, do one of the following:

- Click *Edit Function* on the *Function Details* page in the Console, and select 256 from the *Memory (in MBs)* drop-down list.
- Add the following line to the function's func.yaml file. This will set the maximum memory threshold to 256MB whenever the function is invoked:

```
memory: 256
```

Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you enter the `fn init --runtime python <function-name>` command to create the helloworld function, the line `memory: 256` is added to the func.yaml file automatically.

**Invoking a function returns a FunctionInvokeImagePullTimeout message and a 504 error**

When you invoke a function that you've deployed to Oracle Functions, the function's image is pulled from the Docker registry. Depending on the size of the image, it might take a long time to pull the image. If it takes too long to pull the image, you might see the following error message:

```json
{"code": "FunctionInvokeImagePullTimeout", "message": "Image pull timed out"}

Fn: Error invoking function. status: 504 message: Image pull timed out
```

If you see this error:

- Use standard techniques to reduce the size of the image.
- Double-check that the image specified for the function still exists in the specified location in Oracle Cloud Infrastructure Registry.

**Miscellaneous issues when using Oracle Functions**

You might encounter these miscellaneous issues when using Oracle Functions.
When running Oracle Functions on Ubuntu, Docker login returns an "error getting credentials - err: exit status 1..." message

When you configure your development environment for Oracle Functions, you have to install Docker (see Installing Docker for Use with Oracle Functions on page 2769). If your development environment is running Ubuntu, when you follow the subsequent instructions to log in to Oracle Cloud Infrastructure Registry using Docker (see Logging in to Oracle Cloud Infrastructure Registry on page 2774), you might see a message similar to the following:

```
error getting credentials - err: exit status 1, out: Error spawning command
line 'dbus-launch --autolaunch=d7159335070ef1c0854c75de55c8f588 --binary-syntax --close-stderr': Child process exited with code 1
```

For more information about this Docker issue, including likely causes and possible resolutions, see https://github.com/docker/docker-credential-helpers/issues/60.

Appendix: Configuration Notes for Oracle Functions

To get set up and running quickly with Oracle Functions, use the Functions QuickStart Guides on page 2663.

This section provides more information and notes about the tasks you perform using the Functions QuickStart Guides on page 2663 to configure your tenancy and development environment for Oracle Functions:

- Tenancy Configuration Notes for Oracle Functions on page 2764
- Client Environment Configuration Notes for Oracle Functions on page 2768
- Verifying Your Configuration for Function Development on page 2775

Tenancy Configuration Notes for Oracle Functions

Before you can start using Oracle Functions to create and deploy functions, you have to set up your tenancy for function development.

Use the Functions QuickStart Guides on page 2663 to get set up quickly.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. Oracle Functions users are typically not members of the Administrators group, and do not have to be. However, a member of the Administrators group does need to perform a number of administrative tasks to enable users to use Oracle Functions.

This section provides more information and notes about the tasks you perform using the Functions QuickStart Guides on page 2663 to configure your tenancy for Oracle Functions.

When you have set up your tenancy for function development, you can go on to use the Functions QuickStart Guides on page 2663 to set up your client development environment.

Creating Groups and Users to use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create Oracle Cloud Infrastructure user accounts, along with a group to which the user accounts belong. Later on, you'll define policies to give the group (and the user accounts that belong to it) access to function-related resources. If a suitable group and user accounts already exist, there's no need to create new ones.

For more information about creating groups and users, see:

- To create a group on page 3116
- To create a user on page 3113
- To add a user to a group on page 3113

Creating Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create:
• a compartment to own network resources (a VCN, a public or private subnet, and other resources such as an internet gateway or service gateway, a route table, security lists)
• a compartment to own function-related resources (functions, applications)

Note that the same compartment can own both network resources and function-related resources. Alternatively, you can create two separate compartments for network resources and function-related resources.

If suitable compartments already exist, there's no need to create new ones.

For more information about creating a compartment to own network resources and/or function-related resources in the tenancy, see To create a compartment on page 3137.

Creating the VCN and Subnets to Use with Oracle Functions, if they don’t exist already

Before users can start using Oracle Functions to create and deploy functions, a VCN containing the subnets in which to create functions and applications must already exist. The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong.

Each subnet in the VCN must have a CIDR block that provides at least a certain minimum number of free IP addresses, as follows:
• AD-specific subnets must have a minimum of 12 free IP addresses
• regional subnets must have a minimum of 32 free IP addresses

Note that Oracle strongly recommends each subnet has a CIDR block that provides more than the minimum number of free IP addresses.

To support the largest possible number of concurrent connections, Oracle also strongly recommends that the security lists used by subnets in the VCN only have stateless rules.

If a suitable VCN already exists, there's no need to create a new one.

If you do decide to create a new VCN, you have several options, including the following:

• You can create the new VCN and have related resources created automatically at the same time, using one of the VCN wizards (such as the VCN with Internet Connectivity wizard). As well as creating the VCN, the VCN with Internet Connectivity wizard creates a public regional subnet and a private regional subnet, along with an internet gateway, a NAT gateway, and a service gateway. The VCN with Internet Connectivity wizard also creates route tables and security lists. For more information about the VCN wizards, see Virtual Networking Quickstart on page 3692.

• You can create just the VCN initially, and then create the related resources yourself later (see VCNs and Subnets on page 3693). In this case, you can choose which of the following to create:
  • Public subnets and an internet gateway (see Internet Gateway on page 4114). In this case, a route table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to All <region> services In Oracle Services Network, and its IP Protocol property set to All).
  • Private subnets and a service gateway (see Access to Oracle Services: Service Gateway on page 4127). In this case, the service gateway must be set up to allow access to All <region> Services In Oracle Services Network. A route table must include a route rule that targets the service gateway, with its Destination Service property set to All <region> Services In Oracle Services Network. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to All <region> services In Oracle Services Network, and its IP Protocol property set to All).

For example, if you don't want to expose traffic over the public internet, create private subnets and a service gateway (see Oracle Functions Support for Private Network Access on page 2713).

Note that to use an external logging destination like Papertrail, you have to create a VCN with public subnets (see Storing and Viewing Function Logs on page 2724).
**Creating Policies to Control Access to Network and Function-Related Resources**

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create a number of Oracle Cloud Infrastructure policy statements to grant access to function-related and network resources.

Use the Policy Builder to create a suitable policy, by selecting Functions as the **Policy Use Case**, and then selecting the **Let users create, deploy, and manage functions and applications using Cloud Shell** on page 2822 policy template. That policy template contains all the necessary policy statements required to use Oracle Functions. See **Writing Policy Statements with the Policy Builder** on page 3145.

Alternatively, you can create one or more policies containing the policy statements (follow the instructions in **To create a policy** on page 3147).

**Policy statements**

**Policy Statements to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories**

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables users to obtain the Object</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to read objectstorage-namespaces in tenancy</td>
</tr>
<tr>
<td>Storage namespace string of the</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tenancy</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Gives users access to repositories</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to manage repos in tenancy</td>
</tr>
<tr>
<td>in Oracle Cloud Infrastructure</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Registry</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When Oracle Functions users work with functions, they have to access repositories in Oracle Cloud Infrastructure Registry. Users can only access repositories that the groups to which they belong have been granted access. To enable users to access a repository, policy statements must grant the groups access to that repository.

The policy statement **Allow group <group-name> to read objectstorage-namespaces in tenancy** enables users to obtain the auto-generated Object Storage namespace string of the tenancy, which is required to log in to Oracle Cloud Infrastructure Registry. This policy statement also provides access to function logs stored in a storage bucket in Oracle Cloud Infrastructure Object Storage (see **Storing and Viewing Function Logs** on page 2724).

The policy statement **Allow group <group-name> to manage repos in tenancy** gives users access to repositories in Oracle Cloud Infrastructure Registry. This policy statement gives the group permission to manage all repositories in the tenancy. If you consider this to be too permissive, then you can restrict the repositories to which the group has access by including a where clause in the manage repos statement. Note that if you do include a where clause, you must also include a second statement in the policy to enable the group to inspect all repositories in the tenancy (when using the Console). For example, the following policy statements restrict the group to accessing only repositories with names that start 'acme-web-app', but also enables the group to inspect all repositories in the tenancy:

```plaintext
Allow group acme-functions-developers to inspect repos in tenancy

Allow group acme-functions-developers to manage repos in tenancy where all
{target.repo.name=/acme-web-app*/ }
```

**Policy Statements to Give Oracle Functions Users Access to Function-Related Resources**

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to function-</td>
<td>Compartment that owns</td>
<td>Allow group &lt;group-name&gt; to manage functions-family in compartment</td>
</tr>
<tr>
<td>related resources</td>
<td>function-related resources</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 2766
When Oracle Functions users create functions and applications, they have to specify a compartment for those function-related resources (including for metrics emitted by Oracle Functions). Users can only specify a compartment that the groups to which they belong have been granted access. To enable users to specify a compartment, policy statements must grant the groups access to that compartment.

The policy statement `Allow group <group-name> to manage functions-family in compartment <compartment-name>` gives users access to function-related resources.

The policy statement `Allow group <group-name> to read metrics in compartment <compartment-name>` gives users access to metrics emitted by Oracle Functions.

**Policy Statement to Give Oracle Functions Users Access to Logging Resources**

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to logging resources</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to manage logging-family in compartment &lt;compartment-name&gt;</td>
</tr>
</tbody>
</table>

When Oracle Functions users define an application, they can enable logging to store and view function logs in the Oracle Cloud Infrastructure Logging service. Users can only view logs that the groups to which they belong have been granted access. To enable users to store and view function logs in the Oracle Cloud Infrastructure Logging service, a policy statement must grant the groups access to logging resources.

The policy statement `Allow group <group-name> to manage logging-family in compartment <compartment-name>` gives users full access to logging resources in the compartment that will own logging resources.

**Policy Statement to Give Oracle Functions Users Access to Network Resources**

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to network resources</td>
<td>Compartment that owns network resources</td>
<td>Allow group &lt;group-name&gt; to use virtual-network-family in compartment &lt;compartment-name&gt;</td>
</tr>
</tbody>
</table>

When Oracle Functions users create a function or application, they have to specify a VCN and a subnet in which to create them. Users can only specify VCNs and subnets in compartments that the groups to which they belong have been granted access. To enable users to specify a VCN and subnet, a policy statement must grant the groups access to the compartment.

**Policy Statements to Give Oracle Functions Users and the Oracle Functions Service Access to Tracing Resources**

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to tracing resources</td>
<td>Compartment that owns tracing resources, or the root compartment</td>
<td>Allow group &lt;group-name&gt; to use apm-domains in tenancy</td>
</tr>
<tr>
<td>Purpose:</td>
<td>Create in:</td>
<td>Statement:</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------</td>
<td>----------------------------------------------------</td>
</tr>
<tr>
<td>Gives the Oracle Functions service access to tracing resources</td>
<td>Compartment that owns tracing resources, or the root compartment</td>
<td>Allow service faas to use apm-domains in tenancy</td>
</tr>
</tbody>
</table>

When Oracle Functions users want to investigate why a function doesn't run or perform as expected, they can use tracing to debug execution and performance issues. To use tracing, users have to enable tracing for the application containing the function, and then enable tracing for one or more functions. Users can then view function traces in the Application Performance Monitoring (APM) Trace Explorer. For more information, see Distributed Tracing for Functions on page 2727.

Users can only enable tracing if the group to which they belong can access existing APM domains (or create new APM domains), and if Oracle Functions can access APM domains. To enable users to turn on tracing and view traces, policy statements must grant the group and Oracle Functions access to APM domains.

The policy statement `Allow group <group-name> to use apm-domains in tenancy|compartment <compartment-name>` gives users access to tracing resources in the compartment or in the entire tenancy. If you want to enable users to create new APM domains (and delete APM domains), specify `manage apm-domains` instead of `use apm-domains`.

The policy statement `Allow service faas to use apm-domains in tenancy|compartment <compartment-name>` gives Oracle Functions access to APM domains in the compartment or in the entire tenancy.

**Client Environment Configuration Notes for Oracle Functions**

Before you can start using Oracle Functions to create and deploy functions, you have to set up your client environment for function development.

Use the Functions QuickStart Guides on page 2663 to get set up quickly.

Note that prior to setting up your client environment, you must already have set up your tenancy.

This section provides more information and notes about the tasks you perform using the Functions QuickStart Guides on page 2663 to configure your client development environment for Oracle Functions:

**Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions**

Before using Oracle Functions, you have to set up an Oracle Cloud Infrastructure API signing key.

If you are using Cloud Shell as your development environment, an Oracle Cloud Infrastructure API signing key has already been set up for you.

If you are using a local host as your development environment and your user account doesn't already have an Oracle Cloud Infrastructure API signing key, follow the instructions in Functions QuickStart on Local Host to set up an API signing key. Note that if the ~/.oci directory already exists and already contains a private key file and public key file, there's no need to create new private and public key files. Instead, follow the instructions to upload or paste an API key in To add an API signing key on page 3154, and obtain a configuration file snippet containing a fingerprint.

If you are using a local host as your development environment and your user account already has an API signing key, go straight to Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768.

**Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File**

Before using Oracle Functions, you must have an Oracle Cloud Infrastructure CLI configuration file that contains the credentials of the user account that you will be using to create and deploy functions. These user account credentials
Functions

are referred to as a 'profile'. By default, the Oracle Cloud Infrastructure CLI configuration file is located at ~/.oci/config.

If you are using Cloud Shell as your development environment, an ~/.oci/config file with a suitable profile has already been created for you.

If you are using a local host as your development environment, follow the instructions in the Functions QuickStart on Local Host to create a profile in the ~/.oci/config file by copying and pasting a configuration file snippet. Note the following:

• You might already have a configuration file as a result of installing the Oracle Cloud Infrastructure CLI. However, you don't need to have installed the Oracle Cloud Infrastructure CLI in order to use Oracle Functions.
• The ~/.oci/config file can contain several profiles. If you already have an ~/.oci/config file containing one or more profiles, you have to add a new profile to the existing file for the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions.
• Change the name of the new profile you paste into the ~/.oci/config file in the configuration file snippet, from DEFAULT to a name of your choosing. Note that the ~/.oci/config file cannot contain two profiles with the same name.

This topic assumes you have already obtained an API signing key, as described in Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 2768. When you have created a profile in the ~/.oci/config file, go on to Installing Docker for Use with Oracle Functions on page 2769.

Installing Docker for Use with Oracle Functions

Before using Oracle Functions, a version of Docker supported by Fn Project must be installed in your development environment.

If you are using Cloud Shell as your development environment, a suitable version of Docker has already been installed for you.

If Docker is not already installed, or the installed version of Docker is not supported, you'll have to install or upgrade Docker.

The instructions in this topic assume:

• you are not using Cloud Shell as your development environment
• you are using Linux
• you have already completed the steps in Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768

To confirm that a supported version of Docker is installed in your development environment:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that Docker is installed by entering:

   
   docker version

3. Do one of the following, depending on the message you see:

   • If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding to the next step. See the Docker documentation for information about installing Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.
   • If you see a message indicating the version of Docker that's installed, go to the next step.

4. Assuming Docker is installed, go to the Fn Project home page on GitHub to confirm that the installed version of Docker is at least the minimum version specified in the Pre-requisites section.

   If the installed version of Docker is not supported by Fn Project, you have to upgrade the version of Docker before proceeding. See the Docker documentation for information about upgrading Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.

When you have completed the steps in this topic, go on to Installing the Fn Project CLI on page 2770.
Installing the Fn Project CLI

Before using Oracle Functions, the Fn Project CLI must be installed in your development environment.

If you are using Cloud Shell as your development environment, the Fn Project CLI has already been installed for you.

You can install the Fn Project CLI in a number of different ways according to your environment.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Installing Docker for Use with Oracle Functions on page 2769

To install the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. Open the README.md file in the fnproject/cli repository on GitHub and follow the appropriate instructions for installing the Fn Project CLI in your development environment. As a convenient overview, the instructions are summarized below:

   - In a MacOS environment using Homebrew, install the Fn Project CLI by entering:
     
     ```
     brew update && brew install fn
     ```

   - In a Linux or MacOS environment, install the Fn Project CLI by entering:
     
     ```
     curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install| sh
     ```

     If prompted for a password, enter the superuser's password.

   - In a Windows environment, install the Fn Project CLI by following the Install Fn Client instructions in the How-to: Run Fn client on Windows and connect to a remote Fn server topic on GitHub.

   - In a Linux, MacOS, or Windows environment, install the Fn Project CLI by downloading the binary from the Releases page and running it.

3. In a terminal window, confirm that the CLI has been installed by entering:

   ```
   fn version
   ```

   Assuming the Fn Project CLI has been installed correctly, you'll see a message indicating the version of the CLI that has been installed.

When you have completed the steps in this topic, go on to Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770.

Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure

Before using Oracle Functions, you have to configure the Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy.

When the Fn Project CLI is initially installed, it's configured for a local development 'context'. To configure Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy instead, you have to create a new context. The context specifies Oracle Functions endpoints, the OCID of the compartment to which deployed functions will belong, and the address of the Docker registry to and from which to push and pull images.

You can define multiple contexts, each stored in a different context file in .yaml format. By default, the individual context files are stored in the `~/.fn/contexts` directory. The `~/.fn/config.yaml` file specifies which context file Fn Project uses.

To create a new context, you can create a new context file manually and edit the `~/.fn/config.yaml` file by hand to point to that file. Alternatively, you can use the Fn Project CLI to interactively create the new context file and instruct the Fn Project CLI to start using that file, as described below.
If you are using Cloud Shell as your development environment, two Fn Project CLI contexts have already been created for you (a default context and a context for the current region). For more information, see Oracle Functions on Cloud Shell QuickStart Guide. You simply have to copy and paste commands from the Getting Started page into the Cloud Shell window:

- to instruct the Fn Project CLI to use the context for the current region
- to provide the OCID of the compartment that will own deployed functions
- to provide the Oracle Cloud Infrastructure Registry address that you want to use with Oracle Functions

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Installing the Fn Project CLI on page 2770

To create a new context file using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create the new Fn Project CLI context for Oracle Cloud Infrastructure by entering:
   
   ```
   fn create context <my-context> --provider oracle
   ```
   
   where `<my-context>` is a name of your choosing. For example:
   
   ```
   fn create context johns-oci-context --provider oracle
   ```
   
   Note that you specify `--provider oracle` to enable authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

3. Specify that the Fn Project CLI is to use the new context by entering:
   
   ```
   fn use context <my-context>
   ```
   
   where `<my-context>` is the name you specified in the previous step. For example:
   
   ```
   fn use context johns-oci-context
   ```

4. Configure the new context with the OCID of the compartment that you want to own the deployed functions (you might have created a new compartment specifically for this purpose, see Creating Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already on page 2764) by entering:
   
   ```
   fn update context oracle.compartment-id <compartment-ocid>
   ```
   
   For example:
   
   ```
   fn update context oracle.compartment-id ocid1.compartment.oc1..aaaaaaaarvd9a72n...
   ```

5. Configure the new context with the api-url endpoint to use when calling the API by entering:
   
   ```
   fn update context api-url <api-endpoint>
   ```
   
   where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format https://functions.<region-identifier>.oci.oraclecloud.com. The `<region-identifier>` in `<api-endpoint>` is the identifier of the Oracle Cloud Infrastructure region in which you'll be creating and deploying functions. For example, us-phoenix-1.

   For example:
   
   ```
   fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
   ```
6. Configure the new context with the address of the Docker registry that you want to use with Oracle Functions by entering:

```
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name>
```

where:

- `<region-key>` is the key of the Oracle Cloud Infrastructure Registry region. For example, `phx` for Phoenix. See Availability by Region on page 4430.

  Oracle recommends that the Docker registry you specify is in the same region as the subnet on which you intend functions to run.

- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the Tenancy Information page). For example, the namespace of the `acme-dev` tenancy might be `ansh81vrulzp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

- `<repo-name>` is a repository name to pre-pend to the names of functions that you deploy.

For example:

```
fn update context registry phx.ocir.io/ansh81vrulzp/acme-repo
```

7. (Optional) Verify the Fn Project CLI context you've created by viewing the context file. For example, by entering:

```
more ~/.fn/contexts/johns-oci-context.yaml
```

The context file contains:

```
api-url: https://functions.us-phoenix-1.oci.oraclecloud.com
provider: oracle
registry: phx.ocir.io/ansh81vrulzp/acme-repo
```

When you have completed the steps in this topic, go on to Setting the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2772.

**Setting the Context for the Fn Project CLI Using the oracle.profile Parameter**

Before using Oracle Functions, you have to configure the Fn Project CLI to use the new profile you added to the Oracle Cloud Infrastructure CLI configuration file `~/.oci/config` (see Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 2768). The profile you added contains the credentials of the user account you’ll be using to create and deploy functions.

Note that unless you specify otherwise, the Fn Project CLI will attempt to use a profile in the `~/.oci/config` file named `default`.

If you are using Cloud Shell as your development environment, the Fn Project CLI has already been configured for you to use the profile in the Oracle Cloud Infrastructure CLI configuration file.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770

To configure the Fn Project CLI to use the profile you've created for use with Oracle Functions:

1. Log in to your development environment as a functions developer.
2. In a terminal window, configure the Fn Project CLI context with the name of the profile you've created for use with Oracle Functions by entering:

   ```bash
   fn update context oracle.profile <profile-name>
   ```

   For example:

   ```bash
   fn update context oracle.profile john-oci-profile
   ```

When you have completed the steps in this topic, go on to Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2773.

**Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry**

Before using Oracle Functions, the user account you'll be using to create and deploy functions must have an Oracle Cloud Infrastructure auth token. You use the auth token as the password when logging Docker in to Oracle Cloud Infrastructure Registry

The instructions in this topic assume you have already completed the steps in Setting the Context for the Fn Project CLI Using the oracle.profile Parameter on page 2772.

If the user account already has an auth token, go straight on to Starting Docker on page 2773. Otherwise, if the user account does not have an auth token, generate an auth token now.

To generate an auth token for the user account you'll be using to create and deploy functions:

1. Sign in to the Console as a functions developer.
2. In the top-right corner of the Console, open the Profile menu (👤) and then click User Settings to view the details.
3. On the Auth Tokens page, click Generate Token.
4. In the Generate Token dialog:
   a. Enter a meaningful description for the auth token. For example, John's auth token for use with Oracle Functions. Avoid entering confidential information.
   b. Click Generate Token. The new auth token is displayed. For example, 6aN___________6MqX.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

When you have completed the steps in this topic, go on to Starting Docker on page 2773.

**Starting Docker**

Before using Oracle Functions, Docker must be running in your development environment. If it is not running, you must start Docker before proceeding.

If you are using Cloud Shell as your development environment, Docker has already been started for you.

The instructions in this topic assume:
- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2773

To verify that Docker is running:

1. Log in to your development environment as a functions developer.
2. In a terminal window, launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

   ```bash
   docker run hello-world
   ```
3. Do one of the following, depending on the message you see:

- If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation for information about starting Docker on your platform.

- If you see an error message indicating that the network timed out while trying to connect and advising you to check your internet connection or whether you are behind a proxy, your development environment might be behind a corporate proxy server or firewall. In which case, you will probably need to set the http_proxy, https_proxy, and no_proxy environment variables. Ask your network administrator for advice.

- If you see a message like the one shown below, Docker is already running and you can proceed:

  Hello from Docker.

  This message shows that your installation appears to be working correctly.

When you have completed the steps in this topic, go on to Logging in to Oracle Cloud Infrastructure Registry on page 2774.

**Logging in to Oracle Cloud Infrastructure Registry**

Before using Oracle Functions, you have to log Docker in to the Docker registry in which you are going to store your functions as Docker images. This is the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770).

You can store functions in public and private repositories in Oracle Cloud Infrastructure Registry, an Oracle-managed registry built on top of Oracle Cloud Infrastructure.

When you log Docker into a Docker registry, you have to provide the appropriate authentication details. For example, in the case of Oracle Cloud Infrastructure Registry, you have to provide the tenancy Object Storage namespace, the user name, and the user's auth token.

If you are using Cloud Shell as your development environment, you simply have to copy and paste commands from the Getting Started page into the Cloud Shell window. For more information, see Oracle Functions on Cloud Shell QuickStart Guide.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Starting Docker on page 2773

To log Docker into Oracle Cloud Infrastructure Registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, log in to Oracle Cloud Infrastructure Registry by entering:

   
   docker login <region-key>.ocir.io

   where <region-key> is the key for the Oracle Cloud Infrastructure Registry region specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 2770). For example, phx for Phoenix. See Availability by Region on page 4430.

   For example:

   
   docker login phx.ocir.io
3. When prompted for **Username**, enter the name of the user you will be using with Oracle Functions to create and deploy functions, in the format:

```
<tenancy-namespace>/<username>
```

where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the **Tenancy Information** page). For example, `ansh81vrulzp/jdoe@acme.com`.

Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.

You must have already generated an Oracle Cloud Infrastructure auth token for the user you specify (see Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 2773).

4. When prompted for **Password**, enter the user's Oracle Cloud Infrastructure auth token. Having entered the password, Docker might warn you that the password is stored unencrypted in the Docker configuration file. The warning includes a link to the Docker documentation where you can find out how to configure a credential helper. Oracle recommends you review the information in the Docker documentation and consider using an external credentials store for increased security.

When you have completed the steps in this topic, you have completed the configuration tasks for your client environment. Go on to **Verifying Your Configuration for Function Development** on page 2775 to confirm that the Fn Project CLI can communicate with the API endpoint.

**Verifying Your Configuration for Function Development**

Before using Oracle Functions, it's a good idea to confirm that you have successfully completed the prerequisite steps for using Oracle Functions as described in Preparing for Functions on page 2680 and the Functions QuickStart Guides on page 2663. Specifically, that you have:

- set up your tenancy (see Tenancy Configuration Notes for Oracle Functions on page 2764)
- set up your development environment (see Client Environment Configuration Notes for Oracle Functions on page 2768)

If you have successfully completed the configuration tasks, the Fn Project CLI will be able to communicate with the API endpoint.

To confirm that the Fn Project CLI can communicate with the API endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, try and view a list of applications that have been defined in Oracle Functions by entering:

```
fn list apps
```

3. If you see either of the following, you can proceed to create and deploy functions because your system is configured correctly:

   - A message indicating that no applications have been found, which is expected if this is the first time the tenancy has been configured for Oracle Functions.
   - A list of applications that have already been created, which is expected if other users are already using the tenancy for functions development.

4. If you see an error message, it's likely that the Fn Project CLI cannot communicate with the API endpoint due to some incorrect configuration. Do the following:

   - Review the configuration tasks to confirm you completed them as instructed (see Functions QuickStart Guides on page 2663, Tenancy Configuration Notes for Oracle Functions on page 2764, and Client Environment Configuration Notes for Oracle Functions on page 2768).
   - Review the solutions for common problems (see Troubleshooting Oracle Functions on page 2751).
Chapter 26

Health Checks

This chapter explains how to monitor the health of your endpoints.

Overview of the Health Checks Service

The Oracle Cloud Infrastructure Health Checks service provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. By using Health Checks, users can ensure that they are immediately aware of any availability issue affecting their customers.

Health Checks Service Components

The following list describes the key components used in creating a health check.

MONITORS
Monitors allow you to continuously monitor the health of public-facing endpoints. You can configure monitors to use either HTTP and ping protocols. Monitors are classified as either Basic or Premium, based on the configured test interval. A monitor is considered Premium if the test interval is set to 10 seconds, and considered Basic if the test interval is greater than 10 seconds. Behavioral differences do not exist between a Basic and Premium monitor, other than the frequency that the monitor is run.

ON-DEMAND PROBES
On-demand probes allow you to run a one-time probe to assess the health of a public-facing endpoint. You can configure on-demand probes to use either or both HTTP and ping protocols. This feature is only available through the REST API. A limit exists on how many on-demand probes can be run in a 24-hour period. On-demand credits are consumed as the probes are run, and replenished gradually over time.

VANTAGE POINTS
Vantage points are geographic locations from which monitors and probes can be run to your specified target. Oracle Cloud Infrastructure maintains dozens of vantage points around the world.

PROTOCOLS
The Health Checks service allows you to configure both HTTP and ping type monitors. Each type has respective protocols.

Ways to Access the Health Checks Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.
Health Checks

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Health Checks Service Capabilities and Limits

The Oracle Cloud Infrastructure Health Checks service is limited to 1000 endpoint tests per account.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you’re new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Health Checks, see Details for the Health Checks Service on page 2969.

Policy examples:

- To enable all operations on Health Checks for all users in a tenant:

  Allow any-user to manage health-check-family in tenancy

- To enable all operations on Health Checks for all users in a compartment:

  Allow any-user to manage health-check-family in compartment <Compartment Name>

- To enable all operations on Health Checks for a specific user group:

  Allow group <Your Group Name> to manage health-check-family in compartment <Compartment Name>

Moving Health Checks to a Different Compartment

You can move health checks from one compartment to another. When you move a health check to a new compartment, its associated monitor and test results moves with it. After the move, health checks are accessible through the SDK, CLI, and Console. For more information, see Managing Compartments on page 3126.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.
Getting Started With the Health Checks API

The Health Checks service allows you to configure and deploy monitors and on-demand probes using the Health Checks API. Use the following guide to learn how to set up monitors and probes then retrieve their results using the REST API.

Note:

Monitors, metrics, and probes created with the API, SDK and CLI are associated with the region where they were configured. While using the API, you must perform monitor updates (including compartment changes), metrics retrieval, and probe results retrieval in the region where they were configured. However, you can get a list of currently configured monitors and monitor details in every region, no matter where the monitors were configured.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Endpoints

The Health Checks API can be accessed via the following endpoints:

- https://healthchecks.ap-chuncheon-1.oraclecloud.com/20180501
- https://healthchecks.ap-hyderabad-1.oraclecloud.com/20180501
- https://healthchecks.ap-melbourne-1.oraclecloud.com/20180501
- https://healthchecks.ap-mumbai-1.oraclecloud.com/20180501
- https://healthchecks.ap-osaka-1.oraclecloud.com/20180501
- https://healthchecks.ap-seoul-1.oraclecloud.com/20180501
- https://healthchecks.ap-sydney-1.oraclecloud.com/20180501
- https://healthchecks.ap-tokyo-1.oraclecloud.com/20180501
- https://healthchecks.ca-montreal-1.oraclecloud.com/20180501
- https://healthchecks.ca-toronto-1.oraclecloud.com/20180501
- https://healthchecks.eu-amsterdam-1.oraclecloud.com/20180501
- https://healthchecks.eu-frankfurt-1.oraclecloud.com/20180501

- https://healthchecks.us-sanjose-1.oraclecloud.com/20180501

Available Protocols For Probes and Monitors

You can configure monitors and probes to use HTTP or ping requests. You will need to ensure that the endpoint being monitored is configured to accept the specified protocol.

HTTP - Configure a GET or HEAD request using HTTP/1.1 to test the target for availability. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

HTTPS - Configure an encrypted HTTPS GET or HEAD request to test the availability of any secure hosted target. Defaults to port 443. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

ICMP - Configure an ICMP echo request ping. The results include the round trip time (RTT) latency.

TCP - Configure a TCP handshake to the specified end point. You should be sure to own this endpoint as testing this connection can be costly to the recipient. The results include the round trip time (RTT) latency.

Create A Monitor

Monitors allow you to monitor the health of endpoints over time. The following example shows how to create an HTTPS monitor that checks the health of www.example.com at an interval of every 30 seconds using a GET request.

```
POST /20180501/httpMonitors
{
  "compartmentId":"ocid1.compartment.oc1..<unique_ID>" ,
  "protocol":"HTTPS",
  "port":443,
  "targets": [ 
    "www.example.com",
  ],
  "timeoutInSeconds":30,
  "method":"GET",
  "displayName":"Example HTTP monitor",
  "intervalInSeconds":30
}
```

Targets can be either hostnames or IP addresses and the path field can be used to specify an optional path, such as www.example.com/project/help.htm. Optionally, you can specify which geographic locations you would like the monitor to launch from by using the vantagePointNames field. At least one vantage point must be listed when using this field. For a list of available vantage points, see Vantage Points on page 2781.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the resultsUrl field of the response.

```
{
  "id":"ocid1.httpmonitor.oc1...<unique_ID>" ,
  "compartmentId":"ocid1.compartment.oc1..<unique_ID>" ,
  "resultsUrl":"https://healthchecks.us-ashburn-1.oraclecloud.com/20180501/httpProbeResults/ocid1.httpmonitor.oc1...<unique_ID>" ,
  "targets": [ 
    "www.example.com",
    "www.oracle.com"
  ],
  "vantagePointNames": [ 
    "ibm-sjc",
    "aws-dub",
    "dgo-nyc"
  ],
  "protocol":"HTTPS",
}```
Health Checks

For more information about creating an HTTP monitor, see CreateHttpMonitor.

Note:
You can configure a similar style monitors using TCP or ICMP protocols. For more information, see CreatePingMonitor.

Create An On-Demand Probe

Probes are one-off health assessments of an endpoint that can be deployed at anytime. The following example shows how to create an on-demand HTTP probe that checks the health of www.example.com with a GET request.

POST /20180501/httpProbeResults

```
{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>!
    "protocol": "HTTP",
    "targets": [\n        "www.example.com"
    ],
    "timeoutInSeconds": 30,
    "method": "GET"
}
```

Targets can be either hostnames or IP addresses and the path field can be used to specify an optional path, such as www.example.com/project/help.htm. Additionally, you can specify which geographic locations you would like the probe to launch from by using the vantagePointNames field. For a list of available vantage points, see Vantage Points on page 2781.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the resultsUrl field of the response. It will take a few moments for results to display once the tests have been configured.

```
{
    "id": "ocid1.pingprobe.OC2..<unique_ID>!
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>!
    "resultsUrl": "https://healthchecks.us-ashburn-1.oraclecloud.com/20180501/
    pingProbeResults/ocid1.pingprobe.OC2..<unique_ID>!
    "targets": [\n        "www.example.com"
    ],
    "vantagePointNames": [\n        "ibm-sjc",
        "aws-dub",
        "dgo-nyc"
    ],
    "protocol": "ICMP",
    "timeoutInSeconds": 30
}
```

For more information about creating a probe, see CreateOnDemandHttpProbe.

Note:
You can configure similar style probes using TCP or ICMP protocols. For more information, see CreateOnDemandPingProbe.
Retrieving Probe And Monitor Results

Probe and monitor results can be retrieved from URL in the `resultsUrl` field of a monitor or probe creation response. It will take a few moments for results to display once the tests have been configured. Results can also be retrieved at anytime using the following methods:

- **ListPingProbeResults** - For monitors or on-demand probes using TCP or ICMP protocols.
- **ListHttpProbeResults** - For monitors or on-demand probes using HTTP protocols.

Retrieving results for an on-demand probe or monitor requires the probe or monitor's configuration ID as a parameter. On-demand probe and configuration IDs are assigned upon their creation and are returned in the `id` field of the POST response. You can also use the **ListHttpMonitor** method to retrieve a list of currently configured monitors and probes using HTTP protocols. Use the **ListPingMonitors** method to retrieve a list of currently configured monitors and probes using TCP and ICMP protocols.

The following is an example of results retrieved using `GET /httpProbeResults/{probeConfigurationId}`.

```
{
    "key": "651b9f3a46041cace05302060ae27e",
    "probeConfigurationId": "ocid1.httpmonitor.OC2..<unique_ID>",
    "startTime": 1517323711505,
    "target": "www.example.com",
    "vantagePointName": "dgo-nyc",
    "protocol": "HTTPS",
    "connection": {
        "connectDuration": 114,
        "secureConnectDuration": 99,
        "address": "93.184.216.34",
        "port": 443
    },
    "dns": {
        "domainLookupDuration": 29,
        "addresses": [
            "93.184.216.34",
        ]
    },
    "statusCode": 200,
    "fetchStart": 1517323711505,
    "domainLookupStart": 1517323711505,
    "domainLookupEnd": 1517323711534,
    "connectStart": 1517323711535,
    "secureConnectionStart": 1517323711550,
    "connectEnd": 1517323711649,
    "requestStart": 1517323711649,
    "responseStart": 1517323711673,
    "responseEnd": 1517323711676,
    "duration": 171,
    "encodedBodySize": 1270,
    "isTimedOut": false,
    "isHealthy": true
}
```

Vantage Points

Vantage points are geographic locations from which monitors and probes can be launched. Oracle Cloud Infrastructure maintains vantage points on the infrastructure of cloud providers around the world, including AWS, IBM, and Azure. The list below is a sampling of the vantage points available. The list of vantage points is dynamic and changes frequently. Use the **ListHealthChecksVantagePoints** method to return a list of available vantage points.
### Managing Health Checks

The Health Checks service allows you to monitor the health of IP addresses and hostnames, as measured from geographic vantage points of your choosing, using HTTP and ping probes. After configuring a health check, you can view the monitor’s results. The results include the location from which the host was monitored, the availability of the endpoint, and the date and time the test was performed.

### Using the Console

To add a health check:

**Important:**

If you have selected the HTTPS protocol for this monitor and have entered an IP address as a Target to be monitored, you must specify a Host header with the domain name associated with the TLS certificate for that target. If you do not add the Host header, the TLS connection phase will not complete.
Health Checks

2. Click Create Health Check.
3. In the Create Health Check dialog box, enter the following:
   - **Health Check Name**: The name used for the health check. Avoid entering confidential information.
   - **Compartment**: Select the compartment the health check runs in.
   - **Target(s)**: The IP address or fully qualified domain name (FQDN) of the host being monitored. Additional targets can be added.
   - **Vantage Points**: Select the location from which the health of the target is monitored. No more than ten vantage points can be added.
   - **Request Type**: Select the type of request sent to monitor the target.
     - **HTTP** - Enter the following:
       - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
       - **Port**: The port for the monitor to look for a connection. The default is port 80 for HTTP. For HTTPS, use port 443.
       - **Path**: The specific path on the target to be monitored.
       - **Header Name**: (Optional) The name displayed in the request header as part of the health check. Avoid entering confidential information.
       - **Header Value**: (Optional) Specifies the data requested by the header. Click + Add Header to add multiple headers in succession.
       - **Method**: Select the HTTP method used for the health check.
       - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
       - **Interval**: Select the period of time between health checks of the target.
     - **Ping** - Enter the following:
       - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
       - **Port**: If you have selected the TCP protocol, enter the port for the monitor to look for a connection. The default port is 80.
       - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
       - **Interval**: Select the period of time between health checks of the target.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create Health Check.

The health check is added to the health check list. To view more details, click the health check name. It will take a few moments for results to display once the tests have been configured.

To edit a health check

2. Select the check box for the health check you want to edit.
3. Select Edit from the Actions drop-down menu.
4. In the Edit Health Check dialog box, make the needed changes, and then click Edit Health Check.
To disable a health check
2. Select the check box for the health check you want to disable.

   Tip:
   To help find a health check, you can enter the name of the health check in the Search field.
3. Select Disable from the Actions drop-down menu.

   The status of the health check changes to Disabled in the health check list.

To duplicate a health check
2. Select the check box for the health check you want to duplicate.
3. Select Duplicate from the Actions drop-down menu.
4. In the Create Health Check dialog box, make any updates to the duplicated health check, and then click Create Health Check.

To delete a health check
2. Select the check box for the health check you want to delete.

   Tip:
   To help find a health check, you can enter the name of the health check in the Search field.
3. Select Delete from the Actions drop-down menu.
4. In the confirmation dialog box, click Delete.

To view the history of a health check
2. Click the name of the health check you want to view.

   The Health Check history displays a list of results for the past 90 days.

   Tip:
   To help find a result, you can use the Start Date, Start Time, End Date, End Time, and Targets filter options.
3. Click the drop-down arrow beside the Timestamp to view the monitor result details. You can use the API to download the data.

To manage tags for a health check
2. Click the name of the health check you want to view.
3. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

   For more information, see Resource Tags on page 239.

To move a health check to a different compartment
2. In the Scope section, select a compartment.
3. Find the health check in the list, click the Actions icon (three dots), and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click Move Resource.

   For more information, see Managing Compartments on page 3126.
Tip:
If your health checks are continually failing, please ensure that you have permission to monitor the host and that the ports on the host have been configured to receive traffic from Health Checks.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- Use the CreateHTTPMonitor operation to create a Health Check monitor that uses the HTTP protocol.
- Use the CreatePingMonitor operation to create a Health Check monitor that uses the ping protocol.
- Use the ListHealthChecksVantagePoints to retrieve a list of available vantage points from which to execute monitors.
- Use the UpdateHttpMonitor operation to update the configuration of an HTTP health check monitor. You can also use this operation to disable an HTTP monitor by setting the isEnabled field to false.
- Use the UpdatePingMonitor operation to update the configuration of ping health check monitor. You can also use this operation to disable a ping monitor by setting the isEnabled field to false.
- Use the DeleteHttpMonitor operation to remove an HTTP health check monitor from your setup.
- Use the DeletePingMonitor operation to remove a ping health check monitor from your setup.
- Use the ListHttpProbeResults operation to retrieve the results of an HTTP health check monitor.
- Use the ListPingProbeResults operation to retrieve results of a ping health check monitor.

Health Checks Metrics

You can monitor the health, capacity, and performance of your health checks by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_healthchecks (the Health Checks service).

Overview of the Health Checks Service Metrics

Oracle Cloud Infrastructure Health Checks provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. The Health Checks service metrics help you monitor the performance of your endpoints over a 24 hour period.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_healthchecks

The metrics listed in the following table are automatically available for each health check that you create. You do not need to enable monitoring on the health check to get these metrics.

Each metric includes the following dimensions:

**RESOURCEID**

The OCID of the policy to which the metric applies.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PING.isHealthy</td>
<td>Ping Test Success Rate</td>
<td>percent</td>
<td>Displays availability of end point being monitored.</td>
<td>target, vantagePoint, resourceId, resourceDisplayName, protocol, errorMessage, icmpCode</td>
</tr>
<tr>
<td>HTTP.DNSLookupTime</td>
<td>HTTP(S) DNS Lookup Time</td>
<td>ms</td>
<td>The time taken for domain name lookup in milliseconds.</td>
<td>target, vantagePoint, resourceId, resourceDisplayName, protocol, errorMessage</td>
</tr>
<tr>
<td>HTTP.TCPConnectTime</td>
<td>HTTP(S) Connection Duration</td>
<td>ms</td>
<td>The total TCP connection duration for the test which applies to both HTTP and HTTPS protocols.</td>
<td>target, vantagePoint, resourceId, resourceDisplayName, protocol, errorMessage</td>
</tr>
<tr>
<td>HTTP.RequestTime</td>
<td>HTTP(S) Request Duration</td>
<td>ms</td>
<td>The total duration of the request in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>HTTP.ResponseTime</td>
<td>HTTP(S) Response Duration</td>
<td>ms</td>
<td>The total duration of response in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>HTTP.TotalDuration</td>
<td>HTTP(S) Total Duration</td>
<td>ms</td>
<td>The total duration of the test run in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>PING.Latency</td>
<td>Ping Latency Measurement</td>
<td>ms</td>
<td>Latency measurement for ping test in milliseconds.</td>
<td></td>
</tr>
</tbody>
</table>

**Using the Console**

To view metric charts for resources related to a health check monitor:

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.
2. Click the name of the health check you want to view metrics for.
3. Click Metrics.

To view health check metric charts using monitoring

   For Metric Namespace, select oci_healthchecks.
2. Select a metric to view from the Metric Name field.
3. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId is specified in the metric definition for BasicCount.
4. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.
5. Click Update Chart.

   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 27

IAM

This chapter explains how to set up administrators, users, and groups and specify their permissions.

Overview of Oracle Cloud Infrastructure Identity and Access Management

Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who has access to your cloud resources. You can control what type of access a group of users have and to which specific resources. This section gives you an overview of IAM components and an example scenario to help you understand how they work together.

Note:
This document uses the term "you" broadly to mean any administrator in your company who has access to work with IAM.

Components of IAM

IAM uses the components described in this section. To better understand how the components fit together, see Example Scenario on page 2790.

RESOURCE
The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure. For example: compute instances, block storage volumes, virtual cloud networks (VCNs), subnets, route tables, etc.

USER
An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources. Users might need to launch instances, manage remote disks, work with your virtual cloud network, etc. End users of your application are not typically IAM users. Users have one or more IAM credentials (see User Credentials on page 3056).

GROUP
A collection of users who all need the same type of access to a particular set of resources or compartment.

DYNAMIC GROUP
A special type of group that contains resources (such as compute instances) that match rules that you define (thus the membership can change dynamically as matching resources are created or deleted). These instances act as "principal" actors and can make API calls to services according to policies that you write for the dynamic group.

NETWORK SOURCE
A group of IP addresses that are allowed to access resources in your tenancy. The IP addresses can be public IP addresses or IP addresses from a VCN within your tenancy. After you create the network source, you use policy to restrict access to only requests that originate from the IPs in the network source.
COMPARTMENT
A collection of related resources. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating your cloud resources. You use them to clearly separate resources for the purposes of measuring usage and billing, access (through the use of policies), and isolation (separating the resources for one project or business unit from another). A common approach is to create a compartment for each major part of your organization. For more information, see “Setting Up Your Tenancy” in the Oracle Cloud Infrastructure Getting Started Guide.

TENANCY
The root compartment that contains all of your organization's Oracle Cloud Infrastructure resources. Oracle automatically creates your company's tenancy for you. Directly within the tenancy are your IAM entities (users, groups, compartments, and some policies; you can also put policies into compartments inside the tenancy). You place the other types of cloud resources (e.g., instances, virtual networks, block storage volumes, etc.) inside the compartments that you create.

POLICY
A document that specifies who can access which resources, and how. Access is granted at the group and compartment level, which means you can write a policy that gives a group a specific type of access within a specific compartment, or to the tenancy itself. If you give a group access to the tenancy, the group automatically gets the same type of access to all the compartments inside the tenancy. For more information, see Example Scenario on page 2790 and How Policies Work on page 2800. The word “policy” is used by people in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named “policy” document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

HOME REGION
The region where your IAM resources reside. All IAM resources are global and available across all regions, but the master set of definitions reside in a single region, the home region. You must make changes to your IAM resources in your home region. The changes will be automatically propagated to all regions. For more information, see Managing Regions on page 3140.

FEDERATION
A relationship that an administrator configures between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

Services You Can Control Access To
You can write policies to control access to all of the services within Oracle Cloud Infrastructure.

The Administrators Group and Policy
When your company signs up for an Oracle account and Identity Domain, Oracle sets up a default administrator for the account. This person will be the first IAM user for your company and will be responsible for initially setting up additional administrators. Your tenancy comes with a group called Administrators, and the default administrator automatically belongs in this group. You can't delete this group, and there must always be at least one user in it.

Your tenancy also automatically has a policy that gives the Administrators group access to all of the Oracle Cloud Infrastructure API operations and all of the cloud resources in your tenancy. You can neither change nor delete this policy. Any other users you put into the Administrators group will have full access to all of the services. This means they can create and manage IAM resources such as, groups, policies, and compartments. And they can create and manage the cloud resources such as virtual cloud networks (VCNs), instances, block storage volumes, and any other new types of Oracle Cloud Infrastructure resources that become available in the future.
Example Scenario

The goal of this scenario is to show how the different IAM components work together, and basic features of policies.

In this scenario, Acme Company has two teams that will be using Oracle Cloud Infrastructure resources for infrastructure: Project A and Project B. In reality, your company may have many more.

Acme Company plans to use a single virtual cloud network (VCN) for both teams, and wants a network administrator to manage the VCN.

Acme Company also wants the Project A team and Project B team to each have their own set of instances and block storage volumes. The Project A team and Project B teams shouldn't be able to use each other's instances. These two teams also shouldn't be allowed to change anything about the VCN set up by the network administrator. Acme Company wants each team to have administrators for that team's resources. The administrators for the Project A team can decide who can use the Project A cloud resources, and how. Same for the Project B team.

Acme Company Gets Started with Oracle Cloud Infrastructure

Acme Company signs up to use Oracle Cloud Infrastructure and tells Oracle that an employee named Wenpei will be the default administrator. In response, Oracle:

• Creates a tenancy for Acme Company (see the following diagram).
• Creates an IAM user account for Wenpei in the tenancy.
• Creates the Administrators group in the tenancy and places Wenpei in that group.
• Creates a policy in Acme Company's tenancy that gives the Administrators group access to manage all of the resources in the tenancy. Here's that policy:

  Allow group Administrators to manage all-resources in tenancy

The default setup for a new tenancy:

<table>
<thead>
<tr>
<th>CompanyA Tenancy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policies attached to the tenancy:</td>
</tr>
<tr>
<td>- Allow group Administrators to manage all-resources in tenancy</td>
</tr>
<tr>
<td>Users</td>
</tr>
<tr>
<td>Groups</td>
</tr>
</tbody>
</table>

The Default Administrator Creates Some Groups and Another Administrator

Wenpei next creates several groups and users (see the following diagram). She:

• Creates groups called NetworkAdmins, A-Admins, and B-Admins (these last two are for Project A and Project B within the company)
• Creates a user called Alex and puts him in the Administrators group.
• Leaves the new groups empty.

To learn how to create groups, see Working with Groups on page 3116. To learn how to create users and put them in groups, see Working with Users on page 3111.
The Default Administrator Creates Some Compartments and Policies

Wenpei next creates compartments to group resources together (see the following diagram). She:

• Creates a compartment called Networks to control access to the Acme Company's VCN, subnets, Site-to-Site VPN, and other components from Networking.
• Creates a compartment called Project-A to organize Project A team's cloud resources and control access to them.
• Creates a compartment called Project-B to organize Project B team's cloud resources and control access to them.

To learn how to manage compartments, see Working with Compartments on page 3127.

Wenpei then creates a policy to give the administrators for each compartment their required level of access. She attaches the policy to the tenancy, which means that only users with access to manage policies in the tenancy can later update or delete the policy. In this scenario, that is only the Administrators group. The policy includes multiple statements that:

• Give the NetworkAdmins group access to manage networks and instances (for the purposes of easily testing the network) in the Networks compartment
• Give both the A-Admins and B-Admins groups access to use the networks in the Networks compartment (so they can create instances into the network).
• Give the A-Admins group access to manage all resources in the Project-A compartment.
• Give the B-Admins group access to manage all resources in the Project-B compartment.

Here's what that policy looks like (notice it has multiple statements in it):

- Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
- Allow group NetworkAdmins to manage instance-family in compartment Networks
- Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
- Allow group A-Admins to manage all-resources in compartment Project-A
- Allow group B-Admins to manage all-resources in compartment Project-B

Notice the difference in the verbs (manage, use), as well as the resources (virtual-network-family, instance-family, all-resources). For more information about them, see Verbs on page 2802 and Resource-Types on page 2803. To learn how to create policies, see To create a policy on page 3147.
Acme Company wants to let the administrators of the Project-A and Project-B compartments decide which users can use the resources in those compartments. So Wenpei creates two more groups: A-Users and B-Users. She then adds six more statements that give the compartment admins the required access they need in order to add and remove users from those groups:

- Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
- Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
- Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
- Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'
- Allow group A-Admins,B-Admins to inspect users in tenancy
- Allow group A-Admins,B-Admins to inspect groups in tenancy

Notice that this policy doesn't let the project admins create new users or manage credentials for the users. It lets them decide which existing users can be in the A-Users and B-Users groups. The last two statements are necessary for A-Admins and B-Admins to list all the users and groups, and confirm which users are in which groups.
An Administrator Creates New Users

At this point, Alex is in the Administrators group and now has access to create new users. So he provisions users named Leslie, Jorge, and Cheri and places them in the NetworkAdmins, A-Admins, and B-Admins groups,
respectively. Alex also creates other users who will eventually be put in the A-Users and B-Users groups by the admins for Project A and Project B.
The Network Admin Sets Up the Network

Leslie (in the NetworkAdmins group) has access to manage `virtual-network-family` and `instance-family` in the Networks compartment. She creates a virtual cloud network (VCN) with a single subnet in that compartment. She also sets up an Internet gateway for the VCN, and updates the VCN's route table to allow traffic via that gateway. To test the VCN's connectivity to the on-premises network, she launches an instance in the subnet in the VCN. As part of the launch request, she must specify which compartment the instance should reside in. She specifies the Networks compartment, which is the only one she has access to. She then confirms connectivity from the on-premises network to the VCN by logging in to the instance via SSH from the on-premises network.

Leslie terminates her test instance and lets Jorge and Cheri know that the VCN is up and running and ready to try out. She lets them know that their compartments are named Project-A and Project-B respectively. For more information about setting up a cloud network, see Networking on page 3604. For information about launching instances into the network, see Compute on page 926.

Compartment Admins Set Up Their Compartments

Jorge and Cheri now need to set up their respective compartments. Each admin needs to do the following:

- Launch instances in their own compartment
- Put users in their "users" group (e.g., A-Users)
- Decide the type of access to give those users, and accordingly attach a policy to their compartment

Jorge and Cheri both launch instances into the subnet in the VCN, into their respective team's compartments. They create and attach block volumes to the instances. Only the compartment admins can launch/terminate instances or attach/detach block volumes in their respective team's compartments.

**Important:**

Network Topology and Compartment Access Are Different Concepts

It's important to understand the difference between the network topology of the VCN and the access control that the compartments provide. The instances Jorge launched reside in the VCN from a network topology standpoint. But from an access standpoint, they're in the Project-A compartment, not the Networks compartment where the VCN is. Leslie (the Networks admin) can't terminate or reboot Jorge's instances, or launch new ones into the Project-A compartment. But Leslie controls the instances' network, so she controls what traffic will be routed to them. If Jorge had specified the Networks compartment instead of the Project-A compartment when launching his instances, his request would have been denied. The story is similar for Cheri and the Project-B compartment.

But it's also important to note that Wenpei and Alex in the Administrators group do have access to the resources inside the compartments, because they have access to manage all kinds of resources in the tenancy. Compartments inherit any policies attached to their parent compartment (the tenancy), so the Administrators access also applies to all compartments within the tenancy.

Next, Jorge puts several of the users that Alex created into the A-Users group. Cheri does the same for B-Users.

Then Jorge writes a policy that gives users the level of access they need in the Project-A compartment.

