**What VM and bare metal options are available for Windows Server operating systems?**

The following table shows support for Microsoft Windows Server operating systems on Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Use Case</th>
<th>Bare Metal Machines</th>
<th>Virtual Machines (VMs)</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an Oracle-provided Windows Server operating system image for Windows Server 2012 R2 and later versions.</td>
<td>Supported</td>
<td>Supported</td>
<td>SPLA volume license issued by Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Bring your own virtual machine image. You can import your own custom virtual machine Windows Server OS image.</td>
<td>Not supported</td>
<td>Supported</td>
<td>SPLA volume license issued by Oracle Cloud Infrastructure</td>
</tr>
<tr>
<td>Bring your own Windows Server ISO image.</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Customer-owned license</td>
</tr>
</tbody>
</table>
Does Oracle Cloud Infrastructure support Bring Your Own Image (BYOI) for Windows Server?

Yes, you are permitted to import your own generalized custom image of Windows Server.

When you create an instance with an imported image on a VM or a shared bare metal machine, Oracle Cloud Infrastructure licenses the instance. For more information about imported images, see Creating Windows Custom Images on page 668.

If you want to use your own license, BYOI is supported only for bare metal machines on a dedicated host.

How am I charged for Windows Server on Oracle Cloud Infrastructure?

The cost of a Microsoft Windows Server license is an additional cost, on top of the underlying Compute instance price. You pay separately for the Compute instance and the Windows Server license. For more information about Microsoft Windows Server pricing, see Compute Pricing.

Billing for the Windows Server license is based on per-OCPU, per-second usage. Billing starts when an instance is in the “running” state and ends when you terminate (delete) the instance.

When an instance is stopped, billing for the Windows Server license depends on the shape that was used to create the instance. Billing pauses for instances that use a Standard shape. Billing continues for instances that use a Dense I/O shape, GPU shape, or HPC shape. Depending on the shape, you might also be billed for the underlying Compute instance when the instance is stopped.

How does Windows Server get updated with the latest patches?

You must update your VCN’s security list to enable egress traffic for port 80 (HTTP) and port 443 (HTTPS) to install patches from Microsoft. Oracle Cloud Infrastructure enables automatic updates for Microsoft Windows Server and uses the default settings for applying Windows Server patches.

Can I take a snapshot image after customizing a running Window Server instance?

Yes, there are several options available on both bare metal and virtual machines:

- **Create a custom image:** Creates a custom image that you can use to launch other instances. Instances that you launch from your image include the customizations, configuration, and software installed when you created the image.
- **Clone a boot volume:** Makes a copy of an existing boot volume without needing to go through the backup and restore process. A boot volume clone is a point-in-time direct disk-to-disk deep copy of the source boot volume, so all the data that is in the source boot volume when the clone is created is copied to the boot volume clone.
- **Back up a block volume:** Makes a point-in-time backup of data on a block volume. You can restore a backup to a new volume either immediately after a backup or at a later time that you choose.
- **Back up a boot volume:** Makes a backup of a boot volume. Boot volume backup capabilities are the same as block volume backup capabilities and are in-region only. Windows boot volume backups cannot be copied across regions.

Can I export a custom Windows Server image?

Yes, exporting custom Windows Server operating system images is supported.
When exporting Windows-based images, you are responsible for complying with the Microsoft Product Terms and all product use conditions, as well as verifying your compliance with Microsoft.

For steps to export an image, see Image Import/Export on page 670.

**What support is available for Microsoft Windows Server on Oracle Cloud Infrastructure?**

Oracle Support provides limited assistance for Oracle-provided Microsoft Windows Server images if the Windows Server version has not reached end of support with Microsoft. All other Microsoft software is supported directly by Microsoft Support.

Oracle Support can help verify that the operating system boots, that the operating system connects to the network, and that attached storage connects and performs as expected. If you encounter other issues with Microsoft Windows Server, work directly with Microsoft Support to resolve the issue. For more information, see Support Options for Microsoft Windows on page 812.

**How do I upgrade to a newer version of Windows Server?**

To upgrade to a newer version of Windows Server, you can do either of the following things:

- Obtain the installation media from Microsoft or your Microsoft reseller, and then upgrade the existing Compute instance. The license issued by Oracle Cloud Infrastructure remains in effect.
- Create a new Compute instance using the desired version of the Windows Server platform image, and then migrate your applications and data to the new instance.

**Licensing - Windows Server**

**What is BYOL?**

BYOL stands for "bring your own license." BYOL lets you use software licenses that you already own to deploy software on Oracle Cloud Infrastructure, without any additional licensing fees. This process uses the License Mobility through Microsoft Software Assurance benefit provided by Microsoft. You must have active Software Assurance with Microsoft to bring your licenses to Oracle Cloud Infrastructure.

**What is Microsoft License Mobility?**

License Mobility through Software Assurance is a Microsoft benefit that permits you to move your eligible Microsoft licenses to cloud services providers such as Oracle Cloud Infrastructure. Oracle is an Authorized Mobility Partner for License Mobility.

With License Mobility through Software Assurance, you can deploy eligible application servers on bare metal hosts or virtual shared hardware in Oracle Cloud Infrastructure. An example of an application eligible for License Mobility through Software Assurance is Microsoft SQL. Windows Server operating systems are not eligible.

You may move Microsoft licenses from on-premises or another Authorized Mobility Partner only after more than 90 days have passed since the last license move.

For more information about this Microsoft benefit, see License Mobility through Microsoft Software Assurance. For steps to move your Microsoft licenses to Oracle Cloud Infrastructure, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 811.

**Is Oracle a Microsoft Authorized Mobility Partner?**

Yes, Oracle is an Authorized Mobility Partner for the Microsoft License Mobility through Software Assurance benefit.

**Can I bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?**

Yes. You can bring your own license (BYOL) for Microsoft Windows Server on a dedicated bare metal or dedicated virtual machine host, subject to the Microsoft Product Terms. You are responsible for managing your own licenses to maintain compliance with Microsoft licensing terms. For more information, see Licensing Options for Microsoft Windows on page 809.

The following table shows the BYOL requirements for Microsoft licenses on Oracle Cloud Infrastructure.
<table>
<thead>
<tr>
<th>Microsoft License</th>
<th>Bare Metal Machines and Dedicated Virtual Machine Hosts</th>
<th>Virtual Machines (Multi-Tenant Shared Host)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Windows Server</strong></td>
<td>BYOL on a bare metal dedicated host is only eligible when using a KVM hypervisor. BYOL is not eligible for Microsoft Windows Server using Oracle-provided images or when importing your own Microsoft Windows Server image.</td>
<td>Not eligible. Shared hosts must use Oracle-provided images that include the Microsoft license.</td>
</tr>
<tr>
<td><strong>SQL Server</strong></td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
</tr>
<tr>
<td><em>Subject to the Microsoft Product Terms</em></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Microsoft 365 Apps for enterprise (Office 365 ProPlus) and Office Professional Plus</strong></td>
<td>Eligible. You must have an Enterprise Agreement license with Software Assurance or a Windows Virtual Desktop Access (VDA) license.</td>
<td>Not eligible.</td>
</tr>
<tr>
<td><strong>Windows 7, Windows 8, and Windows 10</strong></td>
<td>Eligible. You must have an Enterprise Agreement license with Software Assurance or a Windows Virtual Desktop Access (VDA) license.</td>
<td>Not eligible.</td>
</tr>
<tr>
<td><strong>Other Microsoft applications</strong></td>
<td>Eligible. Subject to the Microsoft Product Terms.</td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
</tr>
</tbody>
</table>

Application licenses such as SQL Server or System Center require License Mobility through Software Assurance when running on Oracle Cloud Infrastructure VM instances. License Mobility is not used for Microsoft Office, Windows clients, or Windows Server BYOL. Review the Microsoft Product Terms to validate which applications support License Mobility.

Direct questions about your licensing rights to Microsoft or your Microsoft reseller.

**Can I use virtual machines and bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?**

You cannot migrate your Windows Server OS licenses when using Oracle Cloud Infrastructure virtual machines. However, you can `bring your own hypervisor` (KVM) to run a Windows Server VM with your own Windows Server OS license.