```
Allow group A-Users to use instance-family in compartment Project-A
Allow group A-Users to use volume-family in compartment Project-A
Allow group A-Users to inspect virtual-network-family in compartment Networks
```

This lets them use existing instances (with attached block volumes) that the compartment admins already launched in the compartment, and stop/start/reboot them. It does not let A-Users create/delete or attach/detach any volumes. To give that ability, the policy would need to include `manage volume-family`. 
Jorge attaches this policy to the Project-A compartment. Anyone with the ability to manage policies in the compartment can now modify or delete this policy. Right now, that is only the A-Admins group (and the Administrators group, which can do anything throughout the tenancy).

Cheri creates and attaches her own policy to the Project-B compartment, similar to Jorge's policy:

| Allow group B-Users to use instance-family in compartment Project-B |
| Allow group B-Users to use volume-family in compartment Project-B |
| Allow group B-Users to inspect virtual-network-family in compartment Networks |

Now the A-Users and B-Users can work with the existing instances and attached volumes in the Project-A and Project-B compartments, respectively. Here's what the layout looks like:
CompanyA Tenancy

Policies attached to the tenancy:

- Allow group Administrators to manage all-resources in tenancy
- Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
- Allow group NetworkAdmins to manage instance-family in compartment Networks
- Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
- Allow group A-Admins to manage all-resources in compartment Project-A
- Allow group B-Admins to manage all-resources in compartment Project-B
- Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
- Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
- Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
- Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'
- Allow group A-Admins,B-Admins to inspect users in tenancy
- Allow group A-Admins,B-Admins to inspect groups in tenancy

<table>
<thead>
<tr>
<th>Users</th>
<th>Alex</th>
<th>Fred</th>
<th>Jorge</th>
<th>Tarik</th>
<th>Dylan</th>
<th>Jenna</th>
<th>Laura</th>
<th>Wenpei</th>
</tr>
</thead>
</table>

Groups

- Administrators: Wenpei, Alex
- NetworkAdmins: Leslie
- A-Admins: Jorge
- B-Admins: Cheri
- A-Users: Laura, Helali, Dylan
- B-Users: Fred, Jenna, Tarik

Compartments

- Networks
- Project-A: Policy attached and managed by Jorge
  - Allow group A-Users to use instance-family in compartment Project-A
  - Allow group A-Users to use volume-family in compartment Project-A
- Project-B: Policy attached and managed by Cheri
  - Allow group B-Users to use instance-family in compartment Project-B
  - Allow group B-Users to use volume-family in compartment Project-B
  - Allow group B-Users to inspect virtual-network-family in compartment Networks
Viewing Resources by Compartment in the Console

In the Console, you view your cloud resources by compartment. This means that after you sign in to the Console, you'll choose which compartment to work in (there's a list of the compartments you have access to on the left side of the page). Notice that compartments can be nested inside other compartments. The page will update to show that compartment's resources that are within the current region. If there are none, or if you don't have access to the resource in that compartment, you'll see a message.

This experience is different when you're viewing the lists of users, groups, dynamic groups, and federation providers. Those reside in the tenancy itself (the root compartment), not in an individual compartment.

As for policies, they can reside in either the tenancy or a compartment, depending on where the policy is attached. Where it's attached controls who has access to modify or delete it. For more information, see Policy Attachment on page 2805.

The Scope of IAM Resources

Oracle Cloud Infrastructure uses the concepts of regions and availability domains (see Regions and Availability Domains). Some resources are available regionally, whereas others are available only within a certain availability domain. IAM resources (users, groups, dynamic groups, compartments, tag namespaces, federation providers, and policies) are global and available across all regions. See Managing Regions on page 3140.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

The following IAM resources emit events:

- Authentication policies
- Credentials
- Dynamic groups
- Groups
- Identity Providers
- Multi-factor Authentication TOTP Devices
- Policies
- Users

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later
For general information about using the API, see REST APIs on page 5528.

Limits on IAM Resources

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Getting Started with Policies

If you’re new to Oracle Cloud Infrastructure Identity and Access Management (IAM) policies, this topic gives guidance on how to proceed.

If You're Doing a Proof-of-Concept

If you're just trying out Oracle Cloud Infrastructure or doing a proof-of-concept project with infrastructure resources, you may not need more than a few administrators with full access to everything. In that case, you can simply create any new users you need and add them to the Administrators group. The users will be able to do anything with any kind of resource. And you can create all your resources directly in the tenancy (the root compartment). You don’t need to create any compartments yet, or any other policies beyond the Tenant Admin Policy, which automatically comes with your tenancy and can’t be changed.

Note:

Don't forget to add your new users to the Administrators group; it’s easy to forget to do that after creating them.

If You're Past the Proof-of-Concept Phase

If you're past the proof-of-concept phase and want to restrict access to your resources, first:

• Make sure you're familiar with the basic IAM components, and read through the example scenario: Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788
• Think about how to organize your resources into compartments: See "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide
• Learn the basics of how policies work: How Policies Work on page 2800
• Check out some typical policies: Common Policies on page 2806
• Read the FAQs below

Policy FAQs

Which of the services within Oracle Cloud Infrastructure can I control access to through policies?

All of them, including IAM itself. You can find specific details for writing policies for each service in the Policy Reference on page 2837.

Can users do anything without an administrator writing a policy for them?

Yes. All users can automatically do these things without an explicit policy:

• Change or reset their own Console password.
• Manage their own API signing keys and other credentials.

Why should I separate resources by compartment? Couldn't I just put all the resources into one compartment and then use policies to control who has access to what?

You could put all your resources into a single compartment and use policies to control access, but then you would lose the benefits of measuring usage and billing by compartment, simple policy administration at the compartment level, and clear separation of resources between projects or business units.

Can I control or deny access to an individual user?

Yes. However, there are a couple things to know first:
• Enterprise companies typically have multiple users that need similar permissions, so policies are designed to give access to groups of users, not individual users. A user gains access by being in a group.
• Policies are designed to allow access; there's no explicit "deny" when you write a policy.

If you need to grant access to a particular user, you can add a condition to the policy that specifies the user’s OCID in a variable. This construction restricts the access granted in the policy to only the user specified in the condition. For example:

```
allow any-user to read object-family in compartment ObjectStorage where request.user.id = 'ocid1.user.oc1..<user_OCID>'
```

For information about using conditions and variables in policies, see Conditions on page 2828.

If you need to restrict a particular user's access, you can:
• Remove the user from the particular group of interest
• Delete the user entirely from IAM (you have to remove the user from all groups first)

**How do I delete a user?**
First ensure the user isn't in any groups. Only then can you delete the user.

**How do I delete a compartment?**
See To delete a compartment on page 3139.

**How can I tell which policies apply to a particular group or user?**
You need to look at the individual statements in all your policies to see which statements apply to which group. There's not currently an easy way to get this information.

**How can I tell which policies apply to a particular compartment?**
You need to look at the individual statements in all the policies in the tenancy to see if any apply to the particular compartment. You also need to look at any policies in the compartment itself. Policies in any of the sibling compartments cannot refer to the compartment of interest, so you don't need to check those policies.

**How Policies Work**
This topic describes how policies work and the basic features.

**Overview of Policies**
A policy is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a group to work in certain ways with specific types of resources in a particular compartment. If you're not familiar with users, groups, or compartments, see Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

In general, here’s the process an IAM administrator in your organization needs to follow:

1. Define users, groups, and one or more compartments to hold the cloud resources for your organization.
2. Create one or more policies, each written in the policy language. See Common Policies on page 2806.
3. Place users into the appropriate groups depending on the compartments and resources they need to work with.
4. Provide the users with the one-time passwords that they need in order to access the Console and work with the compartments. For more information, see User Credentials on page 3056.

After the administrator completes these steps, the users can access the Console, change their one-time passwords, and work with specific cloud resources as stated in the policies.
Policy Basics

To govern control of your resources, your company will have at least one policy. Each policy consists of one or more policy statements that follow this basic syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

Notice that the statements always begin with the word `Allow`. Policies only `allow` access; they cannot deny it. Instead, there's an implicit deny, which means by default, users can do nothing and have to be granted access through policies. (There's one exception to this rule; see Can users do anything without an administrator writing a policy for them? on page 2799)

An administrator in your organization defines the groups and compartments in your tenancy. Oracle defines the possible verbs and resource-types you can use in policies (see Verbs on page 2802 and Resource-Types on page 2803).

In some cases, you'll want the policy to apply to the tenancy and not a compartment inside the tenancy. In that case, change the end of the policy statement like so:

```
Allow group <group_name> to <verb> <resource-type> in tenancy
```

For more details about the syntax, see Policy Syntax on page 2834.

For information about how many policies you can have, see Service Limits on page 243.

A Few Examples

Let's say your administrator creates a group called `HelpDesk` whose job is to manage users and their credentials. Here is a policy that enables that:

```
Allow group HelpDesk to manage users in tenancy
```

Notice that because users reside in the tenancy (the root compartment), the policy simply states the word `tenancy`, without the word `compartment` in front of it.

Next, let's say you have a compartment called `Project-A`, and a group called `A-Admins` whose job is to manage all of the Oracle Cloud Infrastructure resources in the compartment. Here's an example policy that enables that:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Be aware that the policy directly above includes the ability to write policies **for that compartment**, which means A-Admins can control access to the compartment's resources. For more information, see Policy Attachment on page 2805.

If you wanted to limit A-Admins' access to only launching and managing compute instances and block storage volumes (both the volumes and their backups) in the Project-A compartment, but the network itself lives in the Networks compartment, then the policy could instead be:

```
Allow group A-Admins to manage instance-family in compartment Project-A
Allow group A-Admins to manage volume-family in compartment Project-A
Allow group A-Admins to use virtual-network-family in compartment Networks
```

The third statement with the `virtual-network-family` resource-type enables the instance launch process, because the cloud network is involved. Specifically, the launch process creates a new VNIC and attaches it to the subnet where the instance resides.

For additional examples, see Common Policies on page 2806.
Details about Specifying Groups and Compartments

Typically you'll specify a group or compartment by name in the policy. However, you can use the OCID instead. Just make sure to add "id" before the OCID. For example:

```
Allow group
  id ocid1.group.oc1..aaaaaaaaqjihfhvxmumrl3isyryjw3n6c4rzwskaawuc7i5xwe6s7qmnsbc6a
to manage instance-family in compartment Project-A
```

You can specify multiple groups separated by commas:

```
Allow group A-Admins, B-Admins to manage instance-family in compartment Projects-A-and-B
```

Verbs

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. <strong>Important:</strong> The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td>read</td>
<td>Includes inspect plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the &quot;update&quot; operation has the same effective impact as the &quot;create&quot; operation (e.g., UpdatePolicy, UpdateSecurityList, etc.), in which case the &quot;update&quot; ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td>manage</td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

The verb gives a certain general type of access (e.g., inspect lets you list and get resources). When you then join that type of access with a particular resource-type in a policy (e.g., Allow group XYZ to inspect compartments in the tenancy), then you give that group access to a specific set of permissions and API operations (e.g., ListCompartments, GetCompartment). For more examples, see Details for Verbs + Resource-Type Combinations on page 2972. The Policy Reference on page 2837 includes a similar table for each service, giving you a list of exactly which API operations are covered for each combination of verb and resource-type.

There are some special exceptions or nuances for certain resource-types.

**Users:** Access to both manage users and manage groups lets you do anything with users and groups, including creating and deleting users and groups, and adding/removing users from groups. To add/remove users from groups without access to creating and deleting users and groups, only both use users and use groups are required. See Common Policies on page 2806.
**Policies:** The ability to update a policy is available only with `manage policies`, not `use policies`, because updating a policy is similar in effect to creating a new policy (you can overwrite the existing policy statements). In addition, `inspect policies` lets you get the full contents of the policies.

**Object Storage objects:** `inspect objects` lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, `read objects` lets you download the object itself.

**Load Balancing resources:** Be aware that `inspect load-balancers` lets you get all information about your load balancers and related components (backend sets, etc.).

**Networking resources:**

Be aware that the `inspect` verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).

Also, the following types of abilities are available only with the `manage verb`, not the `use verb`:

- Update (enable/disable) `internet-gateways`
- Update `security-lists`
- Update `route-tables`
- Update `dhcp-options`
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
- Peer VCNs

**Important:**

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to `update` that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you're implicitly trusting them with controlling the network's behavior.

**Resource-Types**

Oracle also defines the resource-types you can use in your policies. First, there are `individual` types. Each individual type represents a specific type of resource. For example, the `vcns` resource-type is specifically for virtual cloud networks (VCNs).

To make policy writing easier, there are `family` types that include multiple individual resource-types that are often managed together. For example, the `virtual-network-family` type brings together a variety of types related to the management of VCNs (e.g., `vcns`, `subnets`, `route-tables`, `security-lists`, etc.). If you need to write a more granular policy that gives access to only an individual resource-type, you can. But you can also easily write a policy to give access to a broader range of resources.

In another example: Block Volume has `volumes`, `volume-attachments`, and `volume-backups`. If you need to give access to only making backups of volumes, you can specify the `volume-backups` resource-type in your policy. But if you need to give broad access to all of the Block Volume resources, you can specify the family type called `volume-family`. For a full list of the family resource-types, see Resource-Types on page 2839.
Important:

If a service introduces new individual resource-types, they will typically be included in the family type for that service. For example, if Networking introduces a new individual resource-type, it will be automatically included in the definition of the virtual-network-family resource type. For more information about future changes to the definitions of resource-types, see Policies and Service Updates on page 2806.

Note that there are other ways to make policies more granular, such as the ability to specify conditions under which the access is granted. For more information, see Advanced Policy Features on page 2828.

Important:

If a service introduces new permissions for an existing resource-type, you must update the policy statement for the existing resource-type to make the new permissions take effect. See this known issue for more information.

Access that Requires Multiple Resource-Types

Some API operations require access to multiple resource-types. For example, LaunchInstance requires the ability to create instances and work with a cloud network. The CreateVolumeBackup operation requires access to both the volume and the volume backup. That means you'll have separate statements to give access to each resource-type (for an example, see Let volume backup admins manage only backups on page 2810). These individual statements do not have to be in the same policy. And a user can gain the required access from being in different groups. For example, George could be in one group that gives the required level of access to the volumes resource-type, and in another group that gives the required access to the volume-backups resource-type. The sum of the individual statements, regardless of their location in the overall set of policies, gives George access to CreateVolumeBackup.

Policy Inheritance

A basic feature of policies is the concept of inheritance: Compartments inherit any policies from their parent compartment. The simplest example is the Administrators group, which automatically comes with your tenancy (see The Administrators Group and Policy on page 2789). There's a built-in policy that enables the Administrators group to do anything in the tenancy:

```
Allow group Administrators to manage all-resources in tenancy
```

Because of policy inheritance, the Administrators group can also do anything in any of the compartments in the tenancy.

To illustrate further, consider a tenancy with three levels of compartments: CompartmentA, CompartmentB, and CompartmentC, shown here:
Policies that apply to resources in CompartmentA also apply to resources in CompartmentB and CompartmentC. So this policy:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentA
```

allows the group NetworkAdmins to manage VCNs in CompartmentA, CompartmentB, and CompartmentC.

**Policy Attachment**

Another basic feature of policies is the concept of attachment. When you create a policy you must attach it to a compartment (or the tenancy, which is the root compartment). Where you attach it controls who can then modify it or delete it. If you attach it to the tenancy (in other words, if the policy is in the root compartment), then anyone with access to manage policies in the tenancy can then change or delete it. Typically that's the Administrators group or any similar group you create and give broad access to. Anyone with access only to a child compartment cannot modify or delete that policy.

If you instead attach the policy to a child compartment, then anyone with access to manage the policies in that compartment can change or delete it. In practical terms, this means it's easy to give compartment administrators (i.e., a group with access to manage all-resources in the compartment) access to manage their own compartment's policies, without giving them broader access to manage policies that reside in the tenancy. For an example that uses this kind of compartment administrator design, see Example Scenario on page 2790. (Recall that because of policy inheritance, users with access to manage policies in the tenancy automatically have the ability to manage policies in compartments inside the tenancy.)

The process of attaching the policy is easy (whether attaching to a compartment or the tenancy): If you're using the Console, when you add the policy to IAM, simply make sure you're in the desired compartment when you create the policy. If you're using the API, you specify the OCID of the desired compartment (either the tenancy or other compartment) as part of the request to create the policy.

When you attach a policy to a compartment, you must be in that compartment and you must indicate directly in the statement which compartment it applies to. If you are not in the compartment, you'll get an error if you try to attach the policy to a different compartment. Notice that attachment occurs during policy creation, which means a policy can be attached to only one compartment. To learn how to attach a policy to a compartment, see To create a policy on page 3147.

**Policies and Compartment Hierarchies**

As described in the previous section, a policy statement must specify the compartment for which access is being granted (or the tenancy). Where you create the policy determines who can update the policy. If you attach the policy to the compartment or its parent, you can simply specify the compartment name. If you attach the policy further up the hierarchy, you must specify the path. The format of the path is each compartment name (or OCID) in the path, separated by a colon:

```
<compartment_level_1>::<compartment_level_2>::...<compartment_level_n>
```

For example, assume you have a three-level compartment hierarchy, shown here:

![Compartment Hierarchies Diagram](image)
You want to create a policy to allow NetworkAdmins to manage VCNs in CompartmentC. If you want to attach this policy to CompartmentC or to its parent, CompartmentB, write this policy statement:

```
Allow group NetworkAdmins to manage virtual-network-family in compartment CompartmentC
```

However, if you want to attach this policy to CompartmentA (so that only administrators of CompartmentA can modify it), write this policy statement that specifies the path:

```
Allow group NetworkAdmins to manage virtual-network-family in compartment CompartmentB:CompartmentC
```

To attach this policy to the tenancy, write this policy statement that specifies the path from CompartmentA to CompartmentC:

```
Allow group NetworkAdmins to manage virtual-network-family in compartment CompartmentA:CompartmentB:CompartmentC
```

**Policies and Service Updates**

It's possible that the definition of a verb or resource-type could change in the future. For example, let's say that the `virtual-network-family` resource-type changes to include a new kind of resource that's been added to Networking. By default, your policies automatically stay current with any changes in service definition, so any policy you have that gives access to `virtual-network-family` would automatically include access to the newly added resource.

**Important:**

If a service introduces new permissions for an existing resource-type, you must update the policy statement for the existing resource-type to make the new permissions take effect. See this [known issue](#) for more information.

**Writing Policies for Each Service**

The [Policy Reference](#) on page 2837 includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.

**Common Policies**

This section includes some common policies you might want to use in your organization.

**Note:**

These policies use example group and compartment names. Make sure to replace them with your own names.

**Let the Help Desk manage users**

**Type of access:** Ability to create, update, and delete users and their credentials. It does not include the ability to put users in groups.

**Where to create the policy:** In the tenancy, because users reside in the tenancy.

```
Allow group HelpDesk to manage users in tenancy
```

**Let auditors inspect your resources**

**Type of access:** Ability to list the resources in all compartments. Be aware that:

- The operation to list IAM policies includes the contents of the policies themselves
• The list operations for Networking resource-types return all the information (for example, the contents of security lists and route tables)
• The operation to list instances requires the read verb instead of inspect, and the contents include the user-provided metadata.
• The operation to view Audit service events requires the read verb instead of inspect.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, auditors can then inspect both the tenancy and all compartments beneath it. Or you could choose to give auditors access to only specific compartments if they don't need access to the entire tenancy.

| Allow group Auditors to inspect all-resources in tenancy |
| Allow group Auditors to read instances in tenancy |
| Allow group Auditors to read audit-events in tenancy |

Let network admins manage a cloud network

Type of access: Ability to manage all components in Networking. This includes cloud networks, subnets, gateways, virtual circuits, security lists, route tables, and so on. If the network admins need to launch instances to test network connectivity, see Let users launch compute instances on page 2807.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage a cloud network in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

| Allow group NetworkAdmins to manage virtual-network-family in tenancy |

Let network admins manage load balancers

Type of access: Ability to manage all components in Load Balancing. If the group needs to launch instances, see Let users launch compute instances on page 2807.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage load balancers in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

| Allow group NetworkAdmins to manage load-balancers in tenancy |

If the group uses the Console to manage load balancers, an additional policy to use the associated networking resources is required:

| Allow group NetworkAdmins to manage load-balancers in tenancy |
| Allow group NetworkAdmins to use virtual-network-family in tenancy |

If a particular group needs to update existing load balancers (for example, modify the backend set) but not create or delete them, use this statement:

| Allow group LBUsers to use load-balancers in tenancy |

Let users launch compute instances

Type of access: Ability to do everything with instances launched into the cloud network and subnets in compartment XYZ, and attach/detach any existing volumes that already exist in compartment ABC. The first statement also lets the group create and manage instance images in compartment ABC. If the group doesn't need to attach/detach volumes, you can delete the volume-family statement.
**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (ABC and XYZ) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2805.

```
Allow group InstanceLaunchers to manage instance-family in compartment ABC
Allow group InstanceLaunchers to read app-catalog-listing in tenancy
Allow group InstanceLaunchers to use volume-family in compartment ABC
Allow group InstanceLaunchers to use virtual-network-family in compartment XYZ
```

To allow users to create new cloud networks and subnets, see Let network admins manage a cloud network on page 2807.

**Let users launch compute instances from a specific custom image**

**Type of access:** Ability to launch instances into the cloud network and subnets in compartment XYZ using only the specified custom image. The policy also includes the ability to attach/detach any existing volumes that already exist in compartment ABC. If the group doesn't need to attach/detach volumes, you can delete the `volume-family` statement.

To specify multiple custom images, you can use conditions.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (ABC and XYZ) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2805.

```
Allow group ImageUsers to inspect instance-images in compartment ABC
Allow group ImageUsers to {INSTANCE_IMAGE_READ} in compartment ABC where target.image.id='<image_OCID>'
Allow group ImageUsers to manage instances in compartment ABC
Allow group ImageUsers to read app-catalog-listing in tenancy
Allow group ImageUsers to use volume-family in compartment ABC
Allow group ImageUsers to use virtual-network-family in compartment XYZ
```

**Let image admins manage custom images**

**Type of access:** Ability to do everything with custom images and compute instances. Also includes the ability to do everything with Object Storage buckets, objects, and namespaces in compartment Y (for creating images from objects and creating pre-authenticated requests to images); to attach/detach any existing volumes in compartment X; and to launch instances into the cloud network and subnets in compartment Z (for creating new instances to base an image on). If the group doesn't need to attach/detach volumes, you can delete the `volume-family` statement.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (X, Y, and Z) to have control over the individual policy statements for their compartments, see Policy Attachment on page 2805.

```
Allow group ImageAdmins to manage instances in compartment X
Allow group ImageAdmins to manage instance-images in compartment X
Allow group ImageAdmins to read app-catalog-listing in tenancy
Allow group ImageAdmins to manage object-family in compartment Y
Allow group ImageAdmins to use volume-family in compartment X
Allow group ImageAdmins to use virtual-network-family in compartment Z
```

**Let users manage Compute instance configurations, instance pools, and cluster networks**

**Type of access:** Ability to do all things with instance configurations, instance pools, and cluster networks in all compartments.
Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the instance configurations, instance pools, and cluster networks in a particular compartment, specify that compartment instead of the tenancy.

Allow group InstancePoolAdmins to manage compute-management-family in tenancy

If a group needs to create instance configurations using existing instances as a template, and uses the API, SDKs, or command line interface (CLI) to do this, add the following statements to the policy:

Allow group InstancePoolAdmins to read instance-family in tenancy
Allow group InstancePoolAdmins to inspect volumes in tenancy

If a particular group needs to start, stop, or reset the instances in existing instance pools, but not create or delete instance pools, use this statement:

Allow group InstancePoolUsers to use instance-pools in tenancy

If resources used by the instance pool contain default tags, add the following statement to the policy to give the group permission to the tag namespace Oracle-Tags:

Allow group InstancePoolUsers to use tag-namespaces in tenancy where target.tag-namespace.name = 'oracle-tags'

Let users manage Compute autoscaling configurations

Type of access: Ability to create, update, and delete autoscaling configurations.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the autoscaling configurations in a particular compartment, specify that compartment instead of the tenancy.

Allow group AutoscalingAdmins to manage auto-scaling-configurations in tenancy
Allow group AutoscalingAdmins to manage instance-pools in tenancy

Let users list and subscribe to images from the Partner Image catalog

Type of access: Ability to list and create subscriptions to images in the Partner Image catalog. It does not include the ability to create instances using images from the Partner Image catalog (see Let users launch compute instances on page 2807).

Where to create the policy: In the tenancy. To reduce the scope of access to just creating subscriptions in a particular compartment, specify that compartment instead of the tenancy in the third statement.

Allow group CatalogSubscribers to inspect app-catalog-listing in tenancy
Allow group CatalogSubscribers to read app-catalog-listing in tenancy
Allow group CatalogSubscribers to manage app-catalog-listing in tenancy

Let users create Compute instance console connections

Type of access: Ability to create instance console connections.

Where to create the policy: In the tenancy.

Allow group <group_name> to manage instance-console-connection in tenancy
Allow group <group_name> to read instance in tenancy
Let users manage Compute dedicated virtual machine hosts

**Type of access:** Ability to create, update, and delete dedicated virtual machine hosts as well as launch instances on dedicated virtual machine hosts.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

| Allow group DedicatedVMHostAdmins to manage dedicated-vm-hosts in tenancy |
| Allow group DedicatedVMHostAdmins to manage instances in tenancy |

Let users launch Compute instances on dedicated virtual machine hosts

**Type of access:** Ability to launch instances on dedicated virtual machine hosts.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

| Allow group DedicatedVMHostAdmins to use dedicated-vm-hosts in tenancy |
| Allow group DedicatedVMHostAdmins to manage instances in tenancy |

Let volume admins manage block volumes, backups, and volume groups

**Type of access:** Ability to do all things with block storage volumes, volume backups, and volume groups in all compartments with the exception of copying volume backups across regions. This makes sense if you want to have a single set of volume admins manage all the volumes, volume backups, and volume groups in all the compartments. The second statement is required in order to attach/detach the volumes from instances.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and instances in a particular compartment, specify that compartment instead of the tenancy.

| Allow group VolumeAdmins to manage volume-family in tenancy |
| Allow group VolumeAdmins to use instance-family in tenancy |

If the group needs to also copy volume backups and boot volume backups across regions, add the following statements to the policy:

| Allow group VolumeAdmins to use volume-backups in tenancy where request.permission='VOLUME_BACKUP_COPY' |
| Allow group VolumeAdmins to use boot-volume-backups in tenancy where request.permission='BOOT_VOLUME_BACKUP_COPY' |

Let volume backup admins manage only backups

**Type of access:** Ability to do all things with volume backups, but not create and manage volumes themselves. This makes sense if you want to have a single set of volume backup admins manage all the volume backups in all the compartments. The first statement gives the required access to the volume that is being backed up; the second statement enables creation of the backup (and the ability to delete backups). The third statement enables the creation and management of user defined backup policies; the fourth statement enables assignment and removal of assignment of backup policies.

| Allow group VolumeBackupAdmins to manage only backups in tenancy |
**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and backups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeBackupAdmins to use volumes in tenancy
Allow group VolumeBackupAdmins to manage volume-backups in tenancy
Allow group VolumeBackupAdmins to manage backup-policies in tenancy
Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy
```

If the group will be using the Console, the following policy gives a better user experience:

```
Allow group VolumeBackupAdmins to use volumes in tenancy
Allow group VolumeBackupAdmins to manage volume-backups in tenancy
Allow group VolumeBackupAdmins to manage backup-policies in tenancy
Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy
```

The last two statements are not necessary in order to manage volume backups. However, they enable the Console to display all the information about a particular volume and the available backup policies.

**Let boot volume backup admins manage only backups**

**Type of access:** Ability to do all things with boot volume backups, but not create and manage boot volumes themselves. This makes sense if you want to have a single set of boot volume backup admins manage all the boot volume backups in all the compartments. The first statement gives the required access to the boot volume that is being backed up; the second statement enables creation of the backup (and the ability to delete backups). The third statement enables the creation and management of user defined backup policies; the fourth statement enables assignment and removal of assignment of backup policies.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the boot volumes and backups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group BootVolumeBackupAdmins to use volumes in tenancy
Allow group BootVolumeBackupAdmins to manage boot-volume-backups in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policies in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policy-assignments in tenancy
```

If the group will be using the Console, the following policy gives a better user experience:

```
Allow group BootVolumeBackupAdmins to use volumes in tenancy
Allow group BootVolumeBackupAdmins to manage boot-volume-backups in tenancy
Allow group BootVolumeBackupAdmins to inspect instances in tenancy
```
Allow group BootVolumeBackupAdmins to manage backup-policies in tenancy
Allow group BootVolumeBackupAdmins to manage backup-policy-assignments in tenancy

The last two statements are not necessary in order to manage volume backups. However, they enable the Console to display all the information about a particular boot volume and the available backup policies.

Let users create a volume group

Type of access: Ability to create a volume group from a set of volumes.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

Let users clone a volume group

Type of access: Ability to clone a volume group from an existing volume group.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

Let users create a volume group backup

Type of access: Ability to create a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.

Let users restore a volume group backup

Type of access: Ability to create a volume group by restoring a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.
Let users create, manage, and delete file systems

**Type of access:** Ability to create, manage, or delete a file system or file system clone. Administrative functions for a file system include the ability to rename or delete it or disconnect from it.

**Where to create the policy:** In the tenancy, so that the ability to create, manage, or delete a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

- Allow group StorageAdmins to manage file-family in tenancy

Let users create file systems

**Type of access:** Ability to create a file system or file system clone.

**Where to create the policy:** In the tenancy, so that the ability to create a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

- Allow group Managers to manage file-systems in tenancy
- Allow group Managers to read mount-targets in tenancy

The second statement is required when users create a file system using the Console. It enables the Console to display a list of mount targets that the new file system can be associated with.

Let Object Storage admins manage buckets and objects

**Type of access:** Ability to do all things with Object Storage buckets and objects in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the buckets and objects in a particular compartment, specify that compartment instead of the tenancy.

- Allow group ObjectAdmins to manage buckets in tenancy
- Allow group ObjectAdmins to manage objects in tenancy

Let users write objects to Object Storage buckets

**Type of access:** Ability to write objects to any Object Storage bucket in compartment ABC (imagine a situation where a client needs to regularly write log files to a bucket). This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and create a new object in a bucket. Although the second statement gives broad access with the manage verb, that access is then scoped down to only the OBJECT_INSPECT and OBJECT_CREATE permissions with the condition at the end of the statement.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment on page 2805.

- Allow group ObjectWriters to read buckets in compartment ABC
- Allow group ObjectWriters to manage objects in compartment ABC where any
  {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}

**Access limited to a specific bucket:** To limit access to a specific bucket in a particular compartment, add the condition where target.bucket.name='<bucket_name>'. The following policy allows the user to list all the buckets in a particular compartment, but they can only list the objects in and upload objects to BucketA:

- Allow group ObjectWriters to read buckets in compartment ABC
Allow group ObjectWriters to manage objects in compartment ABC where all
{target.bucket.name='BucketA', any {request.permission='OBJECT_CREATE',
request.permission='OBJECT_INSPECT'}}

For more information about using conditions, see Advanced Policy Features on page 2828.

Let users download objects from Object Storage buckets

**Type of access:** Ability to download objects from any Object Storage bucket in compartment ABC. This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and read existing objects in a bucket.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment on page 2805.

| Allow group ObjectReaders to read buckets in compartment ABC |
| Allow group ObjectReaders to read objects in compartment ABC |

**Access limited to a specific bucket:** To limit access to a specific bucket in a particular compartment, add the condition where target.bucket.name='<bucket_name>'. The following policy allows the user to list all buckets in a particular compartment, but they can only read the objects in and download from BucketA:

| Allow group ObjectReaders to read buckets in compartment ABC |
| Allow group ObjectReaders to read objects in compartment ABC where target.bucket.name='BucketA' |

For more information about using conditions, see Advanced Policy Features on page 2828.

Let database admins manage Oracle Cloud database systems

**Type of access:** Ability to do all things with the following system types and their associated resources in all compartments:

- Exadata Cloud Service instances
- bare metal DB systems
- virtual machine DB systems

This makes sense if you want to have a single set of database admins manage all the bare metal, virtual machine, and Exadata systems in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the database systems in a particular compartment, specify that compartment instead of the tenancy.

| Allow group DatabaseAdmins to manage database-family in tenancy |

Let database admins manage Exadata Cloud@Customer instances

**Type of access:** Ability to do all things with the Exadata Cloud@Customer resources in all compartments. This makes sense if you want to have a single set of database admins manage all the Exadata Cloud@Customer systems in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Exadata Cloud@Customer systems in a particular compartment, specify that compartment instead of the tenancy.

| Allow group ExaCCAdmins to manage database-family in tenancy |
Let database admins manage Oracle Cloud external database resources

**Type of access:** Ability to do all things with the following OCI external database resources in all compartments:

- OCI external container database resources
- OCI external pluggable database resources
- OCI external non-container database resources
- OCI external database connectors

This makes sense if you want to have a single set of database admins manage all the OCI external database resources in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the OCI external database resources in a particular compartment, specify that compartment instead of the tenancy.

```allow group OnPremDatabaseAdmins to manage external-database-family in tenancy```

Let database and fleet admins manage Autonomous Databases

**Type of access:** Ability to do all things with Autonomous Database instances in all compartments. Applicable if you want to have a single set of database administrators manage all the Autonomous Database databases in all the compartments.

**Where to create the policy:** In the tenancy, so that the access is granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Autonomous Databases in a particular compartment, specify that compartment instead of the tenancy.

**Example 1:** For fleet administrators. Enables Autonomous Database fleet administrator access to the any workload types, and to dedicated Exadata infrastructure resources (container databases and Autonomous Exadata Infrastructure instances).

```allow group DatabaseAdmins to manage autonomous-database-family in tenancy```

If you must restrict access to the Autonomous Exadata Infrastructure and Autonomous Container Database resource types (applicable only to dedicated Exadata infrastructure systems), then you can do so by creating separate policy statements for database administrators that allow access to only Autonomous Databases and their backups. Because a policy statement can only specify one resource type, you must create separate statements for the database and backup resources.

**Example 2:** For database administrators. Enables Autonomous Database database administrators access to databases and backups of the various workload types, but denies access to Autonomous Container Databases and Autonomous Exadata Infrastructure instances.

```allow group ADB-Admins to manage autonomous-database in tenancy
allow group ADB-Admins to manage autonomous-backup in tenancy```

To reduce the scope of access for databases and backups to either the a specific workload type, use a `where` clause.

**Example 3:** For database administrators. Limits Autonomous Database access to databases and backups for a specific workload type.

```allow group ADB-Admins to manage autonomous-database in tenancy where target.workloadType = 'workload_type'
allow group ADB-Admins to manage autonomous-backup in tenancy where target.workloadType = 'workload_type'```
In the preceding code examples, `workload_type` is one of the strings listed in the following table.

### Autonomous Database Workload Type Strings

<table>
<thead>
<tr>
<th>Database Workload Type</th>
<th><code>workload_type</code> String for Policies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Transaction Processing</td>
<td>OLTP</td>
</tr>
<tr>
<td>Autonomous Data Warehouse</td>
<td>DW</td>
</tr>
<tr>
<td>Autonomous JSON Database</td>
<td>AJD</td>
</tr>
<tr>
<td>Oracle APEX Application Development</td>
<td>APEX</td>
</tr>
</tbody>
</table>

Let security admins manage vaults, keys, and secrets

**Type of access:** Ability to do all things with the Vault service in all compartments. This makes sense if you want to have a single set of security admins manage all the vaults, keys, and secret components (including secrets, secret versions, and secret bundles) in all compartments.

**Where to create the policy:** In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the vaults, keys, and secret components in a particular compartment, specify that compartment instead of the tenancy. To reduce the scope of access to just vaults, keys, or secret components, include only the policy statement that pertains to the respective individual or aggregate resource-type, as appropriate.

- Allow group SecurityAdmins to manage vaults in tenancy
- Allow group SecurityAdmins to manage keys in tenancy
- Allow group SecurityAdmins to manage secret-family in tenancy

Let security admins manage all keys in a specific vault in a compartment

**Type of access:** Ability to do all things with keys in a specific vault in compartment ABC.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2805.

- Allow group SecurityAdmins to manage keys in compartment ABC where target.vault.id='*<vault_OCID>*'

Let security admins use a specific key in a compartment

**Type of access:** Ability to list, view, and perform cryptographic operations with a specific key in a compartment.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2805.

- Allow group SecurityAdmins to use keys in compartment ABC where target.key.id='*<key_OCID>*'

Let a user group delegate key usage in a compartment

**Type of access:** Ability to associate an Object Storage bucket, Block Volume volume, File Storage file system, Kubernetes cluster, or Streaming stream pool with a specific key authorized for use in a specific compartment. With this policy, a user in the specified group does not have permission to use the key itself. Rather, by association, the key
IAM can be used by Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming on behalf of the user to:

- Create or update an encrypted bucket, volume, or file system and to encrypt or decrypt data in the bucket, volume, or file system.
- Create Kubernetes clusters with encrypted Kubernetes secrets at rest in the etcd key-value store.
- Create a stream pool to encrypt data in the streams in the stream pool.

This policy requires that you also have a companion policy that lets Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming use the key to perform cryptographic operations.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see [Policy Attachment](#) on page 2805.

```
Allow group ObjectWriters, VolumeWriters, FileWriters, ClusterWriters, StreamWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
```

**Let Block Volume, Object Storage, File Storage, Container Engine for Kubernetes, and Streaming services encrypt and decrypt volumes, volume backups, buckets, file systems, Kubernetes secrets, and stream pools**

**Type of access:** Ability to list, view, and perform cryptographic operations with all keys in compartment ABC. Because Object Storage is a regional service, it has regional endpoints. As such, you must specify the regional service name for each region where you’re using Object Storage with Vault encryption. This policy also requires that you have a companion policy that allows a user group to use the delegated key that Object Storage, Block Volume, File Storage, Container Engine for Kubernetes, or Streaming will use.

**Where to create the policy:** The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see [Policy Attachment](#) on page 2805.

```
Allow service blockstorage, objectstorage-<region_name>, FssOc1Prod, oke, streaming to use keys in compartment ABC where target.key.id = '<key_OCID>'
```

For Object Storage, replace `<region_name>` with the appropriate region identifier, for example:

- objectstorage-us-phoenix-1
- objectstorage-us-ashburn-1
- objectstorage-eu-frankfurt-1
- objectstorage-uk-london-1
- objectstorage-ap-tokyo-1

To determine the region name value of an Oracle Cloud Infrastructure region, see [Regions and Availability Domains](#) on page 208.

For File Storage, the service name used in the policy is `FssOc1Prod`.

For Container Engine for Kubernetes, the service name used in the policy is `oke`.

For Streaming, the service name used in the policy is `streaming`.

**Let security admins manage all secrets in a specific vault in a compartment**

**Type of access:** Ability to do all things with secrets in a specific vault in compartment ABC.
Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment on page 2805.

```
Allow group SecurityAdmins to manage secret-family in compartment ABC where target.vault.id='<vault_OCID>'
```

**Let users read, update, and rotate all secrets**

**Type of access:** Ability to read, update, and rotate all secrets in any vault in the tenancy.

**Where to create the policy:** In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the vaults, keys, and secrets in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group SecretsUsers to use secret-family in tenancy
```

**Let users manage their own passwords and credentials**

No policy is required to let users manage their own credentials. All users have the ability to change and reset their own passwords, manage their own API keys, and manage their own auth tokens. For more information, see User Credentials on page 3056.

**Let a compartment admin manage the compartment**

**Type of access:** Ability to manage all aspects of a particular compartment. For example, a group called A-Admins could manage all aspects of a compartment called Project-A, including writing additional policies that affect the compartment. For more information, see Policy Attachment on page 2805. For an example of this kind of setup and additional policies that are useful, see Example Scenario on page 2790.

**Where to create the policy:** In the tenancy.

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

**Restrict admin access to a specific region**

**Type of access:** Ability to manage resources in a specific region. Remember that IAM resources must be managed in the home region. If the specified region is not the home region, then the Admin will not be able to manage IAM resources. For more information about the home region, see Managing Regions on page 3140.

**Where to create the policy:** In the tenancy.

```
Allow group PHX-Admins to manage all-resources in tenancy where request.region='phx'
```

The preceding policy allows PHX-Admins to manage all aspects of all resources in US West (Phoenix).

Members of the PHX-Admins group can only manage IAM resources if the tenancy’s home region is US West (Phoenix).

**Restrict user access to view only summary announcements**

**Type of access:** Ability to view the summary versions of announcements about the operational status of Oracle Cloud Infrastructure services.

**Where to create the policy:** In the tenancy.

```
Allow group AnnouncementListers to inspect announcements in tenancy
```
The preceding policy allows AnnouncementListers to view a list of summary announcements.

**Let users view details of announcements**

**Type of access:** Ability to view the details of announcements about the operational status of Oracle Cloud Infrastructure services.

**Where to create the policy:** In the tenancy.

Allow group AnnouncementReaders to read announcements in tenancy

The preceding policy allows AnnouncementReaders to view a list of summary announcements and the details of specific announcements.

**Let streaming users manage streams**

**Type of access:** Ability to do all things with the Streaming service in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

Allow group StreamAdmins to manage streams in tenancy

**Let streaming users publish messages to streams**

**Type of access:** Ability to produce messages to streams with the Streaming service in all compartments.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

Allow group StreamUsers to use stream-push in tenancy

**Let streaming users publish messages to a specific stream**

**Type of access:** Ability to produce messages to a stream with the Streaming service.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

Allow group StreamUsers to use stream-push in tenancy where target.stream.id = '<stream_OCID>'

**Let streaming users publish messages to a stream in a specific stream pool**

**Type of access:** Ability to produce messages to a stream with the Streaming service.

**Where to create the policy:** In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

Allow group StreamUsers to use stream-push in tenancy where target.streampool.id = '<stream_OCID>'

**Let streaming users consume messages from streams**

**Type of access:** Ability to consume messages from streams with the Streaming service in all compartments.
Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

| Allow group StreamUsers to use stream-pull in tenancy |

Let users view metric definitions in a compartment

Type of access: Ability to view metric definitions in a specific compartment. For more information about metrics, see Metrics Feature Overview on page 3462.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metric definitions in a particular compartment, specify that compartment instead of the tenancy.

| Allow group MetricReaders to inspect metrics in compartment ABC |

Let users access monitoring metrics in a compartment

Type of access: Ability to view and retrieve monitoring metrics for supported resources in a specific compartment. For more information about metrics, see Metrics Feature Overview on page 3462.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metrics in a particular compartment, specify that compartment instead of the tenancy.

| Allow group MetricReaders to read metrics in compartment ABC |

Restrict user access to a specific metric namespace

Type of access: Ability to view and retrieve monitoring metrics for resources under a specific metric namespace. For more information about metrics, see Metrics Feature Overview on page 3462.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to the specified metric namespace to just within a particular compartment, specify that compartment instead of the tenancy.

| Allow group MetricReaders to read metrics in compartment ABC where target.metrics.namespace='oci_computeagent' |

The preceding policy allows MetricReaders to view and retrieve metric data points from all monitoring-enabled Compute instances in the ABC compartment.

Let users publish custom metrics

Type of access: Ability to publish custom metrics under a specific metric namespace to the Monitoring service. For instructions, see Publishing Custom Metrics on page 3521.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just metrics in a particular compartment, specify that compartment instead of the tenancy.

| Allow group MetricPublishers to use metrics in tenancy where target.metrics.namespace='mycustomnamespace' |

The preceding policy allows MetricPublishers to publish data points for the custom metric namespace mycustomnamespace in the tenancy.
IAM

Let instances make API calls to access monitoring metrics in the tenancy

**Type of access:** Ability to call the Monitoring API for access to monitoring *metrics*. The instances on which API requests originate must be members of the dynamic group indicated in the policy. For more information, see *Calling Services from an Instance* on page 3106 and *Metrics Feature Overview* on page 3462.

**Where to create the policy:** In the tenancy.

| Allow dynamic-group MetricInstances to read metrics in tenancy |

The preceding policy allows applications that are running on Compute instances in the dynamic group *MetricInstances* to send API requests to the Monitoring service in the tenancy.

Let users view alarms

**Type of access:** Ability to view *alarms* for supported resources in tenancy. Does not include the ability to create alarms or to create or delete topics. For more information about alarms, see *Alarms Feature Overview* on page 3463.

**Where to create the policy:** In the tenancy. Because of the concept of *policy inheritance*, AlarmUsers can then view alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

| Allow group AlarmUsers to read alarms in tenancy |
| Allow group AlarmUsers to read metrics in tenancy |

Let users manage alarms

**Type of access:** Ability to view and create *alarms* with existing notification topics for supported resources in the tenancy. Does not include the ability to create or delete topics. For more information about alarms, see *Alarms Feature Overview* on page 3463.

All statements are required to let AlarmUsers create alarms.

**Where to create the policy:** In the tenancy. Because of the concept of *policy inheritance*, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

| Allow group AlarmUsers to manage alarms in tenancy |
| Allow group AlarmUsers to read metrics in tenancy |
| Allow group AlarmUsers to use ons-topics in tenancy |

Let users manage alarms and create topics

**Type of access:** Ability to view and create *alarms* (with new or existing *topics*) for supported resources in tenancy. Also includes the ability to create *subscriptions* in the tenancy, to publish *messages* (broadcast notification messages) to all subscriptions in the tenancy, and to move alarms to different compartments in the tenancy. For more information about alarms, see *Alarms Feature Overview* on page 3463.

**Where to create the policy:** In the tenancy. Because of the concept of *policy inheritance*, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

| Allow group AlarmUsers to manage alarms in tenancy |
| Allow group AlarmUsers to read metrics in tenancy |
| Allow group AlarmUsers to manage ons-topics in tenancy |
Let users access usage reports

Type of access: Ability to view usage reports for your tenancy. For more information about usage reports, see Cost and Usage Reports Overview on page 323.

Where to create the policy: This is a special cross-tenancy policy and must be created in the tenancy. For more information, see Cost and Usage Reports Overview on page 323.

```
define tenancy usage-report as
  ocid1.tenancy.oc1..aaaaaaaaned4fkpkisbwjl1r56u7cj631f3wffbilvqknstgtvzub7vhqkggq
endorse group Administrators to read objects in tenancy usage-report
```

Let users analyze costs

Type of access: Ability to see costs for the tenancy. See Checking Your Expenses and Usage on page 79.

Where to create the policy: In the tenancy so that users in the `<Example_Group>` can see costs for the entire account.

```
Allow group `<Example_Group>` to read usage-reports in tenancy
```

Allow a group to manage topics

Type of access: Ability to get, create, update, and delete topics in the tenancy, as well as move topics to different compartments in the tenancy. Also includes the ability to create subscriptions in the tenancy and to publish messages (broadcast notification messages) to all subscriptions in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to manage ons-topics in tenancy
```

Allow a group to manage topic subscriptions

Type of access: Ability to list, create, update, and delete subscriptions for topics in the tenancy. Ability to move subscriptions to different compartments in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to manage ons-subscriptions in tenancy
```

Allow a group to publish messages to topics

Type of access: Ability to broadcast notification messages to all subscriptions in the tenancy, as well as list, create, update, and delete subscriptions in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to use ons-topics in tenancy
```

Let users create, deploy, and manage functions and applications using Cloud Shell

Type of access: Ability to create, deploy, and manage Functions applications and functions using Cloud Shell. These policy statements give the group access to Cloud Shell, repositories in Oracle Cloud Infrastructure Registry, logs, metrics, functions, networks, and tracing.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the resources in a particular compartment, you can specify the compartment instead of the tenancy in the to manage logging-family, to read metrics, to
manage functions-family, to use virtual-network-family, and to use apm-domains policy statements. However, the remaining policy statements (to use cloud-shell, to manage repos, and to read objectstorage-namespaces) must always be scoped to the tenancy.

| Allow group functions-developers to use cloud-shell in tenancy |
| Allow group functions-developers to manage repos in tenancy |
| Allow group functions-developers to read objectstorage-namespaces in tenancy |
| Allow group functions-developers to manage logging-family in tenancy |
| Allow group functions-developers to read metrics in tenancy |
| Allow group functions-developers to manage functions-family in tenancy |
| Allow group functions-developers to use virtual-network-family in tenancy |
| Allow group functions-developers to use use apm-domains in tenancy |
| Allow service faas to use apm-domains in tenancy |

**Let users list Events rules in a compartment**

**Type of access:** Ability to list Events rules.

**Where to create the policy:** In the tenancy.

| Allow group RuleReaders to read cloudevents-rules in tenancy |

The preceding policy allows RuleReaders to list rules in the tenancy.

**Let admins manage Events rules in a compartment**

**Type of access:** Ability to manage Events rules, including creating, deleting and updating rules.

**Where to create the policy:** In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

| allow group <RuleAdmins> to inspect compartments in tenancy |

This line gives the user access to defined tags to apply filter tags to rules.

| allow group <RuleAdmins> to use tag-namespaces in tenancy |

These lines give the user access to Streaming resources for actions

| allow group <RuleAdmins> to inspect streams in tenancy |
| allow group <RuleAdmins> to use stream-push in tenancy |
| allow group <RuleAdmins> to use stream-pull in tenancy |

These lines give the user access to Functions resources for actions.

| allow group <RuleAdmins> to use virtual-network-family in tenancy |
| allow group <RuleAdmins> to manage function-family in tenancy |

This line gives the user access to Notifications topics for actions.

| allow group <RuleAdmins> to use ons-topic in tenancy |

This line gives the user manage access to rules for Events.

| allow group <RuleAdmins> to manage cloudevents-rules in tenancy |
**Allow a group to access all of Cloud Guard**

**Type of access:** Read-only access to all of Cloud Guard. In the example policy, the group is "CloudGuard_ReadOnly."

```
allow group CloudGuard_ReadOnly to read cloud-guard-family in tenancy
allow group CloudGuard_ReadOnly to read compartments in tenancy
allow group CloudGuard_ReadOnly to read announcements in tenancy
```

**Allow a group to access Cloud Guard problems**

**Type of access:** Read-only access to Cloud Guard problems. In the example policy, the group is "CloudGuard_ReadOnlyProblems."

```
allow group CloudGuard_ReadOnlyProblems to read cloud-guard-family in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-detectors in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-targets in tenancy
allow group CloudGuard_ReadOnlyProblems to inspect cloud-guard-resource-types in tenancy
allow group CloudGuard_ReadOnlyProblems to read announcements in tenancy
allow group CloudGuard_ReadOnlyProblems to read compartments in tenancy
allow group CloudGuard_ReadOnlyProblems to read cloud-guard-config in tenancy
```

**Allow a group to access Cloud Guard detector recipes**

**Type of access:** Read-only access to Cloud Guard detector recipes. In the example policy, the group is "CloudGuard_ReadOnlyDetectors."

```
allow group CloudGuard_ReadOnlyDetectors to read cloud-guard-detector-recipes in tenancy
allow group CloudGuard_ReadOnlyDetectors to read announcements in tenancy
allow group CloudGuard_ReadOnlyDetectors to read compartments in tenancy
allow group CloudGuard_ReadOnlyDetectors to read cloud-guard-config in tenancy
```

**Allow a group to access Cloud Guard in a single compartment**

**Type of access:** Read-only access to Cloud Guard in a single compartment. In the example policy, the group is "CloudGuard_ReadOnly_SingleCompartment" and the compartment name is "cgDemo_RestrictedAccess."

```
allow group CloudGuard_ReadOnly_SingleCompartment to read compartments in tenancy where target.compartment.name = 'cgDemo_RestrictedAccess'
allow group CloudGuard_ReadOnly_SingleCompartment to read cloud-guard-family in compartment cgDemo_RestrictedAccess
allow group CloudGuard_ReadOnly_SingleCompartment to read announcements in compartment cgDemo_RestrictedAccess
allow group CloudGuard_ReadOnly_SingleCompartment to read cloud-guard-config in tenancy
```

**Let security admins manage all bastions and sessions**

**Type of access:** Ability to manage all resources in the Bastion service in all compartments. This makes sense if you want to have a single set of security admins manage all *bastions* and *sessions* in all compartments.
Where to create the policy: In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the bastions and bastion sessions in a particular compartment, specify that compartment instead of the tenancy.

| Allow group SecurityAdmins to manage bastion in tenancy |
| Allow group SecurityAdmins to manage bastion-session in tenancy |
| Allow group SecurityAdmins to manage virtual-network-family in tenancy |
| Allow group SecurityAdmins to read instance-family in tenancy |
| Allow group SecurityAdmins to read instance-agent-plugins in tenancy |
| Allow group SecurityAdmins to inspect work-requests in tenancy |

Let security admins manage bastion sessions

Type of access: Ability to manage all sessions on all bastions and in all compartments, including creating, connecting to, and terminating sessions.

Where to create the policy: In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the bastion sessions in a particular compartment, specify that compartment instead of the tenancy.

| Allow group SecurityAdmins to use bastion in tenancy |
| Allow group SecurityAdmins to manage bastion-session in tenancy |
| Allow group SecurityAdmins to manage virtual-network-family in tenancy |
| Allow group SecurityAdmins to read instance-family in tenancy |
| Allow group SecurityAdmins to read instance-agent-plugins in tenancy |
| Allow group SecurityAdmins to inspect work-requests in tenancy |

Let security admins manage bastion sessions for a specific target host in a compartment

Type of access: Ability to manage sessions on a bastion in a specific compartment, and only for sessions that provide connectivity to a specific Compute instance.

Where to create the policy: In the tenancy, so that access is easily granted to all compartments by way of policy inheritance.

| Allow group SecurityAdmins to use bastion in compartment ABC |
| Allow group SecurityAdmins to manage bastion-session in compartment ABC where target.resource.ocid = '<instance_OCID>' and target.bastion-session.username='<session_username>' |
| Allow group SecurityAdmins to manage virtual-network-family in tenancy |
| Allow group SecurityAdmins to read instance-family in tenancy |
| Allow group SecurityAdmins to read instance-agent-plugins in tenancy |
| Allow group SecurityAdmins to inspect work-requests in tenancy |

Allow a group to manage service connectors

Type of access: Ability to list, create, update, and delete service connectors in the tenancy. Ability to move service connectors to different compartments in the tenancy.

Where to create the policy: In the tenancy.

| Allow group A-Admins to manage serviceconnectors in tenancy |

Allow a group to call Operations Insights ingest operations at tenancy

Type of access: Ability to call ingest operations at the tenancy level only.
**Where to create the policy:** In the tenancy.

```
allow group opsi-users to use opsi-database-insights in tenancy
where any
{request.operation='IngestSqlBucket',
  request.operation='IngestSqlText',
  request.operation='IngestSqlPlanLines'}
```

**Let users create and delete workspaces without networking (Data Integration)**

Ability to create, delete, and modify workspaces within a compartment.

```
allow group <group-name> to manage dis-workspaces in <compartment-name>
allow group <group-name> to manage dis-work-requests in <compartment-name>
allow group <group-name> to manage tag-namespaces in <compartment-name>
```

**Let users create and delete workspaces with networking (Data Integration)**

Ability to create, delete, and modify workspaces within a virtual network.

```
allow service dataintegration to use virtual-network-family in <compartment-name>
allow group <group-name> to manage dis-workspaces in <compartment-name>
allow group <group-name> to manage dis-work-requests in <compartment-name>
allow group <group-name> to use virtual-network-family in <compartment-name>
allow group <group-name> to manage tag-namespaces in <compartment-name>
```

**Let users and resource principal access and use Object Storage for a given workspace (Data Integration)**

Ability to create and use Object Storage data assets within all workspaces.

```
allow any-user to use buckets in <compartment-name> where ALL
{request.principal.type='disworkspace'}
allow any-user to manage objects in <compartment-name> where ALL
{request.principal.type='disworkspace'}
allow group <group-name> to use object-family in <compartment-name>
```

To give access to an individual workspace, specify the OCID for the workspace where you want to allow access. For example:

```
allow any-user to use buckets in <compartment-name> where ALL
{request.principal.type='disworkspace', request.principal.id='workspace-ocid'}
allow any-user to manage objects in <compartment-name> where ALL
{request.principal.type='disworkspace', request.principal.id='workspace-ocid'}
```

**Let users and resource principal access and use autonomous databases as a target for a given workspace (Data Integration)**

Ability to create and use autonomous database data assets within all workspaces.

```
allow any-user to use buckets in <compartment-name> where ALL
{request.principal.type='disworkspace'}
allow any-user to manage objects in <compartment-name> where ALL
{request.principal.type='disworkspace'}
allow group <group-name> to use object-family in <compartment-name>
```
allow any-user to manage buckets in `<compartment-name>` where ALL {request.principal.type='disworkspace', request.permission='PAR_MANAGE'}

To give access to an individual workspace, specify the OCID for the workspace where you want to allow access. For example:

allow any-user to use buckets in `<compartment-name>` where ALL {request.principal.type='disworkspace', request.principal.id='<workspace-ocid>'}
allow any-user to manage objects in `<compartment-name>` where ALL {request.principal.type='disworkspace', request.principal.id='<workspace-ocid>'}
allow any-user to manage buckets in `<compartment-name>` where ALL {request.principal.type='disworkspace', request.principal.id='<workspace-ocid>'}, request.permission='PAR_MANAGE'}

**Let users search objects within a workspace (Data Integration)**

Ability to search the components of Data Integration in a given workspace.

This policy must be applied at the tenancy (root compartment) level.

allow service dataintegration to (TENANCY_INSPECT) in tenancy
allow service dataintegration to (DIS_METADATA_INSPECT) in tenancy

**Let users move workspaces to a new compartment (Data Integration)**

Ability to move workspaces to a new compartment.

allow service dataintegration to inspect compartments in `<compartment-name>`
allow group `<group-name>` to manage dis-workspaces in `<compartment-name>`

**Let users publish tasks to the OCI Data Flow service (Data Integration)**

Ability to publish the different tasks within all workspaces to the OCI Data Flow service.

allow any-user to manage dataflow-application in `<compartment-name>` where ALL {request.principal.type='disworkspace'}

To give access to an individual workspace, specify the OCID for the workspace where you want to allow access. For example:

allow any-user to manage dataflow-application in `<compartment-name>` where ALL {request.principal.type='disworkspace', request.principal.id='<workspace-ocid>'}

**Let users access the OCI Vault service for a given workspace (Data Integration)**

Ability to use OCI Vault secrets within all workspaces.

allow any-user to read secret-bundles in `<compartment-name>` where ALL {request.principal.type='disworkspace'}
allow group `<group-name>` to read secret-bundles in `<compartment-name>`
To give access to an individual workspace, specify the OCID for the workspace where you want to allow access. For example:

```sql
allow any-user to read secret-bundles in <compartment-name> where ALL
{request.principal.type='disworkspace', request.principal.id='<workspace-ocid>'}
```

### Advanced Policy Features

This section describes policy language features that let you grant more granular access.

#### Conditions

As part of a policy statement, you can specify one or more *conditions* that must be met in order for access to be granted.

Each condition consists of one or more predefined variables that you specify values for in the policy statement. Later, when someone requests access to the resource in question, if the condition in the policy is met, it evaluates to *true* and the request is allowed. If the condition is not met, it evaluates to *false* and the request is not allowed.

There are two types of variables: those that are relevant to the request itself, and those relevant to the resource being acted upon in the request, also known as the *target*. The name of the variable is prefixed accordingly with either *request* or *target* followed by a period. For example, there's a request variable called *request-operation* to represent the API operation being requested. This variable lets you write a broad policy statement, but add a condition based on the specific API operation. For an example, see Let users write objects to Object Storage buckets on page 2813.

**Important:**

Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment.

If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

#### Variables that Aren't Applicable to a Request Result in a Declined Request

If the variable is *not applicable* to the incoming request, the condition evaluates to *false* and the request is declined.

For example, here are the basic policy statements that together let someone add or remove users from any group except Administrators:

```sql
Allow group GroupAdmins to use users in tenancy
where target.group.name != 'Administrators'

Allow group GroupAdmins to use groups in tenancy
where target.group.name != 'Administrators'
```

Given the above policy, if GroupAdmins tried to call a general API operation for users such as `ListUsers` or `UpdateUser` (which lets you change the user's description), the request would be declined, even though those API operations are covered by `use users`. This is because the above policy statement for `use users` also includes the `target.group.name` variable, but the `ListUsers` or `UpdateUser` request doesn't involve specifying a group. There is no `target.group.name` for those requests, so the request is declined.

If you want to also grant access to general user API operations that don't involve a particular group, you would need an additional statement that gives the level of access you want to grant, but *without the condition*. For example, if you want to grant access to `ListUsers`, you need this additional statement:

```sql
Allow group GroupAdmins to inspect users in tenancy
```
Or if you want to grant access to `UpdateUser`, you need this additional statement (which also covers `ListUsers` because the `use` verb includes the capabilities of the `inspect` verb):

```
Allow group GroupAdmins to use users in tenancy
```

This general concept also applies to groups (e.g., `ListGroups` and `UpdateGroup`), and any other resource type with target variables.

For more information about the syntax of conditions, see *Conditions* on page 2836. For a list of all the variables you can use in policies, see the tables in the *Policy Reference* on page 2837.

**Tag-Based Access Control**

Using conditions and a set of tag variables, you can write policy to scope access based on the tags that have been applied to a resource. Access can be controlled based on a tag that exists on the requesting resource (the group or dynamic group in the policy) or on the target of the request (resource or compartment). Tag-based access control provides additional flexibility to your policies by allowing you to define access that spans compartments, groups, and resources. For details about how to write policies to scope access by tags, see *Using Tags to Manage Access* on page 4985.

**Permissions**

*Permissions* are the atomic units of authorization that control a user's ability to perform operations on resources. Oracle defines all the permissions in the policy language. When you write a policy giving a group access to a particular verb and resource-type, you're actually giving that group access to one or more predefined permissions. The purposes of verbs is to simplify the process of granting multiple related permissions that cover a broad set of access or a particular operational scenario. The next sections give more details and examples.

**Relation to Verbs**

To understand the relationship between permissions and verbs, let's look at an example. A policy statement that allows a group to inspect volumes actually gives the group access to a permission called `VOLUME_INSPECT` (permissions are always written with all capital letters and underscores). In general, that permission enables the user to get information about block volumes.

As you go from `inspect` > `read` > `use` > `manage`, the level of access generally increases, and the permissions granted are cumulative. The following table shows the permissions included with each verb for the `volumes` resource-type. Notice that no additional permissions are granted going from `inspect` to `read`.