The following restrictions apply:

- You can use VMs with their own license only if you use bring your own hypervisor on a dedicated bare metal host.
- BYOL of Microsoft Windows Server is not supported for VMs running on a shared host. Oracle Cloud Infrastructure-provided VMs offer Windows Server.
  - You can use a bare metal instance under bring your own hypervisor.
  - You must install and manage a hypervisor (KVM or Hyper-V) and launch your own VMs. This will ensure isolation, because all Oracle VMs are running on a dedicated bare metal server.
• BYOL on a dedicated host (KVM hypervisor only) is permitted for Microsoft Windows Server.
• VMs can run Windows Server with a Visual Studio (MSDN) subscription license when used for development use only.

Licensing - Other Microsoft Software

What other Microsoft applications can I bring to Oracle Cloud Infrastructure?

Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licensing agreements with Microsoft permit you to bring on-premises perpetual Microsoft licenses to Oracle Cloud Infrastructure and are eligible licensed products according to the latest Microsoft Product Terms. Microsoft application products that are currently eligible for License Mobility require an active Software Assurance benefit to move your license. For more information, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 811.

Can I bring my own SQL Server license to Oracle Cloud Infrastructure?

Yes, you can bring your own SQL Server license using License Mobility through Active Software Assurance. The following restrictions apply:

• When you move your Microsoft SQL license using the license mobility process, the Microsoft Windows Server license is not included. Microsoft Windows Server licenses are not permitted to be moved under License Mobility. Windows Server operating systems must use the license issued by Oracle Cloud Infrastructure.
• Perpetual licenses can be moved from on-premises or other cloud providers only after more than 90 days have passed since the last license move.
• End-of-support versions are not supported on shared host virtual machines on Oracle Cloud Infrastructure.

Follow the license mobility process to move your SQL Server license to Oracle Cloud Infrastructure.

Can I use my Visual Studio (MSDN) license on Microsoft Windows Server on Oracle Cloud Infrastructure?

Yes, you can use your Visual Studio (MSDN) subscription license for non-production purposes on Oracle Cloud Infrastructure on either bare metal or virtual machine instances. You are responsible for complying with the Visual Studio subscription terms.

Can I buy a Visual Studio (MSDN) subscription from Oracle Cloud Infrastructure?

No, Oracle does not sell Visual Studio (MSDN) subscriptions. Contact Microsoft or your Microsoft reseller.

Can I use a Visual Studio (MSDN) license for a production environment?

No, Visual Studio (MSDN) subscription licenses are for development, testing, or demonstration purposes only.

How can I remote access to a Windows Server instance on Oracle Cloud Infrastructure?

Follow the steps to connect to a Windows instance. Windows operating systems permit remote access for a maximum of two users using Remote Desktop Services (RDS) for Administration purposes.

RDS Client Access Licenses (CALs) are required for each user or device using Remote Desktop.

Does Oracle Cloud Infrastructure offer additional Remote Desktop Services licenses for applications running on Windows VMs?

No, Oracle Cloud Infrastructure does not offer Microsoft RDS (Remote Desktop Server) Subscriber Access Licenses (SALs). You can bring your own license (BYOL) and use your RDS Client Access Licenses (CALs) on Oracle Cloud Infrastructure bare metal or virtual machines only if you have active Software Assurance coverage and move those licenses using the license mobility process.

Can I bring my own RDS CALs if I want more than two users to access my Windows Server instance?

Yes, you can use your Remote Desktop Services (RDS) Client Access Licenses (CALs) on Oracle Cloud Infrastructure if you use the Oracle Cloud Infrastructure bare metal offering. In addition, you can use virtual machines with their own Visual Studio (MSDN) subscription license if you bring your own hypervisor (KVM).
You can use your RDS CAL licenses on Oracle Cloud Infrastructure virtual machines only if you have active Software Assurance coverage and move your CALs using the license mobility process.

**Can I bring my own System Center Management Licenses to Oracle Cloud Infrastructure?**

You can bring Microsoft System Center server Management Licenses (server MLs) using the license mobility process. There are minimums to take into consideration with System Center Management License 2-core licenses and 16-core licenses. A virtual machine requires a minimum of 16 core licenses to be assigned to it, and more if the VM has more than 16 virtual cores.

System Center client Management Licenses (client MLs) are not eligible for license mobility and cannot be moved to Oracle Cloud Infrastructure.

**Other Windows Server Questions**

**Are there user data capabilities when launching Windows Server images?**

Yes, Oracle-provided Windows images include cloudbase-init installed by default. You can use cloudbase-init to run PowerShell scripts, batch scripts, or other user data content on instance launch. Cloudbase-init is the equivalent of cloud-init on Linux-based images.

**Can I use Windows Remote Management on Oracle Cloud Infrastructure?**

Yes, Microsoft Windows Remote Management (WinRM) is enabled by default on Oracle-provided Windows images. WinRM enables you to remotely manage the operating system.

**What is Microsoft end of support?**

Microsoft establishes the support lifecycle policy for its products. When a product reaches the end of its support lifecycle, Microsoft no longer provides security updates for the product. You should upgrade to the latest version to remain secure.

**Can I use Windows Server 2008 R2 even though it's past the end-of-support date?**

Windows Server 2008 R2 reached the end of its support lifecycle on January 14, 2020. Although you can continue to import your own Windows 2008 R2 images and run your existing instances, you are at a higher risk of security issues, incompatibility, or failures. Oracle does not provide any operating system support for end-of-support operating systems.

Oracle Cloud Infrastructure does not provide platform images after the end-of-support date. However, you can import your own image and launch it on a shared host VM.

There are no restrictions to running end-of-support operating systems on bare metal machines on a dedicated host. You may bring your own image (BYOI) of a Windows Server 2008 R2 image, but you must import a custom OS image and run the image on a dedicated host.

**Can I purchase Microsoft Extended Security Updates for end-of-support Windows OSs?**

Yes, you can purchase Extended Security Updates (ESUs) from Microsoft for use on Oracle Cloud Infrastructure. For VMs on shared infrastructure, you must have an enterprise agreement in place with Microsoft. With that agreement in place, you can purchase ESUs per virtual core matching the number of OCPUs per VM instance, with a minimum requirement of 16 virtual core licenses per VM instance.

For bare metal machines, you must have an enterprise agreement in place with Microsoft. With that agreement in place, you can purchase ESUs per physical core of the dedicated bare metal host.

Oracle Cloud Infrastructure cannot purchase ESUs on your behalf.

You are fully responsible for purchasing the correct number of ESUs for your instances. Oracle Cloud Infrastructure does not keep track of whether you have enough ESUs.

**Licensing Options for Microsoft Windows**

You can choose to bring your own license (BYOL) for Microsoft applications that you want to run on Oracle Cloud Infrastructure, or use a license that is issued by Oracle.
The following table describes the licensing models that are available for using Microsoft Windows images on Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Image</th>
<th>License</th>
<th>Additional Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle-provided image</td>
<td>Issued by Oracle</td>
<td>VM instances on a shared host, bare metal instances, and VM instances launched on a dedicated host are all permitted. BYOL for Oracle-provided images is not available.</td>
</tr>
<tr>
<td>Bring your own image (BYOI)</td>
<td>Issued by Oracle</td>
<td>VM instances on a shared host, bare metal instances, and VM instances launched on a dedicated host are all permitted. Import the image. Oracle will issue a license when an instance is created using the imported image.</td>
</tr>
<tr>
<td>Bring your own image (BYOI)</td>
<td>BYOL</td>
<td>Instances must be launched on a dedicated host. Create a bare metal instance using the KVM image from Marketplace. Then, copy your Windows guest OS to the hypervisor.</td>
</tr>
<tr>
<td>Bring your own Hyper-V</td>
<td>Issued by Oracle</td>
<td>Instances must be launched on a dedicated host. Create a bare metal instance using the Oracle-provided Windows Server Datacenter platform image. Then, copy your on-premises guest OS to Hyper-V on the bare metal instance.</td>
</tr>
</tbody>
</table>

**Bringing Your Own Microsoft License**

You can BYOL for Microsoft application licenses that are eligible for License Mobility with active Software Assurance onto virtual machines and dedicated hosts. According to the Microsoft Product Terms, some of the applications that are permitted for BYOL include the following:

- Microsoft SQL Server
- Microsoft Exchange Server
- Microsoft SharePoint Server
- Microsoft System Center
- Microsoft Dynamics products

Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licensing agreements with Microsoft permit you to bring on-premises perpetual Microsoft licenses to Oracle Cloud Infrastructure and are eligible licensed products according to the latest Microsoft Product Terms. Microsoft application products that are currently eligible for License Mobility require an active Software Assurance benefit to move your license. For more information, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 811.
For Microsoft Windows Server OS, there are restrictions. BYOL is only permitted for eligible Windows OS licenses with active Software Assurance running on a dedicated bare metal host or a dedicated VM host using a KVM hypervisor.

For Windows clients (Windows 8 and Windows 10), BYOL is permitted for Enterprise Agreement licenses with an active Software Assurance benefit or with Windows Virtual Desktop Access (VDA) licenses.

Activating licenses can either be scripted on startup using the slmgr.vbs command line tool or by using your own Microsoft Key Management Service (KMS) server.

**Activating Licenses on a Dedicated Host**

When you bring your own Microsoft licenses, you are responsible for validating that your licensing agreements with Microsoft permit you to move your own licenses to Oracle Cloud Infrastructure. It is your responsibility to ensure that you comply with all Microsoft product terms and product use conditions.

**Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility**

Microsoft Volume Licensing customers can move eligible Microsoft server application licenses purchased under a Volume Licensing agreement to Oracle Cloud Infrastructure. To do this, you must enroll in the License Mobility through Microsoft Software Assurance benefit. This benefit is included with an active Software Assurance contract. You don't need to purchase additional Microsoft software licenses, and there are no associated mobility fees.

For more information about this Microsoft benefit, see [License Mobility through Microsoft Software Assurance](https://www.microsoft.com).

**Eligibility Requirements**

To enroll in Microsoft License Mobility through Software Assurance, you must be a Microsoft Volume License customer with eligible server application products. The following are key requirements:

- Windows Server operating systems, desktop client operating systems, and desktop applications such as Microsoft Office are not eligible under License Mobility through Software Assurance. You can bring your own license (BYOL) outside of License Mobility onto a dedicated host. For more information, see [Can I bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?](https://www.oracle.com) on page 806.
- Active Software Assurance coverage is required on eligible licenses migrated to Oracle Cloud Infrastructure.
- All licenses that are used to run and access your licensed software require active Software Assurance coverage. This includes server licenses, processor licenses, Client Access Licenses (CALs), External Connector (EC) licenses, and server management licenses. Your rights to run licensed software and manage instances on Oracle Cloud Infrastructure expire with the expiration of the Software Assurance coverage on those licenses.
- Eligible Volume Licensing programs include the Microsoft Enterprise Agreement, Microsoft Enterprise Subscription Agreement, and Microsoft Open Value agreement, where Software Assurance is included, and other Volume Licensing programs where Software Assurance is an option, such as the Microsoft Open License agreement and the Microsoft Select Plus agreement.
- You may move Microsoft licenses from on-premises or another cloud services provider only after more than 90 days have passed since the last license move.
- Eligible Microsoft licenses on Oracle Cloud Infrastructure must be maintained for a minimum period of 90 days in a specific Oracle Cloud Infrastructure region. After the 90-day period, you may move the licensed software to a shared host in another Oracle Cloud Infrastructure region.
- Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licenses you bring to Oracle Cloud Infrastructure are eligible according to the latest Microsoft Product Terms.

**Enrolling in License Mobility through Software Assurance**

All customers using License Mobility through Software Assurance must complete a license verification process. Microsoft verifies that you have eligible licenses with active Software Assurance and sends confirmation when the verification process is complete.

You can deploy your application server software before completing the verification process, but you must submit the license verification form within 10 days of deployment.
You are responsible for managing true ups and renewals as required under your Volume Licensing agreement. You must submit a new form each time that you deploy additional licenses, when you renew your agreement, and when you deploy any previously unverified products.

To enroll in License Mobility through Software Assurance:

1. Verify that you are a Microsoft Volume Licensing customer with eligible application server licenses that are covered by active Software Assurance.
2. Download the license verification form:
   a. Go to the Microsoft Product Licensing search page.
   b. In the Document Type area, select License Verification.
   c. Filter the results by language, region, and business sector. Note that the verification form is not available in the WW (World Wide) region.
   d. Download the LicenseMobilityVerif document.
3. Complete the license verification form. To specify Oracle as the Authorized Mobility Partner, provide the following information:
   • Authorized Mobility Partner Name: Oracle America, Inc.
   • Authorized Mobility Partner Website URL: http://www.oracle.com/
   • Authorized Mobility Partner Email Address: microsoftlm_us_grp@oracle.com
   For instructions to complete the form, see the Microsoft License Mobility Verification Guide (PDF).
4. Submit the completed verification form to both Microsoft and Oracle:
   • Microsoft: Submit the form through your Microsoft reseller or directly to the email address in the form.
   • Oracle: Send the form to microsoftlm_us_grp@oracle.com.

Microsoft and Oracle verify that the product licenses for the workloads you deploy to Oracle Cloud Infrastructure are eligible according to the terms of your License Mobility through Software Assurance benefit. Microsoft will communicate your verification status to you and to Oracle as an Authorized Mobility Partner.

Support Options for Microsoft Windows

Oracle Support provides limited assistance for Microsoft Windows Server operating systems running on Oracle Cloud Infrastructure and for SQL Server images provided by Oracle Cloud Marketplace. For product issues, work directly with Microsoft Support.

**Microsoft Windows Server**

Oracle Support provides limited assistance for Microsoft Windows Server operating systems running on Oracle Cloud Infrastructure as long as the Windows Server version has not reached end of support with Microsoft. For details about Microsoft Windows lifecycles, see Lifecycle FAQ - Windows.

In order for Oracle to provide support for Bring Your Own Image (BYOI) images, the images must follow the guidelines outlined in Importing Custom Windows Images on page 677 and must meet all Microsoft licensing requirements.

Under these conditions, Oracle Support can help verify that:

- the operating system boots
- the operating system connects to the network
- attached storage connects and performs as expected

If you encounter other issues with Microsoft Windows Server, work directly with Microsoft Support to resolve the issue. Microsoft Support provides assistance when you have an existing Premier Support agreement or when you pay for professional support.

**SQL Server**

Oracle Support provides limited assistance with SQL Server images provided by Oracle Cloud Marketplace. For product issues, work directly with Microsoft Support.
For SQL Server images provided by Oracle Cloud Marketplace, Oracle Support can help verify that the services start and that they allow local connections.

The following tasks fall outside the scope of Oracle Support and should be addressed directly with Microsoft Support. Microsoft Support provides assistance when you have an existing Premier Support agreement or when you pay for professional support.

- Query optimization
- Failover clustering
- Issues with third-party applications and with Microsoft applications that are not included in the Oracle Cloud Marketplace image. For example, software fails to install errors.
- Image configurations that diverge from Oracle’s standard configurations. For example, requests such as Roaming Profiles are going into read-only mode when our users log in via terminal server/RDS are out of scope.
- Activities that breach the Microsoft license terms of use

Troubleshooting Compute Instances

For information about how to troubleshoot issues with compute instances, see the following topics:

- Troubleshooting Instances Using Instance Console Connections on page 813. To debug issues that happen during instance launch or during the OS boot sequence, use a serial console connection or a VNC console connection.
- Sending a Diagnostic Interrupt on page 825. To debug a running virtual machine (VM) instance that becomes unresponsive, you can generate a copy of the system memory (also called a crash dump) by sending a diagnostic interrupt to the instance.

Troubleshooting Instances Using Instance Console Connections

The Oracle Cloud Infrastructure Compute service provides console connections that enable you to remotely troubleshoot malfunctioning instances, such as:

- An imported or customized image that does not complete a successful boot
- A previously working instance that stops responding

Two types of instance console connections exist: serial console connections and VNC console connections. Instance console connections are for troubleshooting purposes only. To connect to a running instance for administration and general use with Secure Shell (SSH) or Remote Desktop connection, see Connecting to an Instance on page 733.

To configure your console connection, follow these steps:

1. Make sure you have the correct permissions.
2. Complete the prerequisites, including creating your SSH key pair.
3. Create the instance console connection.
4. Connect to the serial console or connect to the VCN console.
5. If you're trying to connect to the serial console and you think the connection isn't working, test your connection to the serial console using Cloud Shell.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

To create instance console connections, an administrator needs to grant user access to manage instance console connections and to read instances through an IAM policy. The resource name for instance console connections is instance-console-connection. The resource name for instances is instance. The following policies grant users the ability to create instance console connections:

Allow group <group_name> to manage instance-console-connection in tenancy
Allow group <group_name> to read instance in tenancy

Instance console connections also support network sources. The following policies grant users the ability to create instance console connections with a network source:

Allow group <group_name> to manage instance-console-connection in tenancy
where request.networkSource.name='example-network-source'
Allow group <group_name> to read instance in tenancy where
request.networkSource.name='example-network-source'

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

Complete these prerequisites before creating the instance console connection.