<table>
<thead>
<tr>
<th>Inspect Volumes</th>
<th>Read Volumes</th>
<th>Use Volumes</th>
<th>Manage Volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>VOLUME_INSPECT</code></td>
<td><code>VOLUME_INSPECT</code></td>
<td><code>VOLUME_INSPECT</code></td>
<td><code>VOLUME_INSPECT</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>VOLUME_UPDATE</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>VOLUME_WRITE</code></td>
<td><code>VOLUME_CREATE</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><code>VOLUME_DELETE</code></td>
</tr>
</tbody>
</table>

The *policy reference* lists the permissions covered by each verb for each given resource-type. For example, for block volumes and other resources covered by the Core Services, see the tables in *Details for Verb + Resource-Type Combinations* on page 2857. The left column of each of those tables lists the permissions covered by each verb. The other sections of the policy reference include the same kind of information for the other services.

**Relation to API Operations**

Each API operation requires the caller to have access to one or more permissions. For example, to use either `ListVolumes` or `GetVolume`, you must have access to a single permission: `VOLUME_INSPECT`. To attach a volume to an instance, you must have access to multiple permissions, some of which are related to the `volumes`
resource-type, some to the `volume-attachments` resource-type, and some related to the `instances` resource-type:

- `VOLUME_WRITE`
- `VOLUME_ATTACHMENT_CREATE`
- `INSTANCE_ATTACH_VOLUME`

The policy reference lists which permissions are required for each API operation. For example, for the Core Services API operations, see the table in Permissions Required for Each API Operation on page 2901.

### Understanding a User's Access

The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the desired permissions in the statement. However, there may be situations where a security team member or auditor wants to understand the specific permissions a particular user has. The tables in the policy reference show each verb and the associated permissions. You can look at the groups the user is in and the policies applicable to those groups, and from there compile a list of the permissions granted. However, having a list of the permissions isn't the complete picture. Conditions in a policy statement can scope a user's access beyond individual permissions (see the next section). Also, each policy statement specifies a particular compartment and can have conditions that further scope the access to only certain resources in that compartment.

### Scoping Access with Permissions or API Operations

In a policy statement, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (i.e., change their description), but not delete them. To list, get, create, and update groups, you need a policy with `manage groups` as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations on page 2972, the permissions covered are:

- `GROUP_INSPECT`
- `GROUP_UPDATE`
- `GROUP_CREATE`
- `GROUP_DELETE`

To restrict access to only the desired permissions, you could add a condition that explicitly states the permissions you want to allow:

```
Allow group XYZ to manage groups in tenancy
where any {request.permission='GROUP_INSPECT',
          request.permission='GROUP_CREATE',
          request.permission='GROUP_UPDATE'}
```

An alternative would be a policy that allows all permissions except `GROUP_DELETE`:

```
Allow group XYZ to manage groups in tenancy where request.permission !=
  'GROUP_DELETE'
```

However, with this approach, be aware that any new permissions the service might add in the future would automatically be granted to group XYZ. Only `GROUP_DELETE` would be omitted.

Another alternative would be to write a condition based on the specific API operations. Notice that according to the table in Permissions Required for Each API Operation on page 2978, both `ListGroups` and `GetGroup` require only the `GROUP_INSPECT` permission. Here's the policy:

```
Allow group XYZ to manage groups in tenancy
where any {request.operation='ListGroups',
            request.operation='GetGroup',
```
It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-based policy above, that policy will already control XYZ group's access to that new API operation.

But notice that you can further scope a user's access to a permission by also specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to ListGroups.

Allow group XYZ to manage groups in tenancy
where all {request.permission='GROUP_INSPECT',
request.operation='ListGroups'}

Scoping Policy by the IP Address of the Requestor

You can scope access to only a set of allowed IP addresses. For example, you can write policy to allow only requests from a given public IP range to access a specific Object Storage bucket; or, you can allow only specific subnets of a specific VCN to make requests over a service gateway.

To restrict access to a set of IP addresses, do the following:

1. Create a network source object that specifies the allowed IP addresses. See Managing Network Sources on page 3123 for details.
2. Write a policy that uses the network source object in a condition.

Use the following variable in your policy:

request.networkSource.name='<network_source_name>'

For example:

allow group GroupA to manage object-family in tenancy where request.networkSource.name='corpnet'

Restricting Access to Resources Based on Time Frame

You can use time-based variables in your policies to restrict the access granted in the policy to only certain time frames. This feature allows you to restrict actions on resources to particular times. For example, you can create a policy that allows access only through a specified date. A policy like this would be useful if your company hires contractors and you want to ensure access is not allowed past the contract end date. Or, you could allow access to resources only during business hours (for example, Monday-Friday 9:00 AM - 5:00 PM). This restriction can lower the risk of a bad actor making changes when they are more likely to go unnoticed.

The variables that you can use to scope access based on time are:

- request.utc-timestamp
- request.utc-timestamp.month-of-year
- request.utc-timestamp.day-of-month
- request.utc-timestamp.day-of-week
- request.utc-timestamp.time-of-day

Usage for these variables is described in more detail in the following sections.

Information for Working with Time-Based Variables

You must specify the time the variables using ISO 8601 format: YYYY-MM-DDThh:mm:ssZ. Examples of this format are:
• Date and time with seconds: '2020-04-01T15:00:00Z'
• Date and time with minutes: '2020-04-01T05:00Z'
• Date only: '2020-04-01Z'
• Time only: '05:00:00'

Even though you can specify a time down to seconds, you should allow for a 5 minute time difference between the timestamp on the request and the time the request is evaluated by the IAM service. This time difference can be caused by several factors, therefore be aware of this potential discrepancy when you plan and implement your time-based policies.

The time that you specify is evaluated as Coordinated Universal Time (UTC). This means that you must calculate the correct UTC time for the time zone in which the policy is evaluated. For example, to specify 9:00 AM Pacific Standard Time for the value of a variable, you would enter '17:00:00'. If your locale participates in daylight savings, you'll need to update any policies that refer to a specific hour when the time change goes into effect.

**Details for Each Time-Based Variable**

Usage for each variable is described in the following sections:

**request.utc-timestamp**

**Description:** The time the request is received for authorization. You can write a policy that allows access only before or after a specific date-time timestamp. The timestamp must follow the ISO 8601 format: YYYY-MM-DDThh:mm:ssZ and be in Coordinated Universal Time (UTC).

**Supported operators:** before | after

**Allowed values:** Coordinated Universal Time (UTC) timestamp in ISO 8601 format: YYYY-MM-DDThh:mm:ssZ

**Example Values:**
• '2020-04-01T00:00:00Z'
• '2020-04-01T00:00Z'

**Example policy:** Allow group, Contractors, to access the instance-family resources only until a certain date:

```
Allow group Contractors to manage instance-family in tenancy where request.utc-timestamp before '2022-01-01T00:00Z'
```

The access granted by the policy to the group Contractors will expire on January 1, 2022, 12:00 AM, UTC.

**request.utc-timestamp.month-of-year**

**Description:** The month of the year that the request is received for authorization. You can write a policy that allows access only during specific months.

**Supported operators:** = | != | in

**Allowed values:** Numeric month (matching ISO 8601)

**Example Values:** '1', '2', '3', ... '12'

**Example policy:** Allow group, SummerInterns, to access the instance-family resources only during June, July, and August:

```
Allow group SummerInterns to manage instance-family in tenancy where ANY 
{request.utc-timestamp.month-of-year in ('6', '7', '8')}
```

The access granted by the policy to the group SummerInterns is only valid during June, July, and August of a given year.
**request.utc-timestamp.day-of-month**

**Description:** The day of the month that the request is received for authorization. You can write a policy that allows access only for specific days of the month. Keep in mind that the span of the day is calculated based on UTC. For example, suppose you are in Miami, FL, USA, and you enter '1' to indicate the first day of the month. For the month of February, the policy will be in effect for 12:00 AM through 11:59 PM UTC on February 1, which in Miami is 7:00 PM on January 31 through 6:59 PM on February 1.

**Supported operators:** = | != | in

**Allowed values:** Numeric day of month

**Example Values:** '1', '2', '3', ... '31'

**Example policy:** Allow group, ComplianceAuditors, to read all-resources only on the first day of the month.

```
Allow group ComplianceAuditors to read all-resources in tenancy where request.utc-timestamp.day-of-month = '1'
```

The access granted by the policy to the group ComplianceAuditors is only valid on the first day of each month (the day is defined by UTC time).

**request.utc-timestamp.day-of-week**

**Description:** The day of the week that the request is received for authorization. You can write a policy that allows access only for specific days of the week. Note that the span of the day is calculated based on UTC. For example, suppose you are in Miami, FL, USA, and you enter 'monday'. The policy will be in effect for 12:00 AM through 11:59 PM UTC on Monday, which in Miami is 7:00 PM (EST) on Sunday through 6:59 PM on Monday.

**Supported operators:** = | != | in

**Allowed values:** Name of day of week in English

**Example Values:** 'Monday', 'Tuesday', 'Wednesday', etc.

**Example policy:** Allow group, WorkWeek, to manage instance-family only during the company work week.

```
Allow group WorkWeek to manage instance-family where ANY {request.utc-timestamp.day-of-week in ('monday', 'tuesday', 'wednesday', 'thursday', 'friday')}
```

The access granted by the policy to the group WorkWeek is only valid on the days specified (the day is defined by UTC time).

**request.utc-timestamp.time-of-day**

**Description:** The time of day that the request is received for authorization. You can write a policy that allows access only for a specific span of time during the day. Note that the time of the day is calculated based on UTC. If you live in a time zone that implements daylight savings, you will need to update the policy when the time changes.

**Supported operators:** between

**Allowed values:** UTC time interval in ISO 8601 format: hh:mm:ssZ

**Example Values:** '01:00:00Z' AND '2:01:00Z'

**Example policies:** Allow group DayShift to manage instances and related resources between the hours of 9:00 AM and 5:00 PM Pacific Standard Time (PST).

Note that the times are converted to UTC:

```
Allow group DayShift to manage instance-family where request.utc-timestamp.time-of-day between '17:00:00Z' and '01:00:00Z'
```
I want to allow group NightShift to manage instances and related resources between 5:00 PM and 9:00 AM PST.

```
Allow group NightShift to manage instance-family where request.utc-timestamp.time-of-day between '01:00:00Z' and '17:00:00Z'
```

In both of these examples, the current time is calculated and tested to see if it falls within the provided range or not (ignoring which day the time falls on).

**Policy Syntax**

The overall syntax of a policy statement is as follows:

```
Allow <subject> to <verb> <resource-type> in <location> where <conditions>
```

Spare spaces or line breaks in the statement have no effect.

For limits on the number of policies and statements, see [Service Limits](#) on page 243.

**Subject**

Specify one or more comma-separated groups by name or OCID. Or specify `any-user` to cover all users in the tenancy.

**Syntax:**

- `group <group_name>`
- `group id <group_ocid>`
- `dynamic-group <dynamic-group_name>`
- `dynamic-group id <dynamic-group_ocid>`
- `any-user`

**Examples:**

- To specify a single group by name:
  ```
  Allow
group A-Admins
to manage all-resources in compartment Project-A
  ```

- To specify multiple groups by name (a space after the comma is optional):
  ```
  Allow
group A-Admins, B-Admins
to manage all-resources in compartment Projects-A-and-B
  ```

- To specify a single group by OCID (the OCID is shortened for brevity):
  ```
  Allow group
  id ocid1.group.oc1..aaaaaaqjihfhvxum...awuc7i5xwe6s7qmnsc6a
to manage all-resources in compartment Project-A
  ```

- To specify multiple groups by OCID (the OCIDs are shortened for brevity):
  ```
  Allow group
  id ocid1.group.oc1..aaaaaaqjihfhvxumr...wuc7i5xwe6s7qmnsc6a,
id ocid1.group.oc1..aaaaaaavheaa5mellwzb...66yfxcv1462tdgx2oeqcyq
to manage all-resources in compartment Projects-A-and-B
  ```
• To specify any user in the tenancy:

  Allow any-user to inspect users in tenancy

**Verb**

Specify a single verb. For a list of verbs, see Verbs on page 2839. Example:

  Allow group A-Admins to manage all-resources in compartment Project-A

**Resource-Type**

Specify a single resource-type, which can be one of the following:

• An individual resource-type (e.g., vcns, subnets, instances, volumes, etc.)
• A family resource-type (e.g., virtual-network-family, instance-family, volume-family, etc.)
• all-resources: Covers all resources in the compartment (or tenancy).

A family resource-type covers a variety of components that are typically used together. This makes it easier to write a policy that gives someone access to work with various aspects of your cloud network.

For a list of the available resource-types, see Resource-Types on page 2839.

**Syntax:** `<resource_type> | all-resources`

**Examples:**

• To specify a single resource-type:

  Allow group HelpDesk to manage users in tenancy

• To specify multiple resource-types, use separate statements:

  Allow group A-Users to manage instance-family in compartment Project-A
  Allow group A-Users to manage volume-family in compartment Project-A

• To specify all resources in the compartment (or tenancy):

  Allow group A-Admins to manage all-resources in compartment Project-A

**Location**

Specify a single compartment or compartment path by name or OCID. Or simply specify tenancy to cover the entire tenancy. Remember that users, groups, and compartments reside in the tenancy. Policies can reside in (i.e., be attached to) either the tenancy or a child compartment.

**Note:**

Granting Access to Specific Regions or availability domains

To create a policy that gives access to a specific region or availability domain, use the request.region or request.ad variable with a condition. See Conditions on page 2836.

The location is required in the statement. If you want to attach a policy to a compartment, you must be in that compartment when you create the policy. For more information, see Policy Attachment on page 2805.

To specify a compartment that is not a direct child of the compartment you are attaching the policy to, specify the path to the compartment, using the colon (:) as a separator. For more information, see Policies and Compartment Hierarchies on page 2805.
IAM

Syntax: [ tenancy | compartment <compartment_name> | compartment id <compartment_ocid> ]

Examples:

- To specify a compartment by name:
  
  Allow group A-Admins to manage all-resources in compartment Project-A
  
- To specify a compartment by OCID:
  
  Allow group id ocid1.group.oc1..aaaaaexempleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaaaexempleocid
  
- To specify multiple compartments, use separate statements:
  
  Allow group InstanceAdmins to manage instance-family in compartment Project-A
  
  Allow group InstanceAdmins to manage instance-family in compartment Project-B
  
- To specify multiple compartments by OCID, use separate statements:
  
  Allow group id ocid1.group.oc1..aaaaaavheexampleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaayzexampleocid
  
  Allow group id ocid1.group.oc1..aaaaaexempleocid to manage all-resources in compartment id ocid1.compartment.oc1..aaaaexampleocid
  
- To specify a compartment that is not a direct child of the compartment where you are attaching the policy, specify the path:
  
  Allow group InstanceAdmins to manage instance-family in compartment Project-A:Project-A2

Conditions

Specify one or more conditions. Use any or all with multiple conditions for a logical OR or AND, respectively.

Syntax for a single condition: variable =|!= value

Syntax for multiple conditions: any|all {<condition>,<condition>,...}

Additional operators can be used with time-based variables, see Restricting Access to Resources Based on Time Frame on page 2831.

Important:

Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment. If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

For a list of variables supported by all the services, see General Variables for All Requests on page 2840. Also see the details for each service in the Policy Reference on page 2837. Here are the types of values you can use in conditions:
## Type

<table>
<thead>
<tr>
<th>Type</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>'<a href="mailto:johnsmith@example.com">johnsmith@example.com</a>'</td>
</tr>
<tr>
<td></td>
<td>(single quotation marks are required around the value)</td>
</tr>
<tr>
<td>Pattern</td>
<td>/<em>HR</em>/ (matches strings that start with &quot;HR&quot;)</td>
</tr>
<tr>
<td></td>
<td>/*HR/ (matches strings that end with &quot;HR&quot;)</td>
</tr>
<tr>
<td></td>
<td>/<em>HR</em>/ (matches strings that contain &quot;HR&quot;)</td>
</tr>
</tbody>
</table>

### Examples:

**Note:**

In the following examples, the statements that specify the condition do not let GroupAdmins actually list all the users and groups, therefore statements including the inspect verb are added for completeness. To understand why this is required, see Variables that Aren't Applicable to a Request Result in a Declined Request on page 2828.

- **A single condition.**

  The following policy enables the GroupAdmins group to create, update, or delete any groups with names that start with "A-Users-":

  ```
  Allow group GroupAdmins to manage groups in tenancy where target.group.name = /A-Users-*/
  Allow group GroupAdmins to inspect groups in tenancy
  ```

  The following policy enables the NetworkAdmins group to manage cloud networks in any compartment except the one specified:

  ```
  Allow group NetworkAdmins to manage virtual-network-family in tenancy where target.compartment.id != 'ocid1.compartment.oc1..aaaaaexampleocid'
  ```

- **Multiple conditions.**

  The following policy lets GroupAdmins create, update, or delete any groups whose names start with "A-", except for the A-Admins group itself:

  ```
  Allow group GroupAdmins to manage groups in tenancy where all {target.group.name=/A-*/,target.group.name !='A-Admins'}
  Allow group GroupAdmins to inspect groups in tenancy
  ```

Verbs

The verbs are listed in order of least amount of ability to most. The exact meaning of each verb depends on which resource-type it's paired with. The tables later in this section show the API operations covered by each combination of verb and resource-type.

<table>
<thead>
<tr>
<th>Verb</th>
<th>Types of Access Covered</th>
<th>Target User</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td><strong>Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. Important:</strong> The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).</td>
<td>Third-party auditors</td>
</tr>
<tr>
<td>read</td>
<td>Includes inspect plus the ability to get user-specified metadata and the actual resource itself.</td>
<td>Internal auditors</td>
</tr>
<tr>
<td>use</td>
<td>Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the &quot;update&quot; operation has the same effective impact as the &quot;create&quot; operation (e.g., UpdatePolicy, UpdateSecurityList, etc.), in which case the &quot;update&quot; ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.</td>
<td>Day-to-day end users of resources</td>
</tr>
<tr>
<td>manage</td>
<td>Includes all permissions for the resource.</td>
<td>Administrators</td>
</tr>
</tbody>
</table>

Resource-Types

The family resource-types are listed below. For the individual resource-types that make up each family, follow the links.

- **all-resources:** All Oracle Cloud Infrastructure resource-types
- **cluster-family:** See Details for Container Engine for Kubernetes on page 2851
- **compute-management-family:** See Details for the Core Services on page 2855
- **data-catalog-family:** See Data Catalog Policies
- **database-family:** See Details for the Database Service on page 2917
- **dns:** See Details for the DNS Service on page 2950
- **email-family:** See Details for the Email Delivery Service on page 2958
- **file-family:** See Details for the File Storage Service on page 2963
- **instance-agent-command-family:** See Details for the Core Services on page 2855
- **instance-agent-family:** See Details for the Core Services on page 2855
- **instance-family:** See Details for the Core Services on page 2855
- **object-family:** See Details for Object Storage, Archive Storage, and Data Transfer on page 3017
- **virtual-network-family:** See Details for the Core Services on page 2855
- **volume-family:** See Details for the Core Services on page 2855
IAM has no family resource-type, only individual ones. See Details for IAM on page 2971.

### General Variables for All Requests

You use variables when adding conditions to a policy. For more information, see Conditions on page 2828. Here are the general variables applicable to all requests.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>request.user.id</code></td>
<td>Entity (OCID)</td>
<td>The OCID of the requesting user.</td>
</tr>
</tbody>
</table>
| `request.user.mfaTotpVerified` | Boolean          | Whether the user has been verified by multi-factor authentication (MFA). To restrict access to only MFA-verified users, add the condition where
<p>|                          |                    | request.user.mfaTotpVerified='true' See Managing Multi-Factor Authentication on page 3164 for information on setting up MFA. |
| <code>request.groups.id</code>      | List of entities (OCIDs) | The OCIDs of the groups the requesting user is in.                          |
| <code>request.permission</code>     | String             | The underlying permission being requested (see Permissions on page 2829).    |
| <code>request.operation</code>      | String             | The API operation name being requested (for example, <code>ListUsers</code>).           |
| <code>request.networkSource.name</code> | String           | The name of the network source group that specifies allowed IP addresses the request may come from. See Managing Network Sources on page 3123 for information. |
| <code>request.utc-timestamp</code>  | String             | The UTC time that the request is submitted, specified in ISO 8601 format. See Restricting Access to Resources Based on Time Frame on page 2831 for more information. |
| <code>request.utc-timestamp.month-of-year</code> | String          | The month that the request is submitted in, specified in numeric ISO 8601 format (for example, '1', '2', '3', ... '12'). See Restricting Access to Resources Based on Time Frame on page 2831 for more information. |
| <code>request.utc-timestamp.day-of-month</code> | String       | The day of the month that the request is submitted in, specified in numeric format '1' - '31'. See Restricting Access to Resources Based on Time Frame on page 2831 for more information. |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request.utc-timestamp.day-of-week</td>
<td>String</td>
<td>The day of the week that the request is submitted in, specified in English (for example, 'Monday', 'Tuesday', 'Wednesday', etc.). See Restricting Access to Resources Based on Time Frame on page 2831 for more information.</td>
</tr>
<tr>
<td>request.utc-timestamp.time-of-day</td>
<td>String</td>
<td>The UTC time interval that request is submitted during, in ISO 8601 format (for example, '01:00:00Z' AND '02:01:00Z'). See Restricting Access to Resources Based on Time Frame on page 2831 for more information.</td>
</tr>
<tr>
<td>request.region</td>
<td>String</td>
<td>The 3-letter key for the region the request is made in. Allowed values are:</td>
</tr>
<tr>
<td>• AMS - use for Netherlands Northwest (Amsterdam)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• BOM - use for India West (Mumbai)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• CWL - use for UK West (Newport)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• DXB - use for UAE East (Dubai)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• FRA - use for Germany Central (Frankfurt)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• GRU - use for Brazil East (Sao Paulo)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• HYD - use for India South (Hyderabad)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• IAD - use for US East (Ashburn)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• ICN - use for South Korea Central (Seoul)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• JED - use for Saudi Arabia West (Jeddah)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• KIX - use for Japan Central (Osaka)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• LHR - use for UK South (London)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• MEL - use for Australia Southeast (Melbourne)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• NRT - use for Japan East (Tokyo)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• PHX - use for US West (Phoenix)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• SCL - use for Chile (Santiago)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• SJ C - use for US West (San Jose)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• SYD - use for Australia East (Sydney)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• VCP - use for Brazil Southeast (Vinhedo)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• YNY - use for South Korea North (Chuncheon)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• YUL - use for Canada Southeast (Montreal)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• YYZ - use for Canada Southeast (Toronto)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• ZRH - use for Switzerland North (Zurich)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>request.ad</td>
<td>String</td>
<td>The name of the availability domain the request is made in. To get a list of availability domain names, use the ListAvailabilityDomains operation.</td>
</tr>
<tr>
<td>request.principal.compartment.tag</td>
<td>String</td>
<td>The tags applied to the compartment that the requesting resource belongs to are evaluated for a match. For usage instructions, see Using Tags to Manage Access on page 4985.</td>
</tr>
<tr>
<td>request.principal.group.tag</td>
<td>String</td>
<td>The tags applied to the groups that the user belongs to are evaluated for a match. For usage instructions, see Using Tags to Manage Access on page 4985.</td>
</tr>
<tr>
<td>target.compartment.name</td>
<td>String</td>
<td>The name of the compartment specified in target.compartment.id.</td>
</tr>
<tr>
<td>target.compartment.id</td>
<td>Entity (OCID)</td>
<td>The OCID of the compartment containing the primary resource. Note: target.compartment.id and target.compartment.name cannot be used with a &quot;List&quot; API operation to filter the list based on the requesting user's access to the compartment.</td>
</tr>
<tr>
<td>target.resource.compartment.tag</td>
<td>String</td>
<td>The tag applied to the target compartment of the request is evaluated. For usage instructions, see Using Tags to Manage Access on page 4985.</td>
</tr>
<tr>
<td>target.resource.tag</td>
<td>String</td>
<td>The tag applied to the target resource of the request is evaluated. For usage instructions, see Using Tags to Manage Access on page 4985.</td>
</tr>
</tbody>
</table>

Details for the Announcements Service

This topic covers details for writing policies to control access to the Announcements service.

**Resource-Types**

- announcements

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the announcements resource-type includes the same permissions and API operations as the inspect verb, plus the ANNOUNCEMENT_READ permission and an additional API operation, GetAnnouncement. However, the use verb and manage verbs cover no extra permissions or API operations compared to read.
announcements

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>ANNOUNCEMENT_LIST</td>
<td>ListAnnouncements</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT</td>
<td>INSPECT +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>ANNOUNCEMENT_READ</td>
<td>GetAnnouncement</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>

Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2829.

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListAnnouncements</td>
<td>ANNOUNCEMENT_LIST</td>
</tr>
<tr>
<td>GetAnnouncement</td>
<td>ANNOUNCEMENT_READ</td>
</tr>
</tbody>
</table>

Details for API Gateway

This topic covers details for writing policies to control access to API Gateway.

Resource-Types

Aggregate Resource-Type

api-gateway-family

Individual Resource-Types

- api-gateways
- api-deployments
- api-definitions
- api-workrequests
- api-certificates
- api-sdks

Comments

A policy that uses `<verb> api-gateway-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2843 for details of the API operations covered by each verb, for each individual resource-type included in api-gateway-family.

Supported Variables

API Gateway supports all the general variables (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access..
For example, the `read` verb for the `api-gateways` resource-type includes the same permissions and API operations as the `inspect` verb, plus the `API_GATEWAY_READ` permission and a number of API operations (e.g., `GetGateway`, etc.). The `use` verb covers additional permissions and API operations compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

### api-gateways

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td><code>API_GATEWAY_LIST</code></td>
<td><code>ListGateways</code></td>
<td>none</td>

**Details for Application Performance Monitoring**

This topic covers details for writing policies to control access to the Application Performance Monitoring (APM) service.

**Resource-Types**

apm-domains

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following table shows the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use and manage verbs for the apm-domains resource-type cover no extra permissions or API operations compared to the read verb.

**apm-domains**

### Details for the Audit Service

This topic covers details for writing policies to control access to the Audit service.

**Resource-Types**

- audit-events

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).
Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use and manage verbs for the audit-events resource-type cover no extra permissions or API operations compared to the read verb.

<table>
<thead>

</tbody>
</table>

Details for Container Engine for Kubernetes

This topic covers details for writing policies to control access to Container Engine for Kubernetes.

Resource-Types

Aggregate Resource-Type
- cluster-family

Individual Resource-Types
- clusters
- cluster-node-pools
- cluster-work-requests

Comments
A policy that uses <verb> cluster-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2852 for details of the API operations covered by each verb, for each individual resource-type included in cluster-family.

Supported Variables
Container Engine for Kubernetes supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.
The `clusters` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.cluster.id</code></td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

The `cluster-node-pools` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.nodepool.id</code></td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `clusters` resource-type includes the same permissions and API operations as the `inspect` verb, plus the CLUSTER_READ permission and a number of API operations (e.g., `GetCluster`, etc.). The `use` verb covers still another permission and API operation compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

### clusters

Details for the Core Services

This topic covers details for writing policies to control access to the Core Services (Networking, Compute, and Block Volume).

**Resource-Types**

*Networking*

**Aggregate Resource-Type**

- virtual-network-family
- drgs (covers drg-object, drg-route-table, drg-route-distribution, drg-attachment)

**Individual Resource-Types**

- vcn
- subnets
- route-tables
- network-security-groups
- security-lists
- dhcp-options
- private-ips
- public-ips
- ipv6s
- internet-gateways
- nat-gateways
- service-gateways
- local-peering-gateways (which includes local-peering-from, and local-peering-to)
- remote-peering-connections (which includes remote-peering-from, and remote-peering-to)
- drg-object
- drg-attachments
- drg-route-tables
- drg-route-distributions
- cpes
- ipsec-connections
- cross-connects
- cross-connect-groups
- virtual-circuits
- vnics
vnic-attachments
vlans
byoiprange
publicippool

Comments
A policy that uses <verb> virtual-network-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2857 for details of the API operations covered by each verb, for each individual resource-type included in virtual-network-family.

Compute

instance-family Aggregate Resource-Type
The instance-family aggregate resource-type covers these individual resource-types:
app-catalog-listing
calendar-histories
instances
instance-console-connection
instance-images
volume-attachments (includes only the permissions required for attaching volumes to instances)

compute-management-family Aggregate Resource-Type
The compute-management-family aggregate resource-type covers these individual resource-types:
instance-configurations
instance-pools
cluster-networks

instance-agent-family Aggregate Resource-Type
The instance-agent-family aggregate resource-type covers this individual resource-type:
instance-agent-plugins

instance-agent-command-family Aggregate Resource-Type
The instance-agent-command-family aggregate resource-type covers this individual resource-type:
instance-agent-commands

Additional Individual Resource-Types
auto-scaling-configurations
compute-capacity-reservations
dedicated-vm-hosts
instance-agent-commands
work-requests
Comments

A policy that uses `<verb>` instance-family or `<verb>` compute-management-family is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual resource-types in the family.

See the table in Details for Verb + Resource-Type Combinations on page 2857 for details of the API operations covered by each verb, for each individual resource-type.

Block Volume

Aggregate Resource-Type

volume-family

Individual Resource-Types

volumes
volume-attachments
volume-backups
boot-volume-backups
backup-policies
backup-policy-assignments
volume-groups
volume-group-backups

Comments

A policy that uses `<verb>` volume-family is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2857 for details of the API operations covered by each verb, for each individual resource-type included in volume-family.

Supported Variables

The Core Services support all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests on page 2840.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.boot-volume.kms-key.id</td>
<td>String</td>
<td>Use this variable to control whether Compute instances can be launched with boot volumes that were created without a Vault service master encryption key.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read and use verbs for the vcns resource-type cover no extra permissions or API operations compared to the inspect verb. However, the manage verb includes several extra permissions and API operations.
For virtual-network-family Resource Types

The following tables list the permissions and API operations covered by each of the individual resource-types included in virtual-network-family.

vcns

<table>
<thead>
<tr>

</tbody>
</table>

**Note:** The above operations in this cell are covered with just manage virtual-network-family.

### For instance-family Resource Types

The instance-family aggregate resource-type includes extra permissions beyond the sum of the permissions for the individual resource-types included in instance-family. For example: It includes a few permissions for vnics and volumes, even though those resource-types aren't generally considered part of the instance-family. Why are there extras included? So you can write fewer policy statements to cover general use cases, like working with an instance that has an attached block volume. You can write one statement for instance-family instead of multiple statements covering instances, vnics, and volumes.

Here's a list of the extra permissions:

**For inspect instance-family:**
- VNIC_READ
- VNIC_ATTACHMENT_READ
- VOLUME_ATTACHMENT_INSPECT

**For read instance-family:**
- VOLUME_ATTACHMENT_READ

**For use instance-family:**
- VNIC_ATTACH
- VNIC_DETACH
- VOLUME_ATTACHMENT_UPDATE

**For manage instance-family:**
- VOLUME_ATTACHMENT_CREATE
- VOLUME_ATTACHMENT_DELETE

The following tables list the permissions and API operations covered by each of the individual resource-types included in instance-family.
### instances

<table>

<td>USE +</td>
<td>AUTO_SCALING_CONFIGURATION_CREATE</td>
<td>USE +</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AUTO_SCALING_CONFIGURATION_UPDATE</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>AUTO_SCALING_CONFIGURATION_DELETE</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>AUTO_SCALING_CONFIGURATION_MOVE</td>
<td></td>
</tr>
</tbody>
</table>

For manage, you also need manage instance-pools.

---

For compute-capacity-reservations:

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>CAPACITY_RESERVATION_INSPECT</td>
<td>ListComputeCapacityReservationInstanceShapes</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>READ +</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

For dedicated-vm-hosts:

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>DEDICATED_VM_HOST_INSPECT</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>
### Verbs

<table>
<thead>
<tr>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>use</td>
<td>INSPECT +</td>
<td>INSPECT +</td>
</tr>
<tr>
<td></td>
<td>DEDICATED_VM_HOST_LAUNCH_INSTANCE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DEDICATED_VM_HOST_UPDATE</td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>USE +</td>
</tr>
<tr>
<td></td>
<td>DEDICATED_VM_HOST_CREATE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DEDICATED_VM_HOST_MOVE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DEDICATED_VM_HOST_DELETE</td>
<td></td>
</tr>
</tbody>
</table>

All also need create instance in the compartment to launch the instance in and dedicated vm host launch instance in the compartment for the dedicated virtual machine host.

### work-requests

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>WORKREQUEST_INSPECT</td>
<td>ListWorkRequests</td>
<td>none</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td></td>
<td>UpdateVolumeBackup (also need read volume-backups)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DeleteVolumeBackup (also need manage volume-backups)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>GetVolumeAttachment (also need inspect instances and inspect volume-attachments). If you need to get the CHAP secret if it exists, read volume-attachments is required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>CreateInstanceConfiguration (if using the CreateInstanceConfigurationFromInstanceDetails subtype. Also need read instances, inspect vnics, inspect vnic-attachments, and inspect volume-attachments.)</td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>no extra</td>
</tr>
<tr>
<td>use</td>
<td>READ +</td>
<td>no extra</td>
<td>READ +</td>
</tr>
<tr>
<td></td>
<td>VOLUME_UPDATE</td>
<td></td>
<td>AttachVolume and DetachVolume (both also need manage volume-attachments, use instances)</td>
</tr>
<tr>
<td></td>
<td>VOLUME_WRITE</td>
<td></td>
<td>CreateVolumeBackup (also need manage volume-backups)</td>
</tr>
<tr>
<td>Verbs</td>
<td>Permissions</td>
<td>APIs Fully Covered</td>
<td>APIs Partially Covered</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------</td>
<td>-------------------------------------------------------</td>
<td>-------------------------------------------------------------</td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>USE +</td>
<td>USE +</td>
</tr>
<tr>
<td></td>
<td>VOLUME_CREATE</td>
<td>CreateVolume</td>
<td>If creating a volume <em>from a backup</em>, also need read volume-backups.</td>
</tr>
<tr>
<td></td>
<td>VOLUME_DELETE</td>
<td>DeleteVolume</td>
<td></td>
</tr>
<tr>
<td></td>
<td>VOLUME_MOVE</td>
<td>ChangeVolumeCompartment</td>
<td>When moving volumes between compartments, the <em>move volume</em> permission is needed for both source and destination compartments.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When moving volumes between compartments, the *move volume* permission is needed for both source and destination compartments.

If creating a volume *encrypted with a Vault service master encryption key*, also need *use key-delegate* (for the caller) and *read keys* (for the service principal). For more information, see Details for the Vault Service on page 3043.

</table>

If creating a volume group from a list of volumes, also need inspect volume for the volumes to include in the group.

If creating a volume group from another volume group, also need the following:

- inspect volume group for the source volume group
- create volume group for the destination volume group
- write volume for the source volumes
- create volume for the destination volumes
- write volume for the destination volumes

If creating a volume group from a volume group backup, also need the following:

- inspect volume group backup for the source volume group
- create volume group for the destination volume group
- read volume backup or read boot volume backup for the source volumes
- create volume for the destination volumes
- write volume for the destination volumes

When moving volume groups between compartments, the move volume group and move volume permissions are needed for both source and destination compartments.

**Details for the Database Service**

See the following topics for details for writing policies to control access to Oracle Cloud Infrastructure Database service resources:

- Policy Details for Autonomous Database on page 2918
- Policy Details for Bare Metal and Virtual Machine DB Systems on page 2937
- Policy Details for Database Software Images on page 2944
Policy Details for Autonomous Database

This topic covers details for writing policies to control access to Autonomous Database resources.

Tip:

For a sample policy, see Let database and fleet admins manage Autonomous Databases on page 2815.

Resource-Types

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the autonomous-database-family is equivalent to writing four separate policies for the group that would grant access to the autonomous-databases, autonomous-backups, autonomous-container-databases, and autonomous-exadatainfrastructures resource-types. For more information, see Resource-Types on page 2803.

Resource-Types for Autonomous Database

Aggregate Resource-Type

autonomous-database-family

Individual Resource-Types:

autonomous-databases
autonomous-backups
autonomous-container-databases
autonomous-exadatainfrastructures

Supported Variables

General variables are supported. See General Variables for All Requests on page 2840 for more information.

Additionally, you can use the target.workloadType variable, as shown in the following table:

<table>
<thead>
<tr>
<th>target.workloadType value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OLTP</td>
<td>Online Transaction Processing, used for the Autonomous Transaction Processing database.</td>
</tr>
<tr>
<td>DW</td>
<td>Data Warehouse, used for the Autonomous Data Warehouse database</td>
</tr>
<tr>
<td>AJD</td>
<td>Autonomous JSON Database</td>
</tr>
<tr>
<td>APEX</td>
<td>Oracle APEX Application Development</td>
</tr>
</tbody>
</table>

Example policy using the target.workloadType variable:

Allow group ADB-Admins to manage autonomous-database in tenancy where target.workloadType = 'workload_type'

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.
For example, the read verb for the autonomous-databases resource-type covers the same permissions and API operations as the inspect verb, plus the AUTONOMOUS_DATABASE_CONTENT_READ permission. The read verb partially covers the CreateAutonomousDatabaseBackup operation, which also needs manage permissions for autonomous-backups.

For autonomous-database-family Resource Types

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>AUTONOMOUS_DATABASE_INSPECT</td>

For autonomous-data-warehouse-family Resource Types

**Note:**

The **autonomous-data-warehouse-family** permissions are deprecated. You can use the resource family **autonomous-database-family** to grant access.
to the Autonomous Database resources used by both Autonomous Data Warehouse databases and Autonomous Transaction Processing databases.

### Permissions Required for Each API Operation

The following tables list the API operations for Autonomous Database resources in a logical order, grouped by resource type.

For information about permissions, see Permissions on page 2829.

**Autonomous Database API Operations**

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions Required to Use the Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListAutonomousExadataInfrastructureShapes</td>
<td>permission required</td>
</tr>
<tr>
<td>ListAutonomousExadataInfrastructures</td>
<td>AUTONOMOUS_EXADATA_INFRASTRUCTURE_INSPECT</td>
</tr>
<tr>
<td>API Operation</td>
<td>Permissions Required to Use the Operation</td>
</tr>
<tr>
<td>---------------------------------------------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LaunchAutonomousExadataInfrastructure</td>
<td>AUTONOMOUS_EXADATA_INFRASTRUCTURE_CREATE and VNIC_CREATE and SUBNET_ATTACH and VNIC_ATTACH</td>
</tr>
<tr>
<td>GetAutonomousExadataInfrastructure</td>
<td>AUTONOMOUS_EXADATA_INFRASTRUCTURE_INSPECT</td>
</tr>
<tr>
<td>TerminateAutonomousExadataInfrastructure</td>
<td>AUTONOMOUS_EXADATA_INFRASTRUCTURE_DELETE and VNIC_DELETE and SUBNET_DETACH and VNIC_DETACH</td>
</tr>
<tr>
<td>UpdateAutonomousExadataInfrastructure</td>
<td>AUTONOMOUS_EXADATA_INFRASTRUCTURE_UPDATE and AUTONOMOUS_DB_SYSTEM_INSPECT</td>

</table>

**Policy Details for Exadata Cloud Service Instances**

This topic covers details for writing policies to control access to bare metal, virtual machine, and Exadata Cloud Service resources.

**Tip:**

For a sample policy, see Let database admins manage Oracle Cloud database systems on page 2814.

**Resource-Types**

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the database-family is equivalent to writing separate policies for the group that would grant access to the cloud-exadata-infrastructures, cloud-vmclusters, db-nodes, db-homes, databases, database-software-image, and backups resource-types. For more information, see Resource-Types on page 2803.

**Resource-Types for Exadata Cloud Service Instances**

**Aggregate Resource-Type**

database-family

**Individual Resource-Types:**

cloud-exadata-infrastructures
cloud-vmclusters
db-nodes
db-homes
databases
backups

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.
For example, the read and use verbs for the `cloud-exadata-infrastructures` resource-type cover no extra permissions or API operations compared to the inspect verb. However, the manage verb includes two more permissions and partially covers two more API operations.

### For database-family Resource Types

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>CLOUD_EXADATA_INFRASTRUCTURE_INSPECT</td>
<td>GetCloudExadataInfrastructure</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td>CLOUD_EXADATA_INFRASTRUCTURE_UPDATE</td>
<td>ChangeCloudExadataInfrastructure (also needs use cloud-vmclusters, use db-homes, use databases, and inspect db-backups)</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>UpdateCloudExadataInfrastructure</td>
<td>CreateCloudExadataInfrastructure, DeleteCloudExadataInfrastructure</td>
</tr>
</tbody>
</table>

#### cloud-vmclusters

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>CLOUD_VM_CLUSTER_INSPECT</td>

**Policy Details for External Database**

This topic covers details for writing policies to control access to external database resources.

**Tip:**

For a sample policy, see [Let database admins manage Oracle Cloud external database resources](#) on page 2815.

**Resource-Types**

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the external-database-family is equivalent to writing four separate policies for the group that would grant access to the external-container-databases, external-pluggable-databases, external-non-container-databases, and external-database-connectors resource-types. For more information, see [Resource-Types](#) on page 2803.

**Aggregate Resource-Type**

external-database-family

**Individual Resource-Types:**

external-container-databases
external-pluggable-databases
external-non-container-databases
external-database-connectors

**Supported Variables**

Only the general variables are supported (see [General Variables for All Requests](#) on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the external-container-databases resource-type covers the same permissions and API operations as the read verb, plus the EXTERNAL_CONTAINER_DATABASE_UPDATE permission.
permission. The `use` verb partially covers the `ScanPluggableDatabases` operation, which also needs read permissions for `external-pluggable-databases`.

### external-container-databases

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>

**Policy Details for Bare Metal and Virtual Machine DB Systems**

This topic covers details for writing policies to control access to bare metal and virtual machine DB system resources.

**Tip:**

For a sample policy, see Let database admins manage Oracle Cloud database systems on page 2814.

**Resource-Types**

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the database-family is equivalent to writing separate policies for the group that would grant access to the db-systems, db-nodes, db-homes, databases, database-software-image, and backups resource-types. For more information, see Resource-Types on page 2803.

**Resource-Types for Bare Metal, Virtual Machine, and Exadata DB Systems**

**Aggregate Resource-Type**

database-family

**Individual Resource-Types:**

db-systems
db-nodes
db-homes
databases
pluggable databases
backups

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).
Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read and use verbs for the db-systems resource-type cover no extra permissions or API operations compared to the inspect verb. However, the manage verb includes two more permissions and partially covers two more API operations.

For database-family Resource Types

db-systems

**Policy Details for Database Software Images**

This topic covers details for writing policies to control access to database software images. These are used by Exadata Cloud Service instances, virtual machine DB systems, and bare metal DB systems.

**Tip:**

For a sample policy, see Let database admins manage Oracle Cloud database systems on page 2814.

**Resource-Types**

The database-software-image resource-type covers the Oracle-published and custom database software images available through the Database Software Image feature. The database-family aggregate resource-type
IAM covers the database software image resource-type as well as other resources related to DB systems and Exadata Cloud Service instances. For more information, see Resource-Types on page 2803, and the policy details for Exadata Cloud Service instances and DB systems.

**Aggregate Resource-Type**

There are no aggregate resource-types for database software images.

**Individual Resource-Types:**

database-software-image (covered under the database-family aggregate resource-type)

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions Required to Use the Operation</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>DB_SOFTWARE_IMG_INSPECT</td>
<td>ListDatabaseSoftwareImages</td>
<td>GetDatabaseSoftwareImage</td>
</tr>
<tr>

<tr>
<td>ChangeDatabaseSoftwareImageCompartment</td>
<td>DB_SOFTWARE_IMG_INSPECT and DB_SOFTWARE_IMG_UPDATE</td>
</tr>
<tr>
<td>CreateDatabaseSoftwareImage</td>
<td>DB_SOFTWARE_IMG_INSPECT and DB_SOFTWARE_IMG_CREATE</td>
</tr>
</tbody>
</table>
Details for Database Management

This topic covers details for writing policies to control access to the Database Management service.

Resource-Types

Aggregate Resource-Type

dbmgmt-family

Individual Resource-Types

- dbmgmt-jobs
- dbmgmt-managed-database-groups
- dbmgmt-managed-databases

Comments

A policy that uses `<verb> dbmgmt-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types in the family.

See the table in Details for Verb + Resource-Type Combinations on page 2946 for details of the API operations covered by each verb, for each individual resource-type.

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for the DNS Service

This topic covers details for writing policies to control access to the DNS service.

Aggregate Resource-Type
dns

Individual Resource-Types
dns-zones
dns-records
dns-steering-policies
dns-steering-policy-attachments
dns-tsig-keys
dns-views
dns-resolvers

Comments
A policy that uses `<verb>` dns is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual resource-types.
See the table in Details for Verb + Resource-Type Combinations on page 2953 for details of the API operations covered by each verb, for each individual resource-type included in `dns`.

**Supported Variables**

The DNS service supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.

The `dns-zones` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-zone.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific DNS zones by OCID.</td>
</tr>
<tr>
<td>target.dns-zone.name</td>
<td>String</td>
<td>Use this variable to control access to specific DNS zones by name.</td>
</tr>
<tr>
<td>target.dns-zone.apex-label</td>
<td>String</td>
<td>The most significant DNS label for the target zone. Example: If the target zone's name is &quot;service.example.com&quot;, the value of this variable would be &quot;service&quot;.</td>
</tr>
<tr>
<td>target.dns-zone.parent-domain</td>
<td>String</td>
<td>The domain name of the target zone's parent zone.</td>
</tr>
<tr>
<td>target.dns.scope</td>
<td>String</td>
<td>Valid values are &quot;public&quot; and &quot;private&quot;.</td>
</tr>
</tbody>
</table>

The `dns-records` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-zone.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific DNS zones by OCID.</td>
</tr>
<tr>
<td>target.dns-zone.name</td>
<td>String</td>
<td>Use this variable to control access to specific DNS zones by name.</td>
</tr>
<tr>
<td>target.dns-record.type</td>
<td>List (String)</td>
<td>Use this variable to control access to specific DNS records by type. Valid values in the list can be any supported DNS resource type. For example, &quot;A&quot;, &quot;AAAA&quot;, &quot;TXT&quot;, and so on. See Supported Resource Records on page 2274.</td>
</tr>
<tr>
<td>target.dns-domain.name</td>
<td>List (String)</td>
<td>Use this variable to control access to specific domain names. Applicable to the following API operations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GetDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PatchDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UpdateDomainRecords</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DeleteRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GetRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PatchRRSet</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UpdateRRSet</td>
</tr>
</tbody>
</table>
### IAM

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.dns-zone.source-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of the DNS zone by OCID.</td>
</tr>
<tr>
<td><code>target.dns-zone.destination-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the DNS zone by OCID.</td>
</tr>
</tbody>
</table>

**Note:**

Use the `target.dns-record.type` and `target.dns-domain.name` variables in your authorization policy to restrict users when modifying records of a specific type in a specific subdomain. A policy like this would allow a specific group of users to modify "A" records in the "example.com" domain: `Allow group <GroupName> to use dns in compartment <CompartmentName> where all {target.dns-record.type='A', target.dns-domain.name = 'example.com'} Users will only be authorized to use RRSet API operations with this type of authorization policy.```

The `dns-steering-policies` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.dns-steering-policy.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific steering policies by OCID.</td>
</tr>
<tr>
<td><code>target.dns-steering-policy.display-name</code></td>
<td>String</td>
<td>Use this variable to control access to specific steering policies by name.</td>
</tr>
<tr>
<td><code>target.dns-steering-policy.source-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of the steering policy by OCID.</td>
</tr>
<tr>
<td><code>target.dns-steering-policy.destination-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the steering policy by OCID.</td>
</tr>
</tbody>
</table>

The `dns-tsig-keys` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.dns-tsig-key.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific TSIG keys by OCID.</td>
</tr>
<tr>
<td><code>target.dns-tsig-key.name</code></td>
<td>String</td>
<td>Use this variable to control access to specific TSIG keys by name.</td>
</tr>
<tr>
<td><code>target.dns-tsig-key.source-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific TSIG key by OCID.</td>
</tr>
<tr>
<td><code>target.dns-tsig-key.destination-compartment.id</code></td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the specific TSIG key by OCID.</td>
</tr>
</tbody>
</table>

The `dns-view` resource type can use the following variables:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-view.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific view by OCID.</td>
</tr>
<tr>
<td>target.dns-view.display-name</td>
<td>String</td>
<td>Use this variable to control access to specific view by name.</td>
</tr>
<tr>
<td>target.dns-view.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific view by OCID.</td>
</tr>
<tr>
<td>target.dns-view.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the specific view by OCID.</td>
</tr>
</tbody>
</table>

The `dns-resolver` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-resolver.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific resolver by OCID.</td>
</tr>
<tr>
<td>target.dns-resolver.display-name</td>
<td>String</td>
<td>Use this variable to control access to specific resolver by name.</td>
</tr>
<tr>
<td>target.dns-resolver.source-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the current compartment of a specific resolver by OCID.</td>
</tr>
<tr>
<td>target.dns-resolver.destination-compartment.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to the destination compartment of the specific resolver by OCID.</td>
</tr>
</tbody>
</table>

The `dns-resolver-endpoint` resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.dns-resolver-endpoint.name</td>
<td>String</td>
<td>Use this variable to control access to specific resolver endpoints by name.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the manage verb for the `dns-records` resource-type covers no extra permissions or API operations compared to the use verb.

### `dns-zones`:

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>

**Details for the Email Delivery Service**

This topic covers details for writing policies to control access to the Email Delivery service.

**Resource-Types**

email-domains
email-work-requests
email-family
approved-senders
suppressions

**Supported Variables**

The Email Delivery Service supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.approved-sender.email-domain</td>
<td>String</td>
<td>The value matches the domain portion (right-hand-side) of the email address and the name of the associated email-domain object if one exists. Policies should use the U-label form of the domain. Matching is case-insensitive. This is not available for ListSenders.</td>
</tr>
<tr>
<td>target.email-domain.name</td>
<td>String</td>
<td>Scopes permission to domains that match the specified domain name. Policies should use the U-label form of the domain. Matching is case-insensitive. This variable can be used with pattern matching syntax to grant sub-domain access. This is not available for ListEmailDomains.</td>
</tr>
<tr>
<td>target.email-domain.id</td>
<td>Entity (OCID)</td>
<td>Not available for ListEmailDomains or CreateEmailDomain.</td>
</tr>
<tr>
<td>target.email-work-request.id</td>
<td>Entity (OCID)</td>
<td>Not available for ListWorkRequests.</td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

**email-domains**

<table>
<thead>
<tr>
<th>Verbs</th>

Details for the Events Service

This topic covers details for writing user IAM policies that control access to rules for the Events service.

Resource-Types

cloudevents-rules

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for cloudevents-rules includes the same permissions and API operations as the inspect verb, plus the EVENTRULE_READ permissions and the corresponding API operation GetEventRule.
The `use` verb adds no extra permissions or API operations compared to `read`. However, `manage` adds more permissions and operations compared to `use`.

### cloudevents-rules

<table>
<thead>
<tr>
<th>Verbs</th>

</tbody>
</table>

### Details for the File Storage Service

This topic covers details for writing policies to control access to the File Storage Service.

**Aggregate Resource-Type**

- `file-family`

**Individual Resource-Types**

- `file-systems`
- `mount-targets`
- `export-sets`

**Comments**

A policy that uses `<verb> file-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.
See the table in Details for Verb + Resource-Type Combinations on page 2964 for details of the API operations covered by each verb, for each individual resource-type included in file-family.

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the file-systems resource-type includes the same permissions and API operations as the inspect verb, plus the FILE_SYSTEM_READ permission and a number of API operations (e.g., GetFileSystem, ListMountTargets, etc.). The use verb covers still another permission and set of API operations compared to read. Lastly, manage covers two more permissions and operations compared to use.

**export-sets**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>

</tbody>
</table>

#### Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

**Tip:**

If a group uses the Console to create file systems, permissions to read mount targets is required. See the file storage policy examples for further guidance.

For information about permissions, see Permissions on page 2829.

<table>
<thead>
<tr>

**Details for Functions**

This topic covers details for writing policies to control access to Oracle Functions.

**Resource-Types**

**Aggregate Resource-Type**

- functions-family

**Individual Resource-Types**

- fn-app
- fn-function
- fn-invocation

**Comments**

A policy that uses `<verb> functions-family` is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 2967 for details of the API operations covered by each verb, for each individual resource-type included in functions-family.

**Supported Variables**

Oracle Functions supports all the general variables (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the fn-app resource-type includes the same permissions and API operations as the inspect verb, plus the FN_APP_READ permission and the GetApp API operation. In the case of the fn-app resource-type, the use verb covers no additional permissions or API operations compared to read. Lastly, manage covers more permissions and operations compared to use.

**fn-app**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>

</table>

Details for the Health Checks Service

This topic covers details for writing policies to control access to the Health Checks service.

Resource-Types

- health-check-monitor
- health-check-results
- on-demand-probe
- vantage-points
- health-check-family

Supported Variables

The Health Checks Service supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here. Values in the list can be any valid test type. For example, HTTP, HTTPS, ICMP, etc.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.health-check-monitor.test-type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>target.on-demand-probe.test-type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>target.health-check-results.test-type</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the health-check-monitor resource-type covers no extra permissions or API operations compared to the read verb.

**health-check-monitor**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>

<td>HEALTH_CHECK_RESULTS_READ</td>
</tr>
<tr>
<td>ListVantagePoints</td>
<td>VANTAGE_POINTS_INSPECT</td>
</tr>
<tr>
<td>CreateOnDemandOHCProbe</td>
<td>ON_DEMAND_PROBE_MANAGE</td>
</tr>
<tr>
<td>MoveOHCMonitor</td>
<td>HEALTH_CHECK_MONITOR_MOVE</td>
</tr>
</tbody>
</table>

### Details for IAM

This topic covers details for writing policies to control access to IAM.

**Resource-Types**

- authentication-policies
- compartments
- credentials
- dynamic-groups
- groups
- identity-providers
- network-sources
- policies
- tag-defaults
- tag-namespaces
- tenancies
- users
- workrequest

**Supported Variables**

IAM supports all the general variables (see [General Variables for All Requests](#) on page 2840), plus additional ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use These Variables...</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>users</td>
<td>target.user.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreateUser.</td>
</tr>
<tr>
<td></td>
<td>target.user.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>groups</td>
<td>target.group.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreateGroup.</td>
</tr>
<tr>
<td></td>
<td>target.group.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Operations for This Resource-Type...</td>
<td>Can Use These Variables...</td>
<td>Variable Type</td>
<td>Comments</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------</td>
<td>---------------</td>
<td>----------</td>
</tr>
<tr>
<td>policies</td>
<td>target.group.member</td>
<td>Boolean</td>
<td>True if request.user is a member of target.group.</td>
</tr>
<tr>
<td></td>
<td>target.policy.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with CreatePolicy.</td>
</tr>
<tr>
<td></td>
<td>target.policy.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>compartments</td>
<td>target.compartment.id</td>
<td>Entity (OCID)</td>
<td>For CreateCompartment, this will be the value of the parent compartment (e.g., the root compartment). This is a universal variable available to use with any request across all services (see General Variables for All Requests on page 2840).</td>
</tr>
<tr>
<td></td>
<td>target.compartment.name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>tag-namespace</td>
<td>target.tag-namespace.id</td>
<td>Entity (OCID)</td>
<td>This variable is supported only in statements granting permissions for the tag-namespaces resource-type. For an example, see Required Permissions for Working with Defined Tags on page 4968. Not available to use with CreateTagNamespace.</td>
</tr>
<tr>
<td></td>
<td>target.tag-namespace.name</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

### Details for Verbs + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for compartments covers no extra permissions or API operations compared to the inspect verb. The use verb includes the same ones as the read verb, plus the COMPARTMENT_UPDATE permission and UpdateCompartment API operation. The manage verb includes the same permissions and API operations as the use verb, plus the COMPARTMENT_CREATE permission and two API operations: CreateCompartment and DeleteCompartment

**authentication-policies**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>AUTHENTICATION_POLICY_INSPECT</td>
<td>GetAuthenticationPolicy</td>
<td></td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>
**compartments**

To move a compartment (that is, use the `MoveCompartment` operation) you must belong to a group that has `manage all-resources` permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>COMPARTMENT_INSPECT</td>
<td>ListCompartments</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetCompartment</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListAvailabilityDomains</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListFaultDomains</td>
<td></td>
</tr>
<tr>
<td>read</td>
<td>no extra</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td>READ +</td>
<td>READ +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>COMPARTMENT_UPDATE</td>
<td>UpdateCompartment</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetWorkRequest</td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>USE +</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>COMPARTMENT_CREATE</td>
<td>CreateCompartment</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>COMPARTMENT_DELETE</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>COMPARTMENT_RECOVER</td>
<td></td>
</tr>
</tbody>
</table>

**credentials**

The `credentials` resource type refers to only the SMTP credentials. Permissions to work with other credentials that can be added to a user (such as auth tokens, API keys, and customer secret keys) are included with `users` resource permissions.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>CREDENTIAL_INSPECT</td>
<td>ListSmtpCredentials</td>
<td>none</td>

### Details for the Java Management Service

This topic covers details for writing policies to control access to the Java Management service.

**Resource-Types**

`fleet`

**Supported Variables**

Only the general variables are supported (see [General Variables for All Requests](http://example.com) on page 2840).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

#### fleet

<table>
<thead>
<tr>
<th>Verbs</th>

Details for Load Balancing

This topic covers details for writing policies to control access to the Load Balancing service.

Resource-Types

load-balancers
Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for load-balancers includes the same permissions and API operations as the inspect verb, plus the LOAD_BALANCER_READ permission and a number of API operations (e.g., GetLoadBalancer, ListWorkRequests, etc.). The use verb covers still another permission and set of API operations compared to read. And manage covers two more permissions and operations compared to use.

### load-balancers

<table>
<thead>
<tr>
<th>Verbs</th>

</table>

**Permissions Required for Each API Operation**

The following table lists the API operations in a logical order, grouped by resource type.

**Tip:**

If a group uses the Console to manage load balancers, permissions to use the associated networking resources are required. See the load balancing policy examples for further guidance.

For information about permissions, see Permissions on page 2829.

<table>
<thead>
<tr>
<th>API Operation</th>

**Details for Logging**

This topic covers details for writing policies to control access to Logging.