Installing an SSH Client and a Command-line Shell (Windows)

Windows does not include an SSH client by default. If you are connecting from a Windows client, you need to install an SSH client. You can use PuTTY plink.exe with Windows PowerShell or software that includes a version of OpenSSH such as:

- Git for Windows
- Windows Subsystem for Linux

The instructions in this topic frequently use PuTTY and Windows PowerShell.

If you want to make the console connection from Windows with Windows PowerShell, PowerShell might already be installed on your Windows operating system. If not, follow the steps at the link. If you are connecting to the instance from a Windows client using PowerShell, plink.exe is required. plink.exe is the command link connection tool included with PuTTY. You can install PuTTY or install plink.exe separately. For installation information, see http://www.putty.org.

Creating SSH Key Pairs

To create the secure console connection, you need an SSH key pair. The method to use for creating key pairs depends on your operating system. When connecting to the serial console, you must use an RSA key. The instructions in this section show how to create an RSA SSH key pair.

Creating the SSH key pair for Linux

For detailed instructions about creating an SSH key pair to use on Linux, see Managing Key Pairs on Linux Instances on page 693.

To create an SSH key pair on the command line

If you're using a UNIX-style system, you probably already have the ssh-keygen utility installed. To determine whether the utility is installed, type ssh-keygen on the command line. If the utility isn't installed, you can download OpenSSH for UNIX from http://www.openssh.com/portable.html and install it.

1. Open a shell or terminal for entering the commands.
2. At the prompt, enter ssh-keygen and provide a name for the key when prompted. Optionally, include a passphrase.

   The keys will be created with the default values: RSA keys of 2048 bits.

Alternatively, you can type a complete ssh-keygen command, for example:

```
ssh-keygen -t rsa -N "" -b 2048 -C "<key_name>" -f <path/root_name>
```

The command arguments are shown in the following table:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-t rsa</td>
<td>Use the RSA algorithm.</td>
</tr>
</tbody>
</table>
### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-N &quot;&lt;passphrase&gt;&quot;</td>
<td>A passphrase to protect the use of the key (like a password). If you don't want to set a passphrase, don't enter anything between the quotes. A passphrase is not required. You can specify one as a security measure to protect the private key from unauthorized use. If you specify a passphrase, when you connect to the instance you must provide the passphrase, which typically makes it harder to automate connecting to an instance.</td>
</tr>
<tr>
<td>-b 2048</td>
<td>Generate a 2048-bit key. You don't have to set this if 2048 is acceptable, as 2048 is the default. A minimum of 2048 bits is recommended for SSH-2 RSA.</td>
</tr>
<tr>
<td>-C &quot;&lt;key_name&gt;&quot;</td>
<td>A name to identify the key.</td>
</tr>
<tr>
<td>-f &lt;path/root_name&gt;</td>
<td>The location where the key pair will be saved and the root name for the files.</td>
</tr>
</tbody>
</table>

---

### Creating the SSH key pair for Windows using PuTTY

If you are using a Windows client to connect to the instance console connection, use an SSH key pair generated by PuTTY.

**To create the SSH key pair using PuTTY**

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, `C:\Program Files (x86)\PuTTY`. Double-click `puttygen.exe` to open it.

2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the **Key** menu, confirm that the default value of **SSH-2 RSA key** is selected.
   - For the **Type of key to generate**, accept the default key type of **RSA**.
   - Set the **Number of bits in a generated key** to 2048 if not already set.

3. Click **Generate**.

4. To generate random data in the key, move your mouse around the blank area in the PuTTY window.

5. When the key is generated, it appears under **Public key for pasting into OpenSSH authorized_keys file**.

6. A **Key comment** is generated for you, including the date and timestamp. You can keep the default comment or replace it with your own more descriptive comment.

7. Leave the **Key passphrase** field blank.
7. Click **Save private key**, and then click **Yes** in the prompt about saving the key without a passphrase.

The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.

You can name the key anything you want, but use the .ppk file extension. For example, *mykey.ppk*.

8. Select **all** of the generated key that appears under **Public key for pasting into OpenSSH authorized_keys file**, copy it using **Ctrl + C**, paste it into a text file, and then save the file in the same location as the private key.

(Do not use **Save public key** because it does not save the key in the OpenSSH format.)

You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of pub. For example, *mykey.pub*.

9. Write down the names and location of your public and private key files. You need the public key when creating an instance console connection. You need the private key to connect to the instance console connection using PuTTY.

**Signing in to an instance from the serial console (optional)**

To troubleshoot instances and see serial output using the serial console, you don't need to sign in. To connect to a running instance for administration and general use with Secure Shell (SSH) or Remote Desktop connection, see **Connecting to an Instance** on page 733.

If you want to sign in to an instance using an instance console connection, you can use Secure Shell (SSH) or Remote Desktop connection to sign in. If you want to sign in with a username and password, you need a user account with a password. Oracle Cloud Infrastructure does not set a default password for the **opc** user. Therefore, if you want to sign in as the opc user, you need to create a password for the opc user. Otherwise, add a different user with a password and sign in as that user.

**Connecting Through Firewalls**

If your system is behind a firewall, the system must be able to reach the console servers. The client system connecting to the serial console must be able to reach the serial or VCN console server (for example, *instance-console.us-ashburn-1.oraclecloud.com*) over SSH using port 443, directly or through a proxy.

**Supported Instance Types**

Serial console connections are supported on the following types of instances:

- Virtual machine (VM) instances launched in September 2017 or later
- Bare metal instances launched in November 2017 or later

VNC console connections are supported on the following types of instances:

- VM instances launched on October 13, 2017 or later
- Bare metal instances that use one of the following shapes:
  - BM.Standard2.52 - launched on February 21, 2019 or later
  - BM.Standard.E2.64 - launched after September 17, 2020 in the Oracle Cloud Infrastructure commercial realm
  - BM.Standard.E3.128 - launched on February 21, 2019 or later
  - BM.DenseIO2.52 - launched on February 21, 2019 or later
  - BM.GPU2.2 - launched on February 21, 2019 or later
  - BM.GPU3.8 - launched on February 21, 2019 or later
  - BM.GPU.4.8 - launched on February 21, 2019 or later
  - BM.HPC2.36 - launched on February 21, 2019 or later

**Creating the Instance Console Connection**

Before you can connect to the serial console or VNC console, you need to create the instance console connection.

**Note:**

Instance console connections are limited to one client at a time. If the client fails, the connection remains active for approximately five minutes. During this time, no other client can connect. After five minutes, the connection is
closed, and a new client can connect. During the five-minute timeout, any attempt to connect a new client fails with the following message:

```
channel 0: open failed: administratively prohibited: console access is limited to one connection at a time
Connection to <instance and OCID information> closed.
```

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console Connection.
4. Click Create Console Connection.
5. Upload the public key portion for the SSH key. You have three options for adding the SSH key.
   - **Generate SSH key pair**: You can have Oracle Cloud Infrastructure generate an SSH key pair to use. If you are using PowerShell or PuTTY to connect to the instance from a Windows client, you cannot use the generated SSH key pair without first converting it to a .ppk file.
     - To convert a generated .key private key file
       a. Open PuTTYgen.
       b. Click Load, and select the private key generated when you created the instance. The extension for the key file is .key.
       c. Click Save private key.
       d. Specify a name for the key. The extension for new private key is .ppk.
       e. Click Save.
   - **Choose public key file**: Browse to a public key file on your computer. If you followed the steps in Creating SSH Key Pairs on page 814 in the Prerequisites section to create a key pair, use this option to navigate to the .pub file.
   - **Paste public key**: Paste the content of your public key file into the text box.
6. Click Create Console Connection.

When the console connection has been created and is available, the state changes to Active.

Connecting to the Serial Console

After you create the console connection for the instance, you can connect to the serial console using a Secure Shell (SSH) connection. When connecting to the serial console, you must use an RSA key. You can use the same SSH key for the serial console that was used when you launched the instance, or you can use a different SSH key.