**Resource-Types**

**Aggregate Resource-Type**

- logging-family

**Individual Resource-Types**

- log-groups
- log-content
- unified-configuration

**Comments**

A policy that uses `<verb> logs` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `logs`. 
**Supported Variables**

Logging supports all the general variables (see General Variables for All Requests on page 2840), plus additional ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use These Variables...</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>log-groups</td>
<td>target.loggroup.id</td>
<td>Entity (OCID)</td>
<td></td>
</tr>
<tr>
<td>log-content</td>
<td>target.loggroup.id</td>
<td>Entity (OCID)</td>
<td></td>
</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the log-groups resource-type includes the same permissions and API operations as the inspect verb, plus the LOG_GROUPS_READ permission and the corresponding API operations GetLog and GetLogGroup.

**log-groups**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSPECT</td>

</tbody>
</table>

Details for Logging Analytics

This topic covers details for writing policies to control access to the Logging Analytics service.

Resource-Types

Individual Resource-Types

loganalytics-config-work-request
loganalytics-entity
loganalytics-entity-type
loganalytics-field
loganalytics-label
loganalytics-lifecycle
loganalytics-log-group
loganalytics-lookup
loganalytics-object-collection-rule
loganalytics-ondemand-upload
loganalytics-parser
loganalytics-query
loganalytics-queryjob-work-request
loganalytics-scheduled-task
loganalytics-source
loganalytics-storage
loganalytics-storage-work-request

Aggregate Resource-Types

The loganalytics-features-family aggregate resource-type covers these individual resource-types (resource kinds that are not modeled as resources; that is, resource kinds that do not belong to a compartment):

loganalytics-entity-type
loganalytics-field
loganalytics-label
loganalytics-lifecycle
loganalytics-lookup
loganalytics-ondemand-upload
loganalytics-parser
loganalytics-query
loganalytics-source
loganalytics-storage
loganalytics-storage-work-request

The loganalytics-resources-family aggregate resource-type covers these individual resource-types (resource kinds that are modeled as resources; that is, resource kinds that belong to a compartment):

loganalytics-config-work-request
loganalytics-entity
loganalytics-log-group
loganalytics-object-collection-rule
loganalytics-queryjob-work-request
loganalytics-scheduled-task
loganalytics-storage-work-request

Comments

A policy that uses <verb> loganalytics-features-family or <verb> loganalytics-resources-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types in the family.

See the table in Permissions Required for Each API Operation on page 3000 for details of the API operations covered by each verb, for each individual resource-type.

Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

### loganalytics-config-work-request

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>LOG_ANALYTICS_CONFIG_WORK_REQUEST_INSPECT</td>
<td>ListConfigWorkRequests</td>
<td></td>
</tr>
<tr>
<td>read</td>
<td>INSPECT +</td>
<td>GetConfigWorkRequest</td>
<td>none</td>
</tr>
<tr>
<td>use</td>
<td>LOG_ANALYTICS_CONFIG_WORK_REQUEST_READ</td>
<td>no extra</td>
<td>none</td>
</tr>
<tr>
<td>manage</td>
<td>USE +</td>
<td>no extra</td>
<td>none</td>
</tr>
</tbody>
</table>
The image contains a table with three sections: `loganalytics-entity`, `loganalytics-entity-type`, and `loganalytics-field`. Each section details permissions, verbs, and APIs associated with different actions.

### loganalytics-entity

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>LOG_ANALYTICS_ENTITY_INSPECT</td>
<td>ListEntityAssociations, ListLogAnalyticsEntities</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT + LOG_ANALYTICS_ENTITY_READ</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>READ + AddEntityAssociation, ChangeLogAnalyticsEntityCompartment, CreateLogAnalyticsEntity, DeleteLogAnalyticsEntity, RemoveEntityAssociations, UpdateLogAnalyticsEntity</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE + no extra</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

### loganalytics-entity-type

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>LOG_ANALYTICS_ENTITY_TYPE_INSPECT</td>
<td>ListLogAnalyticsEntityTypes</td>
<td>none</td>
</tr>
<tr>
<td>read</td>
<td>INSPECT + GetLogAnalyticsEntityType</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>READ + CreateLogAnalyticsEntityType, DeleteLogAnalyticsEntityType, UpdateLogAnalyticsEntityType</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>manage</td>
<td>USE + no extra</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

### loganalytics-field

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>

## Details for Management Agent

This topic covers details for writing policies to control access to the Management Agent service.

### Resource-Types

- management-agents
- management-agent-install-keys

### Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

### management-agents

<table>
<thead>

</table>
**API Operation** | **Permissions Required to Use the Operation**
---|---
ListWorkRequestLogs | MGMT_AGENT_INSPECT
ListWorkRequests | MGMT_AGENT_INSPECT
UpdateManagementAgent | MGMT_AGENT_UPDATE
UpdateManagementAgentInstallKey | MGMT_AGENT_INSTALL_KEY_UPDATE

For more details and examples, see Set Up Oracle Cloud Infrastructure for Management Agents.

**Details for Management Dashboard**

This topic covers details for writing policies to control access to Management Dashboard.

**Resource-Types**

**Individual Resource-Types**

management-dashboard
management-saved-search

**Aggregate Resource-Type**

management-dashboard-family

**Comments**

A policy that uses `<verb> management-dashboard-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types. The resource-type `management-dashboard` allows a user group to work with dashboards while the resource-type `management-saved-search` allows a user group to work with saved searches (widgets) that are displayed in dashboards.

See the table in Details for Verb + Resource-Type Combinations on page 3008 for details of the API operations covered by each verb, for each individual resource-type included in `management-dashboard-family`.

**Supported Variables**

Only the general variables are supported (see General Variables for All Requests on page 2840).

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

</tbody>
</table>

### Example Policies

This section provides example policies for use with Management Dashboard.

#### Dashboard Policies

Here are examples of policy statements that authorize access to dashboards (`management-dashboard` resource-type):

- To allow a user group to list the dashboards in a compartment, use the `inspect` verb:

  ```
  Allow group dashboard-users to inspect management-dashboard in compartment myCompartment1
  ```

- To allow a user group to list dashboards and obtain details regarding the dashboards in a compartment, use the `read` verb:

  ```
  Allow group dashboard-users to read management-dashboard in compartment myCompartment1
  ```

- To allow a group of administrators to list dashboards, obtain details regarding dashboards, and update the dashboards in a compartment, use the `use` verb:

  ```
  Allow group dashboard-admins to use management-dashboard in compartment myCompartment1
  ```

- To allow a group of administrators to list dashboards, obtain details regarding dashboards, update dashboards, and manage (create, move, and delete) the dashboards in a compartment, use the `manage` verb:

  ```
  Allow group dashboard-admins to manage management-dashboard in compartment myCompartment1
  ```

#### Saved Search Policies

Here are examples of policy statements that authorize access to saved searches (`management-saved-search` resource-type):

- To allow a user group to list the saved searches in a compartment, use the `inspect` verb:

  ```
  Allow group saved-search-users to inspect management-saved-search in compartment myCompartment1
  ```

- To allow a user group to list saved searches and obtain details regarding the saved searches in a compartment, use the `read` verb:

  ```
  Allow group saved-search-users to read management-saved-search in compartment myCompartment1
  ```
• To allow a group of administrators to list saved searches, obtain details regarding saved searches, update the saved searches in a compartment, use the `use` verb:

```
Allow group saved-search-admins to use management-saved-search in compartment myCompartment1
```

• To allow a group of administrators to list saved searches, obtain details regarding saved searches, update saved searches, and manage (create, move, and delete) the saved searches in a compartment, use the `manage` verb:

```
Allow group saved-search-admins to manage management-saved-search in compartment myCompartment1
```

**Aggregate Policies**

Here's an example of a policy that simultaneously authorizes access to both dashboards and saved searches by using the aggregate `management-dashboard-family` resource-type. In this example, the `inspect` verb is used to allow a user group to list both the dashboards and saved searches in a compartment:

```
Allow group dashboard-family-admins to inspect management-dashboard-family in compartment myCompartment1
```

Similarly, the other Oracle Cloud Infrastructure verbs can be used to allow user groups to perform the corresponding tasks for dashboards and saved searches in one policy.

**Details for the Marketplace Service**

This topic covers details for writing policies to control access to the Marketplace service.

**Individual Resource-Type**

- marketplace-listings
- marketplace-publications
- marketplace-community-listings

**Supported Variables**

Marketplace supports all the general variables, plus the ones listed here. Specifically, you can use the variables listed here when writing policies that grant `read`, `use`, and `manage` verbs. You cannot use them with the `inspect` verb. For more information about general variables supported by Oracle Cloud Infrastructure services, see [General Variables for All Requests](#) on page 2840.

<table>
<thead>
<tr>
<th>Resource-Type</th>
<th>Variable</th>
<th>Variable Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>marketplace-listings</td>
<td>listing.id</td>
<td>String</td>
<td>Use this variable to control whether to return a specific listing (based on the given listing ID) in response to a request.</td>
</tr>
<tr>
<td>marketplace-listings</td>
<td>listing.publisher.id</td>
<td>String</td>
<td>Use this variable to control whether to return only listings from a specific publisher (based on the given publisher ID) in response to a request.</td>
</tr>
<tr>
<td>marketplace-community-listings</td>
<td>listing.id</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Resource-Type</td>
<td>Variable</td>
<td>Variable Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>

<td>Use this variable to control whether to return a specific publication (based on the given listing ID) in response to a request.</td>
</tr>
<tr>
<td>marketplace-listings</td>
<td>listing.type</td>
<td>String</td>
<td>Use this variable to control whether to return only listings from a specific publisher category (based on the given listing type) in response to a request. A publication's publisher category informs where the listing appears for use.</td>
</tr>
<tr>
<td>marketplace-listings</td>
<td>listing.destination-compartment.id</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>marketplace-listings</td>
<td>listing.source-compartment.id</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` verb for the `marketplace-listings` resource-type includes the same permissions and API operations as the `read` verb, plus the `MARKETPLACE_LISTING_LAUNCH` permission and an additional API operation, `LaunchListing`. However, the `manage` verb covers no extra permissions or API operations compared to `use`.

#### marketplace-listings

**Details for Monitoring**

This topic covers details for writing policies to control access to the Monitoring service.

**Resource-Types**

alarms
metrics

Supported Variables

Monitoring supports all the general variables (see General Variables for All Requests on page 2840), plus the one listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use This Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics</td>
<td>target.metrics.namespace</td>
<td>String</td>
<td>Use this variable to control access to specific resource types. Surround the namespace value with single quotes. For example, to control access to metrics for Compute instances, use the following phrase: \where target.metrics.namespace='oci_computeagent'. For an example policy, see Restrict user access to a specific metric namespace on page 2820. For valid namespace values, see Supported Services on page 3468.</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for Object Storage, Archive Storage, and Data Transfer

This topic covers details for writing policies to control access to Archive Storage, Object Storage, and Data Transfer.
Tip:

The object lifecycle policies feature requires that you grant permissions to the Object Storage service to archive and delete objects on your behalf. See Using Object Lifecycle Policies for more information.

Resource-Types

Individual Resource-Types

objectstorage-namespaces
buckets
objects

Aggregate Resource-Type

object-family

A policy that uses <verb> object-family is equivalent to writing one with a separate <verb> <individual resource-type> statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 3019 for details of the API operations covered by each verb, for each individual resource-type included in object-family.

Additional Individual Resource-Type for Data Transfer

data-transfer-jobs

Supported Variables

Object Storage supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here:

<table>
<thead>
<tr>
<th>Operations for This Resource-Type...</th>
<th>Can Use This Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>buckets and objects</td>
<td>target.bucket.name</td>
<td>String</td>
<td>Use this variable to control access to a specific bucket. For an example policy, see Let users write objects to Object Storage buckets on page 2813. Important: Condition matching is case insensitive. If you have a bucket named &quot;BucketA&quot; and a bucket named &quot;bucketA&quot;, the condition where target.bucket.name=&quot;BucketA&quot; applies to both. To avoid potential issues with resource names in policy, give your resources distinct names.</td>
</tr>
</tbody>
</table>

Note:

The request.ipv4.ipaddress and the request.vcn.id variables are deprecated. Instead of using these variables, create a network source to
specify either an IP address range or a specific VCN ID. You can then use the network source in your policy to restrict access to only requests coming from the allowed networks. For more information, see Managing Network Sources on page 3123.

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

## Details for Oracle Cloud VMware Solution

This topic covers details for writing policies to control access to Oracle Cloud VMware Solution resources.
### Resource-Types

**sddcs**

### Supported Variables

Only the general variables are supported (see General Variables for All Requests on page 2840).

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for sddcs includes the same permissions and API operations as the inspect verb, plus the SDDC_READ permission and a number of API operations (e.g., GetSddc, ListWorkRequests, etc.). The use verb covers two more permissions and set of API operations compared to read. And manage covers five more permissions and operations compared to use.

#### sddcs

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>

Details for Container Registry

This topic covers details for writing policies to control access to Oracle Cloud Infrastructure Registry (also known as Container Registry).

**Resource-Types**

- repos

**Supported Variables**

Oracle Cloud Infrastructure Registry supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.
The repos resource-type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.repo.name</td>
<td>String</td>
<td>Use this variable to control access to specific repositories. For an example policy, see Policies to Control Repository Access on page 4457.</td>
</tr>
</tbody>
</table>

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the read verb for the repos resource-type includes the same permissions and API operations as the inspect verb, plus the REPOSITORY_READ permission and a number of API operations (e.g., GetContainerRepository, etc.). The use verb covers still another permission and API operation compared to read. Lastly, manage covers more permissions and operations compared to use.

**repos**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>REPOSITORY_INSPECT</td>
<td>ListContainerRepositories, ListContainerImages, GetContainerConfiguration</td>

</table>

**Details for Resource Manager**

This topic covers details for writing policies to control access to the Resource Manager service.

**Aggregate Resource-Type**

orm-family

**Individual Resource-Types**

orm-config-source-providers

orm-jobs

orm-stacks

orm-template

orm-work-requests

**Supported Variables**

Resource Manager supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.

The orm-jobs resource type can use the following variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.job.operation</td>
<td>String</td>
<td>Use this variable to control access for running specified job types. For example, to limit access to PLAN and APPLY jobs, use the following phrase: where any {target.job.operation = 'PLAN', target.job.operation = 'APPLY'}</td>
</tr>
</tbody>
</table>
### Variable

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.stack.id</td>
<td>String</td>
<td>Use this variable to limit access to specified stacks. For example, use the following phrase: where any {target.stack.id = ocid1.ormstack.uniqueid1, target.stack.id = ocid1.ormstack.uniqueid2}</td>
</tr>
</tbody>
</table>

### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

#### orm-config-source-providers

<table>

</table>

**Details for Search**

The Search service does not require permissions for its API operations. You do not need to write policies specifically to control access to Search. However, what you can see in search or query results depends on the permissions you have. If a policy exists to give you access to the `inspect` verb for a particular resource type, you have access to the permissions needed to view that resource type and its associated metadata in search results. If a service does not
recognize the `inspect` verb or if the resource type's `inspect` verb does not fully cover list operations, permissions to view the service's supported resource types are granted by the `read` verb instead.

For more information about permissions, see the Permissions section of [Advanced Policy Features](#).

### Permissions Required to View Each Resource Type

The following table lists the resource types grouped by service, which are listed in alphabetical order. The Search API operations that can access the metadata for these resource types with these permissions are `GetResourceType`, `ListResourceTypes`, and `SearchResources`.

<table>
<thead>
<tr>

### Details for Service Connector Hub

This topic covers details for writing policies to control access to the Service Connector Hub service.

#### Individual Resource-Types

`serviceconnectors`

#### Supported Variables

Service Connector Hub supports all the general variables (see [General Variables for All Requests](#) on page 2840), plus the ones listed here.

The `serviceconnectors` resource type can use the following variables.
### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for the Streaming Service

This topic covers details for writing policies to control access to the Streaming service.

Resource-Types

- streams
- stream-pull
- stream-push
- connect-harnesses
- stream-pools

Supported Variables

The Streaming service supports all the general variables (see General Variables for All Requests on page 2840) plus the following:

The streams resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.stream.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

The connect-harnesses resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.connectharness.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

The stream-pools resource type can use the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.streampool.id</td>
<td>Entity (OCID)</td>
<td>Request</td>
</tr>
</tbody>
</table>

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

**Details for the Vault Service**

This topic covers details for writing policies to control access to the Vault service.

**Individual Resource-Types**
- vaults
- keys
- key-delegate
- secrets
- secret-versions
- secret-bundles

**Aggregate Resource-Type**
- secret-family

A policy that uses `<verb>` secret-family is equivalent to writing one with a separate `<verb>` `<individual resource-type>` statement for each of the individual secret resource-types. (Secret resource-types include only secrets, secret-versions, and secret-bundles.)

See the table in Details for Verb + Resource-Type Combinations on page 3044 for details of the API operations covered by each verb, for each individual resource-type included in secret-family.

**Supported Variables**

Vault supports all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests on page 2840.
### Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use verb for the keys resource-type includes the same permissions and API operations as the read verb, plus the KEY_ENCRYPT and KEY_DECRYPT permissions and a number of API operations (Encrypt, Decrypt, and GenerateDataEncryptionKey). The manage verb allows even more permissions and API operations when compared to the use verb.

**Details for the WAF Service**

This topic covers details for writing policies to control access to the WAAS service.

**Aggregate Resource-Type**

waas-family

**Individual Resource-Types**

waas-policy
waas-certificate
waas-work-request
waas-metering
waas-custom-protection-rule
waas-address-list
http-redirects

**Comments**

A policy that uses `<verb> waas` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations on page 3050 for details of the API operations covered by each verb, for each individual resource-type included in `waas`.

**Supported Variables**

The WAF Service supports all the general variables (see General Variables for All Requests on page 2840), plus the ones listed here.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>target.waas-policy.id</td>
<td>Entity (OCID)</td>
<td>Use this variable to control access to specific WAAS policies by OCID.</td>
</tr>
<tr>
<td>target.waf-rule-key</td>
<td>String</td>
<td>Use this variable to control access to specific WAF rules by name.</td>
</tr>
<tr>
<td>target.waas-work-request.id</td>
<td>Entity (OCID)</td>
<td>The OCID of WAAS work requests.</td>
</tr>
<tr>
<td>target.waas-policy-certificate.id</td>
<td>Entity (OCID)</td>
<td>The OCID of SSL certificates configured in a WAAS policy.</td>
</tr>
<tr>
<td>Variable</td>
<td>Variable Type</td>
<td>Comments</td>
</tr>
<tr>
<td>----------</td>
<td>---------------</td>
<td>----------</td>
</tr>
<tr>
<td>target.certificate.destination-compartment.id</td>
<td>(OCID)</td>

</tr>
</tbody>
</table>

**Details for Verb + Resource-Type Combinations**

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the use and manage verbs for the waas-policy resource-type cover no extra permissions or API operations compared to the read verb.

**User Credentials**

There are several types of credentials that you manage with Oracle Cloud Infrastructure Identity and Access Management (IAM):

- **Console password**: For signing in to the Console, the user interface for interacting with Oracle Cloud Infrastructure. Note that federated users can't have Console passwords because they sign in through their identity provider. See Federating with Identity Providers on page 3058.
- **API signing key (in PEM format)**: For sending API requests, which require authentication.
- **Auth token**: An Oracle-generated token that you can use to authenticate with third-party APIs. For example, use an auth token to authenticate with a Swift client when using Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage.
- **Customer Secret Keys**: For using the Amazon S3 Compatibility API with Object Storage. See Amazon S3 Compatibility API on page 4408.
- **OAuth 2.0 Client Credentials**: For interacting with the APIs of those services that use OAuth 2.0 authorization. See OAuth 2.0 Client Credentials on page 3058.
- **SMTP Credentials**: For using the Email Delivery service.

**Important:**

API signing keys are different from the SSH keys you use to access a compute instance (see Security Credentials on page 207). For more information about API signing keys, see Required Keys and OCIDs on page 5303. For more information about instance SSH keys, see Managing Key Pairs.
User Password

The administrator who creates a new user in IAM also needs to generate a one-time Console password for the user (see To create or reset another user's Console password on page 3154). The administrator needs to securely deliver the password to the user by providing it verbally, printing it out, or sending it through a secure email service.

When the user signs in to the Console the first time, they'll be immediately prompted to change the password. If the user waits more than 7 days to initially sign in and change the password, it will expire and an administrator will need to create a new one-time password for the user.

Once the user successfully signs in to the Console, they can use Oracle Cloud Infrastructure resources according to permissions they've been granted through policies.

Note:
A user automatically has the ability to change their password in the Console.
An administrator does not need to create a policy to give a user that ability.

Changing a Password

If a user wants to change their own password sometime after they change their initial one-time password, they can do it in the Console. Remember that a user can automatically change their own password; an administrator does not need to create a policy to give the user that ability.

For more information, see To change your Console password on page 3153.

If a User Needs Their Console Password Reset

If a user forgets their Console password and also has no access to the API, they can use the Console's Forgot Password link to have a temporary password sent to them. This option is available if the user has an email address in their user profile.

If the user does not have an email address in their user profile, then they need to ask an administrator to reset their password for them. All administrators (and anyone else who has permission to the tenancy) can reset Console passwords. The process of resetting the password generates a new one-time password that the administrator needs to deliver to the user. The user will need to change their password the next time they sign in to the Console.

If you're an administrator who needs to reset a user's Console password, see To create or reset another user's Console password on page 3154.

If a User Is Blocked from Signing In to the Console

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further attempts. They'll need to contact an administrator to get unblocked (see To unblock a user on page 3154).

API Signing Keys

A user who needs to make API requests must have an RSA public key in PEM format (minimum 2048 bits) added to their IAM user profile and sign the API requests with the corresponding private key (see Required Keys and OCIDs on page 5303).

Important:
A user automatically has the ability to generate and manage their own API keys in the Console or API. An administrator does not need to write a policy to give the user that ability. Remember that a user can't use the API to change or delete their own credentials until they themselves save a key in the Console, or an administrator adds a key for that user in the Console or the API.

If you have a non-human system that needs to make API requests, an administrator needs to create a user for that system and then add a public key to the IAM service for the system. There's no need to generate a Console password for the user.
OAuth 2.0 Client Credentials

Note:

OAuth 2.0 Client Credentials are not available in the United Kingdom Government Cloud (OC4).

OAuth 2.0 client credentials are required to interact programmatically with those services that use the OAuth 2.0 authorization protocol. The credentials enable you to obtain a secure token to access those service REST API endpoints. The allowed actions and endpoints granted by the token depend on the scopes (permissions) that you select when you generate the credentials. For more information, see Working with OAuth 2.0 Client Credentials on page 3151.

Auth Tokens

Auth tokens are authentication tokens generated by Oracle. You use auth tokens to authenticate with third-party APIs that do not support the Oracle Cloud Infrastructure signature-based authentication, for example, the Swift API. If your service requires an auth token, the service-specific documentation instructs you to generate one and how to use it.

Federating with Identity Providers

This topic describes identity federation concepts. Oracle Cloud Infrastructure supports federation with Oracle Identity Cloud Service, and Microsoft Active Directory (via Active Directory Federation Services (AD FS)), Microsoft Azure Active Directory, Okta, and other identity providers that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

Overview

Enterprise companies commonly use an identity provider (IdP) to manage user login/passwords and to authenticate users for access to secure websites, services, and resources.

When someone in your company wants to use Oracle Cloud Infrastructure resources in the Console, they must sign in with a user login and password. Your administrators can federate with a supported IdP so that each employee can use an existing login and password and not have to create a new set to use Oracle Cloud Infrastructure resources.

To federate, an administrator goes through a short process to set up a relationship between the IdP and Oracle Cloud Infrastructure (commonly referred to as a federation trust). After an administrator sets up that relationship, any person in your company who goes to the Oracle Cloud Infrastructure Console is prompted with a "single sign-on" experience provided by the IdP. The user signs in with the login/password that they've already set up with the IdP. The IdP authenticates the user, and then that user can access Oracle Cloud Infrastructure.

When working with your IdP, your administrator defines groups and assigns each user to one or more groups according to the type of access the user needs. Oracle Cloud Infrastructure also uses the concept of groups (in conjunction with IAM policies) to define the type of access a user has. As part of setting up the relationship with the IdP, your administrator can map each IdP group to a similarly defined IAM group, so that your company can re-use the IdP group definitions when authorizing user access to Oracle Cloud Infrastructure resources. Here's a screenshot from the mapping process:
For information about the number of federations and group mappings you can have, see Service Limits on page 243. There’s no limit on the number of federated users.

Note:
Any users who are in more than 50 IdP groups cannot be authenticated to use the Oracle Cloud Infrastructure Console.

Automated User Provisioning and Synchronization with SCIM
Tenancies federated with Oracle Identity Cloud Service or the third-party provider Okta, can also leverage SCIM (System for Cross-domain Identity Management) to enable provisioning of federated users in Oracle Cloud Infrastructure. Federated users that have been provisioned in Oracle Cloud Infrastructure through this process can have the additional user credentials such as API keys and auth tokens that are managed in the User Settings page. This enables federated users to use the SDK and CLI, and other features that require the additional user credentials. For more information, see User Provisioning for Federated Users on page 3100.

General Concepts
Here's a list of the basic concepts you need to be familiar with.

**IDP**

IdP is short for identity provider, which is a service that provides identifying credentials and authentication for users.

Tenancies created after December 18, 2017 are automatically federated with Oracle Identity Cloud Service as the IdP. Oracle Cloud Infrastructure can be federated with any IdP that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

**SERVICE PROVIDER (SP)**

A service (such as an application, website, and so on) that calls upon an IdP to authenticate users. In this case, Oracle Cloud Infrastructure is the SP.

**FEDERATION TRUST**

A relationship that an administrator configures between an IdP and SP. You can use the Oracle Cloud Infrastructure Console or API to set up that relationship. Then, the specific IdP is "federated" to that SP. In the Console and API, the process of federating is thought of as adding an identity provider to the tenancy.
SAML METADATA DOCUMENT

An IdP-provided XML-based document that provides the required information to an SP to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. Depending on which IdP you are federating with, you must either provide the metadata URL (see below) to this document or upload the document to Oracle Cloud Infrastructure.

METADATA URL

An IdP-provided URL that enables an SP to get required information to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. The metadata URL points to the SAML metadata document the SP needs.

FEDERATED USER

Someone who signs in to use the Oracle Cloud Infrastructure Console by way of a federated IdP.

LOCAL USER

A non-federated user. In other words, someone who signs in to use the Oracle Cloud Infrastructure Console with a login and password created in Oracle Cloud Infrastructure.

GROUP MAPPING

A mapping between an IdP group and an Oracle Cloud Infrastructure group, used for the purposes of user authorization.

SCIM

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. Using a SCIM client to provision users in Oracle Cloud Infrastructure enables you to assign credentials to the users in Oracle Cloud Infrastructure.

PROVISIONED (OR SYNCHRONIZED) USER

A user provisioned by the identity provider's SCIM client in Oracle Cloud Infrastructure. These users can be listed in the Oracle Cloud Infrastructure Console and can have all the Oracle Cloud Infrastructure user credentials except for a Console password.

Encrypt Assertion

Some IdPs support the encryption of the SAML assertion. When enabled, the service provider expects the SAML assertion to be encrypted by the identity provider, using the service provider's encryption key. In this case, the service provider is Oracle Cloud Infrastructure authentication service. If you choose to enable this feature of your IdP, you must also enable the feature when you set up your Federation provider in the IAM service. Note that Microsoft AD FS enables the encryption of the SAML assertion by default. If your IdP is Microsoft AD FS, you must either enable this feature in IAM or disable it for Microsoft AD FS.

Experience for Federated Users

Federated users can use the Console to access Oracle Cloud Infrastructure (according to IAM policies for the groups the users are in).

They'll be prompted to enter their Oracle Cloud Infrastructure tenant (for example, ABCCorp).

They then see a page with two sets of sign-in instructions: one for federated users and one for non-federated (Oracle Cloud Infrastructure) users. See the following screenshot.
The tenant name is shown on the left. Directly below is the sign-in area for federated users. On the right is the sign-in area for non-federated users.

Federated users choose which identity provider to use for sign-in, and then they're redirected to that identity provider's sign-in experience for authentication. After entering their login and password, they are authenticated by the IdP and redirected back to the Oracle Cloud Infrastructure Console.

The federated users (without SCIM configuration) cannot access the "User Settings" page in the Console. This page is where a user can change or reset their Console password and manage other Oracle Cloud Infrastructure credentials such as API signing keys and auth tokens.

**Experience for Federated Users with SCIM Configuration**

If your IdP has also been configured with a SCIM client, a user signed in through their identity provider can access the User Settings page and have user capabilities such as API keys, auth tokens, and other user credentials. *(Note: This is currently available for Oracle Identity Cloud Service and Okta federations only.)*

**Required IAM Policy**

To add and manage identity providers in your tenancy, you must be authorized by an IAM policy. If you're in the Administrators group, then you have the required access.

Here's a more limited policy that restricts access to only the resources related to identity providers and group mappings:

```plaintext
Allow group IdPAdmins to manage identity-providers in tenancy
Allow group IdPAdmins to manage groups in tenancy
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.
Supported Identity Providers

- Federating with Microsoft Azure Active Directory on page 3087
- Cloud Infrastructure Okta Configuration for Federation and Provisioning (white paper)
- Federating with SAML 2.0 Identity Providers on page 3097

Federating with Oracle Identity Cloud Service

This topic points to the appropriate topics for federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service depending on when you activated your tenancy.

**Tenancies created December 21, 2018 and after**

These tenancies are automatically federated with Oracle Identity Cloud Service and configured to provision federated users in Oracle Cloud Infrastructure.

To manage your federated users and groups, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 3068.

For information about the federation, see Frequently Asked Questions for Oracle Identity Cloud Service Federated Users on page 3079.

**Tenancies created between December 18, 2017 and December 20, 2018**

These tenancies are automatically federated with Oracle Identity Cloud Service but are not configured to provision federated users in Oracle Cloud Infrastructure to allow these users to have additional credentials (API keys, auth tokens, etc.).

To enable this feature for users, you need to perform a one-time upgrade, see: User Provisioning for Federated Users on page 3100.

After you have performed this upgrade, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 3068 to manage your federated users and groups.

**Tenancies created before December 18, 2017**

These tenancies must be manually federated with Oracle Identity Cloud Service. See Federating with Oracle Identity Cloud Service on page 3062 described below.

Manually Federating with Oracle Identity Cloud Service

Your organization can have multiple Oracle Identity Cloud Service accounts (e.g., one for each division of the organization). You can federate multiple Identity Cloud Service accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Identity Cloud Service account.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before following the steps in this topic, see Federating with Identity Providers on page 3058 to ensure that you understand general federation concepts.</td>
</tr>
</tbody>
</table>
Components of the Manual Federation to Understand

Web Application and Client Credentials

For each trust, you must set up a web application in Oracle Identity Cloud Service (also called a trusted application); instructions are in Instructions for Federating with Oracle Identity Cloud Service on page 3063. The resulting application has a set of client credentials (a client ID and client secret). When you federate your Identity Cloud Service account with Oracle Cloud Infrastructure, you must provide these credentials.

COMPUTEBAREMETAL application

A trusted application in Oracle Identity Cloud Service that contains the set of client credentials (a client ID and client secret) you'll need to provide when you federate your Identity Cloud Service account with Oracle Cloud Infrastructure.

Required URLs

The easiest way to federate with Oracle Identity Cloud Service is through the Oracle Cloud Infrastructure Console, although you could do it programmatically with the API. If you're using the Console, you're asked to provide a base URL instead of the metadata URL. The base URL is the left-most part of the URL in the browser window when you're signed in to the Identity Cloud Service console:

- Base URL: `<Identity Cloud Service account name>.identity.oraclecloud.com`

If you're using the API to federate, you need to provide the metadata URL, which is the base URL with /fed/v1/ metadata appended, like so:

- Metadata URL: `<Identity Cloud Service account name>.identity.oraclecloud.com/fed/v1/metadata`

The metadata URL links directly to the IdP-provided XML required to federate. If you're using the API, you need to provide both the metadata URL and the metadata itself when federating. For more information, see Managing Identity Providers in the API on page 3067.

OCI-V2-<tenancy_name> app

When you manually federate an Oracle Identity Cloud Service account with Oracle Cloud Infrastructure, a new SAML application called OCI-V2-<tenancy_name> is automatically created in that Oracle Identity Cloud Service account. If you later need to delete the Oracle Identity Cloud Service identity provider from your Oracle Cloud Infrastructure tenancy, make sure to also delete the OCI-V2-<tenancy_name> from Oracle Identity Cloud Service. If you don't, and you later try to federate the same Oracle Identity Cloud Service account again, you'll get a 409 error saying that an application with the same name already exists (that is, OCI-V2-<tenancy_name>).

Provisioned User

A provisioned user is provisioned by Oracle Identity Cloud Service in Oracle Cloud Infrastructure and is synched to a federated user that is managed in Oracle Identity Cloud Service. The provisioned user can have the special Oracle Cloud Infrastructure credentials like API keys and auth tokens to enable programmatic access. Provisioned users cannot have Console passwords.

Instructions for Federating with Oracle Identity Cloud Service

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

1. Sign in to Oracle Identity Cloud Service. Perform one of the following, as appropriate:
   - Option A: Get the required information from the COMPUTEBAREMETAL application you'll need to perform the set up steps in Oracle Cloud Infrastructure.
   - Option B: If Oracle Identity Cloud Service does not include the COMPUTEBAREMETAL application, set up a trusted application.

2. In Oracle Cloud Infrastructure, set up the federation:
   - a. Set up Oracle Identity Cloud Service as an identity provider.
   - b. Map Oracle Identity Cloud Service groups to IAM groups.
3. In Oracle Cloud Infrastructure, set up the IAM policies for the IAM groups to define the access you want the members of the mapped groups to have.

Step 1: Get required information from Oracle Identity Cloud Service

Option A: Get information from the COMPUTEBAREMETAL application
1. Go to the Oracle Identity Cloud Service console and sign in with admin privileges. Make sure you're viewing the Admin Console.
2. In the Identity Cloud Service console, click Applications. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL. If your instance does not include the COMPUTEBAREMETAL application, perform Step 1 Option B, instead.
4. Click Configuration.
5. Expand General Information. The client ID is displayed. Click Show Secret to display the client secret.

6. Record the Client ID and Client Secret. They look similar to this:
   - Client ID: de06b81cb45a45a8acdcde923402a9389d8
   - Client Secret: 8a297afd-66df-49ee-c67d-39fcdf3d1c31

Option B: Set up a trusted application and get required information from Oracle Identity Cloud Service

Perform this step only if you were unable to complete Step 1 Option A.

Summary: For Oracle Identity Cloud Service, you need to create a confidential application (also referred to as a trusted application) with particular properties described in the following instructions. For the general Oracle Identity Cloud Service documentation, see Add a Confidential Application.

Instructions for Oracle Identity Cloud Service:
1. Go to the Oracle Identity Cloud Service console and sign in with privileges to create the application. Make sure you're viewing the Admin Console.
2. Add a confidential (or trusted) application, which enables secure, programmatic interaction between Oracle Cloud Infrastructure and Oracle Identity Cloud Service. Specify these items when setting up the application:

   a. On the first page:
      1. Enter an application name (e.g., Oracle Cloud Infrastructure Federation).
      2. Leave other fields empty or unselected.

   b. On the next page:
      1. Select Configure this application as a client now.
      2. For the Allowed Grant Types, select the check box for Client Credentials.
      3. Leave other fields empty.
      4. At the bottom of the page:
         a. Select the check box for Grant the client access to Identity Cloud Service Admin APIs.
         b. Select Identity Domain Administrator from the list of roles.
   c. On the next page, leave any fields empty or unselected and continue until you click Finish.
   d. Copy and paste the displayed client credentials so you can later give them to Oracle Cloud Infrastructure when federating. You can view the application's client credentials any time in the Oracle Identity Cloud Service console. They look similar to this:
      
      • Client ID: de06b81cb45a45a8acdcde923402a9389d8
      • Client Secret: 8a297afd-66df-49ee-c67d-39fcdf3d1c31

3. Record the Oracle Identity Cloud Service base URL, which you'll need when federating.
4. Activate the application.

**Step 2: Add Oracle Identity Cloud Service as an identity provider in Oracle Cloud Infrastructure**

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
3. Click Add identity provider.
4. Enter the following:

   a. **Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console (for example., ABCCorp_IDCS as shown in the screenshot in Experience for Federated Users on page 3060). The name must be unique across all identity providers you add to the tenancy. You cannot change this later.

   b. **Description:** A friendly description.

   c. **IDCS Base URL:** See Required URLs on page 3063.

   d. **Client ID:** From Step 1 Option A or Option B.

   e. **Client secret:** From Step 1 Option A or Option B.

   f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in IDCS. For more information, see General Concepts on page 3059. For information about setting this feature up in the IDCS, see Managing Oracle Identity Cloud Service Applications.

   g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.

   h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party) expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select Custom, then manually enter the class reference.

   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information
about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click Continue.

6. Set up the mappings between Oracle Identity Cloud Service groups and IAM groups in Oracle Cloud Infrastructure. A given Oracle Identity Cloud Service group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Oracle Identity Cloud Service group and a single IAM group. Changes to group mappings take effect typically within seconds.

**Note:**
If you don't want to set up the group mappings now, you can simply click Create and come back to add the mappings later.

To create a group mapping:

a. Select the Oracle Identity Cloud Service group from the list under Identity Provider Group.
b. Choose the IAM group you want to map this group to from the list under OCI Group.

**Tip:**
Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

c. Repeat the above sub-steps for each mapping you want to create, and then click Create.

**After the Federation Set Up**

The identity provider is now added to your tenancy and appears in the list on the Federation page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the Federation page if you want to edit the group mappings or delete the identity provider from your tenancy.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users on page 3104 for more information on assigning these users additional credentials.

**Step 3: Set up IAM policies for the groups**

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Step 4: Give your federated users the name of the tenant and URL to sign in**

Give your federated users need the URL for the Oracle Cloud Infrastructure Console, https://cloud.oracle.com), and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

**Managing Identity Providers in the Console**

To add an Oracle Identity Cloud Service as an identity provider

See Instructions for Federating with Oracle Identity Cloud Service on page 3063.

To delete the identity provider

All the group mappings will also be deleted.
1. Delete the identity provider from your tenancy:
      A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click Delete.
   d. Confirm when prompted.

2. Delete the $OCI-V2-<tenancy_name>$ from your Oracle Identity Cloud Service account:
   a. Go to Oracle Identity Cloud Service and sign in to the federated account.
   b. Click Applications. The list of applications is displayed.
   c. Locate the $OCI-V2-<tenancy_name>$ and click its name to view its details page.
   d. In the upper right of the page, click Deactivate. Confirm when prompted.
   e. Click Remove. Confirm when prompted.

To add group mappings for Oracle Identity Cloud Service

   A list of the identity providers in your tenancy is displayed.
2. Click the name you chose for your Oracle Identity Cloud Service federation to view its details.
3. Click Add Mappings.
   a. Select the Oracle Identity Cloud Service group from the list under Identity Provider Group.
   b. Choose the IAM group you want to map this group to from the list under OCI Group.
   c. To add more mappings, click +Another Mapping.
   d. When you are finished, click Add Mappings.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users on page 3104 for more information on assigning these users additional credentials.

To update or delete a group mapping

You can't update a group mapping, but you can delete the mapping and add a new one.

   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click Delete.
4. Confirm when prompted.
5. Add a new mapping, if wanted.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations:

Identity providers:
IAM

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:
- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console

This topic describes how to use the Oracle Cloud Infrastructure Console to manage your Oracle Identity Cloud Service users and groups. Before you get started, understand basic federation concepts. See Federating with Identity Providers on page 3058.

Overview of Working with Oracle Identity Cloud Service Users and Groups in the Console

The Oracle Cloud Infrastructure Console provides an integration with Oracle Identity Cloud Service (IDCS) that lets you perform many management tasks for your IDCS users and groups in the Console.

User Management Tasks

In the Console, you can do the following user management tasks:
- Add users
- Remove users
- Add users to groups
- Assign roles to users to access services and instances
- Reset user password

For information on more user management tasks, see Managing Oracle Identity Cloud Service Users in Administering Oracle Identity Cloud Service.

Group Management Tasks

In the Console, you can do the following group management tasks:
- Add groups
- Remove groups
- Add users to groups
- Map IDCS groups to IAM groups

For information on more group management tasks, see Managing Oracle Identity Cloud Service Groups in Administering Oracle Identity Cloud Service.

Required Policies and Permissions

To manage Oracle Identity Cloud Service users and groups in the Console, you'll need to be granted permissions in both the Oracle Cloud Infrastructure IAM service and in Oracle Identity Cloud Service.

Members of the OCI_Administrators group have the required permissions to create groups and policies in Oracle Cloud Infrastructure.

Important: To create users and groups in the Oracle Identity Cloud Service federation, you'll need the Identity Domain Administrator role, or be a member of a group that has been granted that role. For information on Oracle Identity Cloud Service roles, see Administering Oracle Identity Cloud Service.
To quickly create a user with the required permissions, see Add a User with Oracle Cloud Administrator Permissions on page 82.

Navigating to Your Oracle Identity Cloud Service Users and Groups in the Console

In the Console, you can add users and groups to Oracle Identity Cloud Service from the Identity Provider Details page.

To view your identity provider details:

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.

From the Identity Provider Details page, click Users to display the users created in Oracle Identity Cloud Service. Click Groups to display the groups created in Oracle Identity Cloud Service.

Working with Oracle Identity Cloud Service Groups

The Console lets you perform the following tasks to manage groups in Oracle Identity Cloud Service:

- Add groups
- Delete groups
- Edit the name and description
- Add users to groups
- Remove users from groups
- Map groups to Oracle Cloud Infrastructure groups

Some tasks you can't perform in the Oracle Cloud Infrastructure Console. To add the predefined application roles for some Oracle Cloud products, you need to assign roles in the Identity Cloud Service console. For more information about using Oracle Identity Cloud Service, see Administering Oracle Identity Cloud Service.

For the members of a group in Oracle Identity Cloud Service to have permissions in Oracle Cloud Infrastructure, you must map the IDCS group to a group in IAM. Before you set up any new groups in IDCS, ensure that you understand how to assign permissions to groups in Oracle Cloud Infrastructure. See Overview of Oracle Cloud Infrastructure Identity and Access Management on page 2788.

Working with Oracle Identity Cloud Service Users

The Console lets you perform the following tasks to manage users in Oracle Identity Cloud Service:

- Add users
- Delete users
- Edit user details
- Add users to groups
- Add roles to users
- Remove users from groups
- Reset user passwords

**User Management Tasks You Can't Perform in the Console**

The Oracle Cloud Console does not support management of the following Oracle Identity Cloud Service user features and tasks:

- Manage multi-factor authentication

For information about managing these tasks, see *Administering Oracle Identity Cloud Service*.

**Managing Oracle Identity Cloud Service Groups in the Console**

To create a group in Oracle Identity Cloud Service

This procedure creates a new group in Oracle Identity Cloud Service. Optionally, you can add users to the group at the time you create it. This group will not have any permissions in Oracle Cloud Infrastructure until you map it to an Oracle Cloud Infrastructure group.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**. A list of the federations in your tenancy is displayed.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.

   The list of existing groups is displayed.
4. Click **Create IDCS Group**.
5. Enter the following:
   - **Name**: A unique name for the group. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Users**: Add Oracle Identity Cloud Service users to this group. You can add users when you create the group, or later. Select users from the list. To find a specific user, you can start typing the user name to filter the list as you type.
6. Click **Create**.

After you create a group in Oracle Identity Cloud Service, you'll want to give the group permissions to user services:

- To grant the group access to map it to an Oracle Cloud Infrastructure group as described in the next procedure.
- To add roles to this group, see *Managing Oracle Identity Cloud Service Roles for Groups* on page 3077.

To map an Oracle Identity Cloud Service group to an IAM group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.
3. Click **Edit Mapping**.
4. In the **Edit Identity Provider** dialog, click **+ Add Mapping**.
5. Select the **Identity Provider Group** you want to map from the list. To find a specific group, you can start typing the group name to filter the list as you type.
6. Select the **OCI Group** you want to map this Identity Cloud Service group to. To find a group without scrolling through the list, you can start typing the group name to filter the list as you type.
7. To add more mappings, click **Add Mapping** and continue adding the mappings.
8. Select the group you want to map this group to from the list under **OCI Mapped User Group**.

Members of this group now have the permissions granted to the OCI Mapped User Group.

To add roles to a group
Oracle Cloud Infrastructure services use policies to control access to services. However, some Oracle Cloud services use roles to manage access. This procedure describes how to add roles to an IDCS group.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**. A list of the identity providers in your tenancy is displayed.
2. Click the Oracle Identity Cloud Service Console link. The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the **Navigation Drawer**, and then click **Applications**. The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in. The Details page is displayed.
5. Click **Application Roles**. The roles are displayed.
6. Click the menu for the role you want to assign and select **Assign Groups**.
7. Select the group you want to assign to the role, and click **OK**.
8. Click the Applications breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to assign to this group.

To remove roles from a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**. A list of the identity providers in your tenancy is displayed.
2. Click the Oracle Identity Cloud Service Console link. The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the **Navigation Drawer**, and then click **Applications**. The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in. The Details page is displayed.
5. Click **Application Roles**. The roles are displayed.
6. Click the menu for the role you want to remove from the group and select **Revoke Groups**.
7. Select the group you want to remove the role from, and click **OK**.
8. Click the Applications breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to remove from this group.

To edit details for an Oracle Identity Cloud Service group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**. A list of the identity providers in your tenancy is displayed.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**. The list of existing groups in the federation is displayed.
4. Find the group you want to edit and click its name. The Group Details page is displayed.
5. Click **Edit**.
6. You can update the **Group Name** or the **Description**. Avoid entering confidential information.

   **Caution:**

   Changing the group name will break mappings to Oracle Cloud Infrastructure (OCI) groups. If you change the group name, ensure that you delete any existing group mappings and add new mappings with the new name. See the previous task on editing mappings.

7. Click **Update** to save your changes.

### To add users to a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   - The list of existing groups is displayed.
4. Find the group you want to add a user to.
   - The **User Group Details** page is displayed.
5. Click **Add IDCS User**.
6. Select the user you want to add to this group from the **Users** list.
7. Click **Add**.

### To remove users from a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   - The list of existing groups is displayed.
4. Find the group you want to remove the user from.
   - The list of users is displayed in the **Group Details** page.
5. Find the user you want to remove, and then click the **Actions** icon (three dots).
6. Click **Remove User**.
7. Confirm when prompted.

### To delete a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   - The list of existing groups is displayed.
4. Find the group you want to edit and click its name.
   - The **Group Details** page is displayed.
5. Click **Delete**.
6. Confirm when prompted.

### Create a policy to grant the group permissions on Oracle Cloud Infrastructure resources

The group you created in Oracle Identity Cloud Service gets permissions to access resources in Oracle Cloud Infrastructure through the policy you assign to the Oracle Cloud Infrastructure group. Before you complete this step, you need to decide what permissions you want to give your new group. For more information, see *Getting Started with Policies* on page 2799 and *Common Policies* on page 2806.

Prerequisite: The group and compartment that you're writing the policy for must already exist.
1. Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.

2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Policy Attachment on page 2805).

3. Click Create Policy.

4. Enter the following:
   - **Name**: A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Statement**: A policy statement. For the correct format to use, see Policy Basics on page 2801 and also Policy Syntax on page 2834. If you want to add more than one statement, click +.

   For example:
   
   To allow your group to manage all resources within a specified compartment enter a statement like the following:

   ```allow group <OCI_group_name> to manage all-resources in compartment <compartment_name>```

   For more policy examples, see Common Policies on page 2806.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click Create.

**Managing Oracle Identity Cloud Service Users in the Console**

After you add a user in Oracle Identity Cloud Service, a user is also automatically provisioned in Oracle Cloud Infrastructure. This provisioned user can have the Oracle Cloud Infrastructure credentials, such as API keys and auth tokens. To understand this provisioning, see User Provisioning for Federated Users on page 3100.

To create a user

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.

3. Click Create IDCS User.

4. In the Create IDCS User dialog enter the following:
   - **User Name**: Enter a unique name or email address for the new user. The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Email**: Enter an email address for this user. The initial sign-in credentials will be sent to this email address.
   - **First Name**: Enter the user's first name.
   - **Last Name**: Enter the user's last name.
   - **Phone Number**: Optionally, enter a phone number.
   - **Groups**: Optionally, select groups to add this user to.

5. Click Create User.

**Important:**

For the user to have permissions in Oracle Cloud Infrastructure, you must assign the user to a group that is mapped to an Oracle Cloud Infrastructure group. Or, if you are also creating a new group, you can perform this mapping later. The user will not be able to sign in to the Console until the mapping is accomplished.
The user creation process generates an email that is sent to the address provided that you entered. The email includes the new user’s username and password to use with the Oracle Cloud Infrastructure Console.

To add API keys, auth tokens, customer secret keys, or SMTP credentials for this user, see Managing User Capabilities for Federated Users on page 3104.

To edit a user

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Users**.
   The list of existing users is displayed.
4. Find the user you want to edit and click its name.
   The **User Details** page is displayed.
5. Click **Edit**.
6. Update the fields.
7. Click **Save** when finished.

To reset a user’s password

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Under **Resources**, click **Users**.
   The list of existing user groups in the federation is displayed.
4. Find the user you want to reset the password for and click the name.
   The **User Details** page is displayed.
5. Click **Reset Password**.
   The user’s password is reset. This user can’t access their account until they complete the password reset steps.
6. Click **Email Password Instructions** to send the password link and instructions to the user.
   The password link is good for 24 hours. If the user does not reset their password in time, you can generate a new password link by clicking **Reset Password** for the user again.

To manage roles for services managed through IDCS

See see Managing Oracle Identity Cloud Service Roles for Users on page 3075.

To add API keys, auth tokens, or other Oracle Cloud Infrastructure credentials

1. View the user’s details:
   - If you’re adding credentials for **yourself**:
     Open the **Profile** menu ( ++) and click **User Settings**.
   - If you’re an administrator adding credentials for **another user**: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
     Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
     Find the user in the list and click the **OCI Synched User** link.

2. Add the credentials for the user.
   For more details about these credentials, see Managing User Credentials on page 3150.

To delete a user

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.

3. Under **Resources**, click **Users**.

   The list of existing user groups in the federation is displayed.

4. Find the user you want to delete and click the name.

   The **User Details** page is displayed.

5. Click **Delete**.

### Managing Group Mappings

To add group mappings for Oracle Identity Cloud Service

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.

   A list of the identity providers in your tenancy is displayed.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named `OracleIdentityCloudService`. The identity provider details page is displayed.

3. Click **Edit Provider Details**.

4. Add at least one mapping:
   
   a. Click **Add Mapping**.
      
   b. Select the Oracle Identity Cloud Service group from the list under **Identity Provider Group**.
      
   c. Choose the IAM group you want to map this group to from the list under **OCI Group**.
      
   d. Repeat the above sub-steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See **Managing User Capabilities for Federated Users** on page 3104 for more information on assigning these users additional credentials.

To update or delete a group mapping

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.

   A list of the identity providers in your tenancy is displayed.

2. Click the identity provider to view its details.

3. Click **Edit Mapping**.

4. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

### Managing Oracle Identity Cloud Service Roles for Users

This topic describes managing user roles for users created in Oracle Identity Cloud Service.

#### About User Roles in Oracle Identity Cloud Service

You can assign roles to a user to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- **Service access roles** - grant access to use the service.
- **Instance access roles** - grant access to specific instances of a service. These can only be granted after the instances are created.

For information about more complex role management including assigning other administrative privileges, see **Managing Oracle Identity Cloud Service Users**.
Available Roles for Each Service

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See About Service Administrator Roles for more information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

Required Permissions to Manage Roles

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

Allow group GroupA to inspect identity-providers in tenancy

where you replace GroupA with the name of the group you want to grant the permission to.

To manage the service roles for another user, you must be assigned the appropriate role in Oracle Identity Cloud Service. See Understanding Administrator Roles.

Managing User Access to a Console

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.
2. Click the name of the user you want to edit.
3. On the user details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this user has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
4. Find the service you want to edit this user's access to, click the Actions icon (three dots), and then click Manage service access or Manage instance access, as appropriate. The list of roles for the selected service is displayed.
5. Edit the user's access as follows:
   • Select each role you want to give to the user.
   • Click the x next to each role you want remove from the user. Note that you can't remove a role that has been granted through a group. These roles are read only.
   If a user is assigned the Cloud Account Administrator role, then you can’t remove the individual entitlement roles for the user.
6. Click Apply Role Settings or Update Instance Settings, as appropriate.
7. If you are granting roles to a user, in the confirmation dialog, click Send Email to User to send an email to the user to notify them of this change.
8. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.
9. Return to the Console and click Close.

Managing Instance Roles in the Console

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage individual user access to the instance.

Managing User Access to an Instance
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.

   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.

2. Click the name of the user you want to edit.

3. On the user details page, click **Manage Roles**. The **Manage Roles** page displays the list of services for which you have Administrator access. The service and instance roles that this user has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.

4. Find the service with instances that you want to edit this user's access to, click the Actions icon (three dots), and then click **Manage instance access**. The list of instances for the selected service is displayed.

5. On the **Manage Access to Instances** page, find the name of the instance you want to edit this user's access to.

   To grant access to this instance:

   - In the **Instance Role** column, select the role you want to grant to the user. You can select multiple roles from the list.

   To remove access to this instance:

   - In the **Instance Role** column, click the x next to the role you want to remove from the user.

6. When you are finished editing roles, click **Update Instance Settings**.

7. On the **Manage Roles** page, click **Apply Role Settings**.

8. If you are granting roles to a user, in the confirmation dialog, click **Send Email to User** to send an email to the user to notify them of this change.

9. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.

10. Return to the Console and click **Close**.

### Managing Oracle Identity Cloud Service Roles for Groups

This topic describes managing roles for groups created in Oracle Identity Cloud Service.

#### About Group Roles in Oracle Identity Cloud Service

You can assign roles to groups to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- Service access roles - grant access to use the service.
- Instance access roles - grant access to specific instances of a service. These can only be granted after the instances are created.

For information about more complex role management, see [Manage Oracle Identity Cloud Service Groups](#).

#### Available Roles for Each Service

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See [About Service Administrator Roles](#) for more information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

#### Required Permissions to Manage Roles

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

```plaintext
Allow group GroupA to inspect identity-providers in tenancy
```
where you replace GroupA with the name of the group you want to grant the permission to.

To manage service roles, you must be assigned the Administrator role for that service.

Managing Group Roles in the Console

To add roles to a group

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Click Groups.

   The list of groups is displayed.
4. Click the name of the group you want to add roles to.
5. On the group details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click Manage service access. The list of roles for the selected service is displayed.
7. Select each role that you want to assign to the group.
8. Click Save Role Selections.
9. To add more service roles to this group, repeat steps 6 - 8.
10. Click Apply Role Settings.
11. In the confirmation dialog, click Send Email to Group to send an email to each member of the group to notify them of this change.

   Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending.
12. Return to the Console and click Close.

To revoke roles from a group

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named OracleIdentityCloudService. The identity provider details page is displayed.
3. Click Groups.

   The list of groups is displayed.
4. Click the name of the group you want to remove roles from.
5. On the group details page, click Manage Roles. The Manage Roles page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.

   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click Manage service access or Manage instance access, as appropriate. The list of roles for the selected service is displayed.
7. Clear the check box for each role you want remove from the group.
8. Click Save Role Selections or Update Instance Settings, as appropriate.
9. To revoke more service or instance roles from this group, repeat steps 6 - 8.
10. Click Apply Role Settings.
11. A confirmation dialog displays the services that you modified access to in this session. Click Close.

Managing Instance Roles in the Console

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage group access to the instance.

Managing Group Access to an Instance
1. Open the navigation menu and click **Identity & Security.** Under **Identity,** click **Federation.**
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService.** The identity provider details page is displayed.
3. Click **Groups.**
   The list of groups is displayed.
4. On the group details page, click **Manage Roles.** The **Manage Roles** page displays the list of services for which you have Administrator access. The service and instance roles that this group has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
5. Find the service with instances that you want to edit this group's access to, click the Actions icon (three dots), and then click **Manage instance access.** The list of instances for the selected service is displayed.
6. On the **Manage Access to Instances** page, find the name of the instance you want to edit this group's access to.
   - To grant access to this instance: In the **Instance Role** column, select the role you want to grant to the group. You can select multiple roles from the list.
   - To remove access to this instance: In the **Instance Role** column, click the x next to the role you want to remove from the group.
7. When you are finished editing roles for this service, click **Update Instance Settings.**
8. To edit more instance roles for this group, repeat steps 6 - 7.
9. On the **Manage Roles** page, click **Apply Role Settings.**
10. If you added roles, in the confirmation dialog, click **Send Email to Group** to send an email to each member of the group to notify them of this change. Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending. Return to the Console and click **Close.**
    If you revoked roles, a confirmation dialog displays the services that you modified access to in this session. Click **Close.**

**Frequently Asked Questions for Oracle Identity Cloud Service Federated Users**

When you sign up for Oracle Cloud Infrastructure, your account is automatically federated with Oracle Identity Cloud Service as your identity provider. This topic answers some frequently asked questions about the federation.

**What resources are created in Oracle Identity Cloud Service?**

**The following resources are created in Identity Cloud Service:**

- **Applications:**
  - **OCI-V2-<tenancy_name>**
    This SAML application that creates the federation with Oracle Cloud Infrastructure.
  - **COMPUTEAREMETAL** application
    A supporting application for the federation.

  **Important:**
  Do not delete these applications.

- **Group:**
  OCL_Administrators group
  This group is mapped to the Administrators group in Oracle Cloud Infrastructure. Members of this group have full administrator privileges in Oracle Cloud Infrastructure.

- **User:**
  A default administrator user (e.g., user@example.com) who is a member of the OCL_Administrators group.
What resources are created in Oracle Cloud Infrastructure?

The following resources are created in Oracle Cloud Infrastructure:

- **Identity Provider:** OracleIdentityCloudService
- **Group Mappings:** The federation is created with one group mapping:
  
  OCI_Administrators group (from Oracle Identity Cloud Service) is mapped to the Administrators group (In Oracle Cloud Infrastructure).
- **Users:**
  
  - The default administrator user created in Oracle Identity Cloud Service is provisioned in Oracle Cloud Infrastructure. This user can have the Oracle Cloud Infrastructure credentials, but not a Console password.
  
  - A default administrator local-user with the same user name (user@example.com) is also created in Oracle Cloud Infrastructure's IAM service. Customers who choose **not** to use the Oracle Identity Cloud Service federation can use this user to administer Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The default administrator created in Oracle Identity Cloud Service and the local default administrator created in Oracle Cloud Infrastructure exist independently in their respective identity systems. Ensure that you manage passwords for them separately.</td>
</tr>
</tbody>
</table>

Why is my account federated with Oracle Identity Cloud Service?

Oracle Identity Cloud Service is the identity provider for multiple Oracle services. Federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service allows you to have a seamless connection between services, without having to create a separate username and password for each one.

How do I know if I am signed in through Oracle Identity Cloud Service?

Click the **Profile** menu to display your username. Users signed in through an identity provider will see their username prefaced with their identity provider name, for example:

oracleidentitycloudservice/user@example.com

How do I add a user to Oracle Identity Cloud Service (a federated user)?

See Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 3068.

Can I add a user just for Oracle Cloud Infrastructure?

Yes. If you don't want to manage the user in Oracle Identity Cloud Service, you can add a user directly to the Oracle Cloud Infrastructure IAM service. See Adding Users on page 81. Using this procedure, you can create users who can sign in directly to the Oracle Cloud Infrastructure Console. Users created with this procedure do not have access to any other Oracle services.

How do I manage groups?

In short, managing groups requires actions in both Oracle Identity Cloud Service and Oracle Cloud Infrastructure. Groups you create in Oracle Identity Cloud Service have no privileges in Oracle Cloud Infrastructure until you map them to a group in Oracle Cloud Infrastructure. You define the policies that permit access to Oracle Cloud Infrastructure resources in the IAM service in Oracle Cloud Infrastructure. For more information, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 3068.

How do I find the client ID and client secret?

To edit mappings of your user groups in Oracle Identity Cloud Service to user groups in Oracle Cloud Infrastructure, you'll need to supply the client ID and client secret. The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

1. Sign in to the Oracle Identity Cloud Service console.
2. In the Identity Cloud Service console, click Applications. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL.
4. Click Configuration.
5. Expand General Information. The client ID is displayed. Click Show Secret to display the client secret.

If I delete the federation, can I later recreate it?
Yes. To recreate the federation with Oracle Identity Cloud Service, follow the instructions in the topic Federating with Oracle Identity Cloud Service on page 3062.

Federating with Microsoft Active Directory
This topic describes how to federate with Microsoft Active Directory using Microsoft Active Federation Services (AD FS).

Note:
Before following the steps in this topic, see Federating with Identity Providers on page 3058 to ensure that you understand general federation concepts.

About Federating with Microsoft Active Directory
Your organization can have multiple Active Directory accounts (for example, one for each division of the organization). You can federate multiple Active Directory accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Active Directory account.

To federate with Active Directory, you set up a trust between Active Directory and Oracle Cloud Infrastructure. To set up this trust, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Active Directory Federation Services.

Following is the general process an administrator goes through to set up federation with Active Directory. Details for each step are given in the sections below.

1. Get required information from Active Directory Federation Services.
2. Federate Active Directory with Oracle Cloud Infrastructure:
   a. Add the identity provider (AD FS) to your tenancy and provide the required information.
   b. Map Active Directory groups to IAM groups.
3. In Active Directory Federation Services, add Oracle Cloud Infrastructure as a trusted, relying party.
4. In Active Directory Federation Services, add the claim rules required in the authentication response by Oracle Cloud Infrastructure.
5. Test your configuration by logging in to Oracle Cloud Infrastructure with your Active Directory credentials.

**Federating with Active Directory**

**Prerequisites**

You have installed and configured Microsoft Active Directory Federation Services for your organization.

You have set up groups in Active Directory to map to groups in Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Consider naming Active Directory groups that you intend to map to Oracle Cloud Infrastructure groups with a common prefix, to make it easy to apply a filter rule. For example, OCI_Administrators, OCI_NetworkAdmins, OCI_InstanceLaunchers.</td>
</tr>
</tbody>
</table>

**Step 1: Get required information from Active Directory Federation Services**

**Summary:** Get the SAML metadata document and the names of the Active Directory groups that you want to map to Oracle Cloud Infrastructure Identity and Access Management groups.

1. Locate the SAML metadata document for your AD FS federation server. By default, it is at this URL:
   ```
   https://<yourservername>/FederationMetadata/2007-06/FederationMetadata.xml
   ```
   Download this document and make a note of where you save it. You will upload this document to the Console in the next step.
2. Note all the Active Directory groups that you want to map to Oracle Cloud Infrastructure IAM groups. You will need to enter these in the Console in the next step.

**Step 2: Add Active Directory as an identity provider in Oracle Cloud Infrastructure**

**Summary:** Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
3. Click **Add identity provider**.
4. Enter the following:
   a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. **Description:** A friendly description.
   c. **Type:** Select Microsoft Active Directory Federation Services (ADFS) or SAML 2.0 compliant identity provider.
   d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.
   e. Click **Show Advanced Options**.
   f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.
      
      To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.
   g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.
   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.

6. Set up the mappings between Active Directory groups and IAM groups in Oracle Cloud Infrastructure. A given Active Directory group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Active Directory group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

   **Note:**
   If you don't want to set up the group mappings now, you can simply click Create and come back to add the mappings later.

To create a group mapping:

   a. Under **Identity Provider Group**, enter the Active Directory group name. You must enter the name exactly, including the correct case.

   Choose the IAM group you want to map this group to from the list under **OCI Group**.

   **Tip:**
   Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

   b. Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

   The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.
Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the Federation page if you want to edit the group mappings or delete the identity provider from your tenancy.

**Step 3: Copy the URL for the Oracle Cloud Infrastructure Federation Metadata document**

**Summary:** The Federation page displays a link to the Oracle Cloud Infrastructure Federation Metadata document. Before you move on to configuring Active Directory Federation Services, you need to copy the URL.

1. On the Federation page, click Download this document.
2. Copy the URL. The URL looks similar to:

   https://auth.r2.oracleiaas.com/v1/saml/ocid1.tenancy.oc1..aaaaaaaaqdt2tvdhsa3jmvc5dzulgs3pcv6imfwdgy4aq/metadata.xml

**Step 4: In Active Directory Federation Services, add Oracle Cloud Infrastructure as a trusted relying party**

1. Go to the AD FS Management Console and sign in to the account you want to federate.
2. Add Oracle Cloud Infrastructure as a trusted relying party:
   a. From the AD FS Management Console, right-click AD FS and select Add Relying Party Trust.
   b. In the Add Relying Party Trust Wizard, click Start.
   c. Select Import data about the relying party published online or on a local network.
      Paste the Oracle Cloud Infrastructure Federation Metadata URL that you copied in Step 3. Click Next.
      AD FS will connect to the URL. If you get an error during the attempt to read the federation metadata, you can alternatively upload the Oracle Cloud Infrastructure Federation Metadata XML document.
      To upload the federation metadata document
      1. In a web browser, paste the Oracle Cloud Infrastructure Federation Metadata URL in the address bar.
      2. Save the XML document to a location that is accessible by your AD FS Management Console.
      3. In the Select Data Source step of the Add Relying Party Trust Wizard, select Import data about the relying party from a file.
      4. Click Browse and select the metadata.xml file that you saved.
      5. Click Next.
   d. Set the display name for the relying party (for example, Oracle Cloud Infrastructure) and then click Next.
   e. Select I do not want to configure multi-factor authentication settings for this relying party trust at this time.
   f. Choose the appropriate Issuance Authorization Rules to either permit or deny all users access to the relying party. Note that if you choose "Deny", then you must later add the authorization rules to enable access for the appropriate users.
      Click Next.
   g. Review the settings and click Next.
   h. Check Open the Edit Claim Rules dialog for this relying part trust when the wizard closes and then click Close.

**Step 5: Add the claim rules for the Oracle Cloud Infrastructure relying party**

**Summary:** Add the claim rules so that the elements that Oracle Cloud Infrastructure requires (Name ID and groups) are added to the SAML authentication response.

**Add the Name ID rule:**
1. In the Add Transform Claim Rule Wizard, select Transform an Incoming Claim, and click Next.
2. Enter the following:
   - **Claim rule name**: Enter a name for this rule, for example, nameid.
   - **Incoming claim type**: Select Windows account name.
   - **Outgoing claim type**: Select Name ID.
   - **Outgoing name ID format**: Select Persistent Identifier.
   - Select **Pass through all claim value**.
   - Click Finish.
3. The rule is displayed in the rules list. Click Add Rule.

Add the groups rule:

**Important:** Any users who are in more than 100 IdP groups cannot be authenticated to use the Oracle Cloud Infrastructure Console. To enable authentication, apply a filter to the groups rule, as described below.

If your Active Directory users are in no more than 100 groups

Add the groups rule:

1. Under Claim rule template, select Send Claims Using a Custom Rule. Click Next.
2. In the Add Transform Claim Rule Wizard, enter the following:
   a. **Claim rule name**: Enter a name, for example, groups.
   b. **Custom rule**: Enter the following custom rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname", Issuer == "AD AUTHORITY"] => add(store = "Active Directory", types = ("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;\{0\}", param = c.Value);
```
   c. Click Finish.

If your Active Directory users are in more than 100 groups

Add the groups rule with a filter:

To limit the groups sent to Oracle Cloud Infrastructure, create two custom claim rules. The first one retrieves all groups the user belongs to directly and indirectly. The second rule applies a filter to limit the groups passed to the service provider to only those that match the filter criteria.

Add the first rule:

1. In the Edit Claim Rules dialog, click Add Rule.
2. Under Claim rule template, select Send Claims Using a Custom Rule. Click Next.
3. In the Add Transform Claim Rule Wizard, enter the following:
   a. **Claim rule name**: Enter a name, for example, groups.
   b. **Custom rule**: Enter the following custom rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname", Issuer == "AD AUTHORITY"] => add(store = "Active Directory", types = ("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;\{0\}", param = c.Value);
```
   c. Click Finish.

Note that in this custom rule you use add instead of issue. This command passes the results of the rule to the next rule, instead of sending the results to the service provider.
4. Now add the filter rule.
   a. In the Edit Claim Rules dialog, click Add Rule.
   b. Under Claim rule template, select Send Claims Using a Custom Rule. Click Next.
   c. In the Add Transform Claim Rule Wizard, enter the following:
      1. Claim rule name: Enter groups.
      2. Custom rule: Enter an appropriate filter rule. For example to send only groups that begin with the string "OCI", enter the following:

         ```
         c:[Type == "https://auth.oraclecloud.com/saml/claims/groupName", Value =~ "(?i)OCI"] => issue(claim = c);
         ```

      This rule filters the list from the first rule to only those groups that begin with the string OCI. The issue command, sends the results of the rule to the service provider.
      
      You can create filters with the appropriate criteria for your organization.
      
      For information on AD FS syntax for custom rules, see the Microsoft document: Understanding Claim Rule Language in AD FS 2.0 and Higher.
      
   3. Click Finish.

Step 6: Set up IAM policies for the groups

If you haven't already, set up IAM policies to control the access the federated users have to your organization’s Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Step 7: Give your federated users the name of the tenant and URL to sign in

Give federated users the URL for the Oracle Cloud Infrastructure Console, https://cloud.oracle.com, and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

To add an identity provider

See About Federating with Microsoft Active Directory on page 3081.

To delete an identity provider

All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
      
      A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click Delete.
   d. Confirm when prompted.

To add group mappings for an identity provider

      
      A list of the identity providers in your tenancy is displayed.

2. Click the identity provider to view its details.
3. Click **Add Mappings**.
   a. Under **Identity Provider Group**, enter the Active Directory group name. The name you enter here must match exactly the name in Active Directory.
   b. Choose the IAM group you want to map this group to from the list under **OCI Group**.
   c. To add more mappings, click **+Another Mapping**.
   d. When you are finished, click **Add Mappings**.

Your changes take effect typically within seconds.

**To update a group mapping**

You can't update a group mapping, but you can delete the mapping and add a new one.

**To delete a group mapping**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click **Delete**.
4. Confirm when prompted.

Your changes take effect typically within seconds.

**Managing Identity Providers in the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use these API operations:

**Identity providers:**
- `CreateIdentityProvider`
- `ListIdentityProviders`
- `GetIdentityProvider`
- `UpdateIdentityProvider`
- `DeleteIdentityProvider`: Before you can use this operation, you must first use `DeleteIdpGroupMapping` to remove all the group mappings for the identity provider.

**Group mappings:**
- `CreateIdpGroupMapping`: Each group mapping is a separate entity with its own OCID.
- `ListIdpGroupMappings`
- `GetIdpGroupMapping`
- `UpdateIdpGroupMapping`
- `DeleteIdpGroupMapping`

**Federating with Microsoft Azure Active Directory**

This topic describes how to federate with Microsoft Azure Active Directory (AD).

**Note:**

Before following the steps in this topic, see [Federating with Identity Providers](#) on page 3058 to ensure that you understand general federation concepts.

**About Federating with Azure AD**

To federate with Azure AD, you set up Oracle Cloud Infrastructure as a basic SAML single sign-on application in Azure AD. To set up this application, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Azure AD.
Following is the general process an administrator goes through to set up the federation. Details for each step are given in the next section.

1. In Oracle Cloud Infrastructure, download the federation metadata document.
2. In Azure AD, set up Oracle Cloud Infrastructure Console as an enterprise application.
3. In Azure AD, configure the Oracle Cloud Infrastructure enterprise application for single sign-on.
4. In Azure AD, set up the user attributes and claims.
5. In Azure AD, download the Azure AD SAML metadata document.
6. In Azure AD, assign user groups to the application.
7. In Oracle Cloud Infrastructure, set up Azure AD as an identity provider.
8. In Oracle Cloud Infrastructure, map your Azure AD groups to Oracle Cloud Infrastructure groups.
9. In Oracle Cloud Infrastructure, set up the IAM policies to govern access for your Azure AD groups.
10. Share the Oracle Cloud Infrastructure sign-in URL with your users.

Steps to Federate with Azure AD

Prerequisites

You have an Azure tenancy with groups and users set up in Azure AD.

Step 1: In Oracle Cloud Infrastructure, download the federation metadata document

Summary: The Oracle Cloud Infrastructure Console Federation page displays a link to the Oracle Cloud Infrastructure federation metadata document. Before you set up the application in Azure AD, you need to download the document.

2. On the Federation page, click Download this document.

After you click the link, the metadata.xml document opens in your browser window. Use your browser's Save page as command to save the xml document locally where you can access it later.

Step 2: In Azure AD, add Oracle Cloud Infrastructure as an enterprise application

1. In the Azure portal, on the left navigation panel, select Azure Active Directory.
2. In the Azure Active Directory pane, select Enterprise applications. A sample of the applications in your Azure AD tenant is displayed.
3. At the top of the All applications pane, click New application.
4. In the Add from gallery region, enter Oracle Cloud Infrastructure Console in the search box.
5. Select the Oracle Cloud Infrastructure Console application from the results.
6. In the application-specific form, you can edit information about the application. For example, you can edit the name of the application.
7. When you are finished editing the properties, select Create.

The getting started page is displayed with the options for configuring the application for your organization.
Step 3: In Azure AD, configure Oracle Cloud Infrastructure as an enterprise application

1. Under the Manage section, select Single sign-on.

2. Select SAML to configure single sign-on. The Set up Single Sign-On with SAML page is displayed.

3. At the top of the page, click Upload metadata file.

4. Locate the federation metadata file (metadata.xml) you downloaded from Oracle Cloud Infrastructure in Step 1, and upload it here. After you upload the file, these Basic SAML Configuration fields are automatically populated:
   - Identifier (Entity ID)
   - Reply URL (Assertion Consumer Service URL)
5. In the **Basic SAML Configuration** section, click **Edit**. On the **Basic SAML Configuration** pane, enter the following required field:

- **Sign on URL**: Enter the URL in the following format:

  `https://console.<oci_home_region>.oraclecloud.com`

  where `oci_home_region` is your tenancy's home region. For example, if your home region is Ashburn, enter:

  `https://console.us-ashburn-1.oraclecloud.com`

  [*How do I find my tenancy home region? on page 161*](#)

![Basic SAML Configuration](image)

6. Click **Save**.

**Step 4: Configure User Attributes & Claims**

The Oracle Cloud Infrastructure Console enterprise application template is seeded with the required attributes, so you don't need to add any. However, you do need to make the following customizations:

1. In the **User Attributes & Claims** section, click **Edit** in the upper-right corner. The **Manage claim** panel is displayed.
2. Next to the **Name identifier value** field, click **Edit**.
   - Under **Required claim**, select Unique User Identifier (Name ID).
   - Select **Email address** and change it to **Persistent**.
   - For **Source**, select **Attribute**.
   - For **Source attribute**, select `user.userprincipalname`.

   ![Manage claim interface]

   - Click **Save**.

3. Click **Add a group claim**.
4. In the **Group Claims** panel, configure the following:
   - Select Security groups.
   - **Source attribute**: Select Group ID.
   - Under **Advanced Options**, select **Customize the name of the group claim**.
   - In the **Name** field, enter: `groupName`.
     
     Ensure that you enter `groupName` with spelling and case exactly as given.
   - In the **Namespace** field, enter: `https://auth.oraclecloud.com/saml/claims`

   ![Image of Group Claims panel](image)

   - Click **Save**.
**Step 5: Download the SAML metadata document**

1. In the **SAML Signing Certificate** section, click the download link next to **Federation Metadata XML**.

2. Download this document and make a note of where you save it. You will upload this document to the Console in the next step.

**Step 6: Assign user groups to the application**

To enable Azure AD users to sign in to Oracle Cloud Infrastructure, you need to assign the appropriate user groups to your new enterprise application.

1. On the left navigation pane, under **Manage**, select **Users and Groups**.
2. Click **Add** at the top of the **Users and Groups** list to open the **Add Assignment** pane.
3. Click the **Users and groups** selector.
4. Enter the name of the group you want to assign to the application into the **Search by name or email address** search box.
5. Hover over the group in the results list to display a check box. Select the check box to add the group to the **Selected** list.
6. When you are finished selecting groups, click **Select** to add them to the list of users and groups to be assigned to the application.
7. Click **Assign** to assign the application to the selected groups.

**Step 7: Add Azure AD as an identity provider in Oracle Cloud Infrastructure**

**Summary:** Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure username and password.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
3. Click **Add identity provider**.
4. Enter the following:

   a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.

   b. **Description:** A friendly description.

   c. **Type:** Select SAML 2.0 compliant identity provider.

   d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.

   e. Click Show Advanced Options.

   f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.

      To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.

   g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.

   h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select Custom, then manually enter the class reference.

   i. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.

   **Note:**

   If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

**Step 8: Add group mappings**

**Summary:** Set up the mappings between Azure AD groups and IAM groups in Oracle Cloud Infrastructure. A given Azure AD group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Azure AD group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions. Note that the Azure AD groups that you choose to map must also be assigned to the enterprise application in Azure AD. See **Step 6: Assign user groups to the application** on page 3093.

**Before you begin:** Have your Azure AD groups page open. From the Azure Dashboard, under **Manage**, select **Groups**. From the list of groups, select the group you want to map to an Oracle Cloud Infrastructure group. In the group’s details page, click the **Copy** icon next to the Object ID for the group.

To create a group mapping:
1. For **Identity Provider Group**, enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: aa0e7d64-5b2c-623g-at32-65058526179c

![Image of Identity Provider Group mapping](image)

2. Choose the IAM group you want to map this group to from the list under **OCI Group**.

3. Repeat the preceding steps for each mapping you want to create, and then click **Create**.

   **Tip:**
   
   Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see **Resource Identifiers**.

In the future, come to the **Federation** page if you want to edit the group mappings or delete the identity provider from your tenancy.

**Step 9: Set up IAM policies for the groups**

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see **Getting Started with Policies** on page 2799 and **Common Policies** on page 2806.

**Step 10: Give your federated users the name of the tenant and URL to sign in**

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, https://cloud.oracle.com/) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

**Managing Identity Providers in the Console**

To **add an identity provider**

See **About Federating with Azure AD** on page 3087.

To **delete an identity provider**

All the group mappings for the identity provider will also be deleted.
1. Delete the identity provider from your tenancy:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
      A list of the identity providers in your tenancy is displayed.
   b. Click the identity provider to view its details.
   c. Click **Delete**.
   d. Confirm when prompted.

*To add group mappings for an identity provider*

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Add Mappings**.
   a. Under **Identity Provider Group**, select Custom Group. Enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: aa0e7d64-5b2c-623g-at32-65058526179c. Note that for groups to be able to sign in to Oracle Cloud Infrastructure, they must also be assigned to the enterprise application in Azure AD. See **Step 6: Assign user groups to the application** on page 3093.
   b. Choose the IAM group you want to map this group to from the list under **OCI Group**.
   c. To add more mappings, click **Another Mapping**.
   d. When you are finished, click **Add Mappings**.

Your changes take effect typically within seconds.

*To update a group mapping*

You can't update a group mapping, but you can delete the mapping and add a new one.

*To delete a group mapping*

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click **Delete**.
4. Confirm when prompted.

Your changes take effect typically within seconds.

**Managing Identity Providers in the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use these API operations:

**Identity providers:**

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use **DeleteIdpGroupMapping** to remove all the group mappings for the identity provider.

**Group mappings:**

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
Federating with SAML 2.0 Identity Providers

This topic describes the general steps to federate Oracle Cloud Infrastructure with any identity provider that supports the Security Assertion Markup Language (SAML) 2.0 protocol. If you want specific instructions for Oracle Identity Cloud Service or Microsoft Active Directory, see Federating with Oracle Identity Cloud Service on page 3062 or Federating with Microsoft Active Directory on page 3081.

Tip:
Find detailed setup steps for more IdPs in the following white papers:
- Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning
- Federating Oracle Access Manager to Oracle Cloud Infrastructure

Instructions for Federating

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

Note:
Before following the steps in this topic, see Federating with Identity Providers on page 3058 to ensure that you understand general federation concepts.

1. In the Oracle Cloud Infrastructure Console, get the federation metadata required to establish a trust relationship with the Identity Provider (IdP).
2. In the IdP, configure Oracle Cloud Infrastructure as an application (sometimes called a trusted relying party).
3. In the IdP, assign users and groups to your new Oracle Cloud Infrastructure application.
4. In the IdP, get the required information needed by Oracle Cloud Infrastructure.
5. In Oracle Cloud Infrastructure:
   a. Add the identity provider to your tenancy and provide information you got from the IdP.
   b. Map the IdP's groups to IAM groups.
6. In Oracle Cloud Infrastructure, make sure you have IAM policies set up for the groups so you can control users' access to Oracle Cloud Infrastructure resources.

Step 1: Get information from Oracle Cloud Infrastructure

Summary: Download the federation metadata document.

The federation metadata document is a standard SAML 2.0 document, which provides information about Oracle Cloud Infrastructure you'll need to provide to your IdP. Depending on your provider's setup requirements, you may need to upload the entire document, or you may be asked to provide only specific metadata values from the document.

1. Sign in to the Oracle Cloud Infrastructure Console as an administrator.
3. Right-click the Download this document link and save the document.

Step 2: Set up Oracle Cloud Infrastructure as a trusted application

Consult your IdP documentation for how to set up a trusted application. Refer to the metadata document you downloaded for required parameters.

Step 3: Assign users and groups to the new application.
Follow your IdP's procedures for adding users and groups to the application you set up for Oracle Cloud Infrastructure.

Step 4: Download the IdP's metadata document.

Your IdP should provide a SAML 2.0 document that contains the information Oracle Cloud Infrastructure needs to complete the federation. See your IdP documentation for instructions on downloading this document.

Step 5: Federate the IdP with Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

Details:

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
3. Click Add Identity Provider.
4. Enter the following:
   a. Name: A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console, so consider making this a friendly, intuitive name your users will understand. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
   b. Description: A friendly description.
   c. Type: Select Microsoft Active Directory Federation Service (ADFS) or SAML 2.0 Compliant Identity Provider.
   d. XML: Upload the metadata.xml document that you downloaded from your IdP.
   e. Encrypt Assertion: Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in your IdP. For more information, see Encrypt Assertion under General Concepts on page 3059. See also your IdP's documentation.
   f. Force Authentication: Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
   g. Authentication Context Class References: This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400. Several common authentication context class references are listed in the menu. To use a different context class, select Custom, then manually enter the class reference.
   h. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Continue.
6. Set up the mappings between the IdP groups and IAM groups in Oracle Cloud Infrastructure. A given IdP group can be mapped to zero, one, or multiple IAM groups, and conversely. However, each individual mapping is
between only a single IdP group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

**Note:**
If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

To create a group mapping:

**a.** Under **Identity Provider Group**, enter the name of the group in your IdP. You must enter the name exactly, including the correct case.

Choose the IAM group you want to map this group to from the list under **OCI Group**.

**Tip:**
Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

**b.** Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit or add group mappings or delete the identity provider from your tenancy.

**Step 6: Set up IAM policies for the groups**

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Step 7: Give your federated users the name of the tenant and URL to sign in**

The federated users need the URL for the Oracle Cloud Infrastructure Console: https://cloud.oracle.com, and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

**Managing Identity Providers in the Console**

-To add an identity provider

See Instructions for Federating on page 3097.

-To delete an identity provider

All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
   **a.** Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
      A list of the identity providers in your tenancy is displayed.
   **b.** Click the identity provider to view its details.
   **c.** Click **Delete**.
   **d.** Confirm when prompted.
2. Follow your IdP's documentation to delete the application from your IdP.

-To add group mappings for an identity provider

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Add Mappings**.
   a. Enter the IdP group name exactly in the **Identity Provider Group** text box.
   b. Choose the IAM group you want to map this group to from the list under **OCI Group**.
   c. To add more mappings, click **+Another Mapping**.
   d. When you are finished, click **Add Mappings**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

**To update a group mapping**

You can't update a group mapping, but you can delete the mapping and add a new one.

**To delete a group mapping**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Federation**.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, select it, and then click **Delete**.
4. Confirm when prompted.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

**Managing Identity Providers in the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use these API operations:

**Identity providers:**

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use **DeleteIdpGroupMapping** to remove all the group mappings for the identity provider.

**Group mappings:**

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

**User Provisioning for Federated Users**

This topic describes how you can use SCIM to provision federated users in Oracle Cloud Infrastructure. Provisioned federated users can have API keys and other service-specific credentials.

**Overview**

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. If your IdP is Oracle Identity Cloud Service or Okta, you can set up SCIM user provisioning.
After you configure the SCIM integration between your IdP and Oracle Cloud Infrastructure, users that belong to
groups mapped to Oracle Cloud Infrastructure groups are automatically provisioned in Oracle Cloud Infrastructure.
Provisioned users are assigned a unique OCID, and can have API keys and other service-specific credentials.

The following functionality is supported for provisioned, federated users:

- Provisioned users are assigned a unique OCID
- Provisioned users can have API keys, auth tokens, and other service-specific credentials
- You can list the users in the Console
- Provisioned users can access the User Settings page to see and manage these credentials for themselves
- When you add or remove users to Oracle Cloud Infrastructure-mapped groups in your IdP, the updates are
  automatically synched with Oracle Cloud Infrastructure

Understanding User Types

The SCIM configuration introduces the concept of the provisioned or synchronized user. The following descriptions
provide details to help you understand the user types you'll be managing.

- Federated users
  A federated user is created and managed in an identity provider. Federated users can sign in to the Console using
  a password managed in their identity provider. Federated users are granted access to Oracle Cloud Infrastructure
  based on their membership in groups that are mapped to Oracle Cloud Infrastructure groups.
- Provisioned (or Synchronized) users
  A synchronized user is systematically provisioned by the identity provider in Oracle Cloud Infrastructure.
  Synchronized users can have Oracle Cloud Infrastructure credentials, but not Console passwords. When listing
  users in the Console, you can identify synchronized users using the User Type filter.
- Local users
  A local user is a user created and managed in Oracle Cloud Infrastructure's IAM service. Federated tenancies
  typically would have few, if any, local users. When listing users in the Console, you can identify local users using
  the User Type filter.

The following graphic summarizes the characteristics of the user types:
Who Should Set Up This Integration?

Set up this integration if your IdP is Oracle Identity Cloud Service or Okta and your federated users need to have the specialized credentials required by some services and features. For example, if you need your federated users to access Oracle Cloud Infrastructure through the SDK or CLI, setting up this integration enables these users to get the API keys needed for this access.

Prerequisite

Perform this synchronization setup after you have successfully set up a federation between your IdP and Oracle Cloud Infrastructure. See Supported Identity Providers on page 3062.

Enabling User Provisioning

Instructions for Oracle Identity Cloud Service Federations

If your identity provider is Oracle Identity Cloud Service, you need to perform a one-time upgrade.

Important:

If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to provision your Oracle Identity Cloud Service users in Oracle Cloud Infrastructure. You do not need to perform the steps in this topic. See Understanding User Types on page 3101 and Managing User...
Upgrading Your Oracle Identity Cloud Service Federation

If your federation with Oracle Identity Cloud service was set up before December 21, 2018, perform this one-time upgrade task.

To upgrade your Oracle Identity Cloud Service federation:

   A list of the identity providers in your tenancy is displayed.

2. Click your Identity Cloud Service federation to view its details. If your tenancy was auto-federated, it is listed as OracleIdentityCloudService.

3. Click Edit Mapping.

4. When prompted, provide the client ID and client secret for the Oracle Identity Cloud Service application, and then click Continue.

Where do I find the client ID and client secret?

The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

   a. 1. Sign in to the Oracle Identity Cloud Service console.

   2. In the Identity Cloud Service console, click Applications. The list of trusted applications is displayed.

   3. Click COMPUTEBAREMETAL.

   4. Click Configuration.

   5. Expand General Information. The client ID is displayed. Click Show Secret to display the client secret.

Allow several minutes for the changes to take effect.

Instructions for Okta Federations

If you do not have an existing federation with Okta, follow the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning. This paper includes instructions for both setting up your federation and provisioning with SCIM.

If you have an existing federation with Okta with group mappings that you want to maintain, you can add SCIM provisioning as follows:
1. In Okta, delete the existing SAML application you originally set up to federate with Oracle Cloud Infrastructure.
2. Set up a new SAML application in Okta according to the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning, with the following exceptions:
   - Skip the steps to Add Identity Provider to Oracle Cloud Infrastructure (you already have this resource in Oracle Cloud Infrastructure).
   - Instead, click Edit Identity Provider and upload the new metadata.xml document from the new Okta app you created.
   - Then, in Oracle Cloud Infrastructure, ensure that you Reset Credentials. Add the new Client ID and Secret to the API integration settings page in Okta (Step 7 in the white paper).

**What to Expect After the Upgrade**

When the system has had time to synchronize, you can manage user capabilities for federated users in the Console. Users that belong to a group mapped to a group in Oracle Cloud Infrastructure are listed on the Users page in the Console. Whenever you add new users to mapped groups in Oracle Identity Cloud Service, they will be available in the Console after the system synchronizes.

By default, the following user capabilities are enabled:
- API keys
- auth tokens
- SMTP credentials
- customer secret keys

Notice that you can't enable a local password. The Oracle Cloud Infrastructure console password is still managed only in your IdP.

For more information about user capabilities, see Managing User Capabilities for Federated Users on page 3104.

**Resetting Credentials**

Use the Reset Credentials button to reset your SCIM client credentials. You can perform this task periodically as a security measure to rotate your credentials. After you reset these credentials, you'll need to update the SAML app in your identity provider with the new credentials.

**Note:** If your IdP is Oracle Identity Cloud Service, Oracle Cloud Infrastructure automatically resets the credentials with Oracle Identity Cloud Service for you. You don't need to manually reset the configuration.

**Actions You Still Perform in Your Identity Provider**

After the integration is set up, continue to perform the following actions in your IdP:
- Create users and assign them to groups.
- Delete users.
  - Users that you delete from your IdP are removed from Oracle Cloud Infrastructure when the next synchronizing cycle completes.
- Query for group membership.
- Manage sign-in passwords for users.

**Managing User Capabilities for Federated Users**

This topic describes managing user capabilities for federated users when your tenancy is federated and configured for user provisioning with a supported identity provider.

**About User Capabilities**

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console, must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.
User capabilities are managed by an Administrator in the user's details. Each user can see their capabilities, but only an Administrator can enable or disable them. The user capabilities available to federated users are:

- API keys
- auth tokens
- SMTP credentials
- customer secret keys
- OAuth 2.0 client credentials

By default, these capabilities are enabled when you provision new users, allowing users to create these credentials for themselves. For information about these user credentials, see Managing User Credentials on page 3150.

**Important:**

The capability "Console password" is not available for federated users. Federated users authenticate to the Console through their IdP, where their sign-in passwords are managed.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing user capabilities. A user can't enable or disable user capabilities for themselves (except for Administrators). However, a user can manage their own credentials that have been enabled for them.

**Prerequisites**

Management of user capabilities for federated users is supported for Oracle Identity Cloud Service and Okta federations only.

- Oracle Identity Cloud Service federations:
  
  If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to manage user capabilities. There are no prerequisites.

  If your tenancy was created before December 21, 2018, you must perform a one-time upgrade. See Enabling User Provisioning on page 3102.

- If your tenancy is federated with Okta, see User Provisioning for Federated Users on page 3100.

**Viewing Provisioned Federated Users in the Console**

After the prerequisites are satisfied, you can view users that you create in your IdP that belong to groups mapped to Oracle Cloud Infrastructure groups. Whenever you add a user to a group mapped to an Oracle Cloud Infrastructure group, the user automatically displays in the Console.

**To list users in the Console:**

Open the navigation menu and click Identity & Security. Under Identity, click Users.

Notice that you can filter the list by user type to include only users that belong to a specified identity provider. Local Users are users created in Oracle Cloud Infrastructure's IAM service. The filter list includes all identity providers you have set up.

**Using the Console**

**To edit user capabilities**

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user to see its details.
3. Click **Edit User Capabilities**.
4. Select or clear the check box to add or remove a capability.
5. Click **Save**.

**To change a user's description**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.
4. Edit the description and save it. This description is maintained in Oracle Cloud Infrastructure and is not synched back to your identity provider.

**To apply tags to a user**

For instructions, see **Resource Tags** on page 239.

**To delete a user**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Find the user you want to delete and click the Actions icon (three dots).
3. Click **Delete**.

**Important**: Deleting a user here does not delete the user in your IdP. If you later want the federated user to have a provisioned user in Oracle Cloud Infrastructure, you must remove the user from all OCI-mapped groups in Oracle Identity Cloud Service and re-add the user.

For information about managing user credentials in the Console, see **Managing User Credentials** on page 3150.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use these API operations to manage user capabilities:

- **ListUsers**
- **GetUser**
- **UpdateUser**: You can update the user capabilities and the user's description.
- **UpdateUserCapabilities**
- **DeleteUser**: This operation deletes the provisioned user in Oracle Cloud Infrastructure, but not the user in the identity provider.

For information about the API operations for managing user credentials, see **Managing User Credentials** on page 3150.

The following operations are not supported for federated users:

- **ListUserGroupMemberships**
- **AddUserToGroup**
- **GetUserGroupMembership**
- **RemoveUserFromGroup**

**Calling Services from an Instance**

This topic describes how you can authorize instances to call services in Oracle Cloud Infrastructure.
Introduction

This procedure describes how you can authorize an instance to make API calls in Oracle Cloud Infrastructure services. After you set up the required resources and policies, an application running on an instance can call Oracle Cloud Infrastructure public services, removing the need to configure user credentials or a configuration file.

Concepts

DYNAMIC GROUP

Dynamic groups allow you to group Oracle Cloud Infrastructure instances as principal actors, similar to user groups. You can then create policies to permit instances in these groups to make API calls against Oracle Cloud Infrastructure services. Membership in the group is determined by a set of criteria you define, called matching rules.

MATCHING RULE

When you set up a dynamic group, you also define the rules for membership in the group. Resources that match the rule criteria are members of the dynamic group. Matching rules have a specific syntax you follow. See Writing Matching Rules to Define Dynamic Groups on page 3120.

INSTANCE PRINCIPALS

The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

Security Considerations

Any user who has access to the instance (who can SSH to the instance), automatically inherits the privileges granted to the instance. Before you grant permissions to an instance using this procedure, ensure that you know who can access it, and that they should be authorized with the permissions you are granting to the instance.

All compute instance principals are granted the compartment_inspect permission. You cannot revoke this permission. This permission allows the instance to ListCompartments in the tenancy to retrieve the following information:

- Compartment names
- Compartment descriptions
- Free-form tags applied to compartments
- Automatic tag defaults applied to compartments. These tags, such as CreatedBy and CreatedOn, are in the Oracle-Tag namespace and are automatically added by Oracle.

Process Overview

The following steps summarize the process flow for setting up and using instances as principals. The subsequent sections provide more details.

1. Create a dynamic group. In the dynamic group definition, you provide the matching rules to specify which instances you want to allow to make API calls against services.
2. Create a policy granting permissions to the dynamic group to access services in your tenancy (or compartment).
3. A developer in your organization configures the application built using the Oracle Cloud Infrastructure SDK to authenticate using the instance principals provider. The developer deploys the application and the SDK to all the instances that belong to the dynamic group.
4. The deployed SDK makes calls to Oracle Cloud Infrastructure APIs as allowed by the policy (without needing to configure API credentials).
5. For each API call made by an instance, the Audit service logs the event, recording the OCID of the instance as the value of principalId in the event log.
Steps to Enable Instances to Call Services

Perform these tasks to enable an instance to call services:

Create a Dynamic Group and Matching Rules
Write Policies for Dynamic Groups
Configure the SDK, CLI, or Terraform

Creating a Dynamic Group and Matching Rules

See Managing Dynamic Groups on page 3118.

Writing Policies for Dynamic Groups

After you have created a dynamic group, you need to create policies to permit the dynamic groups to access Oracle Cloud Infrastructure services.

Policy for dynamic groups follows the syntax described in How Policies Work on page 2800. Review that topic to understand basic policy features.

The syntax to permit a dynamic group access to resources in a compartment is:

```plaintext
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in compartment <compartment_name>
```

The syntax to permit a dynamic group access to a tenancy is:

```plaintext
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in tenancy
```

Here are a few example policies:

To allow a dynamic group (FrontEnd) to use a load balancer in a specific compartment (ProjectA):

```plaintext
Allow dynamic-group FrontEnd to use load-balancers in compartment ProjectA
```

To allow a dynamic group to launch instances in a specific compartment:

```plaintext
Allow dynamic-group FrontEnd to manage instance-family in compartment ProjectA
Allow dynamic-group FrontEnd to use volume-family in compartment ProjectA
Allow dynamic-group FrontEnd to use virtual-network-family in compartment ProjectA
```

For more sample policies, see Common Policies on page 2806.

Configuring the SDK, CLI, or Terraform

For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

For the SDK for Java:

In your SDK for Java, create an InstancePrincipalsAuthenticationDetailsProvider object. For example:

```java
public static void main(String[] args) throws Exception {
    InstancePrincipalsAuthenticationDetailsProvider provider =
        InstancePrincipalsAuthenticationDetailsProvider.builder().build();
    IdentityClient identityClient = new IdentityClient(provider);
```
For the SDK for Python:

In your SDK for Python, create an `oci.auth.signers.InstancePrincipalsSecurityTokenSigner` object. For example:

```python
# By default this will hit the auth service in the region returned by

signer = oci.auth.signers.InstancePrincipalsSecurityTokenSigner()
identity_client = oci.identity.IdentityClient(config={}, signer=signer)
```

To refresh the token without waiting, use the following command:

```python
signer.refresh_security_token()
```

**Enabling Instance Principal Authorization for the CLI**

To enable instance principal authorization from the CLI, you can set the authorization option (`--auth`) for a command. For example:

```bash
oci os ns get --auth instance_principal
```

Alternatively, you can set the following environment variable:

```
OCI_CLI_AUTH=instance_principal
```

Note that if both are set, the value set for `--auth` takes precedence over the environment variable.

For information about using the CLI, see [Working with the Command Line Interface](#).

**Enabling Instance Principal Authorization for Terraform**

To enable instance principal authorization in Terraform, you can set the `auth` attribute to "InstancePrincipal" in the provider definition as shown in the following sample:

```hcl
variable "region" {}

provider "oci" {
  auth = "InstancePrincipal"
  region = "${var.region}"
}
```

Note that when you use instance principal authorization you do not need to include the `tenancy_ocid`, `user_ocid`, `fingerprint`, and `private_key_path` attributes.

**FAQs**

**How do I query the instance metadata service to query the certificate on the instance?**

**How frequently is the certificate rotated on each instance?**

The certificate is rotated multiple times each day.

**What happens if I try to use an expired certificate?**

You will get a 401-Not Authenticated error.
Can I change the frequency at which the certificate is rotated?

No. You can't change the frequency at which the certificate is rotated. However, you can change the policy on the dynamic group. If you think an instance has been compromised, you can either change the policy on the dynamic group to revoke permissions for all members of the group, or you can remove the instance from the dynamic group. See Can I remove an instance from a dynamic group? on page 3110

What happens if the certificate is rotated in the middle of a long running operation?

The token expiration is independent of the certificate expiration period. And, it also depends on the application you are interacting with. For example, if Object Storage does not have a multipart PUT operation, then it does not matter how long the operation runs.

Are the certificates accessible for all users on an instance?

Yes. Ensure that only users who should be granted the access that you have granted to the dynamic group, have access to the instance.

Are dynamic groups created at the tenancy level?

Yes.

Can I remove an instance from a dynamic group?

Yes. You can remove it by modifying the matching rule to exclude it. See below for an example.

Can I exclude specific instances in a compartment from the dynamic group?

Yes. For example, assume you want to exclude two specific instances in a compartment from the dynamic group. Write a matching rule like this:

```
All {instance.compartment.id = '<compartment_ocid>',
       instance.id != '<instance1_to_exclude_ocid>',
       instance.id != '<instance2_to_exclude_ocid>'}
```

The above rule includes all instances in the compartment except those with the OCIDs specified.

Managing Users

This topic describes the basics of working with users.

---

**Important:**

If your tenancy is federated with Oracle Identity Cloud Service, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console on page 3068 to manage users.

---

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing users.

- You can create a policy that gives someone the power to create new users and credentials but not control which groups those users are in. See Let the Help Desk manage users on page 2806.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for users or other IAM components, see Details for IAM on page 2971.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.
Working with Users

When creating a user, you must provide a unique, unchangeable name for the user. The name must be unique across all users within your tenancy. This name is the user's login to the Console. You might want to use a name that's already in use by your company's own identity system (for example, Active Directory, LDAP, etc.). You must also provide the user with a description (although it can be an empty string), which is a non-unique, changeable description for the user. This value could be the user's full name, a nickname, or other descriptive information. Oracle also assigns the user a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note:
If you delete a user and then create a new user with the same name, the two users are considered different users, because they have different OCIDs.

Oracle recommends that you supply a password recovery email address for the user. If the user forgets their password, they can request to have a temporary password sent to them using the Forgot Password link on the sign-on page. If no email address is present for the user, an administrator must intervene to reset their password.

A new user has no permissions until you place the user in one or more groups and at least one policy gives that group permission to either the tenancy or to a compartment. Exception: each user can manage their own credentials they have been enabled to have. An administrator does not need to create a policy to give a user that ability. For more information, see User Credentials on page 3056.

Important:
After creating a user and putting them in a group, let them know which compartment(s) they have access to.

You also need to give the new user some credentials so they can access Oracle Cloud Infrastructure. A user can have one or both of the following credentials, depending on the type of access they need: A password for using the Console and an API signing key for using the API.

About User Capabilities

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.

Administrators manage user capabilities in the User details. Each user can see their capabilities, but only an Administrator can enable or disable those capabilities. The user capabilities are:

- Can use Console password (native users only)
- Can use API keys
- Can use auth tokens
- Can use SMTP credentials
- Can use customer secret keys

By default, all these capabilities are enabled when you create users, allowing users to create these credentials for themselves. For information about working with user credentials, see Managing User Credentials on page 3150.

Enabling Multi-Factor Authentication for a User

See Managing Multi-Factor Authentication on page 3164 for details.

Signing In to the Console

Users created through this procedure are created in IAM and are sometimes called "local users." If your tenancy is federated with another identity provider (such as Oracle Identity Cloud Service, Azure AD, or Okta), your sign-in page to the Console displays two options for signing in. The local users you create in IAM use the Oracle Cloud Infrastructure option to sign in, as shown in the following image:
If your tenancy is not federated, you only have one sign in option.

**Tracking Recent Sign-in Activity**

The Users list page displays information to assist administrators in determining whether user accounts are active. The **Last Sign In** field displays the date and time the user last signed in to Oracle Cloud Infrastructure using the Console. This field is displayed only on the list view of all users, it is not displayed on the individual user details page.

This field only tracks sign in from the Console. If a user accesses Oracle Cloud Infrastructure through other access methods (for example, through the SDK), those occurrences are not tracked.

**Linking a User to a My Oracle Support Account**

To file support requests directly from the Console, each user must link their IAM user account with their My Oracle Support (MOS) account. You only need to complete this step once. For instructions, see *To link a user to their My Oracle Support account* on page 3114.

**Prerequisites**

- Before a user can create this link, they must set up an account in My Oracle Support. For information on setting up a My Oracle Support account, see *Creating an Oracle Single Sign On (SSO) Account* on page 155.
- Before a user can submit service requests for a tenancy, their My Oracle Support account must be associated to their tenancy CSI number. See *Registering Your CSI for Oracle Cloud Infrastructure* on page 156.

**Unblocking a User After Unsuccessful Sign-in Attempts**

If a user unsuccessfully tries to sign in to the Console 10 times in a row, they are blocked from further sign-in attempts. An administrator can unblock the user in the Console (see *To unblock a user* on page 3114) or with the **UpdateUserState** API operation.

**Deleting a User**

You can delete a user, but only if the user is not a member of any groups.

**Limits on Users**

For information about the number of users you can have, see *Service Limits* on page 243.
Using the Console
To create a user

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Click **Create User**.
3. Enter the following:
   - **Name**: A unique name or email address for the user. For tips about what to use, see [*Working with Users*](#) on page 3111. The name must be unique across all users in your tenancy. You cannot change this value later. The name must meet the following requirements: No spaces. Only Basic Latin letters (ASCII), numerals, hyphens, periods, underscores, +, and @.
   - **Description**: This value could be the user's full name, a nickname, or other descriptive information. You can change this value later.
   - **Email**: Enter an email address for the user. This email address is used for password recovery. The email address must be unique in the tenancy. If the user forgets their password, they can click **Forgot Password** on the sign on page, and a temporary password is generated and sent to the email address provided here. The user or an administrator can also update the email address later.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [*Resource Tags*](#) on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click **Create**.

Next, you need to give the user permissions by adding them to at least one group. You also need to give the user the credentials they need (see [*Managing User Credentials*](#) on page 3150).

To add a user to a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user. The user's details are displayed.
4. Click **Groups**.
5. Click **Add User to Group**.
6. Select the group from the drop-down list, and then click **Add**.

Let the user know which compartment(s) they have access to.

To remove a user from a group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user. The user's details are displayed.
4. Click **Groups**.
5. Click the Actions icon (three dots), and then click **Remove**.
6. Confirm when prompted.

To delete a user

Prerequisite: To delete a user, the user must not be in any groups.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. For the user you want to delete, click **Delete**.
3. Confirm when prompted.
To unblock a user

If you are an administrator, you can use the following procedure to unblock a user who has unsuccessfully tried to sign in to the Console 10 times in a row.

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user. The user's details are displayed, including the current status.
3. Click Unblock.
4. Confirm when prompted.

To change a user's description

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.
4. Edit the description and save it.

To edit a user's email

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Under User Information, click the pencil next to Email.
4. Enter the email address and click the save icon. The email address must be unique in the tenancy.

To edit user capabilities

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user to see its details.
3. Click Edit User Capabilities.
4. Select or clear the check box to add or remove a capability.
5. Click Save.

To apply tags to a user

For instructions, see Resource Tags on page 239.

To link a user to their My Oracle Support account

Important: Ensure that you meet the prerequisites before linking your account. See Linking a User to a My Oracle Support Account on page 3112.

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Click Link Support Account. The Oracle account sign in page prompts you to enter your Oracle credentials.
4. Enter the User name and Password of the Oracle support account that you want to link to this user and click Sign in. The IAM user account is linked to the Oracle support account. The e-mail address associated with the support account is displayed in the user details in the field My Oracle Support account.

To unlink a user a user from a My Oracle Support account

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user's details are displayed.
3. Click **Unlink Support Account**.
4. In the confirmation prompt, click **Unlink**.

For information about managing user credentials in the Console, see *Managing User Credentials* on page 3150.

**Using the API**

For information about using the API and signing requests, see *REST APIs* on page 5528 and *Security Credentials* on page 207. For information about SDKs, see *Software Development Kits and Command Line Interface* on page 5351.

**Note:**

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA is able to launch instances in your home region within a minute. However, UserA is not able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage users:

- **CreateUser**
- **ListUsers**
- **GetUser**
- **UpdateUserState**: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.
- **UpdateUser**: You can update the user's description, email, and tags.
- **UpdateUserCapabilities**
- **DeleteUser**
- **ListGroupMemberships**: Use this operation to get a list of which users are in a group, or which groups a user is in.
- **AddUserToGroup**: This operation results in a UserGroupMembership object with its own OCID.
- **GetUserGroupMembership**
- **RemoveUserFromGroup**: This operation deletes a UserGroupMembership object.

For information about the API operations for managing user credentials, see *Managing User Credentials* on page 3150.

**Managing Groups**

This topic describes the basics of working with groups.

**Important:**

If your tenancy is federated with Oracle Identity Cloud Service, see *Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console* on page 3068 to manage groups.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing groups.
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Working with Groups

When creating a group, you must provide a unique, unchangeable name for the group. The name must be unique across all groups within your tenancy. You must also provide the group with a description (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note:

If you delete a group and then create a new group with the same name, they'll be considered different groups because they'll have different OCIDs.

A group has no permissions until you write at least one policy that gives that group permission to either the tenancy or a compartment. When writing the policy, you can specify the group by using either the unique name or the group's OCID. Per the preceding note, even if you specify the group name in the policy, IAM internally uses the OCID to determine the group. For information about writing policies, see Managing Policies on page 3144.

You can delete a group, but only if the group is empty.

For information about the number of groups you can have, see Service Limits on page 243.

If you're federating with an identity provider, you'll create mappings between the identity provider's groups and your IAM groups. For more information, see Federating with Identity Providers on page 3058.

Using the Console

To create a group

1. Open the navigation menu and click Identity & Security. Under Identity, click Groups. A list of the groups in your tenancy is displayed.
2. Click Create Group.
3. Enter the following:
   - Name: A unique name for the group. The name must be unique across all groups in your tenancy. You cannot change this later. The name must be 1-100 characters long and can include the following characters: lowercase letters a-z, uppercase letters A-Z, 0-9, and the period (.), dash (-), and underscore (_). Spaces are not allowed. Avoid entering confidential information.
   - Description: A friendly description. You can change this later if you want to.
   - Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create Group.

Next, you might want to add users to the group, or write a policy for the group. See To create a policy on page 3147.

To add a user to a group

1. Open the navigation menu and click Identity & Security. Under Identity, click Groups. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group. Its details are displayed.
4. Click **Add User to Group**.
5. Select the user from the drop-down list, and then click **Add User**.

**To remove a user from a group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group to display its details. A list of users in the group is displayed.
4. Locate the user in the list.
5. For the user you want to remove, click **Remove**.
6. Confirm when prompted.

**To delete a group**

Prerequisite: To delete a group, it must not have any users in it.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**. A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. For the group you want to delete, click **Delete**.
4. Confirm when prompted.

**To update a group's description**

This is available only through the API. If you don't have access to the API and need to update a group's description, contact Oracle Support.

**To apply tags to a group**

For instructions, see **Resource Tags** on page 239.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

**Note:**

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage groups:

- **CreateGroup**
- **ListGroup**
- **GetGroup**
- **UpdateGroup**: You can update only the group's description.
- **DeleteGroup**
- **ListUserGroupMemberships**: Use to get a list of which users are in a group, or which groups a user is in.
• **AddUserToGroup**: This operation results in a UserGroupMembership object with its own OCID.
• **GetUserGroupMembership**
• **RemoveUserFromGroup**: This operation deletes a UserGroupMembership object.

For API operations related to group mappings for identity providers, see Federating with Identity Providers on page 3058.

### Managing Dynamic Groups

This topic describes how to manage dynamic groups and define the rules to determine a dynamic group's members.

#### About Dynamic Groups

Dynamic groups allow you to group Oracle Cloud Infrastructure compute instances as “principal” actors (similar to user groups). You can then create policies to permit instances to make API calls against Oracle Cloud Infrastructure services. When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of matching rules to define the group members. For example, a rule could specify that all instances in a particular compartment are members of the dynamic group. The members can change dynamically as instances are launched and terminated in that compartment.

#### Required IAM Policy

If you're in the Administrators group, then you have the required access for managing dynamic groups.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for dynamic groups or other IAM components, see Details for IAM on page 2971.

#### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

#### Working with Dynamic Groups

When creating a dynamic group, you must provide a unique, unchangeable *name* for the dynamic group. The name must be unique across all groups within your tenancy. You must also provide the dynamic group with a *description* (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

**Note:**

If you delete a dynamic group and then create a new dynamic group with the same name, they'll be considered different groups because they'll have different OCIDs.

A dynamic group has no permissions until you write at least one *policy* that gives that dynamic group permission to either the tenancy or a compartment. When writing the policy, you can specify the dynamic group by using either the unique name or the dynamic group's OCID. Per the preceding note, even if you specify the dynamic group name in the policy, IAM internally uses the OCID to determine the dynamic group. For information about writing policies, see Managing Policies on page 3144.

You can delete a dynamic group, but only if the group is empty.

#### Updating Dynamic Groups

You can update the matching rules that define the members of a dynamic group. For example, you might change a matching rule that includes all instances in a compartment to exclude a particular instance. Or, you might update a rule to include a new tag value.
Important:
When you make a change to a matching rule you must allow about one hour for the updated policy to take effect. For example, if you update tags on an instance to either include or exclude that instance from a dynamic group, you must wait for that policy to take effect to include or exclude the instance.

Limits on Dynamic Groups
A single compute instance can belong to a maximum of 5 dynamic groups.
You can have a maximum of 50 dynamic groups in your tenancy.

Using the Console
To create a dynamic group
2. Click Create Dynamic Group.
3. Enter the following:
   • Name: A unique name for the group. The name must be unique across all groups in your tenancy (dynamic groups and user groups). You can't change this later. Avoid entering confidential information.
   • Description: A friendly description.
4. Enter the Matching Rules. Resources that meet the rule criteria are members of the group.
   • Rule 1: Enter a rule following the guidelines in Writing Matching Rules to Define Dynamic Groups on page 3120. You can manually enter the rule in the text box or launch the rule builder.
   • Enter additional rules as needed. To add a rule, click +Additional Rule.
5. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click Create Dynamic Group.

   The matching rule syntax is verified, but the OCIDs are not. Be sure that the OCIDs you enter are correct.

Next, to give the dynamic group permissions, you need to write a policy. See Writing Policies for Dynamic Groups on page 3108.

To delete a dynamic group
1. Open the navigation menu and click Identity & Security. Under Identity, click Dynamic Groups. A list of the dynamic groups in your tenancy is displayed.
2. Locate the dynamic group in the list.
3. For the dynamic group you want to delete, click Delete.
4. Confirm when prompted.

To update a dynamic group's description
1. Open the navigation menu and click Identity & Security. Under Identity, click Dynamic Groups. A list of the groups in your tenancy is displayed.
2. Click the dynamic group you want to update. The dynamic's group's details are displayed.
3. Click Edit Dynamic Group.
4. Edit the description. When finished, click Save Changes.

To update a dynamic group's matching rules
1. Open the navigation menu and click Identity & Security. Under Identity, click Dynamic Groups. A list of the dynamic groups in your tenancy is displayed.
2. Click the dynamic group you want to update. The dynamic group's details are displayed.
3. Click **Edit All Matching Rules**.
4. Edit the matching rule in the text box; or, you can use the rule builder if the change is supported by the rule builder.

**Writing Matching Rules to Define Dynamic Groups**

Matching rules define the resources that belong to the dynamic group. In the Console, you can either enter the rule manually in the provided text box, or you can use the rule builder. The rule builder lets you make selections and entries in a dialog, then writes the rule for you, based on your entries.

You can define the members of the dynamic group based on the following:

- compartment ID - include (or exclude) the instances that reside in that compartment based on compartment OCID
- instance ID - include (or exclude) an instance based on its instance OCID
- tag namespace and tag key - include (or exclude) instances tagged with a specific tag namespace and tag key. All tag values are included. For example, include all instances tagged the with tag namespace `department` and the tag key `operations`.
- tag namespace, tag key, and tag value - include (or exclude) instances tagged with a specific value for the tag namespace and tag key. For example include all instances tagged with the tag namespace `department` and the tag key `operations` and with the value '45'.

A matching rule has the following syntax:

For a single condition:

```plaintext
variable =|!= 'value'
```

For multiple conditions:

```plaintext
any|all {<condition>,<condition>,...}
```

Supported variables are:

- `instance.compartment.id` - the OCID of the compartment where the instance resides
- `instance.id` - the OCID of the instance
- `tag.<tagnamespace>.<tagkey>.value` - the tag namespace and tag key. For example, `tag.department.operations.value`
- `tag.<tagnamespace>.<tagkey>.value='tagvalue'` - the tag namespace, tag key, and tag value. For example, `tag.department.operations.value='45'`

Here are some examples:

**Include All Instances in a Specific Compartment in the Dynamic Group**

To include all instances that are in a specific compartment, add a rule with the following syntax:

```plaintext
instance.compartment.id = '<compartment_ocid>'
```

You can type the rule directly in the text box, or you can use the rule builder.

Example entry in text box:

```plaintext
instance.compartment.id = 'ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv'
```

To add the same rule using the Console rule builder:

- For **Include Instances That Match**: Select All of the following.
- For **Match Instances with**: Select Compartment OCID.
- For **Value**: Enter the compartment OCID. For this example, you would enter
  ```plaintext
  ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv
  ```
All instances that currently exist or get created in the compartment (identified by the OCID) are members of this group.

### Include All Instances in Any of Two or More Compartments

To include all instances that reside in any of two (or more) compartments, add a rule with the following syntax:

```plaintext
Any {instance.compartment.id = '"compartment_ocid"', instance.compartment.id = '"compartment_ocid"'}
```

separating each compartment entry with a comma.

You can type the rule directly in the text box, or you can use the rule builder.