When you are finished with the serial console and have terminated the SSH connection, you should delete the serial console connection. If you do not disconnect from the session, Oracle Cloud Infrastructure terminates the serial console session after 24 hours and you must reauthenticate to connect again.

Connecting from Mac OS X and Linux Operating Systems

Use an SSH client to connect to the serial console. Mac OS X and most Linux distributions include the SSH client OpenSSH by default.

**To connect to the serial console for an instance using OpenSSH on Mac OS X or Linux**

1. On the instance details page in the Oracle Cloud Infrastructure Console, under Resources, click Console Connection.
2. Click the Actions icon (three dots), and then click Copy Serial Console Connection for Linux/Mac.
3. Paste the connection string into a terminal window on a Mac OS X or Linux system, and then press Enter to connect to the console.

If you are not using the default SSH key or ssh-agent, modify the serial console connection string to include the identity file flag, -i, to specify the private key portion for the SSH key to use, for example id_rsa. Specify this flag for both the SSH connection and the SSH ProxyCommand, as shown in the following line:

   `ssh -i /path/<ssh_key> -o ProxyCommand='ssh -i /path/<ssh_key> -W %h:%p -p 443...`

4. Press Enter again to activate the console. If the connection is active, a message appears in the console:

   **IMPORTANT:** Use a console connection to troubleshoot a malfunctioning instance.

5. In the Oracle Cloud Infrastructure Console, reboot your instance. If the instance is functional and the connection is active, the serial output appears in your console. If serial output does not appear in the console, the instance operating system is not booting.

Connecting from Windows Operating Systems

The steps to connect to the serial console from Windows Powershell are different from the steps for OpenSSH. The following steps do not work in the Windows terminal.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are connecting to the instance from a Windows client using PowerShell, plink.exe is required. plink.exe is the command link connection tool included with PuTTY. You can install PuTTY or install plink.exe separately. For more information, see Installing an SSH Client and a Command-line Shell (Windows) on page 814.</td>
</tr>
</tbody>
</table>

To connect to the serial console for an instance on Microsoft Windows

1. On the instance details page in the Oracle Cloud Infrastructure Console, under **Resources**, click **Console Connection**.
2. Click the Actions icon (three dots). Depending on which SSH client you are using, do one of the following:
   - If you are using Windows PowerShell, click **Copy Serial Console Connection for Windows**.
   - If you are using OpenSSH, click **Copy Serial Console Connection for Linux/Mac**.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The copied connection string for Windows contains the parameter -i specifying the location of the private key file. The default value for this parameter in the connection string references an environment variable which might not be configured on your Windows client, or it might not represent the location where the private key file is saved. Verify the value specified for the -i parameter and make any required changes before proceeding to the next step.</td>
</tr>
</tbody>
</table>

3. Paste the connection string copied from the previous step into a text file so that you can add the file path to the private key file.
4. In the text file, replace `$env:homedrive$env:homepath\oci\console.ppk` with the file path to the `.ppk` file on your computer. This file path appears twice in the string. Replace it in both locations.
5. Paste the modified connection string into the PowerShell window or your OpenSSH client, and then press Enter to connect to the console.
6. Press Enter again to activate the console.
7. In the Oracle Cloud Infrastructure Console, reboot your instance. If the instance is functional and the connection is active, the serial output appears in your client. If serial output does not appear in the client, the instance operating system is not booting.
Connecting from Cloud Shell

If you encounter issues when connecting to your instance's serial console using the steps for connection from Mac OS X, Linux, or Windows, test connecting to the serial console using Cloud Shell. Cloud Shell is a web browser-based terminal accessible from the Console, see Cloud Shell for more information. This procedure includes steps to access Cloud Shell. For an introductory walkthrough of using Cloud Shell, see Using Cloud Shell.

Note:

You cannot use Cloud Shell for VNC console connections. You can only use it for serial console connections.

To connect to the serial console for an instance using Cloud Shell

1. Sign in to the Console.
2. Click the Cloud Shell icon in the Console header as shown in the following screenshot:

This action displays the Cloud Shell in a "drawer" at the bottom of the console as shown in the following screenshot:
Welcome to Oracle Cloud Shell.

Your Cloud Shell machine comes with 5GB of storage for your home directory.

john_doe@cloudshell:~ (us-ashburn-1)$
3. Run the following command in Cloud Shell to generate an SSH key pair:

```
ssh-keygen -t rsa
```

4. At the prompt to enter the file in which to save the key, press **Enter** to use the default location.

5. At the passphrase prompt, press **Enter** for no passphrase, and then press **Enter** again to confirm.

6. Run the following command to display the public key, and then copy the output:

```
cat $HOME/.ssh/id_rsa.pub
```

7. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

8. Click the instance that you're interested in.

9. Under **Resources**, click **Console Connection**.

10. Click **Create Console Connection**.

11. Select **Paste SSH Key** and paste the public key contents you copied in step 6.

12. Click **Create Console Connection**.

After the console connection state changes to **Active** proceed to the next step.

13. Click the Actions icon (three dots), and then click **Copy Serial Console Connection for Linux/Mac**.

14. Paste the connection string copied from the previous step to Cloud Shell, and then press **Enter** to connect to the console.

15. Press **Enter** again to activate the console.

### Connecting to the VNC Console

After you create the console connection for the instance, you need to set up a secure tunnel to the VNC server on the instance, and then you can connect with a VNC client.

**Caution:**

The VNC console connection uses SSH port forwarding to create a secure connection from your local system to the VNC server attached to your instance's console. Although this method is a secure way to use VNC over the internet, owners of multiuser systems should know that opening a port on the local system makes it available to all users on that system until a VNC client connects. For this reason, we don't recommend using this product on a multiuser system unless you take proper actions to secure the port or you isolate the VNC client by running it in a virtual environment, such as Oracle VM VirtualBox.

To set up a secure tunnel to the VNC server on the instance using OpenSSH on Mac OS X or Linux

1. On the instance details page in the Oracle Cloud Infrastructure Console, under **Resources**, click **Console Connection**.

2. Click the Actions icon (three dots), and then click **Copy VNC Connection for Linux/Mac**.

3. Paste the connection string copied from the previous step to a terminal window on a Mac OS X or Linux system, and then press **Enter** to set up the secure connection.

4. After the connection is established, open your VNC client and specify **localhost** as the host to connect to and **5900** as the port to use.

**Note:**

Mac OS X Screen Sharing.app Not Compatible with VNC Console Connections

The Mac OS X built-in VNC client, Screen Sharing.app does not work with VNC console connections in Oracle Cloud Infrastructure. Use another VNC client, such as Real VNC Viewer or Chicken.

To set up a secure tunnel to the VNC server on the instance using PowerShell on Windows
Important:

If you are connecting to the VNC server on the instance from a Windows
client using PowerShell, plink.exe is required. plink.exe is the command
link connection tool included with PuTTY. You can install PuTTY or install
plink.exe separately. For installation information, see http://www.putty.org.

1. On the instance details page in the Oracle Cloud Infrastructure Console, under Resources, click Console
Connection.
2. Click the Actions icon (three dots), and then click Copy VNC Connection for Windows.

Tip:

The copied connection string for Windows contains the parameter –i
specifying the location of the private key file. The default value for this
parameter in the connection string references an environment variable
which might not be configured on your Windows client, or it might not
represent the location where the private key file is saved. Verify the value
specified for the –i parameter and make any required changes before
proceeding to the next step.

3. Paste the connection string copied from the previous step to Windows Powershell, and then press Enter to set up
the secure connection.
4. After the connection is established, open your VNC client and specify localhost as the host to connect to and
5900 as the port to use.

Note:

Secure Connection Warning

When you connect, you might see a warning from the VNC client that the
connection is not encrypted. Because you are connecting through SSH, the
connection is secure, so this warning is not an issue.

Troubleshooting Instances from Instance Console Connections on Linux

The following tasks describe steps specific to instances running Oracle Autonomous Linux 7.x, Oracle Linux 8.x,
and Oracle Linux 7.x, connecting from OpenSSH. Other operating system versions and SSH clients might require
different steps.

After you are connected with an instance console connection, you can perform various tasks, such as:

• Edit system configuration files.
• Add or reset the SSH keys for the opc user.
• Reset the password for the opc user.

These tasks require you to boot into a bash shell in maintenance mode.

To boot into maintenance mode

1. Reboot the instance from the Console.
2. When the reboot process starts, switch back to the terminal window, and you see Console messages start to appear
in the window. As soon as the GRUB boot menu appears, use the up/down arrow key to stop the automatic boot
process, enabling you to use the boot menu.
3. In the boot menu, highlight the top item in the menu, and press e to edit the boot entry.
4. In edit mode, use the down arrow key to scroll down through the entries until you reach the line that starts with
linuxefi for instances running Oracle Autonomous Linux 7.x, Oracle Linux 8.x, and Oracle Linux 7.x.
5. At the end of that line, add the following:

```
init=/bin/bash
```
6. Reboot the instance from the terminal window by entering the keyboard shortcut CTRL+X.
When the instance has rebooted, you see the Bash shell command line prompt, and you can proceed with the following procedures.

**To edit the system configuration files**

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying:

   ```bash
   /usr/sbin/load_policy -i
   ```

2. Run the following command to remount the root partition with read/write permissions:

   ```bash
   /bin/mount -o remount, rw /
   ```

3. Edit the configuration files as needed to try to recover the instance.

4. After you have finished editing the configuration files, to start the instance from the existing shell, run the following command:

   ```bash
   exec /usr/lib/systemd/systemd
   ```

   Alternatively, to reboot the instance, run the following command:

   ```bash
   /usr/sbin/reboot -f
   ```

**To add or reset the SSH key for the opc user**

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying:

   ```bash
   /usr/sbin/load_policy -i
   ```

2. Run the following command to remount the root partition with read/write permissions:

   ```bash
   /bin/mount -o remount, rw /
   ```

3. From the Bash shell, run the following command to change to the SSH key directory for the opc user:

   ```bash
   cd ~opc/.ssh
   ```

4. Rename the existing authorized keys file with the following command:

   ```bash
   mv authorized_keys authorized_keys.old
   ```

5. Replace the contents of the public key file with the new public key file with the following command:

   ```bash
   echo '<contents of public key file>' >> authorized_keys
   ```

6. Restart the instance by running the following command:

   ```bash
   /usr/sbin/reboot -f
   ```

**To reset the password for the opc user**

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying. This step is necessary to sign in to your instance using SSH and the Console.

   ```bash
   /usr/sbin/load_policy -i
   ```

2. Run the following command to remount the root partition with read/write permissions:

   ```bash
   /bin/mount -o remount, rw /
   ```
3. Run the following command to reset the password for the opc user:

```
sudo passwd opc
```

4. Restart the instance by running the following command:

```
sudo reboot -f
```

### Exiting the Instance Console Connection

#### To exit the serial console connection

When using SSH, the ~ character at the beginning of a new line is used as an escape character.

- To exit the serial console, enter:

```
~.
```

- To suspend the SSH session, enter:

```
~^z
```

The ^ character represents the CTRL key.

- To see all the SSH escape commands, enter:

```
~?
```

#### To exit the VNC console connection

1. Close the VNC client.
2. In the Terminal or PowerShell window, type `CTRL C`

When you are finished using the console connection, delete the connection for the instance.

#### To delete the console connection for an instance

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you’re interested in.
3. Under Resources, click Console Connection.
4. Click the Actions icon (three dots), and then click Delete. Confirm when prompted.

### Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 211.

#### To manage tags for an instance console connection

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click the instance that you’re interested in.
3. Under Resources, click Console Connection.
4. For the console connection that you’re interested in, click the Actions icon (three dots) and then click Add Tags.
   To view existing tags, click View Tags.

### Sending a Diagnostic Interrupt

**Caution:**

This feature is for advanced users. Sending a diagnostic interrupt to a live system can cause data corruption or system failure.

You can send a diagnostic interrupt to debug an unresponsive or unreachable compute virtual machine (VM) instance.
A diagnostic interrupt causes the instance's OS to crash and reboot. Before you send a diagnostic interrupt, you must configure the OS to generate a crash dump (also called a memory dump file) when it crashes. The crash dump captures information about the state of the OS at the time of the crash. After the OS restarts, you can analyze the crash dump to identify and debug the issue.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let users launch compute instances on page 2143 includes the ability to send a diagnostic interrupt to an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2181.

**Prerequisites**

- The instance's OS must be configured to generate a crash dump file.
- The instance must be in the Running state. For more information, see Stopping and Starting an Instance on page 779.
- There are no in-progress actions affecting the instance, such as block volumes or secondary VNICs in the process of being attached or detached.

**Configuring the OS to Generate a Crash Dump**

Before you send a diagnostic interrupt to an instance, you must configure the OS to generate a crash dump when it crashes. The diagnostic interrupt is received as a non-maskable interrupt (NMI) on the target instance.

The steps depend on the OS.

**Linux**

**Note:**

On Oracle-provided images for Oracle Linux, the OS is either fully configured or partially configured to generate a crash dump, depending on the image release date.

**Oracle Linux 8**

- **Images released in August 2020 or later:** The image is fully configured to generate a crash dump.
- **Earlier images:** The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

**Oracle Linux 7**

- **Images released in August 2020 or later:** The image is fully configured to generate a crash dump.
- **Earlier images:** The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

**Oracle Linux 6**

- **Images released in September 2020 or later:** The image is fully configured to generate a crash dump.
Earlier images: The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

1. Connect to the instance.
2. Install and configure the dump-capture kernel:
   a. Install kdump and kexec by running the following command:
      
      ```bash
      sudo yum install kexec-tools
      ```
   b. Reserve memory on the kernel to save the crash dump. Do the following:
      1. Open the `etc/default/grub` file in a text editor.
      2. In the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, add the parameter `crashkernel=<memory-to-reserve>`. For example, to reserve 100 MB, add `crashkernel=100M`.
      3. Save the changes and close the file.
      4. Rebuild the GRUB file by running the following command:
         ```bash
         sudo grub2-mkconfig -o /boot/grub2/grub.cfg
         ```
   3. Configure the kernel to crash when it receives a diagnostic interrupt. To do this, open the `/etc/sysctl.conf` file in a text editor and add the following line:
      ```
      kernel.unknown_nmi_panic=1
      ```
   4. Apply the change to `/etc/sysctl.conf` by running the following command:
      ```bash
      sysctl -p
      ```

Windows Server - Oracle-Provided Image

If you use an Oracle-provided image for Windows Server that was released in April 2020 or later, the image is already configured to generate a crash dump.

If you use an image that was released before April 2020, do the following:

1. Connect to the instance.
2. Download the Oracle Windows VirtIO drivers:
   a. Sign in to the Oracle Software Delivery Cloud site.
   b. In the All Categories list, select Release.
   c. Type Oracle Linux 7.7 in the search box and click Search.
   d. Add REL: Oracle Linux 7.7.x to your cart, and then click Continue.
   e. In the Platforms/Languages list, select x86 64 bit. Click Continue.
   f. Accept the license agreement and then click Continue.
   g. Select the check box next to Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5. Clear the other check boxes.
   h. Click Download and then follow the prompts.
3. Install the drivers and then restart the instance. For steps, see Installing the Oracle VirtIO Drivers for Microsoft Windows on Existing Microsoft Windows Guests.

Windows Server - Customer-Provided Image

Refer to the third-party documentation for your operating system for more information.

Sending a Diagnostic Interrupt

After you configure the instance's OS to generate a crash dump when it crashes, use the following procedures to send a diagnostic interrupt.
To send a diagnostic interrupt using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Compute and click Instances.
2. Click More Actions, and then click Send Diagnostic Interrupt.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sending a diagnostic interrupt to a live system can cause data corruption or system failure.</td>
</tr>
</tbody>
</table>

3. Review the confirmation message and then click Send Diagnostic Interrupt.

   The lifecycle state that appears in the Console remains Running while the instance's OS crashes and restarts. Do not send multiple diagnostic interrupts.

4. Wait several minutes for the instance's OS to restart, and then connect to the instance. You can now retrieve and analyze the crash dump.

To send a diagnostic interrupt using the API

Use the InstanceAction operation, passing the value SENDDIAGNOSTICINTERRUPT as the action to perform.

Analyzing a Crash Dump

The crash dump is saved locally on the instance's OS.