Example entry in the text box:

```plaintext
Any {instance.compartment.id = 'ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv', 
    instance.compartment.id = 'ocid1:compartment:oc1:phx:samplecompartmentocidythsk89ekslsoelu2'}
```

To add the same rule using the Console rule builder:

1. For **Include Instances That Match**: Select **Any of the following**.
2. For **Match Instances With**: Select **Compartment OCID**.
3. For **Value**: Enter the compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`
4. Click **+Additional Line**. Enter the following on the second line:
   - For **Match Instances With**: Select **Compartment OCID**.
   - For **Value**: Enter the additional compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocidythsk89ekslsoelu2`

Instances that currently exist or are later created in either of the specified compartments are members of this group.

### Include All Instances Tagged with a Specific Namespace and Tag Key

To include all instances that are tagged with a specific tag namespace and tag key, add a rule with the following syntax:

```plaintext
tag.<tagnamespace>.<tagkey>.value
```

All instances assigned the tagnamespace.tagkey combination are included. Note that the tag value is not evaluated, so all values are included.

**Example**: Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the namespace and tag key.

Enter the following rule in the text box:

```plaintext
tag.department.operations.value
```

All instances that currently exist or get created with the tag namespace and tag key `department.operations` are members of this group.

### Include All Instances In a Specific Compartment with a Specific Tag Namespace, Tag Key, and Tag Value

To include all instances in a specific compartment that are tagged with a specific tag namespace, key, and value, add a rule with the following syntax:

```plaintext
All {instance.compartment.id = '"compartment_ocid"', 
tag.<tagnamespace>.<tagkey>.value = '"tagvalue"'}
```

All instances that are in the identified compartment and that are assigned the tagnamespace.tagkey with the specified tag value are included.

**Example:** Assume you have a tag namespace called department and a tag key called operations. You want to include all instances that are tagged with the value 45, that are in a particular compartment.

Enter the following statement in the text box:

```plaintext
All
 
 {instance.compartment.id='ocid1:compartment:oc1:phx:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv,'
tag.department.operations.value='45'}
```

**Using the Rule Builder**

The rule builder is a tool available from the Console to help you write matching rules. The rule builder provides menus and text boxes for you to make entries and then writes the rule for you. The rule builder does have some limitations, so you can't use it for all cases.

**Limitations of the Rule Builder**

The rule builder does not support the following:

- Exclusion rules - the rule builder lets you select compartment IDs and instance IDs to include only.
- Rules based on tags - the rule builder does not allow you to select tags to include in your rule. To add a rule based on tag values, you need to enter the rule in the Rule text box using the syntax above.

**Launching the Rule Builder**

When you click **Create Dynamic Group**, the Rule Builder is displayed in the **Create Dynamic Group** dialog.

To create a matching rule using the rule builder

1. Under the **Matching Rules** section, click **Rule Builder**.
2. From the **Include Instances That Match** menu, select **All of the following** or **Any of the following**.
   - **All of the following** includes only instances that match all of the statements in the rule.
   - **Any of the following** includes instances that match any of the statements in the rule.
3. Select a resource type from the **Match Instances With** menu, and then enter the OCID for the resource in the **Value** field:
   - **Compartment OCID** includes instances in the compartment you specify.
   - **Instance OCID** includes the instances with the OCIDs you specify.
4. Click **+Additional line** to add more statements to this rule.

When you add multiple statements to a rule, remember that **Any of the following** includes instances that match any of the statements. If you choose **All of the following**, instances must match all of the specifications in the statements to be included in the group.

**Examples Using the Rule Builder**

**Include All Instances in a Specific Compartment in the Dynamic Group**

To include all instances that are in a specific compartment, using the rule builder:

- Select **All of the following**.
- For **Match Instances With**: Select **Compartment OCID**.
- For **Value**: Enter the compartment OCID, for example,
  ```plaintext
  ocid1:compartment:oc1:phx:samplecompartmentocidythsk89ekslsoeluu2
  ```

All instances that currently exist or are later created in the compartment (identified by the OCID) are members of this group.

**Include All Instances in Any of Two or More Compartments**

To include all instances that reside in any of two (or more) compartments using the rule builder:
1. From the **Include Instances That Match** menu, select **Any of the following.**
2. In the first line, enter:
   - For **Match Instances With**, select **Compartment OCID**.
   - For **Value**, enter the compartment OCID, for example: `ocid1:compartment:oci:phx:samplecompartmentocid6q6igvfauxmima74jv`
3. Click **+Additional Line**. Enter the following on the second line:
   - For **Match Instances With**, select **Compartment OCID**
   - For **Value**, enter the compartment OCID, for example: `ocid1:compartment:oci:phx:samplecompartmentocidythksk89ekslsoelu2`
4. Continue adding additional lines as needed for each compartment you want to include.

Instances that currently exist or get created in any of the specified compartments are members of this group.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use these API operations to manage dynamic groups:

- `CreateDynamicGroup`
- `ListDynamicGroups`
- `GetDynamicGroup`
- `UpdateDynamicGroup`
- `DeleteDynamicGroup`

**Managing Network Sources**

This topic describes the basics of working with network sources.

**Required IAM Policy**

If you're in the Administrators group, then you have the required access for managing network sources. To write policies specifically for network sources, use the network-sources resource type, found with the other IAM components, in [Details for IAM](#) on page 2971.

If you're new to policies, see [Getting Started with Policies](#) on page 2799 and [Common Policies](#) on page 2806.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see [Resource Tags](#) on page 239.

**Introduction to Network Sources**

A network source is a set of defined IP addresses. The IP addresses can be public IP addresses or IP addresses from VCNs within your tenancy. After you create the network source, you can reference it in policy or in your tenancy's authentication settings to control access based on the originating IP address.

Network resources can only be created in the tenancy (or root compartment) and, like other Identity resources, reside in the home region. For information about the number of network sources you can have, see [IAM Limits](#) on page 259.

You can use network sources to help secure your tenancy in the following ways:
• Specify the network source in IAM policy to restrict access to resources.
  When specified in a policy, IAM validates that requests to access a resource originate from an allowed IP address.
  For example, you can restrict access to Object Storage buckets in your tenancy to only users that are signed in to Oracle Cloud Infrastructure through your corporate network. Or, you can allow only resources belonging to specific subnets of a specific VCN to make requests over a service gateway.
• Specify the network source in your tenancy's authentication settings to restrict sign in to the Console.
  You can set up your tenancy's authentication policy to allow sign in to the Console from only those IP addresses specified in your network source. Users attempting to sign in from an IP address not on the allowed list in your network source will be denied access. For information on using a network source restriction in authentication policy, see Managing Authentication Settings on page 3162.

### Allowing Access to Resources from Only Specified IP Addresses

To restrict access to requests made from a set of IP addresses, do the following:

1. Create a network source that specifies the allowed IP addresses.
2. Write a policy that uses the network source variable in a condition.

#### 1. Create the Network Source

Follow the instructions provided for the Console or the API to create the network source.

A single network source can include IP addresses from a specific VCN, public IP addresses, or both.

To specify the VCN, you need the VCN OCID and the subnet IP ranges that you want to allow.

**Examples:**
- **Public IP addresses or CIDR blocks:** 192.0.2.143 or 192.0.2.0/24
- **VCN OCID:** ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID
- **Subnet IP addresses or CIDR blocks:** 10.0.0.4, 10.0.0.0/16
  
  To allow any IP address from a specific VCN, use 0.0.0.0/0.

#### 2. Write the Policy

The IAM service includes a variable to use in policy that allows you to scope your policy using a condition. The variable is:

```
request.networkSource.name
```

After you have created your network source, you can scope policies by using this variable in a condition. For example, assume you create a network source named "corpnet". You can restrict users of the group "CorporateUsers" to access your Object Storage resources only when their requests originate from IP addresses you specified in corpnet. To do this, write a policy like the following:

```
allow group CorporateUsers to manage object-family in tenancy where
  request.networkSource.name='corpnet'
```

This policy allows users in the CorporateUsers group to manage Object Storage resources only when their requests originate from an allowed IP address specified in the network source "corpnet". Requests made from outside the specified IP ranges are denied. For general information about writing policies, see How Policies Work on page 2800.

### Using the Console to Manage Network Sources

#### To create a network source

1. Open the navigation menu and click Identity & Security. Under Identity, click Network Sources. A list of the network sources in your tenancy is displayed.
2. Click Create Network Source.
3. Enter the following:
   - **Name**: A unique name for the network source. The name must be unique in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Allow OCI Services**: This check box is selected by default to allow Oracle Cloud Infrastructure services access, even if the request comes from outside the specified IP addresses. Typically, you want this option enabled, for example, to allow a service to interact with objects in a bucket.
   - **Network Type**: Select one of the following:
     - **Public Network**: Enter a specific IP address or CIDR block range. For example: 192.0.2.143.
     - **Virtual Cloud Network**: Enter the following for this option:
       - **VCN OCID**: Enter the OCID from the VCN you want to allow. For example: ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID
       - **IP Address/CIDR Block**: Enter an IP address from the VCN or a subnet CIDR block. For example: 10.0.0.0/16 or 10.0.0.4.
         - Click Another IP Address/CIDR Block to add another allowed address or range.

4. To add more IP ranges to this network source, click Add Source.
5. **Show Advanced Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click Create.

### To update a network source
1. Open the navigation menu and click Identity & Security. Under Identity, click Network Sources. A list of the network sources in your tenancy is displayed.
2. Locate the network source in the list and click its name to view its details.
3. Edit the network source:
   - To add more allowed IP addresses to this network source, click Add Sources. In the Add Sources dialog, click Add Source again, and enter the details for each IP address or CIDR block you want to add to this network source.
   - To remove an allowed source, click the Actions icon (three dots) and click Delete.
   - To change the setting of Allow OCI Services, click Add Sources. Update the check box setting and click Update.

### To delete a network source
1. Open the navigation menu and click Identity & Security. Under Identity, click Groups. The list of network sources in your tenancy is displayed.
2. Locate the network source in the list and click the Actions icon (three dots) for the item.
3. Click Delete.
4. Confirm when prompted.

### To apply tags to a network source
For instructions, see Resource Tags on page 239.
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage network sources:

- CreateNetworkSource
- ListNetworkSources
- GetNetworkSource
- UpdateNetworkSource
- DeleteNetworkSource

Creating the Network Source Object

A sample network source object looks like the following example:

```json
{
  "compartmentId": "ocid1.tenancy.oc1..aaaaaaaabaexampleuniqueID",
  "description": "Corporate IP ranges to be used for IP-based authorization",
  "name": "corpnet",
  "virtualSourceList": [
    {
      "vcnId": "ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID",
      "ipRanges": ["129.213.39.0/24"]
    }
  ],
  "publicSourceList": ["192.0.2.5", "192.0.2.6"],
  "services": ["all"]
}
```

The elements are:

- **virtualSourceList** - specifies the VCN (OCID) and subnet IP ranges within that VCN that are allowed access. The `virtualSourceList` must contain both the VCN OCID and the subnet IP ranges:
  - **vcnID** - the OCID of the VCN
  - **IpRanges** - comma-separated list of the IP addresses or CIDR blocks of the subnets belonging to the specified VCN that are allowed to access the resource. To allow all ranges in the specified VCN, enter 0.0.0.0/0.
- **publicSourceList** - comma-separated list of the public IP ranges that are allowed access.
- **services** - currently, "all" or "none" are the only supported values. The default is "all". Specifying "all" allows Oracle Cloud Infrastructure services to access the resource.

Example:

```json
{
  "virtualSourceList": [
    {
      "vcnId": "ocid1.vcn.oc1.iad.aaaaaaaaexampleuniqueID",
      "ipRanges": ["129.213.39.0/24"]
    }
  ],
  "publicSourceList": ["192.0.2.0/25", "192.0.2.200"],
  "services": ["all"]
}
```

Managing Compartments

This topic describes the basics of working with compartments.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing compartments.

For an additional policy related to compartment management, see Let a compartment admin manage the compartment on page 2818.
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for compartments or other IAM components, see Details for IAM on page 2971.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

**Working with Compartments**

When you first start working with Oracle Cloud Infrastructure, you need to think carefully about how you want to use compartments to organize and isolate your cloud resources. Compartments are fundamental to that process. Most resources can be moved between compartments. However, it's important to think through your compartment design for your organization up front, before implementing anything. For more information, see "Setting Up Your Tenancy" in the Oracle Cloud Infrastructure Getting Started Guide.

The Console is designed to display your resources by compartment within the current region. When you work with your resources in the Console, you must choose which compartment to work in from a list on the page. That list is filtered to show only the compartments in the tenancy that you have permission to access. If you're an administrator, you'll have permission to view all compartments and work with any compartment's resources, but if you're a user with limited access, you probably won't.

Compartments are tenancy-wide, across regions. When you create a compartment, it is available in every region that your tenancy is subscribed to. You can get a cross-region view of your resources in a specific compartment with the tenancy explorer. See Viewing All Resources in a Compartment on page 271.

For added security, you can associate a compartment with a security zone. For more information, see Security Zones.

**Creating Compartments**

When creating a compartment, you must provide a name for it (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores) that is unique within its parent compartment. You must also provide a description, which is a non-unique, changeable description for the compartment, from 1 through 400 characters. Oracle will also assign the compartment a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

You can create subcompartments in compartments to create hierarchies that are six levels deep.

For information about the number of compartments you can have, see Service Limits on page 243.
Access Control for Compartments

After creating a compartment, you need to write at least one policy for it, otherwise no one can access it (except administrators or users who have permissions set at the tenancy level). When creating a compartment inside another compartment, the compartment inherits access permissions from compartments higher up its hierarchy. For more information, see Policy Inheritance on page 2804.

When you create an access policy, you need to specify which compartment to attach it to. This controls who can later modify or delete the policy. Depending on how you've designed your compartment hierarchy, you might attach it to the tenancy, a parent, or to the specific compartment itself. For more information, see Policy Attachment on page 2805.

Putting Resources in a Compartment

To place a new resource in a compartment, you simply specify that compartment when creating the resource (the compartment is one of the required pieces of information to create a resource). If you're working in the Console, you just make sure you're first viewing the compartment where you want to create the resource. Keep in mind that most IAM resources reside in the tenancy (this includes users, groups, compartments, and any policies attached to the tenancy) and can't be created in or managed from a specific compartment.

Moving Resources to a Different Compartment

Most resources can be moved after they are created. There are a few resources that you can't move from one compartment to another. Also, you can't move certain resources from a security zone to a standard compartment because it might be less secure. For details about restrictions for resources in security zones, see Restrict Resource Movement.

Some resources have attached resource dependencies and some don’t. Not all attached dependencies behave the same way when the parent resource moves.

For some resources, the attached dependencies move with the parent resource to the new compartment. The parent resource moves immediately, but in some cases attached dependencies move asynchronously and are not visible in the new compartment until the move is complete.

For other resources, the attached resource dependencies do not move to the new compartment. You can move these attached resources independently.

After you move the resource to the new compartment, the policies that govern the new compartment apply immediately and affect access to the resource. Depending on the structure of your compartment organization, metering, billing, and alarms can also be affected.

See the service documentation for individual resources to familiarize yourself with the behavior of each resource and its attachments.

Viewing Resources in a Compartment

It's not possible to get a list of all the resources in a compartment by using a single API call. Instead you can list all the resources of a given type in the compartment (e.g., all the instances, all the block storage volumes, etc.).

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the Console, the tenancy explorer allows you to get a list of resources in a compartment, across regions, with some limitations. For more information, see Viewing All Resources in a Compartment on page 271.</td>
</tr>
</tbody>
</table>

Discovering Resources in Compartments

With Resource Manager you can capture deployed resources as Terraform configuration and state files using resource discovery. The created stack provides you with a Terraform configuration that you can use to programmatically manage, version, and persist your IT infrastructure as "infrastructure as code."

A stack created from a compartment represents all supported resources in the entire compartment, at the appropriate scope. If you select the root compartment for your tenancy, then the scope is the tenancy level, such as users and groups. If you select a non-root compartment, then the scope is compartment level, such as Compute instances.
Stack creation is supported from a single compartment only. Stacks cannot be created from nested compartments. For instructions, see To create a stack on page 4509.

Deleting Compartments

To delete a compartment, it must be empty of all resources. Before you initiate deleting a compartment, be sure that all its resources have been moved, deleted, or terminated, including any policies attached to the compartment.

**Important:**

Some resource types can't be deleted, therefore, compartments containing these resource types can't be deleted. A resource type that can't be deleted is:

- Data transfer jobs

The delete action is asynchronous and initiates a work request. The state of the compartment changes to Deleting while the work request is executing. It typically takes several minutes for the work request to complete. While it is in the Deleting state it is not displayed on the compartment picker. If the work request fails, the compartment is not deleted and it returns to the Active state.

After a compartment is deleted, its state is updated to Deleted and a random string of characters is appended to its name, for example, CompartmentA might become CompartmentA.qR5hP2BD. Renaming the compartment allows you to reuse the original name for a different compartment. Oracle displays the deleted compartment on the Compartments page for 365 days. The deleted compartment is removed from the compartment picker. If any policy statements reference the deleted compartment, the name in the policy statement is updated to the new name.

Troubleshooting tips for when a compartment fails to delete

If the compartment fails to delete, verify that you have removed all the resources:

- For most resources, you can use the tenancy explorer to help you locate them. See Resources Supported by the Tenancy Explorer on page 272 for the list of supported resources.

  **To view resources in a compartment**

  Open the navigation menu and click Governance & Administration. Under Governance, click Tenancy Explorer.

  The tenancy explorer opens with a view of the root compartment. Select the compartment you want to explore from the compartment picker on the left side of the Console. After you select a compartment, the resources that you have permission to view are displayed. The Name and Description of the compartment you are viewing are displayed at the top of the page. To also list all resources in the subcompartments of the selected compartment, select Show resources in subcompartments. When viewing resources in all subcompartments, it is helpful to use the Compartment column in the results list to see the compartment hierarchy where the resource resides.

- Verify that there are no policies in the compartment (polices are not included in Search results).

  **To find policies in a compartment**

  2. From the compartments list on the left, select the compartment you want to delete.

  Policies attached to the compartment are displayed.

- If you can't locate any resources in the compartment, check with your Administrator; you might not have permission to view all resources.

  **Important:**

  There is a known issue causing deleted compartments to continue to count against your service limit of compartments. See Deleted compartments continue to count against service limits.

Recovering Compartments

To recover a compartment, you must first select it from the list on the Compartment page. You may have to use the state filter to see the deleted compartment. Remember that deleted compartments are renamed by appending
a random string of characters to the original compartment name. For example, CompartmentA might become CompartmentA.qR5hP2BD. Oracle displays the deleted compartment on the Compartments page for 365 days.

When you recover a deleted compartment, the name is not changed. For example, if you recover a deleted compartment named CompartmentA.qR5hP2BD, the name remains the same. Because policy statements are updated to use the new names of deleted compartments, any policy statements that had referenced the deleted compartment now reference the recovered compartment.

**Adding Tag Defaults for a Compartment**

Tag defaults let you specify tags to be applied automatically to all resources, at the time of creation, in the current compartment. For more information, see Managing Tag Defaults on page 4980.

**Moving a Compartment to a Different Parent Compartment**

You can move a compartment to a different parent compartment within the same tenancy. When you move a compartment, all its contents (subcompartments and resources) are moved with it. Moving a compartment has implications for the contents. These implications are described in the following sections. Ensure that you are aware of these before you move a compartment.

- **Required IAM Policy** on page 3126
- **Restrictions on Moving Compartments** on page 3130
- **Understanding the Policy Implications When You Move a Compartment** on page 3131
- **Understanding Compartment Quota Implications When You Move a Compartment** on page 3137
- **Understanding Tagging Implications When You Move a Compartment** on page 3137

**Required IAM Policy**

To move a compartment, you must belong to a group that has manage all-resources permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

**Restrictions on Moving Compartments**

- A security zone compartment can only have subcompartments that are also security zone compartments. You can’t move a standard compartment that’s not in a security zone to a destination compartment that is in a security zone. For more information, see Security Zones.
• You can't move a compartment to a destination compartment with the same name as the compartment being moved.

For example, assume compartment A and compartment B are both under the root compartment. Under compartment A is a subcompartment, also called compartment B. You cannot move the compartment B to the parent compartment B.

Understanding the Policy Implications When You Move a Compartment

After you move a compartment to a new parent compartment, the access policies of the new parent take effect and the policies of the previous parent no longer apply. Before you move a compartment, ensure that:

• You are aware of the policies that govern access to the compartment in its current position.
• You are aware of the policies in the new parent compartment that will take effect when you move the compartment.
In some cases, when moving nested compartments with policies that specify the hierarchy, the policies are automatically updated to ensure consistency.

**Policy Examples**

Groups with Permissions in the Current Compartment Lose Access; Groups with Permissions in the Destination Compartment Gain Access

The following figure shows a compartment hierarchy in which compartment C, a child of A:B is moved to the hierarchy A:D.

The tenancy has the following policies defined for compartments B and D:

**Policy1:** Allow group G1 to manage instance-family in compartment A:B

**Policy2:** Allow group G2 to manage instance-family in compartment A:D

Impact when compartment C is moved from B to D:
Group G1 can no longer manage instance-families in compartment C.

Group G2 can now manage instance-families in compartment C.

Ensure that you are aware not only of what groups lose permissions when you move a compartment, but also what groups will gain permissions.

**Automatic Update of Policies**

When you move a compartment, some policies will be automatically updated. Policies that specify the compartment hierarchy down to the compartment being moved will automatically be updated when the policy is attached to a shared ancestor of the current and target parent. Consider the following examples:

**Example 1: Policy automatically updated**
In this example, you move compartment A from Operations:Test to Operations:Dev. The policy that governs compartment A is attached to the shared parent, Operations. When the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy

| Allow group G1 to manage buckets in compartment Test:A |

is updated to

| Allow group G1 to manage buckets in compartment Dev:A |

No manual intervention is required to allow group G1 to continue to access compartment A in its location.

**Example 2: Policy not updated**
In this example, you move compartment A from Operations:Test to Operations:Dev. However, the policy that governs compartment A here is attached directly to the Test compartment. When the compartment is moved, the policy is not automatically updated. The policy that specifies compartment A is no longer valid and must be manually removed. Group G1 no longer has access to compartment A in its new location under Dev. Unless another existing policy grants access to group G1, you must create a new policy to allow G1 to continue to manage buckets in compartment A.

**Example 3: Policy attached to the tenancy is updated**
In this example, you move compartment A from Operations:Test to HR:Prod. The policy that governs compartment A is attached to the tenancy, which is a shared ancestor by the original parent compartment and the new parent compartment. Therefore, when the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy statement:

Allow group G1 to manage buckets in compartment Operations:Test:A

is updated to

Allow group G1 to manage buckets in compartment HR:Prod:A

No manual intervention is required to allow group G1 to continue to access compartment A.
Understanding Compartment Quota Implications When You Move a Compartment

When you move one compartment to another, resource quotas in the destination compartment are not verified and are not enforced. Therefore, if the compartment move results in a quota violation in the destination compartment, the move is not blocked. After the move is complete, the destination compartment will be in an over-quota state. You will not be able to create new resources that are over-quota until you either adjust the quotas for the destination compartment or remove resources to comply with the existing quota. For more information on managing compartment quotas, see Compartment Quotas on page 280.

Understanding Tagging Implications When You Move a Compartment

Tags are not automatically updated after a compartment move. If you have implemented a tagging strategy based on compartment, you must update the tags on the resources after the move. For example, assume CompartmentA has a child compartment, CompartmentB. CompartmentA is set up with tag defaults so that every resource in CompartmentA is tagged with TagA. Therefore CompartmentB and all its resources are tagged with default tag, TagA. When you move CompartmentB to CompartmentC, it will still have the default tags from CompartmentA. If you have set up default tags for CompartmentC, you'll need to add those to the resources in the moved compartment.

Using the Console

To create a compartment

1. Open the navigation menu and click Identity & Security. Under Identity, click Compartments. A list of the compartments you have access to is displayed.
2. Navigate to the compartment in which you want to create the new compartment:
   a. To create the compartment in the tenancy (root compartment) click Create Compartment.
   b. Otherwise, click through the hierarchy of compartments until you reach the detail page of the compartment in which you want to create the compartment. On the Compartment Details page, click Create Compartment.
3. Enter the following:
   - **Name**: A unique name for the compartment (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores). The name must be unique across all the compartments in your tenancy. Avoid entering confidential information.
   - **Description**: A friendly description. You can change this later if you want to.
   - **Compartment**: The compartment you are in is displayed. To choose another compartment to create this compartment in, select it from the list.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Compartment**.

Next, you might want to write a policy for the compartment. See To create a policy on page 3147.

**To update a compartment’s name**

You can't update the name of a compartment that is associated with a security zone. For more information, see Security Zones.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.

   A list of the compartments in your tenancy is displayed.

2. For the compartment you want to rename, click the Actions icon (three dots), and then click **Rename Compartment**.

   **Tip:**
   
   You can't change the name of your root compartment.

3. Enter the new **Name**. The name must be unique across all the compartments in your tenancy. The name can have a maximum of 100 characters, including letters, numbers, periods, hyphens, and underscores. Avoid entering confidential information.

4. Click **Rename Compartment**.

**To update a compartment’s description**

You can't update the description of a compartment that is associated with a security zone. For more information, see Security Zones.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.

   A list of the compartments in your tenancy is displayed.

2. For the compartment you want to update, click the Actions icon (three dots), and then click **Edit Compartment Description**.

3. Enter the new description. Avoid entering confidential information.

4. Click **Save**.

**To view the contents of a compartment**

1. Open the Console,

2. Open the navigation menu and select the type of resource you want to view. For example, to view Compute resources: Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.

3. Choose the compartment from the list on the left side of the page. The page updates to show only the resources in that compartment.

Remember that most IAM resources reside in the tenancy (this includes users, groups, and compartments). Policies can reside in either the tenancy (root compartment) or other compartments.

**To move a compartment**

To move a compartment, you must belong to a group that has **manage all-resources** permissions on the lowest shared parent compartment of the current compartment and the destination compartment.
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**. A list of the compartments in your tenancy is displayed. If the compartment you want to move is not directly beneath the root compartment, click through the hierarchy of compartments to view the wanted compartment.

2. For the compartment you want to move, click the Actions icon (three dots), and then click **Move Compartment**.

3. Select the destination compartment.

4. Confirm that you are aware of the implications of the move.

5. Click **Move Compartment**.

**To move a resource to a different compartment**

1. Open the Console.

2. Open the navigation menu and select the type of resource you want to work with. For example, to view Compute resources: Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.

3. In the List Scope section, select a compartment. Resources in the selected compartment are displayed.

4. Find the resource in the list, click the the Actions icon (three dots), and follow the prompts to move the resource to a new compartment. See the resource documentation for specific steps.

The resource is moved immediately. If attached resource dependencies move with the parent resource, the resource dependencies are moved asynchronously, and do not appear in the new compartment until the move is complete.

**To apply tags to a compartment**

For instructions, see [Resource Tags](#) on page 239.

**To manage tag defaults for a compartment**

See [Managing Tag Defaults](#) on page 4980.

**To delete a compartment**

You must remove all resources from a compartment before you can delete it.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**. A list of the compartments in your tenancy is displayed.

2. For the compartment you want to delete, click the Actions icon (three dots), and then click **Delete Compartment**.

3. At the prompt, click **OK**.

After you click **OK**, a work request is submitted to delete the compartment. The compartment state changes to Deleting. If the work request fails, the state returns to Active.

**To recover a compartment**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**. A list of the compartments in your tenancy is displayed.

2. In **State**, select Deleted.

3. For the compartment you want to recover, click the Actions icon (three dots), and then click **Recover**.

4. At the prompt, click **OK**.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use these API operations to manage compartments:

- **CreateCompartment**
- **ListCompartments**
- **GetCompartment**: Returns the metadata for the compartment, not its contents.
- **UpdateCompartment**
- **DeleteCompartment**
- **MoveCompartment**
IAM

- **GetWorkRequest**: Gets the work requests spawned by the DeleteCompartment operation.
- **RecoverCompartment**

You can retrieve the contents of a compartment only by resource type. There's no API call that lists all resources in the compartment. For example, to list all the instances in a compartment, call the Core Services API `ListInstances` operation and specify the compartment ID as a query parameter.

### Managing Regions

This topic describes the basics of managing your region subscriptions. For more information about regions in Oracle Cloud Infrastructure, see [Regions and Availability Domains](#) on page 208. For information about Platform Services regions, see [Managing Platform Services Regions](#) on page 3142.

### Required IAM Policy

If you're in the Administrators group, then you have the required access to manage region subscriptions.

If you're new to policies, see [Getting Started with Policies](#) on page 2799 and [Common Policies](#) on page 2806. If you want to dig deeper into writing policies for managing regions or other IAM components, see [Details for IAM](#) on page 2971.

### The Home Region

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your *home region*. Your home region is where your IAM resources are defined. When you subscribe to another region, your IAM resources are available in the new region, however, the master definitions reside in your home region and can only be changed there.

**Important:**

Your home region contains your account information and identity resources. It is not changeable after your tenancy is provisioned. If you are unsure which region to select as your home region, contact your sales representative before you create your account.

Resources that you can create and update only in the home region are:

- Users
- Groups
- Policies
- Compartments
- Dynamic groups
- Federation resources

When you use the API to update your IAM resources, you must use the endpoint for your home region. IAM automatically propagates the updates to all regions in your tenancy.

When you use the Console to update your IAM resources, the Console sends the requests to the home region for you. You don't need to switch to your home region first. IAM then automatically propagates the updates to all regions in your tenancy.

When you subscribe your tenancy to a new region, all the policies from your home region are enforced in the new region. If you want to limit access for groups of users to specific regions, you can write policies to grant access to specific regions only. For an example policy, see [Restrict admin access to a specific region](#) on page 2818.

**Note:**

IAM Updates Are Not Immediate Across All Regions

When you create or update an IAM resource, be aware that you need to allow up to several minutes for the changes in your home region to become available in all regions.
Using the Console to Manage Infrastructure Regions

To view the list of infrastructure regions

Open the Console, open the Region menu, and then click Manage Regions. A list of the regions offered by Oracle Cloud Infrastructure is displayed. Regions that you have not subscribed to provide a button to create a subscription.

To subscribe to an infrastructure region

1. Open the Console, open the Region menu, and then click Manage Regions. The list of regions available to your tenancy Oracle Cloud Infrastructure is displayed. Your home region is labeled.
2. Locate the region you want to subscribe to and click Subscribe.

Note that it could take several minutes to activate your tenancy in the new region.

Remember, your IAM resources are global, so when the subscription becomes active, all your existing policies are enforced in the new region.

To switch to the new region, use the Region menu in the Console. See Switching Regions on page 68 for more information.

You cannot unsubscribe from a region.

Using the API to Work with Infrastructure Regions

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage infrastructure regions:

- GetTenancy
- ListRegions: Returns a list of regions offered by Oracle Cloud Infrastructure in your selected realm.
- CreateRegionSubscription
- ListRegionSubscriptions

You cannot unsubscribe from a region.

Region FAQs

Can an individual user subscribe to a region?

A region subscription is at the tenancy level. An administrator can subscribe the tenancy to a region. All IAM polices are enforced in the new region, so all users in the tenancy will have the same access and permissions in the new region.

Can I see my existing resources in the new region?

When you select a region in the Console, you are shown a view of the resources in your selected region. Most cloud resources (instances, VCNs, buckets, etc.) exist only in a specific region, so you only see them when you select the region where they were created. The exception is IAM resources: compartments, users, groups, and policies are global across all regions. See also Working Across Regions on page 68.

How do my service limits apply to the new region?

Service limits can be scoped to the tenant level, the region level, or the availability domain level. When you subscribe to a new region, you get access to the region and its availability domains. Service limits apply accordingly. The service limits page lists the scope of each resource limit.

Can I restrict access to a specific region?

Yes. You can write policies that grant permissions in a specified region only. For an example policy, see Restrict admin access to a specific region on page 2818.

Can I change my home region?

No. Oracle assigns your home region and you can't change it.
Managing Platform Services Regions

This topic describes how to manage Platform Services region subscriptions.

About the Platform Services Regions

You can manage Platform Services regions in the Console.

To use Platform Services that are not natively integrated with Oracle Cloud Infrastructure, you need to subscribe to the Platform Services region as well as the Infrastructure region. For example, to create a Platform Service instance in the Germany Central (Frankfurt) region, you need to subscribe your tenancy to both the Infrastructure region: Germany Central (Frankfurt) and to the Platform Service region: Europe and Middle East.

To know which services require the Platform Service region subscription, in the Console, open the navigation menu and click **OCI Classic Services**. The list of services that require region subscriptions appears in the menu.

Before you can view these services in the Console or access the **Manage Platform Services Regions** page, your tenancy must have entitlements to use the Platform Services.

Managing Platform Services Regions

To view and subscribe to Platform Services regions

1. Open the Console, open the **Region** menu, and then click **Manage Regions**.
2. On the **Manage Regions** page, click **Platform Services Regions**.
   The list of geographical regions is displayed. Regions that you have not subscribed to provide a button to create a subscription. A sample of the **Platform Services Regions** page is shown in the following screenshot:

   ![Platform Services Regions](image)

3. To subscribe to a region, locate the region in the list and click **Subscribe**.
   It might take several minutes to activate your tenancy in the new region.

Managing the Tenancy

This topic describes options on the tenancy details page in the Console.
**Required IAM Policy**

If you're in the Administrators group, then you have the required access to manage the tenancy.

If you're new to policies, see **Getting Started with Policies** on page 2799 and **Common Policies** on page 2806. If you want to dig deeper into writing policies for your tenancy and other IAM components, see **Details for IAM** on page 2971.

**Viewing the Tenancy Details Page**

To view the tenancy details page:

Open the **Profile** menu and click **Tenancy: <your_tenancy_name>**.

**Details About Your Tenancy**

The tenancy details page provides the following information about your tenancy:

**TENANCY OCID**

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your tenancy's OCID to use the API. You'll also need it when contacting support.

**HOME REGION**

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one of the available regions. This is your **home region**. Your home region is where your IAM resources are defined. For more information about the home region, see **The Home Region** on page 3140.

**NAME**

Your tenancy name. Your tenancy name is typically chosen when you set up your Oracle Cloud account.

**CSI NUMBER**

Your Customer Service Identifier for Oracle Support.

**OBJECT STORAGE DESIGNATED COMPARTMENTS AND NAMESPACE**

The Object Storage service provides API support for both Amazon S3 Compatibility API and Swift API. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. You can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in. For more information, see **Designating Compartments for the Amazon S3 Compatibility and Swift APIs** on page 4414. For information about your Object Storage namespace, see **Understanding Object Storage Namespaces** on page 4294.

**TAGS**

Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs. If you have permissions to manage the tenancy, you also have permissions to apply free-form tags. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239.

**SERVICE LIMITS**

The limits allotted to your tenancy and usage against these limits. Not all service resources are included in the list shown here on the Console. For more information or to request an increase, see **Service Limits** on page 243.
Using the API

Many of the options set on this page are managed through the owning service. For example, the Object Storage settings are managed with the Object Storage service API, and setting the Audit log retention period is handled by the Audit service API.

To get information about your tenancy use the following operation:

- GetTenancy

To tag a tenancy, use the following operations:

- GetCompartment
- UpdateCompartment

In the above operations, use the tenancy OCID for the compartmentID parameter.

Managing Policies

This topic describes how to create, edit, and delete policies.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing policies.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies to control who else can write policies or manage other IAM components, see Let a compartment admin manage the compartment on page 2818, and also Details for IAM on page 2971.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Working with Policies

If you haven't already, make sure to read How Policies Work on page 2800 to understand the basics of how policies work.

When creating a policy, you must specify the compartment where it should be attached, which is either the tenancy (the root compartment) or another compartment. Where it's attached governs who can later modify or delete it. For more information, see Policy Attachment on page 2805. When creating the policy in the Console, you attach the policy to a compartment by creating the policy in that compartment. If you're using the API, you specify the identifier of the compartment in the CreatePolicy request.

When creating a policy, you must also provide a non-changeable name for it. The name must be unique across all policies in the compartment where you create it. You must also provide a description, which is a non-unique, changeable description for the policy. Oracle will also assign the policy a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

Note:
If you delete a policy and then create a new policy with the same name, they'll be considered different policies because they'll have different OCIDs.

For information about how to write a policy, see How Policies Work on page 2800 and Policy Syntax on page 2834. When using the Console to write policies, you can use the policy builder to help you construct the syntax of the policies you want to add.

When you create a policy, make changes to an existing policy, or delete a policy, your changes go into effect typically within 10 seconds.
You can view a list of your policies in the Console or with the API. In the Console, the list is automatically filtered to show only the policies attached to the compartment you're viewing. To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console or API.

For information about the number of policies you can have, see Service Limits on page 243.

**Writing Policy Statements with the Policy Builder**

The policy builder in the Console helps you quickly create common policies without the need to manually type the policy statements. The policy builder automatically suggests the permissions that an administrator can grant to groups of users or resources in their tenancy, as well as target resources like instances, networks, and buckets. Most of the policies suggested in the policy builder can also be found in Common Policies on page 2806, where you can learn more details about the access provided by each policy and the use cases for each. Users who don't need the suggestions offered by the policy builder or who have more complex policy requirements can bypass the builder's basic option and go straight to the advanced editor, where you can directly enter the policy statements in a free-form text box.

**Features of the Policy Builder**

The policy builder provides policy templates that you can complete to create policies for your tenancy. A policy template includes all the statements needed to provide the permissions to perform a task or set of related tasks in a service in OCI. To complete the template, select the group from a menu of existing groups and select the location from the list of compartments in your tenancy.

The policy templates in the policy builder are grouped by use case, such as network management, storage management, and account management, to make them easy to browse and find the permission set you need.

For example, assume you are setting up the network administrators for your tenancy. You need to grant a group of users the permissions required to work with all the resources in the Networking service. To create this policy in the policy builder:

- First, find the policy you want: From the Policy Use Cases menu, select Network Management. If you are not sure which use case a policy belongs to, you can leave this option set to All to browse all the templates.
- From the Common Policy Templates menu, select Let network admins manage a cloud network.

The policy builder displays the policy statements that will be created. In this case, there is only one statement:

```allow {group name} to manage virtual-network-family in {location}```

- Now, all you need to do is select the group and location for the policy: When you select a group, the `{group name}` in the displayed policy statement also updates with your selection.
- Finally, select the location. You can traverse the compartment hierarchy to find and select the appropriate compartment. To create the policy in the tenancy, choose the root compartment.
Customizing Policies

If you find that a template doesn't fit your needs exactly, then you can customize the policies provided by adding statements, removing statements, adding conditions, or other changes to create the policy you need. Click Customize (Advanced) to edit the statements in a free-form text box. When entering statements directly in the text box, ensure that you follow the Policy Syntax on page 2834 rules.

Examples of customizing the Network Admins policy:

- You need to include another group, GroupB to this policy. To add a group:
  
  Click Customize (Advanced). In the text box, type the changes to the policy (following the required syntax).

  Allow group GroupA, GroupB to manage virtual-network-family in compartment CompartmentA

- You need to add a condition to the statement. For example, you want to ensure that only users who have been verified by MFA can manage your networks. You can add that condition to the statement as follows:

  Allow group GroupA to manage virtual-network-family in compartment CompartmentA where request.user.mfaTotpVerified='true'

- You want to add another statement to the policy. For example, you want GroupA to be allowed to use instances. To add another statement, enter it on the next line:

  Allow group GroupA to manage virtual-network-family in compartment CompartmentA
  Allow group GroupA to use instance-family in compartment CompartmentA
Editing Policies with the Policy Builder

After you have created the policy, you can enter any statement changes you need to make directly in the policy text. The template selector is only available when creating a new policy. The editor lets you delete, add, edit, or change the statement order.

Using the Console

To create a policy

Prerequisite: The group and compartment that you're writing the policy for must already exist.

1. Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.
2. Click Create Policy.
3. Enter the following:
   - Name: A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - Description: A friendly description. You can change this later if you want to.
   - Compartment: If you want to attach the policy to a compartment other than the one you're viewing, select it from list. Where the policy is attached controls who can later modify or delete it (see Policy Attachment on page 2805).
4. Enter the policy statements using the policy builder. Use the Basic option if you want to choose from common policy templates, which you can also customize. Use the Customize (Advanced) option if you already know how to write the statements you need and you want to simply type them in a text box.

To use the policy builder Basic option:

a. Select from the Policy Use Cases menu to filter the list of policy templates. If you're not sure which use case to choose, you can browse all the templates in the Common Policies Templates list.

b. Select the template that best matches your requirements from the Common Policies Templates list.

The policy builder displays the description of the chosen policy and lists the policy statements that it includes.

c. Select the Group that this policy applies to.

d. Select a Location. The location is the compartment that this policy grants access to. The compartment you choose here must be either the compartment you chose to attach the policy to in Step 3, or a compartment within the hierarchy of that compartment.

e. If you need to modify the policy statements, click Customize (Advanced).

To use the Customize (Advanced) option:

a. Click Customize (Advanced).

b. Enter or edit policy statements following the format described in Policy Syntax on page 2834, entering one statement per line.

5. To add tags to this policy, click Show Advanced Options. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. If you want to create another policy, select Create Another Policy.

7. Click Create.

The new policy will go into effect typically within 10 seconds.

To get a list of your policies

Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're currently viewing is displayed. If you want to view policies attached to a different compartment, select that compartment from the list on the left. You can't get a single list of all policies; they're always displayed by compartment.

To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console.

To update the description for an existing policy

This is available only through the API. A workaround is to create a new policy with the new description and delete the old policy.

To update the statements in an existing policy

1. Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the policy you want to update. The policy's details and statements are displayed.
3. Click **Edit Policy Statements**. Use the **Basic** policy builder option if you want to interact with the statements using graphical controls. Use the **Advanced** policy builder option to edit the statements in a simple text box.  

To use the **Basic** option:

- To revise a statement, enter the changes following the format in *Policy Basics* on page 2801 and *Policy Syntax* on page 2834.
- To add a statement, click **+Another Statement** and enter the statement following the required format.
- To delete a statement, click the **X** next to the statement.
- To rearrange the order of the statements, use the up and down arrows to move statements to the correct order, or grab the handle to drag and drop statements to the preferred position.

To use the **Advanced** option:

- Select **Advanced**.
- Revise the policy statements in the text box following the format in *Policy Basics* on page 2801 and *Policy Syntax* on page 2834.

4. Click **Save Changes** when you are finished editing.

Your changes will go into effect typically within 10 seconds.

**To delete a policy**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**. A list of the policies in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. For the policy you want to delete, click **Delete**.
3. Confirm when prompted.

Your changes will go into effect typically within 10 seconds.

**To apply tags to a policy**

For instructions, see *Resource Tags* on page 239.

**Using the API**

For information about using the API and signing requests, see *REST APIs* on page 5528 and *Security Credentials* on page 207. For information about SDKs, see *Software Development Kits and Command Line Interface* on page 5351.

**Note:**

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage policies:

- **CreatePolicy**
- **ListPolicies**
- **GetPolicy**
- **UpdatePolicy**
Managing User Credentials

This topic describes the basics of working with Oracle Cloud Infrastructure Identity and Access Management (IAM) user credentials. If you're not already familiar with the available credentials, see User Credentials on page 3056.

Working with Console Passwords and API Keys

Each user automatically has the ability to change or reset their own Console password, as well as manage their own API keys. An administrator does not need to create a policy to give a user those abilities.

To manage credentials for users other than yourself, you must be in the Administrators group or some other group that has permission to work with the tenancy. Having permission to work with a compartment within the tenancy is not sufficient. For more information, see The Administrators Group and Policy on page 2789.

IAM administrators (or anyone with permission to the tenancy) can use either the Console or the API to manage all aspects of both types of credentials, for themselves and all other users. This includes creating an initial one-time password for a new user, resetting a password, uploading API keys, and deleting API keys.

Users who are not administrators can manage their own credentials. In the Console, users can:

- Change or reset their own password.
- Upload an API key in the Console for their own use (and also delete their own API keys).

And with the API, users can:

- Reset their own password with CreateOrResetUIPassword.
- Upload an additional API key to the IAM service for their own use with UploadApiKey (and also delete their own API keys with DeleteApiKey). Remember that a user can't use the API to change or delete their own credentials until they themselves upload a key in the Console, or an administrator uploads a key for that user in the Console or the API.

A user can have a maximum of three API keys at a time.

Working with Auth Tokens

Note:
"Auth tokens" were previously named "Swift passwords". Any Swift passwords you had created are now listed in the Console as auth tokens. You can continue to use the existing passwords.

Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. Each user created in the IAM service automatically has the ability to create, update, and delete their own auth tokens in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage auth tokens for other users.

Note that you cannot change your auth token to a string of your own choice. The token is always an Oracle-generated string.

Auth tokens do not expire. Each user can have up to two auth tokens at a time. To get an auth token in the Console, see To create an auth token on page 3157.

Using an Auth Token with Swift

Swift is the OpenStack object store service. If you already have an existing Swift client, you can use it with the Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage. You will need to get an auth token to use as your Swift password. When you sign in to your Swift client, you provide the following:

- Your Oracle Cloud Infrastructure Console user login
• Your Swift-specific auth token, provided by Oracle
• Your organization's Oracle tenant name

Any user of a Swift client that integrates with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work on page 2800. For basic policies that enable use of Object Storage, see Common Policies on page 2806.

**Working with Customer Secret Keys**

Note:

"Customer Secret keys" were previously named "Amazon S3 Compatibility API keys". Any keys you had created are now listed in the Console as Customer Secret keys. You can continue to use the existing keys.

Object Storage provides an API to enable interoperability with Amazon S3. To use this Amazon S3 Compatibility API, you need to generate the signing key required to authenticate with Amazon S3. This special signing key is an Access Key/Secret Key pair. Oracle provides the Access Key that is associated with your Console user login. You or your administrator generates the Customer Secret key to pair with the Access Key.

Each user created in the IAM service automatically has the ability to create, update, and delete their own Customer Secret keys in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage Customer Secret keys for other users.

Any user of the Amazon S3 Compatibility API with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work on page 2800. For basic policies that enable use of Object Storage, see Common Policies on page 2806.

Customer Secret keys do not expire. Each user can have up to two Customer Secret keys at a time. To create keys using the Console, see To create a Customer Secret key on page 3158.

**Working with OAuth 2.0 Client Credentials**

Note:

OAuth 2.0 Client Credentials are not available in the United Kingdom Government Cloud (OC4).

OAuth 2.0 client credentials are required to interact programmatically with those services that use the OAuth 2.0 authorization protocol. The credentials enable you to obtain a secure token to access those service REST API endpoints. The allowed actions and endpoints granted by the token depend on the scopes (permissions) that you select when you generate the credentials. The services that use the OAuth 2.0 protocol are:

• Oracle Analytics Cloud
• Oracle Integration

An OAuth 2.0 access token is valid for 3600 seconds (1 hour).

To create the credentials, you need to know the service resource and scope. Typically, you can select these from a drop-down list. However, if the information is not available in the list, you can manually enter the resource and scope. The scope defines the allowed permissions for the token, so ensure to set the scope at the minimum required access level.

A user can create the credentials for themselves or an Administrator can create the credentials for another user. The lists of available resources and scopes display only those resources and permission levels that the user has been granted access to.

**OAuth 2.0 Client Credential Limits**

Each user can have up to 10 OAuth 2.0 client credentials. You can increase this limit by Requesting a Service Limit Increase on page 245.
Each OAuth 2.0 client credential can have up to 10 scopes.

**Obtaining an OAuth 2.0 Access Token**

To obtain the token, use your credentials in a request against the OAuth2 token service endpoint as follows:

1. Create the OAuth 2.0 client credentials. See To create OAuth 2.0 client credentials on page 3158.

   After you create the OAuth 2.0 client credential note the following information:
   - The generated secret
   - The OCID of the OAuth 2.0 client credential
   - The scope and audience (fully-qualified scope)

2. Using the information from the previous step, make a request against the /oauth2/token endpoint to obtain a token as follows:

   ```bash
   curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded; charset=UTF-8" --user '<Oauth 2.0 client credential OCID>':<credential secret>' https://auth.<oci_region>.oraclecloud.com/oauth2/token -d 'grant_type=client_credentials&scope=<audience>-<scope>'
   ```

   Where:
   - `<Oauth 2.0 client credential OCID>`:<`credential secret>` is the OCID of the OAuth 2.0 client credential that you created joined by a colon (:) with the generated secret for the credential. Note that this secret is only displayed at the time you generate it and it must be copied immediately. You can retrieve the OCID from the details of the credential at any time.
   - `https://auth.<oci_region>.oraclecloud.com/oauth2/token` is the Oracle Cloud Infrastructure OAuth 2.0 authorization endpoint where `<OCI_region>` is a region your tenancy is subscribed to. For example, us-ashburn-1.
   - `<scope>-<audience>` is the fully-qualified scope, that is, the scope and audience joined by a hyphen (-). The scope and audience are available from the details page of the credential.

   Example request:

   ```bash
   ```

The response will include the token. Example response:

```json
{
"access_token" : "eyJraWQiOiJhcDVfwqKdi...8lTILrzec4cof2A",
"token_type" : "Bearer",
"expires_in" : "3600"
}
```

The token string is truncated in the example response. Copy the entire `access_token` string (within the quotation marks) as shown in your response.

**Using the OAuth 2.0 Token in a Request**

After you obtain an OAuth 2.0 access token, you provide the token in a bearer token header of the REST API request. For example:

```bash
```
What to Do When the Token Expires

The token expires after 3600 seconds (1 hour). When the token expires, request a new token following the instructions in Obtaining an OAuth 2.0 Access Token on page 3152.

Adding Scopes

You can add scopes to an existing OAuth 2.0 client credential to add access to more services with the same credential. After you add scopes, you do not need to regenerate the secret.

To request a token for multiple scopes, You can include additional scopes in a token request by appending \&scope=<scope>-<<audience> to the final argument of the request and specifying the scope and audience for the scope you want to add.

Working with SMTP Credentials

Simple Mail Transfer Protocol (SMTP) credentials are needed in order to send email through the Email Delivery service. Each user is limited to a maximum of two SMTP credentials. If more than two are required, they must be generated on other existing users or additional users must be created.

Note:

You cannot change your SMTP username or password to a string of your own choice. The credentials are always Oracle-generated strings.

Each user created in the IAM service automatically has the ability to create and delete their own SMTP credentials in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage SMTP credentials for other users.

Tip:

Although each user can create and delete their own credentials, it is a security best practice to create a new user and generate SMTP credentials on this user rather than generating SMTP credentials on your Console user that already has permissions assigned to it.

SMTP credentials do not expire. Each user can have up to two credentials at a time. To get SMTP credentials in the Console, see To generate SMTP credentials on page 3160.

For information about using the Email Delivery service, see Overview of the Email Delivery Service on page 2326.

Using the Console

To change your Console password

You're prompted to change your initial one-time password the first time you sign in to the Console. The following procedure is for changing your password again later.

Note:

For Federated Users

If your company uses an identity provider (other than Oracle Identity Cloud Service) to manage user logins and passwords, you can't use the Console to update your password. You do that with your identity provider.

1. Sign in to the Console using the Oracle Cloud Infrastructure Username and Password.
2. After you sign in, go to the top-right corner of the Console, open the **Profile** menu and then click **Change Password**.

![Console profile menu](image)

3. Enter the current password.
4. Follow the prompts to enter the new password, and then click **Save New Password**.

**To create or reset another user's Console password**

If you're an administrator, you can use the following procedure to create or reset a user's password. The procedure generates a new one-time password that the user must change the next time they sign in to the Console.

1. View the user's details: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **Create/Reset Password**.

   The new one-time password is displayed. If you're an administrator performing the task for another user, you need to securely deliver the new password to the user. The user will be prompted to change their password the next time they sign in to the Console. If they don't change it within 7 days, the password will expire and you'll need to create a new one-time password for the user.

**To reset your password if you forgot it**

If you have an email address in your user profile, you can use the **Forgot Password** link on the sign on page to have a temporary password sent to you. If you don't have an email address in your user profile, you must ask an administrator to reset your password for you.

**To unblock a user**

If you're an administrator, you can unblock a user who has tried 10 times in a row to sign in to the Console unsuccessfully. See **To unblock a user** on page 3154.

**To add an API signing key**

You can use the Console to generate the private/public key pair for you. If you already have a key pair, you can choose to upload the public key. When you use the Console to add the key pair, the Console also generates a configuration file preview snippet for you.

The following procedures work for a regular user or an administrator. Administrators can manage API keys for either another user or themselves.
About the Config File Snippet

When you use the Console to add the API signing key pair, a configuration file preview snippet is generated with the following information:

- **user** - the OCID of the user for whom the key pair is being added.
- **fingerprint** - the fingerprint of the key that was just added.
- **tenancy** - your tenancy's OCID.
- **region** - the currently selected region in the Console.
- **key_file** - the path to your downloaded private key file. You must update this value to the path on your file system where you saved the private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

You can copy this snippet into your config file, to help you get started. If you don't already have a config file, see SDK and CLI Configuration File on page 5308 for details on how to create one. You can also retrieve the config file snippet later for an API signing key whenever you need it. See: To get the config file snippet for an API signing key.

To generate an API signing key pair

**Prerequisite:** Before you generate a key pair, create the `.oci` directory in your home directory to store the credentials. See SDK and CLI Configuration File on page 5308 for more details.

1. View the user's details:
   - If you're adding an API key for **yourself**:
     - Open the Profile menu (>>) and click User Settings.
   - If you're an administrator adding an API key for **another user**:
     - Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select **Generate API Key Pair**.

4. Click **Download Private Key** and save the key to your `.oci` directory. In most cases, you do not need to download the public key.
   - **Note:** If your browser downloads the private key to a different directory, be sure to move it to your `.oci` directory.

5. Click **Add**.

   The key is added and the Configuration File Preview is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config file`. (If you have not yet created this file, see SDK and CLI Configuration File on page 5308 for details on how to create one.)

   After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:
   - Replace the existing profile and its contents.
   - Rename the existing profile.
   - Rename this profile to a different name after pasting it into the config file.

6. Update the permissions on your downloaded private key file so that only you can view it:
   - **Go to the `.oci` directory where you placed the private key file.**
   - **Use the command `chmod go-rwx ~/.oci/<oci_api_keyfile>.pem` to set the permissions on the file.**
To upload or paste an API key

**Prerequisite:** You have generated a public **RSA key in PEM format (minimum 2048 bits).** The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY-----
```

1. View the user's details:
   • If you're adding an API key for **yourself**:
     - Open the [Profile menu](#) and click **User Settings**.
   • If you're an administrator adding an API key for **another user:** Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **Add API Key**.

3. In the dialog, select **Choose Public Key File** to upload your file, or **Paste Public Key**, if you prefer to paste it into a text box.

4. Click **Add**.

   The key is added and the **Configuration File Preview** is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config` file. (If you have not yet created this file, see [SDK and CLI Configuration File](#) on page 5308 for details on how to create one.)

   After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

   If your config file already has a DEFAULT profile, you'll need to do one of the following:
   • Replace the existing profile and its contents.
   • Rename the existing profile.
   • Rename this profile to a different name after pasting it into the config file.

**To get the config file snippet for an API signing key**

The following procedure works for a regular user or an administrator.

1. View the user's details:
   • If you're getting an API key config file snippet for **yourself**:
     - Open the [Profile menu](#) and click **User Settings**.
   • If you're an administrator getting an API key config file snippet for **another user**: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **API Keys**. The list of API key fingerprints is displayed.

3. Click the the Actions icon (three dots) for the fingerprint, and select **View configuration file**.

   The **Configuration File Preview** is displayed. The file snippet includes required parameters and values you'll need to create your configuration file. Copy and paste the configuration file snippet from the text box into your `~/.oci/config` file. (If you have not yet created this file, see [SDK and CLI Configuration File](#) on page 5308 for details on how to create one.)
After you paste the file contents, you'll need to update the `key_file` parameter to the location where you saved your private key file.

If your config file already has a DEFAULT profile, you'll need to do one of the following:

- Replace the existing profile and its contents.
- Rename the existing profile.
- Rename this profile to a different name after pasting it into the config file.

**To delete an API signing key**

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.

1. View the user's details:
   - If you're deleting an API key for yourself:
     
     Open the Profile menu ( ) and click User Settings.
   
   - If you're an administrator deleting an API key for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. For the API key you want to delete, click Delete.

3. Confirm when prompted.

The API key is no longer valid for sending API requests.

**To create an auth token**

1. View the user's details:
   - If you're creating an auth token for yourself:
     
     Open the Profile menu ( ) and click User Settings.
   
   - If you're an administrator creating an auth token for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click Auth Tokens.

3. Click Generate Token.

4. Enter a description that indicates what this token is for, for example, "Swift password token".

5. Click Generate Token.

The new token string is displayed.

6. Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

If you're an administrator creating an auth token for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

**To delete an auth token**

The following procedure works for a regular user or an administrator. Administrators can delete an auth token for either another user or themselves.

1. View the user's details:
   - If you're deleting an auth token for yourself:
     
     Open the Profile menu ( ) and click User Settings.
   
   - If you're an administrator deleting an auth token for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click Auth Tokens.
3. For the auth token you want to delete, click **Delete**.
4. Confirm when prompted.

The auth token is no longer valid for accessing third-party APIs.

**To create a Customer Secret key**

1. View the user's details:
   - If you're creating a Customer Secret key for yourself:
     
     Open the **Profile** menu (ึก) and click **User Settings**.
   - If you're an administrator creating a Customer Secret key for another user: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **Customer Secret Keys**.

   A Customer Secret key consists of an Access Key/Secret key pair. Oracle automatically generates the Access Key when you or your administrator generates the Secret Key to create the Customer Secret key.

3. Click **Generate Secret Key**.

4. Enter a friendly description for the key and click **Generate Secret Key**.

   The generated **Secret Key** is displayed in the **Generate Secret Key** dialog box. At the same time, Oracle generates the **Access Key** that is paired with the **Secret Key**. The newly generated Customer Secret key is added to the list of **Customer Secret Keys**.

5. Copy the **Secret Key** immediately, because you can't retrieve the **Secret Key** again after closing the dialog box for security reasons.

   If you're an administrator creating a Secret Key for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

6. Click **Close**.

7. To show or copy the **Access Key**, click the **Show** or **Copy** action to the left of the **Name** of a particular Customer Secret key.

**To delete a Customer Secret key**

The following procedure works for a regular user or an administrator. Administrators can delete a Customer Secret key for either another user or themselves.