- **Linux instances**: The default location where the crash dump is saved depends on the Linux distribution.
  - Oracle Linux 8, Oracle Linux 7: saved in /var/oled/crash
  - Other Linux distributions: saved in /var/crash/

To change the location, modify the /etc/kdump.conf file.

- **Windows instances**: The crash dump is saved in %SystemRoot%memory.dmp. On most Windows systems, this is C:\Windows\memory.dmp.

To analyze the crash dump, use a third-party tool such as the crash utility on Linux instances or WinDbg on Windows instances.

Updating the Linux iSCSI Service to Restart Automatically

Oracle Cloud Infrastructure supports iSCSI attached remote boot and block volumes to Compute instances. These iSCSI attached volumes are managed by the Linux iSCSI initiator service, iscsid. In scenarios where this service is stopped for any reason, such as the service crashes or a system administrator inadvertently stops the service, it's important that this service is automatically restarted immediately.

The following platform images distributed by Oracle Cloud Infrastructure are configured so that the iscsid service restarts automatically:

- Oracle Autonomous Linux 7 images.
- Oracle Linux 8 images.
- Oracle Linux 7 images released February 26, 2019 and later. See the release notes for Oracle-Linux-7.6-Gen2-GPU-2019.02.20-0 and Oracle-Linux-7.6-2019.02.20-0.
- Oracle Linux 6 images released February 26, 2019 and later. See the release notes for Oracle-Linux-6.10-2019.02.22-0.
- CentOS 7 images released February 25, 2019 and later. See the release notes for CentOS-7-2019.02.23-0.

Instances created from earlier versions of CentOS 7.x and Oracle Linux platform images, or any versions of Ubuntu platform images, do not have this configuration. You should update these existing instances and custom images created from these images so that the iscsid service restarts automatically. You should also check this configuration on your imported paravirtualized custom images and any instances launched from these images and update the configuration as needed.

This topic describes how to update the iscsid service on an instance so that it will restart automatically.
**Note:**

Configuring an instance to automatically restart the `iscsid` service does not require a reboot and will increase the stability of your infrastructure.

**Oracle Linux 7**

Run the following command to update the `iscsid` service on your Oracle 7 Linux instances:

```
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the `iscsid` service should be 6.2.0.874 or newer.

Run the following command to check the version:

```
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring `iscsid` to restart automatically.

**Oracle Linux 6**

Run the following command to update the `iscsid` service on your Oracle 6 Linux instances:

```
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the `iscsid` service should be 6.2.0.873 or newer.

Run the following command to check the version:

```
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring `iscsid` to restart automatically.

**CentOS 7.x**

**Important:**

Do not directly edit the `systemd iscsid.service` file. You should instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your CentOS 7 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```
Ubuntu 18

Important:
Do not directly edit the systemctl iscsid.service file, instead create an override to ensure that the restart option isn't overwritten the next time the iscsid service is updated.

On your Ubuntu 18 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=
Restart=always
```

Run the following commands to reload systemd and restart the iscsid service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Ubuntu 16

Important:
Do not directly edit the systemctl iscsid.service file, instead create an override to ensure that the restart option isn't overwritten the next time the iscsid service is updated.

On your Ubuntu 16 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=
Restart=always
```

Run the following commands to reload systemd and restart the iscsid service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Ubuntu 14

On your Ubuntu 14 instances run the following command to install the monit package:

```
sudo apt-get install monit
```

Create the `/etc/monit/conf.d/iscsid.conf` file and include the following commands:

```
check process iscid with pidfile /run/iscsid.pid
start program = "/etc/init.d/open-iscsi start" with timeout 60 seconds
stop program = "/etc/init.d/open-iscsi stop"
```
Run the following command to start the `monit` service:

```
/etc/init.d/monit start
```

**Testing the iscsid Service Update**

Perform these steps to verify that the `iscsid` service has been updated successfully, and that it restarts automatically.

```
1. Run the following command to confirm that the `iscsid` service is running:
   `ps -ef | grep iscsid`

2. Run the following command to stop the `iscsid` service:
   `sudo pkill -9 iscsid`

3. Wait 60 seconds and then run the following command to verify that the `iscsid` service has restarted:
   `ps -ef | grep iscsid`
```

**Windows Generalized Image Support Files**

To generalize a Windows custom image, download the appropriate file for your instance based on the shape of the instance. Then, follow the instructions in Creating Windows Custom Images on page 668.

The files apply to the following Windows versions:

- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2

**VM Instances**

Use this download for all VM instances.

Download: `oracle-cloud_windows-server_generalize_2019-02-06.SED.EXE`

**Bare Metal Instances - AMD Shapes**

Use this download for AMD-based bare metal instances.

Download: `oracle-cloud_windows-server-bm-gen2_generalize_2019-01-31.SED.EXE`

**Bare Metal Instances - X7 Shapes**

Use this download for X7-based bare metal instances.

Download: `oracle-cloud_windows-server-bm-gen2_generalize_2019-01-31.SED.EXE`

**Bare Metal Instances - X5 Shapes**

Use this download for X5-based bare metal instances.

Download: `oracle-cloud_windows-server_generalize_2019-02-06.SED.EXE`
Chapter 12

Container Engine for Kubernetes

This chapter explains how to define and create Kubernetes clusters to enable the deployment, scaling, and management of containerized applications.

Overview of Container Engine for Kubernetes

Oracle Cloud Infrastructure Container Engine for Kubernetes is a fully-managed, scalable, and highly available service that you can use to deploy your containerized applications to the cloud. Use Container Engine for Kubernetes (sometimes abbreviated to just OKE) when your development team wants to reliably build, deploy, and manage cloud-native applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing OCI tenancy.

Container Engine for Kubernetes uses Kubernetes - the open-source system for automating deployment, scaling, and management of containerized applications across clusters of hosts. Kubernetes groups the containers that make up an application into logical units (called pods) for easy management and discovery. Container Engine for Kubernetes uses versions of Kubernetes certified as conformant by the Cloud Native Computing Foundation (CNCF). Container Engine for Kubernetes is itself ISO-compliant (ISO-IEC 27001, 27017, 27018).

You can access Container Engine for Kubernetes to define and create Kubernetes clusters using the Console and the REST API. You can access the clusters you create using the Kubernetes command line (kubectl), the Kubernetes Dashboard, and the Kubernetes API.

Container Engine for Kubernetes is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 4368.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.
Container Engine for Kubernetes

See Container Engine for Kubernetes on page 1842 for details about Container Engine for Kubernetes resources that emit events.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 197.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Note that to perform certain operations on clusters created by Container Engine for Kubernetes, you might require additional permissions granted via a Kubernetes RBAC role or clusterrole. See About Access Control and Container Engine for Kubernetes on page 920.

Container Engine for Kubernetes Capabilities and Limits

In each region that is enabled for your tenancy, you can create three clusters (Monthly Universal Credits) or one cluster (Pay-as-You-Go or Promo) by default. Each cluster you create can have a maximum of 1000 nodes. A maximum of 110 pods can run on each node. See Service Limits on page 215.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Container Engine for Kubernetes, see:

• Policy Configuration for Cluster Creation and Deployment on page 868
• Details for Container Engine for Kubernetes on page 2177

Container Engine and Kubernetes Concepts

Clusters and Nodes

A Kubernetes cluster is a group of nodes. The nodes are the machines running applications. Each node can be a physical machine or a virtual machine. The node's capacity (its number of CPUs and amount of memory) is defined when the node is created. A cluster comprises:

• One or more control plane nodes (previously referred to as 'master nodes'). For high availability, typically there will be a number of control plane nodes.
• One or more worker nodes (sometimes known as 'minions').
A Kubernetes cluster can be organized into namespaces, to divide the cluster's resources between multiple users. Initially, a cluster has the following namespaces:

- **default**, for resources with no other namespace
- **kube-system**, for resources created by the Kubernetes system
- **kube-node-lease**, for one lease object per node to help determine node availability
- **kube-public**, usually used for resources that have to be accessible across the cluster

### Kubernetes Processes

The control plane nodes in a cluster run a number of processes:

- **kube-apiserver** to support API operations via the Kubernetes command line tool (kubectl) and the REST API, and includes admissions controllers required for advanced Kubernetes operations
- **kube-controller-manager** to manage different Kubernetes components (for example, replication controller, endpoints controller, namespace controller, and serviceaccounts controller)
- **kube-scheduler** to control where in the cluster to run jobs
- **etcd** to store the cluster's configuration data

Each worker node runs two Kubernetes processes:

- **kubelet** to communicate with the control plane nodes
- **kube-proxy** to handle networking

Each worker node also runs the Docker runtime.