1. View the user's details:
   - If you're deleting a Customer Secret key for **yourself**:
     
     Open the **Profile** menu (ึก) and click **User Settings**.
   - If you're an administrator deleting a Customer Secret key for **another user**: Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **Customer Secret Keys**.

3. For the Customer Secret key you want to delete, click **Delete**.

4. Confirm when prompted.

The Customer Secret key is no longer available to use with the Amazon S3 Compatibility API.

**To create OAuth 2.0 client credentials**

---

**Note:**

OAuth 2.0 Client Credentials are not available in the following **realms**:

- the commercial realm (OC1)
- the United Kingdom Government Cloud (OC4)
1. View the user's details:
   • If you're creating an OAuth 2.0 client credential for yourself:
     
     Open the Profile menu and click User Settings.
   
   • If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click OAuth 2.0 Client Credentials.
3. Click Generate OAuth 2.0 Client Credential.
4. Enter a Name and Description for this credential.
5. Add the URI for the OAuth 2.0 services that this credential will provide access to.

   To Select a Resource-Scope Pair
   
   a. Select the Select a Resource-Scope Pair option.
   
   b. The Resource list displays the resources you have permission to view. Select the resource you want to add credentials for. After you select the resource, the Audience field is automatically populated.
   
   c. Next, select the Scope for this credential. Always select the minimum required privileges.

   To Enter Fully Qualified Scope:
   
   a. Select the Enter Fully Qualified Scope option.
   
   b. Enter the Audience and Scope for this credential.

6. To add more permissions to this credential, click + Another Scope and follow the instructions in the previous step.
7. Click Generate. The new secret string is generated.

Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

If you're an administrator creating a Secret Key for another user, you need to securely deliver it to the user.

You will need the following information from the credential for the token request:

• The generated secret
• The OCID of the OAuth 2.0 client credential
• The scope and audience (fully-qualified scope)

To add scopes to an existing OAuth 2.0 client credential

1. View the user's details:
   
   • If you're creating an OAuth 2.0 client credential for yourself:
     
     Open the Profile menu and click User Settings.
   
   • If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click OAuth 2.0 Client Credentials.
3. Click the name of the credential that you want to add scopes to.
4. Click Add Scopes.
5. Add the URI for the OAuth 2.0 services that you want to add access to.

To Select a Resource-Scope Pair
   a. Select the Select a Resource-Scope Pair option.
   b. The Resource list displays the resources you have permission to view. Select the resource you want to add credentials for. After you select the resource, the Audience field is automatically populated.
   c. Next, select the Scope for this credential. Always select the minimum required privileges.

   To Enter Fully Qualified Scope:
   a. Select the Enter Fully Qualified Scope option.
   b. Enter the Audience and Scope for this credential.

6. To add more permissions to this credential, click + Another Scope and follow the instructions in the previous step.

7. Click Save Changes.

To regenerate the OAuth 2.0 client credential secret

IMPORTANT: When you regenerate the secret for a credential, requests made with the previous secret will be denied access to target scopes.

1. View the user's details:
   • If you're creating an OAuth 2.0 client credential for yourself:
      Open the Profile menu (>Create User Settings.
   • If you're an administrator creating an OAuth 2.0 client credential for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click OAuth 2.0 Client Credentials.
3. Click the name of the credential that you want to regenerate the secret for.
4. Click Add Scopes.
5. Click Regenerate Secret.
6. Acknowledge the warning dialog and click Regenerate Secret.
7. Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

Ensure to update existing token requests with the new secret string.

To generate SMTP credentials

1. View the user's details:
   • If you're generating SMTP credentials for yourself:
      Open the Profile menu (Create User Settings.
   • If you're an administrator generating SMTP credentials for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click SMTP Credentials.
3. Click Generate SMTP Credentials.
4. Enter a Description of the SMTP Credentials in the dialog box.
5. Click Generate SMTP Credentials. A user name and password is displayed.
6. Copy the user name and password for your records and click Close. Copy the credentials immediately, because you can't retrieve the password again after closing the dialog box for security reasons.

   If you're an administrator creating the credential set for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.
To delete SMTP credentials

The following procedure works for a regular user or an administrator. Administrators can delete SMTP credentials for either another user or themselves.

1. View the user's details:
   - If you're deleting SMTP credentials for yourself:
     Open the Profile menu and click User Settings.
   - If you're an administrator deleting SMTP credentials for another user: Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click SMTP Credentials.
3. For the SMTP credentials you want to delete, click Delete.
4. Confirm when prompted.

The SMTP credentials are no longer available to use with the Email Delivery service.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to manage Console passwords and access:
- CreateOrResetUIPassword: This generates a new one-time Console password for the user. The next time the user signs in to the Console, they'll be prompted to change the password.
- UpdateUserState: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.

Use these API operations to manage API signing keys:
- ListApiKeys
- UploadApiKey
- DeleteApiKey

Use these API operations to manage auth tokens:
- CreateAuthToken
- UpdateAuthToken: You can only update the auth token's description, not change the token string itself.
- ListAuthToken
- DeleteAuthToken

Use these API operations to manage Customer Secret keys:
- CreateCustomerSecretKey
- UpdateCustomerSecretKey: You can only update the secret key's description, not change the key itself.
- ListCustomerSecretKeys
- DeleteCustomerSecretKey

Use these API operations to manage OAuth 2.0 client credentials:
- CreateOAuthClientCredential
- UpdateOAuthClientCredential
- ListOAuthClientCredentials
- DeleteOAuthClientCredential

Use these API operations to manage SMTP credentials:
- CreateSmtpCredential
- UpdateSmtpCredential: You can only update the description.
- ListSmtpCredentials
Managing Authentication Settings

This topic describes how to set authentication rules for your tenancy. Authentication settings include policy rules for local IAM users in your tenancy and network source restrictions for all users in your tenancy.

Required IAM Policy

If you're in the Administrators group, then you have the required access for authentication policy and network sources.

To view authentication policy and network sources, you must be granted `inspect` access on the `authentication-policies` resource and the `network-sources` resource. For example:

Allow group GroupA to inspect authentication-policies in tenancy

Allow group GroupA to inspect network-sources in tenancy

To manage authentication policy and network sources, you must be granted manage permissions for both resources. For example:

Allow group GroupA to manage authentication-policies in tenancy

Allow group GroupA to manage network-sources in tenancy

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM on page 2971.

Working with Password Policy Rules

A password policy that you set in the IAM service is applicable for all local (or non-federated) users.

When a user is created or when a user changes their password, the IAM service validates the password that is provided against the password policy to ensure that it meets the criteria for the policy. When a user logs in for the first time to change the password, or resets the password at any time, the password policy is evaluated and enforced.

When Do Changes to Password Policy Rules Take Effect

Changes to password policy rules take effect immediately so that the next time any user changes their password they must create a password that meets the criteria. Existing passwords will continue to work even if they would be invalid under the new rules. Users are not forced to change existing passwords to meet the new criteria. Passwords are evaluated against the rules only at the time they are created or changed.

About the Password Policy Rules

The following table describes the rules that you can include in your password policy:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Setting Options</th>
<th>Default IAM Service Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum password length</td>
<td>Minimum value is 8 (characters). Maximum value is 100.</td>
<td>12 characters</td>
</tr>
</tbody>
</table>
### Rule Setting Options

<table>
<thead>
<tr>
<th>Rule</th>
<th>Setting Options</th>
<th>Default IAM Service Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Special characters</td>
<td>Require passwords to contain at least 1 special character. Special characters allowed in passwords are: !#$%&amp;'()*+,-./:;&lt;=&gt;? @^_`{</td>
<td>}~</td>
</tr>
<tr>
<td></td>
<td>Special characters not listed are not allowed.</td>
<td></td>
</tr>
<tr>
<td>Lowercase characters</td>
<td>Require passwords to contain at least 1 lowercase alphabetic character a-z.</td>
<td>Enforced</td>
</tr>
<tr>
<td>Uppercase characters</td>
<td>Require passwords to contain at least 1 uppercase alphabetic character A-Z.</td>
<td>Enforced</td>
</tr>
<tr>
<td>Numeric characters</td>
<td>Require passwords to contain at least 1 number 0-9.</td>
<td>Enforced</td>
</tr>
</tbody>
</table>

Oracle recommends that you enforce all the password rules.

### Using the Console to Manage Password Policy Rules

**To edit password policy rules**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Authentication Settings**. The authentication settings for your tenancy are displayed.
2. Click **Edit**.
3. Enter the following to set the password policy:
   - **Minimum Password Length**: Enter a number to define the minimum number of characters that a user's password must contain. Allowed values are 8 through 100.
4. Select the **Password Rules** you want to enforce:
   - **Must contain at least 1 numeric character**: Select the check box to require at least 1 number (0-9) in the password.
   - **Must contain at least 1 special character**: Select the check box to require at least 1 special character. Allowed special characters are: !#$%&'()*+,-./:;<=>?@\^_`{|}~
   - **Must contain at least 1 lowercase character**: Select the check box to require at least 1 lowercase alphabetic character (a-z).
   - **Must contain at least 1 uppercase character**: Select the check box to require at least 1 uppercase alphabetic character (A-Z).
5. Click **Save Changes**.

### Working with Network Source Restrictions in Authentication Policy

Network source restrictions let you specify an allowed set of IP ranges from which users can sign in to the Console. Users attempting to sign in from an IP address not on the allowed list will be denied access.

To enforce a network source restriction for your tenancy:

1. Set up a network source that specifies the allowed IP addresses. See **Managing Network Sources** on page 3123 for information on setting up the network source.
2. Select the network source in the Authentication settings page.

An administrator can set only one network source in the authentication settings, but a single network source can include multiple allowed IP addresses.
A network source restriction is applied for every user in the tenancy. If an administrator is unable to access a network with an allowed IP address to sign in from, then they must do one of the following to gain access to the tenancy:

- Use the authentication SDK to sign in and change the network source restriction setting programmatically.
- Contact Oracle Support. If you do not have an API signing key to enable access through the authentication SDK, then you must contact support to regain access to your tenancy.

**Caution:**

Before you set up a network source restriction, ensure that you have an API key set up to enable access to your tenancy in case an allowed network is not available. If you do not set up an API key and an allowed network is not available, then all users will be locked out of the tenancy until you contact Oracle Support. For information about setting up the API signing key, see Required Keys and OCIDs on page 5303.

**When Do Changes to Network Source Restrictions Take Effect**

After a network source restriction is defined, users signed in to the Console can continue with their current session, but after they sign out, the network restriction will be applied the next time they try to sign in.

**Using the Console to Manage Network Source Restrictions**

**To set up a network source restriction**

1. Open the navigation menu and click Identity & Security. Under Identity, click Authentication Settings. The authentication settings for your tenancy are displayed.
2. Click Edit.
3. From the Select Network Source menu, select the network source that specifies the IP range restrictions you want to apply to all Console sign-ins.
4. Click Save Changes.

**To view or edit the value of a network source**

1. Open the navigation menu and click Identity & Security. Under Identity, click Authentication Settings. The authentication settings for your tenancy are displayed.
2. Click the name of the network source displayed for Network Source Restrictions.
   - The details page of the network source is displayed. From here, you can edit or delete the definition. See Managing Network Sources on page 3123 for information on managing network sources.

**Using the API to Work with Authentication Settings**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage authentication settings:

- GetAuthenticationPolicy
- UpdateAuthenticationPolicy

**Managing Multi-Factor Authentication**

This topic describes how users can manage multi-factor authentication (MFA) in Oracle Cloud Infrastructure.

**Required IAM Policy**

Only the user can enable multi-factor authentication (MFA) for their own account. Users can also disable MFA for their own accounts. Members of the Administrators group can disable MFA for other users, but they cannot enable MFA for another user.
About Multi-Factor Authentication

Multi-factor authentication is a method of authentication that requires the use of more than one factor to verify a user’s identity.

With MFA enabled in the IAM service, when a user signs in to Oracle Cloud Infrastructure, they are prompted for their user name and password, which is the first factor (something that they know). The user is then prompted to provide a second verification code from a registered MFA device, which is the second factor (something that they have). The two factors work together, requiring an extra layer of security to verify the user’s identity and complete the sign-in process.

In general, MFA may include any two of the following:

- Something that you know, like a password.
- Something that you have, like a device.
- Something that you are, like your fingerprint.

The IAM service supports two-factor authentication using a password (first factor) and a device that can generate a time-based one-time password (TOTP) (second factor).

General Concepts

Here's a list of the basic concepts you need to be familiar with.

MULTI-FACTOR AUTHENTICATION (MFA)

Multi-factor authentication (MFA) is a method of authentication that requires the use of more than one factor to verify a user’s identity. Examples of authentication factors are a password (something you know) and a device (something you have).

AUTHENTICATOR APP

An app you install on your mobile device that can provide software-based secure tokens for identity verification. Examples of authenticator apps are Oracle Mobile Authenticator and Google Authenticator. To enable MFA for the IAM service, you'll need a device with an authenticator app installed. You'll use the app to register your device and then you'll use the same app (on the same device) to generate a time-based one-time passcode every time you sign in.

REGISTERED MOBILE DEVICE

Multi-factor authentication is enabled for a specific user and for a specific device. The procedure to enable MFA for a user includes the registration of the mobile device. This same device must be used to generate the time-based one-time passcode every time the user signs in. If the registered mobile device becomes unavailable, an administrator must disable MFA for the user so that MFA can be re-enabled with a new device.

TIME-BASED ONE-TIME PASSWORD (TOTP)

A TOTP is a password (or passcode) that is generated by an algorithm that computes a one-time password from a shared secret key and the current time, as defined in RFC 6238. The authenticator app on your registered mobile device generates the TOTP that you need to enter every time you sign in to Oracle Cloud Infrastructure.

Supported Authenticator Apps

The following authenticator apps have been tested with the Oracle Cloud Infrastructure IAM service:

- Oracle Mobile Authenticator
- Google Authenticator

You can find these apps in your mobile device's app store. You must install one of these apps on your mobile device before you can enable MFA.
**Working with MFA**

Keep the following in mind when you enable MFA:

- You must install a supported authenticator app on the mobile device you intend to register for MFA.
- Each user must enable MFA for themselves using a device they will have access to every time they sign in. An administrator *cannot* enable MFA for another user.
- To enable MFA, you use your mobile device’s authenticator app to scan a QR code that is generated by the IAM service and displayed in the Console. The QR code shares a secret key with the app to enable the app to generate TOTPs that can be verified by the IAM service.
- A user can register only one device to use for MFA.
- After you add your Oracle Cloud Infrastructure account to your authenticator app, the account name displays in the authenticator app as Oracle `<tenancy_name>` - `<username>`.

**Restricting Access to Only MFA-Verified Users**

You can restrict access to resources to only users that have been authenticated through the IAM service's time-based one-time password authentication. You set up this restriction in the policy that allows access to the resource.

To restrict the access granted through a policy to only MFA-verified users, add the following `where` clause to the policy:

```sql
where request.user.mfaTotpVerified='true'
```

For example, assume your company has this policy in place to allow GroupA to manage instances:

```sql
allow group GroupA to manage instance-family in tenancy
```

To enhance security, you want to ensure that only users who have been verified through MFA can manage instances. To restrict access to only these users, revise the policy statement as follows:

```sql
allow group GroupA to manage instance-family in tenancy where request.user.mfaTotpVerified='true'
```

With this policy in place, only the members of GroupA who have successfully signed in by entering both their password and the time-based one-time passcode generated by their registered mobile device, are allowed to access and manage instances. Users who have not enabled MFA and sign in using only their password, will not be allowed access to manage instances.

For information on writing policies, see Policy Syntax on page 2834.

**Sign in Process After Enabling MFA**

After you have enabled MFA, use one of the following procedures to sign in to Oracle Cloud Infrastructure:

**To sign in using the Console**

1. Navigate to the Console sign-in page.
2. Enter your Oracle Cloud Infrastructure **User Name** and **Password** and then click **Sign In**.

After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.

![Multi-Factor Authentication Screen](image1)

3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.

![Mobile Authenticator App](image2)

4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click **Sign In**.

   **Important:** The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

**To sign in using the command line interface (CLI)**

1. To sign in with the CLI, run the following command:

   ```bash
   oci session authenticate --region US East (Ashburn)
   ```

   A browser window opens, and a prompt instructs you to use the browser to sign in.

   ```bash
   Please switch to newly opened browser window to log in!
   ```
2. In the browser window, enter your Oracle Cloud Infrastructure User Name and Password and then click Sign In. After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.

3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.

4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click Sign In. **Important:** The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

After you authenticate, prompts instruct you to return to the CLI and enter the name of a profile.

5. In the CLI, type a name for the profile.

---

**Tip:**

For more information about working with the CLI, see Quickstart on page 5320 and Getting Started with the Command Line Interface on page 107.
What To Do If You Lose Your Registered Mobile Device

If you lose your registered mobile device, you will not be able to authenticate to Oracle Cloud Infrastructure through the Console. Contact your administrator to disable multi-factor authentication for your account. You can then repeat the process to enable multi-factor authentication with a new mobile device.

Unblocking a User After Unsuccessful Sign-in Attempts

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further sign-in attempts. An administrator can unblock the user in the Console (see To unblock a user on page 3114) or with the UpdateUserState API operation.

Disabling MFA

Each user can disable MFA for themselves. An administrator can also disable MFA for another user.

| Caution: |
| Do not disable MFA unless you are instructed to by your administrator. |

Using the Console

Use the following procedures to manage MFA in the Console.

To enable MFA for your user account

Prerequisite: You must install a supported authenticator app on the mobile device you intend to register for MFA.

1. In the upper-right corner of the Console, open the Profile menu and then select User Settings. Your user details are displayed.
2. Click Enable Multi-Factor Authentication.
3. Scan the QR code displayed in the dialog with your mobile device’s authenticator app.
   
   Note: If you close the browser, or if the browser crashes before you can enter the verification code, you must generate a new QR code and scan it again with your app. To generate a new QR code, click the Enable Multi-Factor Authentication button again.
4. In the Verification Code field, enter the code displayed on your authenticator app.
5. Click Enable.

Your mobile device is now registered with the IAM service and your account is enabled for MFA. Every time you sign in, you are prompted for your username and password first. After you provide the correct credentials, you will be prompted for a TOTP code generated by the authenticator app on your registered mobile device. You must have your registered mobile device available every time you sign in to Oracle Cloud Infrastructure.

To disable MFA for your user account

1. In the upper-right corner of the Console, open the Profile menu and then select User Settings. Your user details are displayed.
2. Click Disable Multi-Factor Authentication.
3. Confirm when prompted.

To disable MFA for another user

1. Open the navigation menu and click Identity & Security. Under Identity, click Users. A list of the users in your tenancy is displayed.
2. Click the user you want to update. The user’s details are displayed.
3. Click Disable Multi-Factor Authentication.
4. Confirm when prompted.
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Note:

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions.

Use these API operations to manage multi-factor authentication devices:

- `CreateMfaTotpDevice`
- `ListMfaTotpDevices`
- `GetMfaTotpDevice`
- `DeleteMfaTotpDevice`
- `ActivateMfaTotpDevice`
- `GenerateTotpSeed`

Policies for Managing Resources Used with Resource Manager

For example policies, go to one of the following:

- Stacks and jobs
- Private templates
- Configuration source providers

Deprecated IAM Service APIs

This topic lists deprecated APIs for the IAM service.

Federation Management APIs

Date of Notification: October 15, 2020

What is changing?

The following APIs for the management of federations are deprecated. Support for these APIs will end October 15, 2021. The replacement solution for managing federations is to set up the federation for your tenancy between the identity provider and your tenancy's Oracle Identity Cloud Service identity domain. See Manage Oracle Identity Cloud Service Identity Providers for information on managing identity providers in IDCS.

Chapter 28

Language

This chapter explains how to use Language.

Language

Language provides you with the artificial intelligence and machine learning capabilities to detect the language in your unstructured text. Also, it provides other tools to help you further gain insights about your text.

Get Started

Language Overview on page 3172

Learn about the pretrained model tools

Prerequisites

Create IAM policies

Troubleshooting

Frequently Asked Questions on page 3188

Support

Get help and contact Support

Create a service request

Language Overview

Language is serverless and multi-tenant service that is accessible using REST API calls. It provides pretrained models that are frequently retrained and monitored to provide you with the best results.

You can automate sophisticated text analysis at scale without any machine learning expertise.

The Language service contains these pretrained language processing capabilities:

Aspect-Based Sentiment Analysis

Identifies aspects from the given text and classifies each into positive, negative, or neutral polarity.

Named Entity Recognition

Identifies common entities, people, places, locations, email, and so on.

Key Phrase Extraction

Extracts an important set of phrases from a block of text.
Language Detection

Detects languages based on the given text, and includes a confidence score.

Text Classification

Identifies the document category and subcategory that the text belongs to.

Ways to Access Language

You access Language using the Console, REST API, SDKs, or CLI.

Use any of the following options, based on your preference and its suitability for the task you want to complete:

- The OCI Console is an easy-to-use, browser-based interface. To access the Console, you must use a supported browser.
- The REST APIs provide the most functionality, but require programming expertise. API reference and endpoints provide endpoint details and links to the available API reference documents including the Artificial Intelligence Services REST API.
- OCI provides SDKs that interact with Language without the need to create a framework.
- The CLI provides both quick access and full functionality without the need for programming.

Regions and Availability Domains

OCI services are hosted in regions and availability domains. A region is a localized geographic area, and an availability domain is one or more data centers located in that region.

Language is hosted in these regions:

- Australia East (Sydney)
- Australia Southeast (Melbourne)
- Brazil East (Sao Paulo)
- Canada Southeast (Montreal)
- Canada Southeast (Toronto)
- Chile (Santiago)
- Germany Central (Frankfurt)
- India South (Hyderabad)
- India West (Mumbai)
- Japan Central (Osaka)
- Japan East (Tokyo)
- Netherlands Northwest (Amsterdam)
- South Korea Central (Seoul)
- South Korea North (Chuncheon)
- Switzerland North (Zurich)
- UAE East (Dubai)
- UK South (London)
- UK West (Newport)
- US East (Ashburn)
- US West (Phoenix)
- US West (San Jose)

About Language Policies

Learn about the resource policies including API permissions.

To control who has access to Language and the type of access for each group of users, you must create policies. By default, only the users in the Administrators group have access to all Language resources. For everyone else who's using the service, you must create new policies that assign them proper rights to Language resources. For a complete list of OCI policies, see Policy Reference.
Resource Types

Language offers both aggregate and individual resource-types for writing policies. You can use aggregate resource types to write fewer policies. For example, instead of allowing a group to manage all of the individual resource types, you can have a policy that allows the group to manage the aggregate resource type, `ai-service-language-family`.

Individual Resource Types

- ai-service-language-entities
- ai-service-dominant-language
- ai-service-language-sentiments
- ai-service-language-keyphrases
- ai-service-language-text-classification

Aggregate Resource Type

- ai-service-language-family

Example Policies

allow group <language-group> to use <ai-service-language-family> in tenancy

Permissions Required for Each API Operation

You can use the individual resource types with API calls to interact with the service.

The following table lists the API operations for the Language service in a logical order, grouped by resource type, and the permissions required for resource types:

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DetectDominantLanguage</td>
<td>AI_SERVICE_DOMINANT_LANGUAGE_USE</td>
</tr>
<tr>
<td>DetectLanguageEntities</td>
<td>AI_SERVICE_LANGUAGE_ENTITIES_USE</td>
</tr>
<tr>
<td>DetectLanguageKeyPhrases</td>
<td>AI_SERVICE_LANGUAGE_KEYPHRASES_USE</td>
</tr>
<tr>
<td>DetectLanguageSentiments</td>
<td>AI_SERVICE_LANGUAGE_SENTIMENTS_USE</td>
</tr>
<tr>
<td>DetectLanguageTextClassification</td>
<td>AI_SERVICE_LANGUAGE_TEXT_CLASSIFICATION_USE</td>
</tr>
</tbody>
</table>

Pretrained Model Tools

Learn about the Language service pretrained model tools.

Limitations Common to all Model Tools

- The Language Detection model tool supports numerous languages while the other model tools support English only.
- A minimum of one word.
- A maximum of 1,000 characters in a document. The performance might differ across domains.
- The API only supports the English language.
- If your text contains a mix of English and other languages or special non-ascii symbols, the service only processes the English text.
- If your text doesn't follow English grammar, the model performance could degrade.
• Batching inference isn't supported.
• No spelling checking or corrections are performed so the results might not be as you expect with spelling mistakes.
• You can use the Saudi Arabia West (Jeddah) region with our assistance so contact us.

About Aspect-Based Sentiment Analysis
Aspect-based sentiment analysis can be used to gauge the mood or the tone of text.

Sentiment analysis analyzes the subjective information in an expression. For example, opinions, appraisals, emotions, or attitudes toward a topic, person, or entity. Expressions are classified, with a confidence score, as positive, negative, or neutral.

The Language service sentiment analysis uses natural language processing (NLP). The tool understands the text, returns positive, neutral, and negative sentiments, and a confidence score.

The Language service aspect-based sentiment analysis (ABSA) API supports this fine grained task by extracting the individual aspects in the input document. It classifies each of the aspects into one of the three polarity classes, positive, negative, and neutral. With the predicted sentiment for each aspect, the API also provides a confidence score for each of the classes and their corresponding offsets in the input.

In the service, the confidence score is a decimal number of up to four digits. However, the Language API returns long decimal numbers confidence scores.

Scores closer to 1 indicate a higher confidence in the label's classification, while lower scores indicate lower confidence score. The range of the confidence score for each class is between 0–1 and the cumulative scores of all the three classes sum to 1.

For example, a restaurant review "Food is marginal, but the service is so bad." contains positive sentiment toward the food aspect. Also, it has a strong negative sentiment toward the service aspect. Classifying the overall sentiment as negative would neglect the fact that food was good.

ABSA addresses this problem by referring to an aspect as an attribute (or component) of an entity. For example, the screen of a phone, or the picture quality of a camera. An ABSA task typically includes identifying relevant entities and aspects to determine the corresponding sentiment.

The return on investment of a marketing campaign can use sentiment analysis to analyze a sentiment from a tweet stream of a target audience. For example, a marketer wants to run a sentiment analysis on a set of tweets to understand how many positive or negative discussions occur within it.

If the input data is "I had a good day at work today", then the results are work is 100% positive, 0% neutral, and 0% negative.

Use Cases
Some business use cases are:

• Brand monitoring
• Monitoring market research
• Employee feedback analysis
• Customer reviews and emails analysis
• Product surveys

For example, customer and employee raw survey responses can be processed using the sentiment analysis tool. The results can then be aggregated for analysis and follow up, and to facilitate engagements.

Social media monitoring can be employed with sentiment analysis to specifically extract the overall mood swing of the customer. For example, when a new product is launched, or competitive market research is conducted.

Supported Features

• Aspect Level Sentiment
OCI recently added new services to existing compliance program including SOC, HIPAA, and ISO to enable our customers to solve their use cases. We also released new white papers and guidance documents related to Object Storage, the Australian Prudential Regulation Authority (APRA), and the Central Bank of Brazil. These resources help regulated customers better understand how OCI supports their regional and industry-specific compliance requirements. Not only are we expanding our number of compliance offerings and regulatory alignments, we continue to add regions and services at a faster clip.

The JSON for this example is:

**API Request format:**

```json
{
  "text": "OCI recently added new services to existing compliance program including SOC, HIPAA, and ISO to enable our customers to solve their use cases. We also released new white papers and guidance documents related to Object Storage, the Australian Prudential Regulation Authority (APRA), and the Central Bank of Brazil. These resources help regulated customers better understand how OCI supports their regional and industry-specific compliance requirements. Not only are we expanding our number of compliance offerings and regulatory alignments, we continue to add regions and services at a faster clip."}
```

**Response JSON:**

```json

          "neutral": 0
        }
      },
      {
        "offset": 74,
        "length": 6,
        "text": "resources",
        "sentiment": "Positive",
        "score": {
          "positive": 0.9933981895446777,
          "negative": 0,
          "neutral": 0.006601857487112284
        }
      },
      {
        "offset": 88,
        "length": 9,
        "text": "regions",
        "sentiment": "Positive",
        "score": {
          "positive": 0.9908866882324219,
          "negative": 0,
          "neutral": 0.00913257750868797
        }
      }
    ]
  }
}
```
The actual values, and input and output structure might vary by model version, see the SDK documentation.

Limitations

- The identified aspects might be partial matches or split aspects.
- When sentences are semantically or structurally incorrect, the aspects could differ from your expectations.
- Pronouns as an aspect are not supported.
- If no sentiment can be identified, the aspect is identified as neutral.
- Sarcasm is not recognized.

About Named Entity Recognition

Named Entity Recognition (NER) detects named entities in text.

The Language service NER tool uses natural language processing, which uses machine learning to find predefined named entities. This tool also provides a confidence score for each entity and is a value from zero to one.
Use Cases

The NER tool could be used effectively in these scenarios:

Classifying content for news providers

It can be difficult to classify and categorize news article content. The NER tool can automatically scan articles to identify the major people, organizations, and places in them. The extracted entities can be saved as tags with the related articles. Knowing the relevant tags for each article helps with automatically categorizing the articles in defined hierarchies, and enables content discovery.

Customer support

Recognizing relevant entities in customer complaints and feedback, like product specifications, department details, or company branch details, helps to classify the feedback appropriately. The entities can then be forwarded to the person responsible for the identified product.

Similarly, there could be feedback tweets where you can categorize them all based on their locations, and the products mentioned.

Efficient search algorithms

You could use NER to extract entities that are then searched against the query, instead of searching for a query across the millions of articles and websites online. When run on articles, all the relevant entities associated with each article are extracted and stored separately. This separation could speed up the search process considerably. The search term is only matched with a small list of entities in each article, leading to quick and efficient searches.

It can be used for searching content from millions of research papers, Wikipedia articles, blogs, articles, and so on.

Content recommendations

Extracting entities from a particular article, and recommending the other articles that have the most similar entities mentioned in them is possible with NER. For example, it can be used effectively to develop content recommendations for a media industry client. It enables the extraction of the entities associated with historical content or previous activities. NER compares them with the label assigned to other unseen content to filter relevant entities.

Automatically summarizing job candidates

The NER tool could facilitate the evaluation of job candidates, by simplifying the effort required to shortlist candidates with numerous applications. Recruiters could filter and categorize them based on identified entities like location, college degrees, employers, skills, designations, certifications, and patents.

Red Bull Racing Honda, the four-time Formula-1 World Champion team, has chosen Oracle Cloud Infrastructure (OCI) as their infrastructure partner.

601-555-5555
303.555.5555

OCI recently added new services to existing compliance program including SOC, HIPAA, and ISO to enable our customers to solve their use cases. We also released new white papers and guidance documents related to Object Storage, the Australian Prudential Regulation Authority (APRA), and the Central Bank of Brazil. These resources help regulated customers better understand how OCI supports their regional and industry-specific compliance requirements. Not only are we expanding our number of compliance offerings and regulatory alignments, we continue to add regions and services at a faster clip.

The JSON for the first example is:

API Request format:

```
{
  "text": "Red Bull Racing Honda, the four-time Formula-1 World Champion team, has chosen Oracle Cloud Infrastructure (OCI) as their infrastructure partner."
}
```

Response JSON:

```
{
  "entities": [
    {
      "text": "Red Bull Racing Honda",
      "type": "ORG",
      "score": 0.9615446925163269,
      "offset": 0,
      "length": 21,
      "isPii": true
    },
    {
      "text": "Formula-1 World",
      "type": "EVENT",
      "score": 0.6783602237701416,
      "offset": 37,
      "length": 15,
      "isPii": false
    },
    {
      "text": "Oracle Cloud Infrastructure (OCI",
      "type": "ORG",
      "score": 0.9457286934661865,
      "offset": 57,
      "length": 49,
      "isPii": true
    }
  ]
}
```
Limitations

- The text is broken into sentences and there is no minimum number of words. The entities might not get separated or combined as you expect.
- The tool is context-based so your text must contain contextual information for the entities to be extracted as you expect.
- Malformed text (structure and semantics) might reduce the performance.
- Age isn't a separate entity so age-related periods might be identified as a date entity.
- Hierarchical or nested entities aren't supported.

About Key Phrase Extraction

Keyword extraction is the automated process of extracting the words with the most relevance, and expressions from the input text. It helps summarize the content, and recognizes the main topics.

The key phrase extraction tool uses NLP and ML to find insights related to the main points of the text. It understands the unstructured input text, and returns key words and key phrases (KPs).

The KPs consists of subjects and objects that are being talked about in the document. Any modifiers, like adjectives associated with these subjects and objects, are also included in the output. Confidence scores for each key phrase that signify how confident we are about the KP are included. Confidence scores are a value from 0 to 1.

Use Cases

Some business use cases are:

- Brand monitoring
- Monitoring market research
- Competitive market analysis
- Customer support tickets
- Employee feedback analysis
- Customer reviews
- Email analysis
Supported Features

- Key phrases
- Confidence Scores
- English Language
- Single Requests

Examples

Limitations

- Key phrases that are noun phrases with adjective modifiers are identified so words that don't follow this criteria could be ignored.
- This tool is case insensitive.
- Text that contains multiple punctuation between words might be flagged as a key phrase.
- URLs that are well formed (begin with http, https, or www) are identified.
- Numbers and numeric words aren't identified as key phrases.

About Language Detection

The Language service language detection tool identifies which natural language the input text is in.

For example, language detection can help make customer support interactions more personable and quicker. Customer service chatbots can interact with customers based on the language of their input text and respond accordingly. If a customer needs help with a product, the chatbot server can field the corresponding language product manual, or transfer to the call center for the specific language.

Supported Languages

- Afrikaans
- Albanian
- Arabic
- Armenian
- Azerbaijani
- Basque
- Belarusian
- Bengali
- Bosnian
- Bulgarian
- Burmese
- Cantonese
- Catalan
- Cebuano
- Chinese
- Croatian
- Czech
- Danish
- Dutch
- Eastern Punjabi
- Egyptian Arabic
- English
- Esperanto
- Estonian
- Finnish
- French
- Georgian
- German
- Greek
- Hebrew
- Hindi
- Hungarian

         "score": 0.9918076646218955
      }
   ]
}
```

Limitations

• A mix of languages isn't supported. Use only one language.
• Utterances or shorter sentences of fewer than 10 words can have unpredictable results.

About Text Classification

Text classification analyses the text and identifies categories for the content with confidence score.

Text classification uses natural language processing (NLP) service that uses deep learning technique to find insights from textual data. It returns a category from a set of the predefined categories. This text classification uses NLP and relies on main objective lies on zero-shot learning. It classifies text with no or minimal data to train. The content of a collection of documents is analyzed to determine common themes.

For example, you could analyze a collection of financial documents to Credit and Lending, Insurance, Investing, Banking, and so on. The results are given in categories and subcategories format.

Supported Features

• Text Category
• Confidence Scores
• English Language
• Single Requests

Examples

<table>
<thead>
<tr>
<th>Input Text</th>
<th>Categories and Scores</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Bull Racing Honda, the four-time Formula-1 World Champion team, has chosen Oracle Cloud Infrastructure (OCI) as their infrastructure partner.</td>
<td>sports and games/motor sports (0.9998)</td>
</tr>
</tbody>
</table>

The JSON for the first example is:

```
API Request format:

{

```
Red Bull Racing Honda, the four-time Formula-1 World Champion team, has chosen Oracle Cloud Infrastructure (OCI) as their infrastructure partner.

Response JSON:

```json
{
  "textClassification": [
    {
      "label": "sports and games/motor sports",
      "score": 0.9998961687088013
    }
  ]
}
```

Limitations

- A minimum 10 words are required to identify the correct text category.
- If your text is about more than one category, the major category of the text is identified and could differ from human interpretation of the text.

Analyzing Text with the Console

You can use one or more of these text analysis tools to analyze your text with the Language service:

- Aspect-Based Sentiment Analysis
- Named Entity Recognition
- Key Phrase Extraction
- Language Detection
- Text Classification

Use the Console to analyze your text:

1. Open the navigation menu and click Analytics & AI. Under Artificial Intelligence, click Language.
2. Paste, or enter, your text into the dialog box.
3. Select the text analysis tools that you want to use.
4. Click Analyze.

You can reset the page by clicking Reset.

Viewing the Results

After you analyze your text, the Language service displays the results by category for the selected tools as follows:

**Sentiment Analysis**

Renders the results in horizontal bar graphs as a percentage.

**Named Entity Recognition**

Identifies the named entities that were found and their categories are indicated in square brackets.

**Key Phrase Extraction**

Lists the key phrases in a double-quotes delimited list.

**Language Detection**

Lists, by confidence percentage, the languages detected.
Text Classification
Lists the word, identified document category, and the confidence score.

You can click Show JSON to view these results in JSON format. You can copy the JSON text or download it. Click Return to Standard Results to leave the JSON view.

Analyzing with the API or CLI
You can use the Language API or CLI to analyze input text.

Using the API
For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- DetectDominantLanguage
- DetectLanguageEntities
- DetectLanguageKeyPhrases
- DetectLanguageSentiments
- DetectLanguageTextClassification

Using the Command Line Interface (CLI)
For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see the Command Line Reference.

Run the following commands:

```
oci ai language detect-language --text, -? | -h | --help
oci ai language detect-entities --text, -? | -h | --help, --is-pii, --model-version
oci ai language detect-key-phrases --text, -? | -h | --help
oci ai language detect-sentiments --text, -? | -h | --help
oci ai language detect-text-classification --text, -? | -h | --help
```

Frequently Asked Questions
Review often asked questions, with the answers, about the Language service.

General

How do I get started with the Language service?
Use the Language Overview on page 3172 then analyze your text with the Console or API.

How many languages can the service detect?
The language detection tool supports 101 languages.
The Language Detection model tool supports numerous languages while the other model tools support English only.

Can I request support for other languages?
Language detection supports numerous languages. If any you want support for a particular language support, contact us.
Is it possible to use the Language service in Government regions?
No, it is available only in commercial regions.

What does confidence score signify in aspect-based sentiment analysis?
The confidence score magnitude doesn't reflect the intensity of the sentiment. The score is based on the confidence of the model for a particular sentiment, positive, negative, and neutral.

Does Language spell check or grammar check?
No.

Can aspect-based sentiment analysis identify sarcasm?
No.

Why does key phrase extraction return some words, but not others?
Key phrase extraction considers nouns as candidates for output. Adjectives appearing prior to a noun are also considered as part of the key phrase. Once candidates are initialized, we measure the importance of each candidate with statistical measures and remove non-essential candidates.

Why does language detection return multiple languages for some text, but not others?
There are some cases where there is more than one dominant language in the input text, which causes the prediction to result in multiple languages with a confidence score for each.

Is the Language service GDPR compliant?
We don't have visibility into customer data and don't store any customer data in our service. The customer team is responsible for any customer data privacy guidelines.

How many entities does Named Entity Recognition (NER) support?
The service supports 18 entities.

How can contact Oracle for assistance, provide feedback, or report issues with Language service?
You can email us at oci_ai_language_preview_in_grp@oracle.com, or contact us at Cloud Customer Connect. We monitor both regularly.

Data

Does Oracle look at or use the text that I input to the service?
No, Oracle does not use any of your content for any purpose except to provide you with the results in the service.

Does Oracle use my data for improving the service?
No, Oracle does not use the content you input to train and improve any AI services.

Is the text I send to the Language API, the results, or other information about the request itself be stored on Oracle servers?
When you send text to the Language API, it is processed in memory and no customer data is stored. Oracle temporarily logs some metadata about your API requests (like the time and size of the request) to improve the service for billing and metering, and to combat abuse.
API

What is the maximum size and number of requests I can make to the API?
Requests have a 1,000 characters limit and five concurrent requests per tenant. Exceeding these limits results in a 400 API request error.

My use case requires extra size or number of requests than the limit, what can I do?
We need to understand your use case to help you so contact us.

Is it possible to make a high volume call to Language API?
Yes, we need to understand your use case to help you so contact us.

What latencies can I expect from the Language service?
Latency is the amount of time it takes from when a request is made to the time it takes for the response to be returned. The Language service has a maximum latency of 500 milliseconds for every Language API request.

Is it possible to run the Language API in a batch processing mode for a large number of documents?
No, it isn't.

Is it possible to extract additional entities with NER API calls?
No, it isn't.
Chapter 29

Load Balancing

This chapter explains how to set up a load balancer.

Overview of Load Balancing

The Oracle Cloud Infrastructure Load Balancing service provides automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). The service offers a load balancer with your choice of a public or private IP address, and provisioned bandwidth.

A load balancer improves resource utilization, facilitates scaling, and helps ensure high availability. You can configure multiple load balancing policies and application-specific health checks to ensure that the load balancer directs traffic only to healthy instances. The load balancer can reduce your maintenance window by draining traffic from an unhealthy application server before you remove it from service for maintenance.

Load Balancer Types

Learn about the types of load balancers you can create within your VCN.

The Load Balancing service enables you to create a public or private load balancer within your VCN. A public load balancer has a public IP address that is accessible from the internet. A private load balancer has an IP address from the hosting subnet, which is visible only within your VCN. You can configure multiple listeners for an IP address to load balance transport Layer 4 and Layer 7 (TCP and HTTP) traffic. Both public and private load balancers can route data traffic to any backend server that is reachable from the VCN.

The Load Balancing service does not support multiple listeners on same IP and port combination. You can use a single listener for multiple hostnames when combined with a Route Policy.

Public Load Balancers

To accept traffic from the internet, you create a public load balancer. The service assigns it a public IP address that serves as the entry point for incoming traffic. You can associate the public IP address with a friendly DNS name through any DNS vendor.

A public load balancer is regional in scope. If your region includes multiple availability domains, a public load balancer requires either a regional subnet (recommended) or two availability domain-specific (AD-specific) subnets, each in a separate availability domain. With a regional subnet, the Load Balancing service creates a primary load balancer and a standby load balancer, each in a different availability domain, to ensure accessibility even during an availability domain outage. If you create a load balancer in two AD-specific subnets, one subnet hosts the primary load balancer and the other hosts a standby load balancer. If the primary load balancer fails, the public IP address switches to the secondary load balancer. The service treats the two load balancers as equivalent and you cannot specify which one is "primary."

Whether you use regional or AD-specific subnets, each load balancer requires one private IP address from its host subnet. The Load Balancing service supplies a floating public IP address to the primary load balancer. The floating public IP address does not come from your backend subnets.

If your region includes only one availability domain, the service requires just one subnet, either regional or AD-specific, to host both the primary and standby load balancers. The primary and standby load balancers each require...
a private IP address from the host subnet, in addition to the assigned floating public IP address. If an availability
domain outage occurs, the load balancer has no failover.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot specify a private subnet for your public load balancer.</td>
</tr>
</tbody>
</table>

**Private Load Balancers**

To isolate your load balancer from the internet and simplify your security posture, you can create a private load
balancer. The Load Balancing service assigns it a private IP address that serves as the entry point for incoming traffic.

When you create a private load balancer, the service requires only one subnet to host both the primary and standby
load balancers. The load balancer can be regional or AD-specific, depending on the scope of the host subnet. The load
balancer is accessible only from within the VCN that contains the host subnet, or as further restricted by your security
rules.

The assigned floating private IP address is local to the host subnet. The primary and standby load balancers each
requires an extra private IP address from the host subnet.

If an availability domain outage occurs, a private load balancer created in a regional subnet within a multi-AD region
provides failover capability. A private load balancer created in an AD-specific subnet, or in a regional subnet within a
single availability domain region, has no failover capability in response to an availability domain outage.

**All Load Balancers**

Your load balancer has a backend set to route incoming traffic to your Compute instances. The backend set is a
logical entity that includes:

- A list of backend servers.
- A load balancing policy.
- A health check policy.
- Optional SSL handling.
- Optional session persistence configuration.

The backend servers (Compute instances) associated with a backend set can exist anywhere, as long as the associated
network security groups (NSGs), security lists, and route tables allow the intended traffic flow.

If your VCN uses network security groups (NSGs), you can associate your load balancer with an NSG. An NSG has a
set of security rules that controls allowed types of inbound and outbound traffic. The rules apply only to the resources
in the group. Contrast NSGs with a security list, where the rules apply to all the resources in any subnet that uses the
list. For more information about NSGs, see [Network Security Groups](#) on page 3718.

If you prefer to use security lists for your VCN, the Load Balancing service can suggest appropriate security list rules.
You also can configure them yourself through the Networking service. See [Security Lists](#) on page 3727 for more
information.

See [Security Rules](#) on page 3710 for detailed information comparing NSGs and security lists.

Oracle recommends that you create your load balancer in a regional subnet.

Oracle recommends that you distribute your backend servers across all availability domains within the region.

To create a minimal system with a functioning load balancer, you must:

- For a public load balancer, create a VCN with an internet gateway and a public regional subnet.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot specify a private subnet for your public load balancer.</td>
</tr>
</tbody>
</table>

- For a private load balancer, create a VCN with at least one private subnet.
- Create at least two Compute instances, each in a separate availability domain.
- Create a load balancer.
• Create a backend set with a health check policy.
• Add backend servers (Compute instances) to the backend set.
• Create a listener, with optional SSL handling.
• Update the load balancer subnet security rules so they allow the intended traffic.

**Private IP Address Consumption**

A public load balancer created in one public subnet consumes two private IP addresses from the host subnet.

A public load balancer created in two public subnets consumes two private IP addresses, one from each host subnet.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet.

The following diagram provides a high-level view of a simple public load balancing system configuration. Far more sophisticated and complex configurations are common.

**Load Balancing Concepts**

Learn about Load Balancer concepts to better understand and use the feature.
The following concepts are essential to working with Load Balancing.

**BACKEND SERVER**

An application server responsible for generating content in reply to the incoming TCP or HTTP traffic. You typically identify application servers with a unique combination of overlay (private) IPv4 address and port, for example, 10.10.10.1:8080 and 10.10.10.2:8080.

See Backend Server Management on page 3242 for more information.

**BACKEND SET**

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy. SSL configuration is optional. The backend set determines how the load balancer directs traffic to the collection of backend servers.

See Backend Set Management on page 3228 for more information.

**CERTIFICATES**

If you use HTTPS or SSL for your listener, you must associate an SSL server certificate (X.509) with your load balancer. A certificate enables the load balancer to terminate the connection and decrypt incoming requests before passing them to the backend servers.

See SSL Certificate Management on page 3308 for more information.

**health check**

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

See Health Check Management on page 3236 for more information.

**HEALTH STATUS**

An indicator that reports the general health of your load balancers and their components.

See Health Check Management on page 3236 for more information.

**HOSTNAME**

A virtual server name applied to a listener to enhance request routing.

See Hostname Management on page 3283 for more information.

**LISTENER**

A logical entity that checks for incoming traffic on the load balancer's IP address. You configure a listener's protocol and port number, and the optional SSL settings. To handle TCP, HTTP, and HTTPS traffic, you must configure multiple listeners.

Supported protocols include:

- TCP
- HTTP/1.0
Load Balancing

- HTTP/1.1
  See Listener Management on page 3250 for more information.

LOAD BALANCING POLICY
A load balancing policy tells the load balancer how to distribute incoming traffic to the backend servers.
Common load balancer policies include:
- Round robin
- Least connections
- IP hash
  See Load Balancing Policies on page 3199 for more information.

PATH ROUTE SET
A set of path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.
See Request Routing Management on page 3268 for more information.

REGIONS AND availability domains
The Load Balancing service manages application traffic across availability domains within a region. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of several availability domains.
See Regions and Availability Domains on page 208 for more information.

SESSION PERSISTENCE
A method to direct all requests originating from a single logical client to a single backend web server.
See Session Persistence on page 3202 for more information.

shape
A template that determines the load balancer's total pre-provisioned maximum capacity (bandwidth) for ingress plus egress traffic. Available shapes include 10 Mbps, 100 Mbps, 400 Mbps, and 8000 Mbps.
The 10 Mbps shape is Always Free eligible. For more information about Always Free resources, including other capabilities and limitations, see Oracle Cloud Infrastructure Free Tier on page 166.

Note:
Pre-provisioned maximum capacity applies to aggregated connections, not to a single client attempting to use the full bandwidth.

SSL
Secure Sockets Layer (SSL) is a security technology for establishing an encrypted link between a client and a server. You can apply the following SSL configurations to your load balancer:

SSL TERMINATION
The load balancer handles incoming SSL traffic and passes the unencrypted request to a backend server.

POINT-TO-POINT SSL
The load balancer terminates the SSL connection with an incoming traffic client, and then initiates an SSL connection to a backend server.

SSL TUNNELING
If you configure the load balancer's listener for TCP traffic, the load balancer tunnels incoming SSL connections to your application servers.
Load Balancing supports the TLS 1.2 protocol with a default setting of strong cipher strength. The default supported ciphers include:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

See SSL Certificate Management on page 3308 for more information.

**subnet**

A subdivision you define in a virtual cloud network (VCN), such as 10.0.0.0/24 and 10.0.1.0/24. A subnet can span a region or exist within a single availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing and security rules that apply to it.

See VCNs and Subnets on page 3693 and Public IP Address Ranges on page 3611 for more information on subnets.

**TAGS**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

**VIRTUAL CLOUD NETWORK (VCN)**

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice in the allowed IP address ranges.

You need at least one virtual cloud network before you launch a load balancer.

For information about setting up virtual cloud networks, see Networking Overview on page 3604.

**VISIBILITY**

Specifies whether your load balancer is public or private.

**PUBLIC**

A public load balancer has a public IP address that clients can access from the internet.

**PRIVATE**

A private load balancer has a private IP address from a VCN local subnet. Clients can access the private load balancer using methods and technology that can provide access to a private IP, such as:

- Cross-VCN (through LPG peering)
- From another region (through RPC)
- From on-prem (through FC private peering)
For more information, see Load Balancer Management on page 3206.

WORK REQUEST
An object that reports on the current state of a Load Balancing request. The Load Balancing service handles requests asynchronously. Each request returns a work request ID (OCID) as the response. You can view the work request item to see the status of the request. For more information, see Work Request Management on page 3317.

Resource Identifiers
Learn about how Load Balancer resources use resource identifiers.

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure
Learn the different ways you can access Oracle Cloud Infrastructure.

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 5528.

Monitoring Resources
Learn how to monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications.

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For information about monitoring the traffic passing through your load balancer, see Load Balancing Metrics on page 3326.

Authentication and Authorization
Learn how the Load Balancing service uses authentication and authorization to manage access to its features and functionality.

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.
Limits on Load Balancing Resources

Learn about the limits on Load Balancer resources.

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- You cannot convert an AD-specific load balancer to a regional load balancer or the reverse.
- The Load Balancing service supports IPv6 addresses for load balancers in the US Government Cloud only. IPv6 support is only for the load balancer itself, and not the backend.
- The maximum number of concurrent connections is limited when you use stateful security rules for your load balancer subnets. In contrast, no theoretical limit on concurrent connections exists if you use stateless security rules. The practical limitations depend on various factors. The larger your load balancer shape, the greater the connection capacity. Other considerations include system memory, TCP timeout periods, TCP connection state, and so forth.

Tip:
To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

- Each load balancer has the following configuration limits:
  - One IP address
  - 16 backend sets
  - 512 backend servers per backend set
  - 512 backend servers total
  - 16 listeners

Required IAM Policies

Learn about Identify and Access Management policies and how they apply to the Load Balancing service.

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers on page 2807.

Also, be aware that a policy statement with inspect load-balancers gives the specified group the ability to see all information about the load balancers. For more information, see Details for Load Balancing on page 2983.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Load Balancing Policies

Learn how you can apply Load Balancer resource policies to control traffic distribution to your backend servers.

After you create a load balancer, you can apply policies to control traffic distribution to your backend servers. The Load Balancing service supports three primary policy types:

- Round Robin
- Least Connections
- IP Hash

When processing load or capacity varies among backend servers, you can refine each of these policy types with backend server weighting. Weighting affects the proportion of requests directed to each server. For example, a server weighted '3' receives three times the number of connections as a server weighted '1.' You assign weights based on criteria of your choosing, such as each server's traffic-handling capacity.
Load balancer policy decisions apply differently to TCP load balancers, cookie-based session persistent HTTP requests (sticky requests), and non-sticky HTTP requests.

- A TCP load balancer considers policy and weight criteria to direct an initial incoming request to a backend server. All subsequent packets on this connection go to the same endpoint.
- An HTTP load balancer configured to handle cookie-based session persistence forwards requests to the backend server specified by the cookie's session information.
- For non-sticky HTTP requests, the load balancer applies policy and weight criteria to every incoming request and determines an appropriate backend server. Multiple requests from the same client could be directed to different servers.

**Note:**

If you want to create a load Balancer with a reserve IP, add this policy:

```
Allow group group_name to manage floating-ips in tenancy
```

See [Managing Policies](#) on page 3144 for general information on policies.

**Round Robin**

Round Robin is the default load balancer policy. This policy distributes incoming traffic sequentially to each server in a backend set list. After each server has received a connection, the load balancer repeats the list in the same order.

Round Robin is a simple load balancing algorithm. It works best when all the backend servers have similar capacity and the processing load required by each request does not vary significantly.

**Least Connections**

The Least Connections policy routes incoming non-sticky request traffic to the backend server with the fewest active connections. This policy helps you maintain an equal distribution of active connections with backend servers. As with the round robin policy, you can assign a weight to each backend server and further control traffic distribution.

**Note:**

In TCP use cases, a connection can be active but have no current traffic. Such connections do not serve as a good load metric.

**IP Hash**

The IP Hash policy uses an incoming request's source IP address as a hashing key to route non-sticky traffic to the same backend server. The load balancer routes requests from the same client to the same backend server as long as that server is available. This policy honors server weight settings when establishing the initial connection.

IP Hash ensures that requests from a particular client are always directed to the same backend server, as long as the backend server is available.

You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

**Important:**

Multiple clients that connect to the load balancer through a proxy or NAT router appear to have the same IP address. If you apply the IP Hash policy to your backend set, the load balancer routes traffic based on the incoming IP address and sends these proxied client requests to the same backend server. If the proxied client pool is large, the requests could flood a backend server.

**HTTP "X-" Headers and Host Header**

Learn about using HTTP "X" headers in a Load Balancer resource.
HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with X-, are common. The Load Balancing service adds or modifies the Host header and the following X- headers when it passes requests to your servers. Because these headers are automatically added, they cannot be removed or modified using a rule set.

### X-Forwarded-For

Provides a list of connection IP addresses.

The load balancer appends the last remote peer address to the X-Forwarded-For field from the incoming request. A comma and space precede the appended address. If the client request header does not include an X-Forwarded-For field, this value is equal to the X-Real-IP value. The original requesting client is the first (left-most) IP address in the list, assuming that the incoming field content is trustworthy. The last address is the last (most recent) peer, that is, the machine from which the load balancer received the request. The format is:

```
X-Forwarded-For: original_client, proxy1, proxy2
```

Example incoming field:

```
X-Forwarded-For: 202.1.112.187
```

Example field with appended proxy IP address:

```
X-Forwarded-For: 202.1.112.187, 192.168.0.10
```

### X-Forwarded-Host

Identifies the original host and port requested by the client in the Host HTTP request header. This header helps you determine the original host, since the hostname or port of the reverse proxy (load balancer) might differ from the original server handling the request.

```
X-Forwarded-Host: www.oracle.com:8080
```

### X-Forwarded-Port

Identifies the listener port number that the client used to connect to the load balancer. For example:

```
X-Forwarded-Port: 443
```

### X-Forwarded-Proto

Identifies the protocol that the client used to connect to the load balancer, either http or https. For example:

```
X-Forwarded-Proto: https
```

### X-Real-IP

Identifies the client's IP address. For the Load Balancing service, the "client" is the last remote peer.

Your load balancer intercepts traffic between the client and your server. Your server's access logs, therefore, include only the load balancer's IP address. The X-Real-IP header provides the client's IP address. For example:

```
X-Real-IP: 192.168.0.10
```
Host

Identifies the original host and optionally the port requested by the client in the Host HTTP request header. For example:

```
Host: www.oracle.com
```

Session Persistence

Learn about using session persistence with a Load Balancer resource to direct all requests originating from a single logical client to a single backend web server.

Session persistence is a method to direct all requests originating from a single logical client to a single backend web server. Backend servers that use caching to improve performance, or to enable log-in sessions or shopping carts, can benefit from session persistence.

You enable session persistence when you create a load balancer or when you create a backend set. You can also edit an existing backend set to enable, disable, or change the session persistence configuration.

Sticky Cookies

Learn about how to use the sticky cookies feature in a Load Balancer resource to manage session persistence.

The Load Balancing service offers two mutually exclusive cookie-based configurations for enabling session persistence:

- Application cookie stickiness
- Load balancer cookie stickiness

**Note:**

IP Address-driven Session Persistence

Some products offer session persistence support without cookies. These products depend on the IP address of the incoming request. ISP proxies and company exit gateways can issue many requests from a single IP address. In this case, a single backend server can be subject to high traffic volumes. Your backend fleet can become overwhelmed, one server at a time, even though effective load balancing is possible.

Another weakness of IP address-driven session persistence is that the originating IP address can change. In this case, session persistence can be lost or the request redirected to the wrong backend server.

Application Cookie Stickiness

To configure application cookie session persistence, you specify a cookie name and decide whether to disable fallback for unavailable servers.

The Load Balancing service activates application cookie session persistence (stickiness) when a backend server sends a Set-Cookie response header containing a recognized cookie name. The cookie name must match the name specified in the backend set configuration. If the configuration specifies a match-all pattern, `*`, any cookie set by the server activates session persistence. Unless a backend server activates session persistence, the service follows the load balancing policy specified when you created the load balancer.

Requirements:

- Your load balancer must operate in HTTP mode to support server side, cookie-driven session persistence.
- The client computer must accept cookies for Load Balancing session persistence feature to work.
Load Balancing

**How It Works**

The Load Balancing service calculates a hash of the configured cookie and other request parameters, and sends that value to the client in a cookie. The value stored in the cookie enables the service to route subsequent client requests to the correct backend server. If your backend servers change any of the defined cookies, the service recomputes the cookie's value and resends it to the client.

**Note:**

Oracle recommends that you treat cookie data as an opaque entity. Do not use it in your applications.

The backend server can stop application cookie persistence by deleting the session persistence cookie. If you used the match-all pattern, it must delete all cookies. You can delete cookies by sending a `Set-Cookie` response header with a past expiration date. The Load Balancing service routes subsequent requests using the configured load balancing policy.

**Load Balancer Cookie Stickiness**

When you configure load balancer cookie stickiness, the load balancer inserts a cookie into the response. The parameters configured within the cookie enable session stickiness. This method is useful when you have applications and web backend services that cannot generate their own cookies.

To configure load balancer cookie session persistence, you specify:

- *The cookie name.*

  If you do not specify a cookie name, the default name is `X-Oracle-BMC-LBS-Route`.

  **Note:**

  Ensure that the cookie name used at the backend application servers is different from the cookie name used at the load balancer. To minimize the chance of name collision, Oracle recommends that you use a prefix such as `X-Oracle-OCI-`.

  If both a backend server and the load balancer insert cookies with the same name, the client or browser behavior can vary depending on the domain value associated with the cookie. If the name and domain values of the `Set-cookie` header (generated by a backend server) and the `Set-cookie` header (generated by the load balancer) are the same, the client or browser treats them as one cookie. The client returns only one of the cookie values in subsequent requests. If both `Set-cookie` names are the same, but the domain names are different, the client or browser treats them as two different cookies.

  **The domain in which the cookie is valid.** The `Set-cookie` header inserted by the load balancer contains a domain attribute with the specified value.

  This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.

  **Note:**

  - [RFC 6265 - HTTP State Management Mechanism](https://tools.ietf.org/html/rfc6265) describes client and browser behavior when the domain attribute is present or not present in the `Set-cookie` header.

  If the value of the Domain attribute is `example.com` in the `Set-cookie` header, the client includes the same cookie in the `Cookie` header when making HTTP requests to `example.com`, `www.example.com`, and `www.abc.example.com`. If the
Domain attribute is not present, the client returns the cookie only for the domain to which the original request was made.

- Ensure that this attribute specifies the correct domain value. If the Domain attribute in the Set-cookie header does not include the domain to which the original request was made, the client or browser might reject the cookie. As specified in RFC 6265, the client accepts a cookie with the Domain attribute value example.com or www.example.com sent from www.example.com. It does not accept a cookie with the Domain attribute abc.example.com or www.abc.example.com sent from www.example.com.

- The URI path in which the cookie is valid. The Set-cookie header inserted by the load balancer contains a Path attribute with the specified value.

Clients include the cookie in an HTTP request only if the path portion of the request-uri matches, or is a subdirectory of, the cookie's Path attribute.

The default value is `/`.

- The amount of time the cookie remains valid. The Set-cookie header inserted by the load balancer contains a Max-Age attribute with the specified value.

The specified value must be at least one second. No default value for this attribute exists. If you do not specify a value, the load balancer does not include the Max-Age attribute in the Set-cookie header. Usually, the client or browser retains the cookie until the current session ends, as defined by the client.

- Whether the Set-cookie header should contain the Secure attribute. The Secure attribute directs the client or browser to send the cookie only using a secure protocol.

  **Note:**
  
  If you set this field to true, you cannot associate the corresponding backend set with an HTTP listener.

- Whether the Set-cookie header should contain the HttpOnly attribute. The HttpOnly attribute limits the scope of the cookie to HTTP requests. This attribute directs the client or browser to omit the cookie when providing access to cookies through non-HTTP APIs. For example, it restricts the cookie from JavaScript channels.

- Whether to disable fallback for unavailable servers.

  **Note:**
  
  Path route rules take precedence to determine the target backend server. The load balancer verifies that session stickiness is enabled for the backend server and that the cookie configuration is valid for the target. The system ignores invalid cookies.

**Fallback**

Learn about using the fallback feature in a Load Balancer resource.

By default, the Load Balancing service directs traffic from a persistent session client to a different backend server when the original server is unavailable. You can configure the backend set to disable this fallback behavior. When you disable fallback, the load balancer fails the request and returns an HTTP 502 code. The service continues to return an HTTP 502 until the client no longer presents a persistent session cookie.

  **Important:**
  
  If fallback is disabled, cookies with a distant future expiration date can cause a client outage.

The Load Balancing service considers a server marked drain available for existing persisted sessions. New requests that are not part of an existing persisted session are not sent to that server.
Connection Management

Learn how to configure the timeout settings for your Load Balancer resource.

Oracle Cloud Infrastructure load balancers support connection multiplexing. The load balancer can route many incoming requests from multiple clients to the destination backend server through a few (one or multiple) backend connections.

After your load balancer connects a client to a backend server, the connection can be closed because of inactivity. Also, you can configure load balancer listeners to control the maximum idle time allowed during each TCP connection or HTTP request and response pair. Oracle recommends that you do not allow your backend servers to close connections to the load balancer.

The following timeout settings affect your load balancer's behavior:

- **Keep-alive setting between the load balancer and the client**
  The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first.

  **Note:**
  You cannot change the value of this setting.

- **Keep-alive setting between the load balancer and backend server**
  The load balancer closes backend server connections that are idle for more than 300 seconds. See Keep-Alive Settings on page 3205 for more information.

- **Idle timeout**
  You can set the duration of the idle timeout when you create a listener. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase. See Idle Timeout Settings on page 3205 for more information.

Keep-Alive Settings

Learn how the Load Balancer resource sets the keep-alive value to maintain a connection with backend servers.

The Load Balancing service does not honor keep-alive settings from backend servers. The load balancer closes backend server connections that are idle for more than 300 seconds. Oracle recommends that you do not allow your backend servers to close connections to the load balancer. To prevent possible 502 errors, ensure that your backend servers do not close idle connections in less than 310 seconds.

The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first.

Idle Timeout Settings

Learn about how to configure idle timeout settings for a Load Balancer resource.

When you create a TCP or HTTP listener, you can specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase. If the configured timeout has elapsed with no packets sent or received, the client's connection is closed. For HTTP and WebSocket connections, a send operation does not reset the timer for receive operations and a receive operation does not reset the timer for send operations.

  **Note:**
  This timeout setting does not apply to idle time between a completed response and a subsequent HTTP request.

The default timeout values are:

- 300 seconds for TCP listeners.
- 60 seconds for HTTP listeners.
Modify the timeout parameter if either the client or the backend server requires more time to transmit data. Some examples include:

- The client sends a database query to the backend server and the database takes over 300 seconds to run. Therefore, the backend server does not transmit any data within 300 seconds.
- The client uploads data using the HTTP protocol. During the upload, the backend does not transmit any data to the client for more than 60 seconds.
- The client downloads data using the HTTP protocol. After the initial request, it stops transmitting data to the backend server for more than 60 seconds.
- The client starts transmitting data after establishing a WebSocket connection, but the backend server does not transmit data for more than 60 seconds.
- The backend server starts transmitting data after establishing a WebSocket connection, but the client does not transmit data for more than 60 seconds.

The maximum timeout value is 7200 seconds. Contact My Oracle Support to file a service request if you want to increase this limit for your tenancy. See Service Limits on page 243 for more information.

**Load Balancer Management**

Learn how to create and manage Load Balancer resources to provide automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN).

For the purposes of access control, you must specify the compartment where you want the load balancer to reside. Consult an administrator in your organization if you're not sure which compartment to use. For information about compartments and access control, see Managing Compartments on page 3126.

When you create a load balancer within your VCN, you get a public or private IP address, and provisioned total bandwidth. If you need another IP address, you can create another load balancer.

A public load balancer in a region with multiple availability domains requires one public regional subnet or two public AD-specific subnets to host the primary load balancer and a standby. In the latter case, each AD-specific subnet must reside in a separate availability domain. A public load balancer in a region with only one availability domain requires a single public subnet to host the primary load balancer and a standby. For more information on VCNs and subnets, see Networking Overview on page 3604. You can associate the public IPv4 address with a DNS name from any vendor. You can use the public IP address as a front end for incoming traffic. The load balancer can route data traffic to any backend server that is reachable from the VCN.

A private load balancer requires only one subnet to host the primary load balancer and a standby. The private IP address is local to the subnet. The load balancer is accessible only from within the VCN that contains the associated subnet, or as further restricted by your security list rules. The load balancer can route data traffic to any backend server that is reachable from the VCN.

The essential components for load balancing include:

- A load balancer with pre-provisioned bandwidth.
- A backend set with a health check policy. See Backend Set Management on page 3228 for more information.

- Backend servers for your backend set. See Backend Server Management on page 3242 for more information.
- One or more listeners. See Listener Management on page 3250 for more information.
- Load balancer subnet security rules to allow the intended traffic. To learn more about these rules, see Security Rules on page 3710.

**Note:**

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets. See Stateful Versus Stateless Rules on page 3716 for more information.

Optionally, you can associate your listeners with SSL server certificate bundles to manage how your system handles SSL traffic. See SSL Certificate Management on page 3308 for more information.
For information about the number of load balancers you can have, see Service Limits on page 243.

**Prerequisites**

To implement a working load balancer, you need:

- For a public load balancer in a region with multiple availability domains, you need a VCN with a public regional subnet or at least two public AD-specific subnets. In the latter case, each AD-specific subnet must reside in a separate availability domain. For more information on subnets, See VCNs and Subnets on page 3693 and Public IP Address Ranges on page 3611.

  **Note:**
  You cannot specify a private subnet for your public load balancer.

- For a public load balancer in a region with only one availability domain, you need a VCN with at least one public subnet.

- For a private load balancer in any region, you need a VCN with at least one private subnet.

- Two or more backend servers (Compute instances) running your applications. For more information on Compute instances, see Creating an Instance on page 1023.

**Private IP Address Consumption**

A public load balancer created in one public regional subnet consumes two private IPv4 addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IPv4 address from that subnet. The Load Balancing service assigns a floating public IPv4 address, which does not come from the host subnet. If the load balancer is enabled for IPv6, it receives an IPv6 address from the host subnet.

A public load balancer created in two public AD-specific subnets consumes two private IP addresses, one from each host subnet. The primary and secondary load balancers reside within different subnets. Each load balancer requires one private IP address from its host subnet. The Load Balancing service assigns a floating public IPv4 address, which does not come from the host subnets. If the load balancer is enabled for IPv6, it is assigned an IPv6 address from the host subnet.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IP address from that subnet. The floating private IP address also comes from the host subnet. Internet communication with a load balancer enabled for IPv6 and created in a private subnet is prohibited. You can't create a globally routable IPv6-enabled load balancer in a private subnet.

**Configuration Changes and Service Disruption**

For a running load balancer, some configuration changes lead to service disruptions. The following guidelines help you understand the effect of changes to your load balancer.

- Operations that add, remove, or modify a backend server create no disruptions to the Load Balancing service.

- Operations that edit an existing health check policy create no disruptions to the Load Balancing service.

- Operations that trigger a load balancer reconfiguration can produce a brief service disruption with the possibility of some terminated connections.

**Creating Load Balancers**

Create a Load Balancer resource.

Use one of the following methods to create a load balancer.

**To create a load balancer using the Console**

Use the OCI Console to create a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Choose a **Compartment** you have permission to work in under **List Scope**.

   **Note:**
   
   If you select a different compartment in the Management tab (under Advanced Options), that compartment contains the load balancer you are creating instead of the compartment specified here.

3. Click **Create Load Balancer**.

4. Select **Load Balancer** and click **Create Load Balancer**.

   The Create Load Balancer dialog box appears. Creating a load balancer consists of the following sections:
   
   - **Add Details**
   - **Choose Backends**
   - **Configure Listener**
   - **Manage Logging**

   By default, the **Add Details** page appears first.

5. Run each of the following workflows in order. You can return to a previous page by clicking **Previous**.

   **Step 1 - Add Details**

   Specify the attributes of the load balancer.

   - **Load Balancer Name**: Required. Accept the default name or specify a friendly name for the load balancer. It does not have to be unique, but it cannot be changed in the Console. You can, however, change it with the API.
   - **Choose Visibility Type**: Specify whether your load balancer is public or private.
     - **Public**: Choose this option to create a public load balancer. You can use the assigned public IP address as a front end for incoming traffic and to balance that traffic across all backend servers.
     - **Private**: Choose this option to create a private load balancer. You can use the assigned private IP address as a front end for incoming internal VCN traffic and to balance that traffic across all backend servers.
   - **Choose IP Address Type**: Specify whether the public IP address is reserved or ephemeral.
     - **Ephemeral IP Address**: Choose this option to let Oracle specify an ephemeral IP address for you from the Oracle IP pool. This is the default.
     - **Reserved IP Address**: Choose this option to specify an existing reserved IP address by name, or to create a new reserved IP address by assigning a name and selecting a source IP pool for the address. If you don't select a user-created pool, the default Oracle IP pool is used.

   See [Public IP Addresses](#) on page 3753 for more information.
   - **Bandwidth**: The Bandwidth shape options are the following:
     - **Flexible Shapes**: Specify **Minimum Bandwidth** and **Maximum Bandwidth** values to create an upper and lower size range for the load balancer's bandwidth shape. Possible sizes range from 10 Mbps to 8,000 Mbps. You can use the slider to specify the value or enter it directly into the box to the left of each slider.

       The *minimum bandwidth* reflects the amount of bandwidth that is always available to provide instant readiness for the workloads.

       The *maximum bandwidth* is the upper amount of bandwidth the load balancer supports during time of peak workload.

       If you want to specify a fixed shape size, for example 500 Mbps, set the minimum and maximum sliders to the same value.

       If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created.

       You can view your service limits and quotas in the Console by navigating to **Governance > Limits**,
**Quotas and Usage.** Select "LbaaS" from the **Service** list. Your bandwidth size options are listed. See **Service Limits** on page 243 for more information.

Billing is per minute for your load balancer base instance, plus a bandwidth usage fee. If the actual usage is below or equal to your specified minimum bandwidth, you are billed for the minimum bandwidth. If actual usage exceeds the minimum bandwidth, you are billed for the actual bandwidth used for that minute.

The Always Free option is incorporated into your paid account in your home region. The first 10 Mbps of your bandwidth is free, and is indicated as such on your bill.

**Note:**

Government accounts using pre-paid dynamic (fixed) shape sizes run the risk of overage charges when flexible bandwidth shapes exceed the predetermined size. Update government accounts to the flexible load balancer SKU, with the appropriate bandwidth quantity, in their contract before using the flexible load balancer feature.

If you are using non-universal credit SKUs, ensure that your contract includes the shape you are updating to so you can prevent incurring overage charges.

- **Always Free:** If you are creating the load balancer as an Always Free user, you can only select the Always Free (10 Mbps) option. Switching away from Always Free prompts you to upgrade to a paid account.

Always Free shape options are not available to Government accounts.

**Note:**

If you are creating a load balancer in an Always Free tenancy, the Always Free feature is enabled by default, and only Always Free shape options are available. Upgrading is the only way an Always Free tenancy can select a bandwidth shape option other than the default Always Free size. For more information about Always Free resources, including other capabilities and limitations, see **Oracle Cloud Infrastructure Free Tier** on page 166.

You can adjust the bandwidth shape to a different size after you have completed creating the load balancer. See **Changing the Load Balancer Bandwidth Shape** on page 3222: for more information.

- **Enable IPv6 Address Assignment** Available only in the US Government Cloud. Specify whether the load balancer supports IPv6 addresses for incoming requests.

**Note:**

- When you create a load balancer, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. The load balancer and the backend servers do not use IPv6 communication.
- IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.
- **Only VCNs in the US Government Cloud currently support IPv6 addressing.** For more information about Oracle Cloud
• **Choose Networking**

  If the current compartment contains at least one VCN, the Console provides a list of VCNs for you to choose from.

  - **Virtual Cloud Network in <compartment>**: Required. Specify a VCN for the load balancer.

    By default, the Console shows a list of VCNs in the compartment you’re currently working in. Click the Change Compartment link to select a VCN from a different compartment.

  - **Subnet in <compartment>**: Required. Select an available subnet. For a public load balancer, it must be a public subnet.

    By default, the Console shows a list of subnets in the compartment you’re currently working in. Click the Change Compartment link to select a subnet from a different compartment.

    **Note:**

    In addition to *public* or *private*, subnets can be either *regional* or *AD-specific*. Oracle recommends using regional subnets. For more information, see Overview of VCNs and Subnets on page 3694.

• **Subnet (2 of 2) in <compartment>**: Required for a public load balancer when you specify an AD-specific subnet for **Subnet**. Select a second public subnet. The second subnet must reside in a separate availability domain from the first subnet.

    **Note:**

    - If you chose to create a private load balancer under **Visibility Type**, the form prompts you to select only one subnet.
If you are working in a region that includes only one availability domain, a second subnet is not required. The form prompts you to select only one subnet.

If the current compartment contains no virtual cloud networks, the Load Balancing service offers to create a VCN for you.

- **Virtual Cloud Network in <compartment>**: When the current compartment contains no virtual cloud networks, the list is disabled. The system offers to create a VCN for you.

  If you want to use an existing VCN in another compartment, click the Change Compartment link and choose that compartment from the list.

  **Virtual Cloud Network Name**: Optional, when the system creates a VCN for you. Specify a friendly name for the new cloud network. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

  If you do not specify a name for the new VCN, the system generates a name for you.

- **Use Network Security Groups to Control Traffic**: Check this box if you want to add your load balancer to a network security group (NSG). For more information about NSGs, see Network Security Groups on page 3718.

  **Network Security Groups in <compartment>**: Choose an NSG to add your load balancer to.

    By default, the Console shows a list of NSGs in the compartment you’re currently working in. Click the Change Compartment link to select an NSG from a different compartment.

  - (Optional) Click + Another Network Security Group to add your load balancer to another NSG.

Tip:

You can change the NSGs that your load balancer belongs to after you create it. On the Load Balancer Details page, click the Edit link that appears beside the list of associated network security groups.

- **Show Advanced Options**: Click this link to display the following options:

  - **Management**:
    - **Create in Compartment**: Optionally, you can select a different compartment to host the load balancer. The compartment you select here overrides the compartment listed under Scope selected when first creating the load balancer.

  - **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

Note:

The following describes the Dynamic Shapes feature, which is only available to certain legacy customer accounts:

**Dynamic Shapes**: Choose one of the following predefined shape sizes.

- 10 Mbps
- 100 Mbps
- 400 Mbps
- 8,000 Mbps

If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created. You can view your service limits and quotas in the Console by navigating to Governance > Limits, Quotas and Usage. Select "LbaaS" from the
Service list. Your bandwidth size options are listed. See Service Limits on page 243 for more information. You can also select the Always Free option if your one free tier account has not already been used.

You can adjust the bandwidth shape to a different size after you have completed creating the load balancer. See Changing the Load Balancer Bandwidth Shape on page 3222 for more information.

If you adjust a dynamic size value to a flexible size using the sliders, you cannot revert to a dynamic shape of any size. You can achieve the effect of having a dynamic (fixed) size by setting the minimum and maximum sliders to the same size.

Step 2 - Choose Backends

A load balancer distributes traffic to backend servers within a backend set. A backend set is a logical entity defined by a load balancing policy, a list of backend servers (Compute instances), and a health check policy.

The load balancer creation workflow creates one backend set for your load balancer. Optionally, you can add backend sets and backend servers after you create the load balancer.

• Specify a Load Balancing Policy: Required. Choose the load balancer policy for the backend set. The available options are:
  • Weighted Round Robin: This policy distributes incoming traffic sequentially to each server in a backend set list.
  • IP Hash: This policy ensures that requests from a particular client are always directed to the same backend server.
  • Least Connections: This policy routes incoming request traffic to the backend server with the fewest active connections.

For more information on these policies, see Load Balancing Policies on page 3199.

• Select Backend Servers: Optional. Add backend servers to the backend set. Click Add Backends to select resources from a list of available Compute instances.

Important:

When you add backend servers, the Load Balancing service automatically creates security list rules for you. If you prefer to create security list rules manually, click Show Advanced Options and choose the option to Manually configure security list rules after the load balancer is created.

• Add Backends: Select (check) the instances you want to include in the load balancer’s backend set. To select instances from a different compartment, use the Change Compartment link and choose a compartment from the list.

After you select the instances you want to add from the current compartment, click Add Selected Backends.

Tip:

• You can choose instances from one compartment at a time. After you add instances from one compartment, you can choose Add More Backends to add instances from another compartment.
You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

After you add instances to the backend set, they appear in the **Select Backend Servers** table. You can:

- Specify the server **Port** to which the load balancer must direct traffic. The default is port 80.
- Click the **Actions** icon (•) for a server and choose **Delete** to remove it from the backend set.
- **Specify Health Check Policy**: Required. Specify the test parameters that confirm the health of your backend servers.
  - **Protocol**: Required. Specify the protocol to use for health check queries, either HTTP or TCP.
  
  **Important:**
  
  Configure your health check protocol to match your application or service. See **Health Check Management** on page 3236 for more information.

  - **Port**: Optional. Specify the backend server port against which to run the health check.

  **Tip:**

  You can enter the value '0' to have the health check use the backend server's traffic port.

  - **Interval in ms**: Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
  
  - **Timeout in ms**: Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
  
  - **Number of retries**: Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is 3.
  
  - **Status Code**: (HTTP only) Optional. Specify the status code a healthy backend server must return.
  
  - **URL Path (URI)**: (HTTP only) Required. Specify a URL endpoint against which to run the health check.
  
  - **Response Body Regex**: (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.
  
  - **Use SSL**: Optional. Check to apply SSL to the load balancer backend. If you select this option, complete the following:

  **Important:**

  If optimal security is required, it is your responsibility to always use HTTPS for traffic between the load balancer and the backend set.

  - **SSL Certificate**: Select one of these options:

    - **Choose SSL Certificate File**: Drag and drop the certificate file into the **SSL Certificate** field.
      
      Alternatively, click **Select Files** and navigate your system to where you can select the certificate file...
for upload. Certificate files must be in PEM format and must have the .pem, .cer, or .crt file extensions.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.</td>
</tr>
</tbody>
</table>

- **Paste SSL Certificate**: Copy and paste a certificate directly into this field.
- **Specify CA Certificate**: Optional. (Recommended for backend SSL termination configurations.) Check this box if you want to provide a CA certificate. See SSL Certificate Management on page 3308 for more information.
- **Specify Private Key**: Optional. (Required for SSL termination.) Check this box if you want to provide a private key for the certificate.
- **Show Advanced Options**: Click this link to access more options. Select the tab for the corresponding functionality:
  - **Backend Set Name**: Specify a name for the backend set. It must be unique within the load balancer, and it cannot be changed. If you do not specify a name, the Load Balancing service creates one for you.
    
    Use only alphanumeric characters, dashes ("-"), and underscores ("_") for backend set names. Backend set names cannot contain spaces. Avoid entering confidential information.
  - **Security List**: Choose to manually configure subnet security list rules to allow the intended traffic or allow the system to create security list rules for you. To learn more about these rules, see Parts of a Security Rule on page 3714.
    
    - **Manually configure security list rules after the load balancer is created**: When you choose this option, you must configure security list rules after load balancer creation.
    - **Automatically add security list rules**: Default. When you choose this option, the Load Balancing service creates security list rules for you.

    The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet.

    You can choose whether to apply the proposed rules for each affected subnet.
  - **Session Persistence**: Specify how the load balancer manages session persistence.
    
    | Important |
    |-----------|
    | See Session Persistence on page 3202 for important information on configuring these settings. |

    - **Disable Session Persistence**: Choose this option to disable cookie-based session persistence.
    - **Enable Application Cookie Persistence**: Choose this option to enable persistent sessions from a single logical client when the backend application server response includes a Set-cookie header with the cookie name you specify.
      
      - **Cookie Name**: The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.
      - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
    - **Enable Load Balancer Cookie Persistence**: Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
      
      - **Cookie Name**: Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is X-Oracle-BMC-LBS-Route.
        
        Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
      - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
      - **Domain Name**: Optional. Specify the domain in which the cookie is valid.
This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the Set-cookie header.

- **Path**: Optional. Specify the path in which the cookie is valid. The default value is /.
- **Expiration Period in Seconds**: Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

**Attributes**

- **Secure**: Specify whether the Set-cookie header must contain the Secure attribute. If selected, the client sends the cookie only using a secure protocol.
  
  If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.

- **HTTP Only**: Specify whether the Set-cookie header must contain the HttpOnly attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

- **SSL Policy**: Specify the type of cipher suite to use:

  - **TLS Version**: Required. Specify each of the Transport Layer Security (TLS) versions you want:
    
    - 1.0
    - 1.1
    - 1.2 (recommended. Required if using HTTP/2)
  
  You can select any combination of versions.

  - **Specify the Cipher Suite**: Required. Choose one of the following options:
    
    - **Select Cipher Suite**: Select a set of cipher suites from the list. (default).
      
      All cipher suites listed have at least one cipher from each of the TLS versions you selected.
    
    - **Create Custom Cipher Suite**: Add ciphers to a new suite.
      
      Perform the following:
      
      a. Enter the name of the customer cipher suite in the **Suite Name** field.
      
      b. Click **Choose Ciphers**.
        
        The Select Ciphers page appears.
      
      c. Check each cipher that you want to include in the suite.
        
        The TLS versions associated with each cipher are listed in the **Version** column. Ensure that any cipher you choose is compatible with the TLS versions you previously chose.
      
      d. Deselect any ciphers you want to exclude.
        
        e. Click **Select**. Then select that custom cipher suite (or whatever suite you want to use) from the **Select Cipher Suite** list.
      
    - **Click Show Cipher Suite Details** to display the individual ciphers the selected cipher suite contains.

**Step 3 - Configure Listener**

Complete the following:

- **Listener Name**: Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.
  
  If you do not specify a name, the Load Balancing service creates one for you.

- **Specify the type of traffic your listener handles**: Required. Specify the protocol to use. Choices are:
• HTTPS
• HTTP/1.0
• HTTP/1.1
• HTTP/2
• TCP

• Specify the port your listener monitors for ingress traffic: Required. Specify the port. Defaults are:
  • 443 for HTTPS
  • 80 for HTTP/1.0, 1.1
  • 443 for HTTP/2
  • 22 for TCP

• If you chose the HTTPS or HTTP/2 protocols, or if you chose the TCP protocol and selected the Use SSL check box

• Choose SSL Certificate File: Required. Drag and drop the certificate file, in PEM format, into the SSL Certificate field.
  Alternatively, you can choose the Paste SSL Certificate option to paste a certificate directly into this field.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.</td>
</tr>
</tbody>
</table>

• Specify CA Certificate: Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate. See SSL Certificate Management on page 3308 for more information.

• Choose CA Certificate File: Drag and drop the CA certificate file, in PEM format, into the CA Certificate field.
  Alternatively, you can choose the Paste CA Certificate option to paste a certificate directly into this field.

• Specify Private Key: Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.

• Choose Private Key File: Drag and drop the private key, in PEM format, into the Private Key field.
  Alternatively, you can choose the Paste Private Key option to paste a private key directly into this field.

• Enter Private Key Passphrase: Optional. Specify the private key passphrase.

• Use SSL: Required for HTTPS and HTTP/2, optional for TCP, not available for HTTP. Check to apply SSL to the load balancer listener. If you select this option, complete the following:

• SSL Certificate: Select one of these options:

  • Choose SSL Certificate File: Drag and drop the certificate file into the SSL Certificate field.
    Alternatively, click Select Files and navigate your system to where you can select the certificate file
for upload. Certificate files must be in PEM format and must have the .pem, .cer, or .crt file extensions.

**Important:**

If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Paste SSL Certificate**: Copy and paste a certificate directly into this field.
- **Specify CA Certificate**: Optional. (Recommended for backend SSL termination configurations.) Check this box if you want to provide a CA certificate. See SSL Certificate Management on page 3308 for more information.
- **Specify Private Key**: Optional. (Required for SSL termination.) Check this box if you want to provide a private key for the certificate.
- **Show Advanced Options**: Click this link to access more options. Select the tab for the corresponding functionality:
  - **Timeout** tab: Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

  **Note:**

  The maximum value is 7200 seconds. For more information, see Connection Management on page 3205.

- **SSL Policy** tab: Specify the type of cipher suite to use:
  - **TLS Version**: Required. Specify the Transport Layer Security (TLS) versions:
    - 1.0
    - 1.1
    - 1.2 (recommended)

    The HTTP/2 protocol only supports TLS 1.2.

    You can select any combination of versions. Choose the ones you want from the list.

  - **Specify the Cipher Suite**: Required. Choose one of the following options:
    - **Select Cipher Suite**: Select a predefined set of cipher suites. (default).

      Pick a choice from the Select Cipher Suite list. All cipher suites listed have at least one cipher from each of the TLS versions you selected.

      The HTTP/2 protocol only supports a default cipher. You cannot change it.

    - **Create Custom Cipher Suite**: Add ciphers to a new suite.

      Perform the following:

      a. Enter the name of the customer cipher suite in the **Suite Name** field.
      b. Click **Choose Ciphers**.

      The Select Ciphers page appears.
      c. Check each cipher that you want to include in the suite.

      The TLS versions associated with each cipher are listed in the **Version** column. Ensure that any cipher you choose is compatible with the TLS versions you previously chose.
      d. Deselect any ciphers you want to exclude.

  **Note:**

  Assign at least one cipher to a cipher suite you create. You cannot create a cipher suite that contains no ciphers.
e. Click Select. Then select that custom cipher suite (or whatever suite you want to use) from the Select Cipher Suite list.
   • Click Show Cipher Suite Details to display what ciphers the selected cipher suite contains.
   • Server Order Preference: Select Enable to give preference to the server ciphers over the client.

Step 4 - Manage Logging

Enabling error and access logs are optional, but recommended. Reviewing these logs can help you with diagnosing and fixing issues with your backend servers. Standard limits, restrictions, and rates apply when enabling the logging feature. See Log Management on page 3320 for general information on how the Load Balancing service uses logging.

• Error Logs: Optional. Enter the following:
  • Compartment: Select the compartment within which the log file resides from the list.
  • Log Group: Select an existing log group from the list or click Create New Group where you can enter the name and description of a new logging group within which your log resides.
  • Log Name: Enter the name of the log.
  • Log Retention: Select the time period in months each error logging entry is to be retained from the list.

See Managing Logs and Log Groups on page 3350 for more information on log and log groups, including naming syntax guidelines.

Note:

By default, error logging is enabled. Disable this feature if you do not want to pay the associated fees.

• Access Logs: Optional. Slide to enable feature. Enter the following:
  • Compartment: Select the compartment within which the log file resides from the list.
  • Log Group: Select an existing log group from the list or click Create New Group where you can enter the name and description of a new logging group within which your log resides.
  • Log Name: Enter the name of the log.
  • Log Retention: Select the time period in months each access logging entry is to be retained from the list.

See Managing Logs and Log Groups on page 3350 for more information on log and log groups, including naming syntax guidelines.

6. Click Submit.

After the system provisions the load balancer, details appear in the load balancer list. To view more details, click the load balancer name.

Note:

The following describes the Dynamic Shapes feature, which is only available to certain legacy customer accounts:

Dynamic Shapes: Choose one of the following predefined shape sizes.
  • 10 Mbps
  • 100 Mbps
  • 400 Mbps
  • 8,000 Mbps

If you are creating the load balancer as a paid account user, you can create various shape options based on your limits and later adjust the bandwidth by changing the shape after the load balancer has been created. You can view your service limits and quotas in the Console by navigating to Governance > Limits, Quotas and Usage. Select "LbaaS" from the Service list. Your bandwidth size options are listed. See Service Limits on page 243 for more
To create a load balancer using the CLI

Use the command line interface (CLI) to create a Load Balancer resource.

Enter the following command:

```
oci lb load-balancer create --compartment-id compartment_id --display-name display_name --shape-name shape_name --subnet-id subnet_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer create --help
```

See `oci lb load-balancer create` for a complete description of the command.

To create a load balancer using the API

Use the API to create a Load Balancer resource.

Run the `CreateLoadBalancer` method to create a load balancer. See `CreateLoadBalancer` for a complete description.

Listing Load Balancers

List the Load Balancer resources in your OCI tenancy.

Use one of the following methods to display a list of load balancers in your tenancy.

To list the load balancers using the Console

Use the OCI Console to list the Load Balancer resources in your OCI tenancy.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.

To list the load balancers using the CLI

Use the command line interface (CLI) to list the Load Balancer resources in your OCI tenancy.

Enter the following command:

```
oci lb load-balancer list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer list --help
```

See `oci lb load-balancer list` for a complete description of the command.

To list the load balancers using the API

Use the API to list the Load Balancer resources in your OCI tenancy.
Run the `ListLoadBalancers` method to create a load balancer. See `ListLoadBalancers` for a complete description.

**Getting Load Balancer Details**

Get the details of a Load Balancer resource.

Use one of the following methods to display the details of a selected load balancer.

**To get the details of a load balancer using the Console**

Use the OCI Console to get the details of a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Select the load balancer whose details you want to get.

   The Load Balancer Details dialog box appears.

   The Details page contains information about the load balancer, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the load balancer's configuration. See Editing Load Balancers on page 3220.

**To get the details of a load balancer using the CLI**

Use the command line interface (CLI) to get the details of a Load Balancer resource.

Enter the following command:

```
oci lb load-balancer get --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer get --help
```

See `oci lb load-balancer get` for a complete description of the command.

**To get the details of a load balancer using the API**

Use the API to get the details of a Load Balancer resource.

Run the `GetLoadBalancer` method to create a load balancer. See `GetLoadBalancer` for a complete description.

**Editing Load Balancers**

Update a Load Balancer resource.

Use one of the following methods to edit and update a selected load balancer.

**To edit a load balancer using the Console**

Use the OCI Console to update a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Click the load balancer that you want to edit.

   The Load Balancer Details dialog box appears.
6. Click the various links under Resources to edit different aspects of the load balancer as wanted.

   See Creating Load Balancers on page 3207 for details on specific configurations.

**To edit a load balancer using the CLI**

Use the command line interface (CLI) to update a Load Balancer resource.

Enter the following command:

\[ \text{oci lb load-balancer update --load-balancer-id load_balancer_id [OPTIONS]} \]

See the CLI online help for a list of options:

\[ \text{oci lb load-balancer update --help} \]

See oci lb load-balancer update for a complete description of the command.

**To edit a load balancer using the API**

Use the API to update a Load Balancer resource.

Run the UpdateLoadBalancer method to edit a load balancer. See UpdateLoadBalancer for a complete description.

**Terminating Load Balancers**

Terminate a Load Balancer resource.

Use one of the following methods to terminate a selected load balancer.

**To terminate a load balancer using the Console**

Use the OCI Console to terminate a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.

2. Select the Compartment from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a State from the list to limit the load balancers displayed to that state.

4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.

5. Click the load balancer you want to terminate.

   The Load Balancer Details page appears.

6. Click Terminate.

   Alternatively, click the Actions icon (†) associated with the load balancer you want to delete and then click Terminate.

7. Confirm the deletion when prompted.

**To terminate a load balancer using the CLI**

Use the command line interface (CLI) to terminate a Load Balancer resource.

Enter the following command:

\[ \text{oci lb load-balancer delete --load-balancer-id load_balancer_id [OPTIONS]} \]

See the CLI online help for a list of options:

\[ \text{oci lb load-balancer delete --help} \]

See oci lb load-balancer delete for a complete description of the command.

**To terminate a load balancer using the API**

Use the API to terminate a Load Balancer resource.
Run the `DeleteLoadBalancer` method to terminate a load balancer. See `DeleteLoadBalancer` for a complete description.

**Moving Load Balancers Between Compartments**

Change the compartment of a Load Balancer resource.

Use one of the following methods to move a load balancer to a different compartment. See Managing Compartments on page 3126 for information about compartments and access control.

**To move a load balancer between compartments using the Console**

Use the OCI Console to change the compartment of a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Click the **Actions** icon (_right arrow_) associated with the load balancer you want to move, then click **Move Resource**.
   
   The Move Resource dialog box appears.
6. Choose the destination compartment from the list.
7. Click **Move Resource**.

**To move a load balancer between compartments using the CLI**

Use the command line interface (CLI) to change the compartment of a Load Balancer resource.

Enter the following command:

```
oci lb load-balancer change-compartment --compartment-id compartment_id
[OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer change-compartment --help
```

See `oci lb load-balancer change-compartment` for a complete description of the command.

**To move a load balancer between compartments using the API**

Use the API to change the compartment of a Load Balancer resource.

Run the `ChangeLoadBalancerCompartment` method to change the compartment of a load balancer. See `ChangeLoadBalancerCompartment` for a complete description.

**Changing the Load Balancer Bandwidth Shape**

Change a load balancer's bandwidth shape.

If you are not an Always Free user, you can adjust the size of the bandwidth to one of the other predefined sizes.

**Note:**

Always Free users cannot change the bandwidth of a load balancer. Upgrade to a different account if you want to increase your bandwidth size.

**To change a load balancer's bandwidth shape using the Console**

Use the OCI Console to change a load balancer's bandwidth shape.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.

5. Click the load balancer whose bandwidth you want to change.

The selected load balancer's Details page appears.

6. Click **Update Shape**.

The Update Shape dialog box appears. The options displayed vary on what type of existing bandwidth size option you are using.

- Changing a flexible shape: Enter the values for the **Minimum Bandwidth** and **Maximum Bandwidth** shape sizes you want changed.

  **Note:**

  Using flexible bandwidth shapes for Government accounts can result in overages if the pre-paid shape sizes are exceeded.

  If you want to specify a dynamic shape size, for example 500 Mbps, set the minimum and maximum sliders to the same value.

- Changing a dynamic shape: Select the new bandwidth of the load balancer from the **Choose Shape Size** list. The existing bandwidth size of the load balancer is unavailable to select.

You can switch from a dynamic shape size to a flexible shape by checking the **Use a Flexible Load Balancer** option and specifying your shape size using the minimum and maximum sliders (see **Changing a flexible shape**).

  **Note:**

  After you have switched to a flexible shape, you cannot revert to a dynamic shape.

7. Click **Save Changes**.

Changing the bandwidth size of the load balancer requires resetting all existing sessions of the load balancer.

8. Click **Confirm** to continue.

The Details page reappears.

**To change a load balancer's bandwidth shape using the CLI**

Use the command line interface (CLI) to change a load balancer's bandwidth shape.

Enter the following command:

```
oci lb load-balancer update-load-balancer-shape --load-balancer-id load_balancer_id --shape-name shape_name [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer update-load-balancer-shape --help
```

See **oci lb load-balancer update-load-balancer-shape** for a complete description of the command.

**To change a load balancer's bandwidth shape using the API**

Use the API to change a load balancer's bandwidth shape.

Run the **UpdateLoadBalancerShape** method to change the bandwidth of a load balancer. See **UpdateLoadBalancerShape** for a complete description.

**Listing Load Balancer Health Status Summaries**

List the health status summaries for all Load Balancer resources in a specified compartment.

Use one of the following methods to display a list of health status summaries for a load balancers in a specified compartment.
To list the load balancer health status summaries using the Console
Use the OCI Console to list all the health status summaries of the Load Balancer resources in a specified compartment in your tenancy.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.

   All load balancers and network load balancers in that compartment are listed in tabular form.

3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Review the Overall Health column in the list for a summary of each load balancer.

   See Health Status Indicators on page 3236 for descriptions of the load balancer health indicators.

To list the load balancer health status summaries using the CLI
Use the command line interface (CLI) to list the health status summaries for the Load Balancer resources in your tenancy.

Enter the following command:

```
oci lb load-balancer-health list --compartment-id compartment_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb load-balancer-health list --help
```

See oci lb load-balancer-health list for a complete description of the command.

To list the load balancer health status summaries using the API
Use the API to list the health status summaries for the Load Balancer resources in your tenancy.

Run the ListLoadBalancerHealths method to display a list of health status summaries for a network load balancer. See ListLoadBalancerHealths for a complete description.

See Health Status Indicators on page 3236 for descriptions of the load balancer health indicators.

Getting Load Balancer Health Details
Get the health status details of a Load Balancer resource.

The following table lists the health status indicators and their meanings.

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>Red</td>
<td>At least one backend set associated with the load balancer returns a status of Critical.</td>
</tr>
<tr>
<td>Warning</td>
<td>Yellow</td>
<td>All the following conditions are true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• At least one backend set associated with the load balancer returns a status of Warning or Pending.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• No backend sets return a status of Critical.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The load balancer life-cycle state is Active.</td>
</tr>
</tbody>
</table>
### Load Balancing

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
</table>
| Incomplete | Yellow | Any one of the following conditions is true:  
|           |       | • No backend sets are defined for the load balancer.  
|           |       | • All the following conditions are true:  
|           |       | • More than half of the backend sets associated with the load balancer return a status of Incomplete.  
|           |       | • None of the backend sets return a status of Warning or Critical.  
|           |       | • The load balancer life-cycle state is Active. |

| Pending   | Yellow | Any one of the following conditions is true:  
|           |       | • The load balancer life-cycle state is not Active.  
|           |       | • All the following conditions are true:  
|           |       | • More than half of the backend sets associated with the load balancer return a status of Pending.  
|           |       | • None of the backend sets return a status of Warning or Critical.  
|           |       | • The load balancer life-cycle state is Active.  
|           |       | • The system could not retrieve metrics for any reason. |

| OK        | Green  | All backend sets associated with the load balancer return a status of OK. |

Use one of the following methods to display the health details of a selected load balancer.

**To get load balancer health details using the Console**

Use the OCI Console to get the health details of a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Click the load balancer that you want to edit.
   
   The Load Balancer Details dialog box appears.
6. View the **Overall Health** and **Backend Sets Health** indicators.

   See **Getting Load Balancer Health Details** on page 3224 for descriptions of the load balancer health indicators.

**To get load balancer health details using the CLI**

Use the command line interface (CLI) to get the health status of a Load Balancer resource.

Enter the following command:

```
oci lb load-balancer-health get --load-balancer-id load_balancer_id
```

See the CLI online help for a list of options:

```
oci lb load-balancer-health get --help
```

See `oci lb load-balancer-health get` for a complete description of the command.

See **Getting Load Balancer Health Details** on page 3224 for descriptions of the load balancer health indicators.

**To get load balancer health details using the API**

Use the API to get the health details for a Load Balancer resource.

Run the `GetLoadBalancerHealth` method to display the health details for a load balancer. See `GetLoadBalancerHealth` for a complete description.

See **Getting Load Balancer Health Details** on page 3224 for descriptions of the load balancer health indicators.

**Tagging Load Balancers**

Learn how to add metadata to Load Balancer resources, which enables you to define keys and values and associate them with resources.

You can apply tags to your Load Balancer resources to help you organize them according to your business needs. Apply tags at the time you create a network load balancer, or update the network load balancer with tags later. For more information about applying tags, see **Tagging Overview** on page 4958.

**Note:**

If you are not sure whether to apply tags, ask your administrator for guidance.

**To apply tags at create using the Console**

Use the OCI Console to add metadata to a Load Balancer resource when you create it.

1. Begin the steps for creating a load balancer using the OCI Console as described in **Creating Load Balancers** on page 3207.
2. At the end of **Step 1 - Add Details**, click **Show Advanced Options**.

   The advanced options appear.
3. Click the **Tagging** tab.
4. Complete the following. See **Tagging Overview** on page 4958 for descriptions of these fields.
   - Tag Namespace
   - Tag Key
   - Value
5. Click **+Additional Tag** to add another tag. Click **X** to remove the associated tag.
6. Click **Next** to continue with the network load balancer creation.

**To apply tags at create using the CLI**

Use the command line interface (CLI) to add metadata to a Load Balancer resource when you create it.
**Load Balancing**

Use the `--defined-tags` or `--freeform-tags` options when running the following command:

```
oci lb load-balancer create [...] [--defined-tags | --freeform-tags] tags
[OPTIONS]
```

See the CLI online help for more information on these options:

```
oci lb load-balancer create --help
```

See `oci lb load-balancer create` for a complete description of the command, including the tagging options.

**To apply tags at create using the API**

Use the API to add metadata to a Load Balancer resource when you create it.

Run the `CreateLoadBalancer` method to create a load balancer. Include the `definedTags` and `freeformTags` attributes and their values. See `CreateLoadBalancer` for a complete description of these attributes.

**To apply tags at update using the Console**

Use the OCI Console to add metadata to a Load Balancer resource when you update it.

1. Begin the steps for editing a load balancer using the OCI Console as described in Editing Load Balancers on page 3220.
2. In the Details page of the selected load balancer, click Add Tags.

   Alternatively, click the Actions icon ( Pregnant Female ) for the load balancer to which you want to add tags, and then click Add Tags.

   The Add One or More Tags To This Resource dialog box appears.

3. Complete the following:
   - Tag Namespace
   - Tag Key
   - Value

   See Tagging Overview on page 4958 for descriptions of these fields.

4. Click +Additional Tag to add another tag. Click X to remove the associated tag.

5. Click Add Tags.

   The dialog box closes and you are returned to the Details page.

**To apply tags at update using the CLI**

Use the command line interface (CLI) to add metadata to a Load Balancer resource when you update it.

Use the `--defined-tags` or `--freeform-tags` options when running the following command:

```
oci lb load-balancer update --load-balancer-id load_balancer_id [--defined-tags | --freeform-tags] tags [OPTIONS]
```

See the CLI online help for more information on these options:

```
oci lb load-balancer update --help
```

See `oci lb load-balancer update` for a complete description of the command, including the tagging options.

**To apply tags at update using the API**

Use the API to add metadata to a Load Balancer resource when you update it.

Run the `UpdateLoadBalancer` method to create a network load balancer. Include the `definedTags` and `freeformTags` attributes and their values. See `UpdateLoadBalancer` for a complete description of these attributes.
**Backend Set Management**

Learn how to use backend sets to create logical entities consisting of a load balancing policy, health check policy, and a list of backend servers for a Load Balancer resource.

A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers. To create a backend set, you must specify a load balancing policy and health check script, and then add a list of backend servers (Compute instances). SSL and session persistence configuration is optional. A backend set must be associated with one or more listeners for the load balancer to work.

Changing the load balancing policy of a backend set temporarily interrupts traffic and can drop active connections.

Click **Backend Sets** under **Resources** in the Load Balancer Details page to display the Backend Sets page. This page contains a button for creating new backend sets.

**Note:**

You can set up backend servers as compute instance pools. See Creating an Instance Pool on page 1058 for more information.

**Creating Backend Sets**

Create a backend set for a Load Balancer resource.

Use one of the following methods to create a backend set for a selected load balancer.

**To create a backend set using the Console**

Use the OCI Console to create a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Load Balancer** under **Type** to only display network load balancers.
5. Click the load balancer whose backend set you want to edit.
6. Click **Backend Sets** under the **Resources** menu, then click **Create Backend Set**.

   The **Create Backend Set** dialog box appears.
7. Enter the following:

- **Name**: Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.

  Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Traffic Distribution Policy**: Required. Choose the load balancer policy for the backend set. The available options are:
  - IP Hash
  - Least Connections
  - Weighted Round Robin

  For more information on these policies, see Load Balancing Policies on page 3199.

  **Tip:**
  You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

- **Use SSL**: Optional. Check this box to associate an SSL certificate bundle with the backend set.

  If no certificate bundles attached to the load balancer exist, this option is disabled.

  **Note:**
  If you check **Use SSL**, the **SSL Policies** fields appear at the bottom of the page.

  - **Certificate Name**: Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See SSL Certificate Management on page 3308 for more information.
  - **Verify Peer Certificate**: Optional. Select this option to enable peer certificate verification.
  - **Verify Depth**: Optional. Specify the maximum depth for certificate chain verification.
  - **Session Persistence**: Optional. Specify how the load balancer manages session persistence.

    **Important:**
    See Session Persistence on page 3202 for important information on configuring these settings.

  - **Disable Session Persistence**: Choose this option to disable cookie-based session persistence.
  - **Enable Application Cookie Persistence**: Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a `Set-cookie` header with the cookie name you specify.
    - **Cookie Name**: The cookie name used to enable session persistence. Specify * to match any cookie name. Avoid entering confidential information.
    - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
  - **Enable Load Balancer Cookie Persistence**: Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
    - **Cookie Name**: Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is `X-Oracle-BMC-LBS-Route`.
      Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
    - **Disable Fallback**: Check this box to disable fallback when the original server is unavailable.
    - **Domain Name**: Optional. Specify the domain in which the cookie is valid.
      This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.
• **Path:** Optional. Specify the path in which the cookie is valid. The default value is `/.

• **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.

• **Attributes**
  - **Secure:** Specify whether the `Set-cookie` header contains the `Secure` attribute. If selected, the client sends the cookie only using a secure protocol.
    
    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.
  
  - **HTTP Only:** Specify whether the `Set-cookie` header contains the `HttpOnly` attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

• **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.

• **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

  **Important:**
  
  Configure your health check protocol to match your application or service. See Health Check Management on page 3236 for more information.

• **Port:** Optional. Specify the backend server port against which to run the health check.

  **Tip:**
  
  You can enter the value '0' to have the health check use the backend server's traffic port.

• **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.

• **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

• **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).

• **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy." This number also applies when recovering a server to the "healthy" state. The default is '3'.

• **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.

• **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

• **SSL Policy:** Optional. Specify the type of cipher suite to use:

  **Note:**
  
  Check Use SSL for the SSL Policy features to be displayed.

• **TLS Version:** Optional. Specify the Transport Layer Security (TLS) version(s):

  • 1.0
  
  • 1.1
  
  • 1.2 (recommended)

  You can select any combination of versions. Choose the ones you want from the list. If you do not specify the TLS versions, the default TLS is version 1.2 only.

  • **Select Cipher Suite** - Select a set of cipher suites from the list. (default).

    All choices present in the list have at least one cipher associated with each TLS version you selected.

    • Click **Show Cipher Suite Details** to display the individual ciphers the selected cipher suite contains.

8. Click **Create**.
After your backend set is provisioned, you must specify backend servers for the set. See Backend Server Management on page 3242 for more information.

**To create a backend set using the CLI**

Use the command line interface (CLI) to create a backend set for a Load Balancer resource.

Enter the following command:

```bash
oci lb backend-set create --name name --load-balancer-id load_balancer_id --health-checker-protocol [HTTP|TCP] [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb backend-set create --help
```

See [oci lb backend-set create](#) for a complete description of the command.

**To create a backend set using the API**

Use the API to create a backend set for a Load Balancer resource.

Run the `CreateBackendSet` method to create a backend set for a load balancer. See `CreateBackendSet` for a complete description.

**Listing Backend Sets**

List the backend sets for a Load Balancer resource.

Use one of the following methods to display a list of backend sets for a selected load balancer.

**To list the backend sets using the Console**

Use the OCI Console to list the backend sets for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Click Backend Sets under Resources.

The Backend Sets list appears. All backend sets are listed in tabular form.

**To list the backend sets using the CLI**

Use the command line interface (CLI) to list the backend sets for a Load Balancer resource.

Enter the following command:

```bash
oci lb backend-set list --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```bash
oci lb backend-sets list --help
```

See [oci lb backend-set list](#) for a complete description of the command.

**To list the backend sets using the API**

Use the API to list the backend sets for a Load Balancer resource.

Run the `ListBackendSets` method to display a list of backend sets for a load balancer. See `ListBackendSets` for a complete description.

**Getting Backend Set Details**

Get the details of a backend set for a Load Balancer resource.
Use one of the following methods to display the details of a backend set for a selected load balancer.

**To get the details of a backend set using the Console**
Use the OCI Console to get the details of a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Click the load balancer for whose backend set you want to get details.
   
   The Load Balancer Details page appears.
6. Click **Backend Sets** under **Resources**.
   
   The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set whose details you want to get.
   
   The Backend Set Details dialog box appears.
   
   The Details page contains information about the backend set, both general information and links to its resources. Some items in the page are read-only, while other items allow you to edit and update the backend set's configuration. See **Editing Backend Sets** on page 3232.

**To get the details of a backend set using the CLI**
Use the command line interface (CLI) to get the details of a backend set for a Load Balancer resource.

Enter the following command:

```
oci lb backend-set get --backend-set-name backend_set_name --load-balancer-id load_balancer_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb backend-set get --help
```

See [oci lb backend-set get](#) for a complete description of the command.

**To get the details of a backend set using the API**
Use the API to get the details of a backend set for a Load Balancer resource.

Run the **GetBackendSet** method to display a list of backend sets for a load balancer. See **GetBackendSet** for a complete description.

**Editing Backend Sets**
Update a backend set for a Load Balancer resource.

When you edit a backed set, you can choose a new load balancing policy and modify the SSL configuration.

To modify the backend set's health check policy, see **Health Check Management** on page 3236 for more information.

To add or remove backend servers from the backend set, see **Backend Server Management** on page 3242 for more information.

**Note:**

Changing the load balancing policy of a backend set temporarily interrupts traffic and can drop active connections.

Use one of the following methods to edit and update the settings of a backend set for a selected load balancer.
To edit a backend set using the Console
Use the OCI Console to update a backend set for a Load Balancer resource.

1. Open the navigation menu, click Networking, and then click Load Balancers.
2. Select the Compartment from the list.
   All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a State from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck Network Load Balancer under Type to only display load balancers.
5. Click the load balancer whose backend set you want to edit.
   The Load Balancer Details page appears.
6. Click Backend Sets under Resources.
   The Backend Sets list appears. All backend sets are listed in tabular form.
7. Click the backend set you want to edit.
   The Backend Set Details dialog box appears.
8. Click Edit Backend Set.
   Alternatively, click the Actions icon ( ⋅ ) associated with the backend set you want to edit and click Edit.
   The Edit Backend Set dialog box appears.
9. Edit any of the following:
   • Traffic Distribution Policy
   • Session Persistence
   See Creating Backend Sets on page 3228 for more information.
10. Click Update Backend Set.

To edit a backend set using the CLI
Use the command line interface (CLI) to update a backend set for a Load Balancer resource.

Enter the following command:
```
oci lb backend-set update --backend-set-name backend_set_name --backends backends --load-balancer-id load-balancer_id --health-checker-protocol health_checker_protocol --policy policy [OPTIONS]
```

See the CLI online help for a list of options:
```
oci lb backend-set update --help
```

See oci lb backend-set update for a complete description of the command.

To edit a backend set using the API
Use the API to update a backend set for a Load Balancer resource.

Run the UpdateBackendSet method to edit a backend set for a load balancer. See UpdateBackendSet for a complete description.

Deleting Backend Sets
Delete a backend set from a Load Balancer resource.

Use one of the following methods to delete a backend set from a selected load balancer.

Note:
You cannot delete a backend set used by an active listener.

To delete a backend set using the Console
Use the OCI Console to delete a backend set from a Load Balancer resource.
1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Click the load balancer whose backend set you want to delete.
   - The Load Balancer Details page appears.
6. Click **Backend Sets** under **Resources**.
   - The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set you want to delete.
   - The Backend Set Details page appears.
8. Click **Delete**.
   - Alternatively, click the Actions icon (谤) associated with the backend set you want to delete and click **Delete**.
9. Confirm the deletion when prompted.

**To delete a backend set using the CLI**

Use the command line interface (CLI) to delete a backend set from a Load Balancer resource.

Enter the following command:

```
oci lb backend-set delete --backend-set-name backend_set_name --load-balancer-id load_balancer-id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci lb backend-set delete --help
```

See **oci lb backend-set delete** for a complete description of the command.

**To delete a backend set using the API**

Use the API to delete a backend set from a Load Balancer resource.

Run the **DeleteBackendSet** method to delete a backend set from a load balancer. See **DeleteBackendSet** for a complete description.

**Getting Backend Set Health Details**

Get the health details of a backend set for a Load Balancer resource.

The following table lists the health levels and their descriptions.

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>Red</td>
<td>Fewer than half of the backend set's backend servers return a status of OK.</td>
</tr>
</tbody>
</table>
### Load Balancing

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning</strong></td>
<td>Yellow</td>
<td>Both of the following conditions are true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Half or more of the backend set's backend servers return a status of OK.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• At least one backend server returns a status of <strong>Warning</strong>, <strong>Critical</strong>,</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Pending</strong>, or <strong>Incomplete</strong>.</td>
</tr>
<tr>
<td><strong>Incomplete</strong></td>
<td>Yellow</td>
<td>The backend set does not have any backends attached.</td>
</tr>
<tr>
<td><strong>Pending</strong></td>
<td>Yellow</td>
<td>At least one of the following conditions is true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• More than half of the backend set's backend servers return a status of <strong>Pending</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The system could not retrieve metrics for any reason.</td>
</tr>
<tr>
<td><strong>OK</strong></td>
<td>Green</td>
<td>All backend servers in the backend set return a status of <strong>OK</strong>.</td>
</tr>
</tbody>
</table>

Use one of the following methods to display the health details of a backend set for a selected load balancer.

**Getting Backend Set Health Details using the Console**

Use the OCI Console to get the health details of a backend set for a Load Balancer resource.

1. Open the navigation menu, click **Networking**, and then click **Load Balancers**.
2. Select the **Compartment** from the list.
   - All load balancers and network load balancers in that compartment are listed in tabular form.
3. (optional) Select a **State** from the list to limit the load balancers displayed to that state.
4. (optional) Uncheck **Network Load Balancer** under **Type** to only display load balancers.
5. Click the load balancer whose backend set you want to edit.
   - The Load Balancer Details page appears.
6. Click **Backend Sets** under **Resources**.
   - The **Backend Sets** list appears. All backend sets are listed in tabular form.
7. Click the backend set you want to edit.
   - The Backend Set Details dialog box appears.
8. View the **Overall** and **Backend Health** details.
   - See **Getting Backend Set Health Details** on page 3234 for descriptions of the backend set health indicators.

**Getting Backend Set Health Details using the CLI**

Use the command line interface (CLI) to get the health details of a backend set for a Load Balancer resource.

Enter the following command:

```bash
oci lb backend-set-health get --backend-set-name backend_set_name --load-balancer-id load-balancer_id [OPTIONS]
```
See the CLI online help for a list of options:

```
oci lb backend-set-health get --help
```

See `oci lb backend-set-health get` for a complete description of the command.

See Getting Backend Set Health Details on page 3234 for descriptions of the backend set health indicators.

Getting Backend Set Health Details using the API

Use the API to get the health details of a backend set for a Load Balancer resource.

Run the `GetBackendSetHealth` method to get the health details a backend set for a load balancer. See `GetBackendSetHealth` for a complete description.

See Getting Backend Set Health Details on page 3234 for descriptions of the backend set health indicators.

Health Check Management

Learn how to understand and use health status indicators to report on the general health of your Load Balancer resources and their components.

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server later passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

The backend set's Details page provides the same Overall Health status indicator found in the load balancer's list of backend sets. It also includes counters for the Backend Health status values reported by the backend set's backend servers.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

Health Status Indicators

Learn about the different health status indicators for Load Balancer resources.

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components.

The following table provides the general meaning of each level:

<table>
<thead>
<tr>
<th>Level</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>Red</td>
<td>Some or all reporting entities require immediate attention. The resource is not functioning or unexpected failure is imminent.</td>
</tr>
</tbody>
</table>
### Load Balancing