The Kubernetes processes running on the control plane nodes are collectively referred to as the Kubernetes Control Plane. Together, the Control Plane processes monitor and record the state of the cluster and distribute requested operations between the nodes in the cluster.

### Pods

Where an application running on a worker node comprises multiple containers, Kubernetes groups the containers into a single logical unit called a pod for easy management and discovery. The containers in the pod share the same networking namespace and the same storage space, and can be managed as a single object by the Kubernetes Control Plane. A number of pods providing the same functionality can be grouped into a single logical set known as a service.

### Manifest Files (or Pod Specs)

A Kubernetes manifest file comprises instructions in a yaml or json file that specify how to deploy an application to the node or nodes in a Kubernetes cluster. The instructions include information about the Kubernetes deployment, the Kubernetes service, and other Kubernetes objects to be created on the cluster. The manifest is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed). The parameters to include in a Kubernetes manifest file are described in the Kubernetes documentation.

### Node Pools

A node pool is a subset of machines within a cluster that all have the same configuration. Node pools enable you to create pools of machines within a cluster that have different configurations. For example, you might create one pool of nodes in a cluster as virtual machines, and another pool of nodes as bare metal machines. A cluster must have a minimum of one node pool, but a node pool need not contain any worker nodes.

### Admission Controllers

A Kubernetes admission controller intercepts authenticated and authorized requests to the Kubernetes API server before admitting an object (such as a pod) to the cluster. An admission controller can validate an object, or modify it, or both. Many advanced features in Kubernetes require an enabled admission controller. For more information, see the Kubernetes documentation.
Preparing for Container Engine for Kubernetes

Before you can use Container Engine for Kubernetes to create a Kubernetes cluster:

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Container Engine for Kubernetes is available (see Availability by Region on page 836).
- Your tenancy must have sufficient quota on different types of resource (see Service Limits on page 215). More specifically:
  - Compute instance quota: To create a Kubernetes cluster, at least one compute instance (node) must be available in the tenancy. However, you'll probably want more than this minimum. For example, to create a highly available cluster in a region with three availability domains (ADs), at least three compute instances must be available (one in each availability domain).
  - Block volume quota: If you intend to create Kubernetes persistent volumes, sufficient block volume quota must be available in each availability domain to meet the persistent volume claim. Persistent volume claims must request a minimum of 50 gigabytes. See Creating a Persistent Volume Claim on page 947.
  - Load balancer quota: If you intend to create a load balancer to distribute traffic between the nodes running a service in a Kubernetes cluster, sufficient load balancer quota must be available in the region. See Creating Load Balancers to Distribute Traffic Between Cluster Nodes on page 937.
- Within your tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
- Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. For example, to create a highly available cluster in a region with three availability domains, the VCN must include:
  - For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
  - For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

Best practice is to use regional subnets to make failover across availability domains simpler to implement.

When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for the new cluster, or you can specify existing network resources. If you specify existing network resources, you or somebody else must have already configured those resources appropriately. See Network Resource Configuration for Cluster Creation and Deployment on page 836.

- To create and/or manage clusters, you must belong to one of the following:
  - The tenancy's Administrators group
  - A group to which a policy grants the appropriate Container Engine for Kubernetes permissions. If you are creating or modifying clusters using the Console, or want Container Engine for Kubernetes to automatically
create and configure new network resources for a new cluster, policies must also grant the group the following permissions:

- VCN_READ and VCN_CREATE
- SUBNET_READ and SUBNET_CREATE
- COMPARTMENT_INSPECT
- INTERNET_GATEWAY_CREATE
- NAT_GATEWAY_CREATE
- ROUTE_TABLE_UPDATE
- SECURITY_LIST_CREATE

If you want to create a service gateway to enable applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) without exposing data to the public internet, a policy must also grant the group the SERVICE_GATEWAY_CREATE permission.

See Create Required Policy for Groups on page 868.

- To perform operations on a cluster:
  - You must be able to run the Kubernetes command line tool kubectl. You can use the kubectl installation included in Cloud Shell, or you can use a local installation of kubectl (see Accessing a Cluster Using Kubectl on page 890).
  - You must have set up your own copy of the cluster's kubeconfig configuration file (see Setting Up Cluster Access on page 876). Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up.
  - You must have appropriate permissions to access the cluster (see About Access Control and Container Engine for Kubernetes on page 920).

**Availability by Region**

Container Engine for Kubernetes is available in all the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 180. Refer to that topic to see region identifiers, region keys, and availability domain names.

In some cases, you might have to use shortened versions of availability domain names. For example, when defining a persistent volume claim (PVC), to request storage in a particular availability domain by specifying the value of the failure-domain.beta.kubernetes.io/zone Kubernetes label. To find out how to construct shortened versions of availability domain names, see failure-domain.beta.kubernetes.io/zone on page 899.

**Network Resource Configuration for Cluster Creation and Deployment**

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy:

- Within the tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
- Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for a new ‘quick cluster’. Alternatively, you can explicitly specify the existing network resources to use for a ‘custom cluster’. If you specify existing network resources, you or somebody else must have already configured those resources appropriately, as described in this topic.

This topic describes the necessary configuration for each network resource. To see details of a typical configuration, see Example Network Resource Configurations on page 840.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.
**VCN Configuration**

The VCN in which you want to create and deploy clusters must be configured as follows:

- The VCN must have a CIDR block defined that is large enough for the number of subnets you specify for the clusters you create. For example, to create a highly available cluster in a region with three availability domains will typically require two regional subnets (recommended) or five AD-specific subnets to support the necessary number of worker nodes and load balancers. However, you can create clusters with fewer subnets. A /16 CIDR block would be large enough for almost all use cases (10.0.0.0/16 for example). The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for pods and for the Kubernetes services (see **CIDR Blocks and Container Engine for Kubernetes** on page 867).

- The VCN must have an appropriate number of subnets defined. For example, to create a highly available cluster in a region with three availability domains, the VCN must include:
  - For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
  - For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

However, you can create clusters with fewer worker nodes, and fewer or no load balancers, and therefore require fewer subnets. Best practice is to use regional subnets to make failover across availability domains simpler to implement. See **Subnet Configuration** on page 839.

- The VCN must have security lists defined for worker node subnets and load balancer subnets (if specified). See **Security List Configuration** on page 838.

In addition:

- Oracle recommends DNS Resolution is selected for the VCN.

- If you expect applications deployed on a cluster to require worker nodes to initiate connections to the internet, the VCN must have an internet gateway (if the worker nodes are in public subnets) or a NAT gateway (if the worker nodes are in private subnets). See **Internet Gateway Configuration** on page 837 and **NAT Gateway Configuration** on page 837.

- If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you don't want to expose the data to the public internet, you can define a service gateway in the VCN. See **Service Gateway Configuration** on page 837.

- If the VCN has a NAT gateway, an internet gateway, or a service gateway, it must have a route table with appropriate rules defined. See **Route Table Configuration** on page 838.

See **VCNs and Subnets** on page 2821 and **Example Network Resource Configurations** on page 840.

**Internet Gateway Configuration**

If you intend to deploy worker nodes in public subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, the VCN must have an internet gateway. The internet gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 in a route rule in a worker node route table.

See **VCNs and Subnets** on page 2821 and **Example Network Resource Configurations** on page 840.

**NAT Gateway Configuration**

If you intend to deploy worker nodes in private subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, the VCN must have a NAT gateway. The NAT gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 in a route rule in a worker node route table.

See **NAT Gateway** on page 3247 and **Example Network Resource Configurations** on page 840.

**Service Gateway Configuration**

If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you want to protect data from the public internet, you can set up a service gateway. Setting up a service gateway enables worker nodes to access other resources in the same region without exposing data to the public internet.
When setting up the service gateway, create it in the same VCN and compartment as the worker nodes, and select the **All <region> Services in Oracle Services Network** option.

Having created the service gateway, it must be specified as the target for **All <region> Services in Oracle Services Network** in a route rule in the worker node route table.

Note that if you expect deployed applications to require access to public endpoints or services not supported by a service gateway (for example, to download updates or patches), configure additional network resources (such as a NAT gateway) to access the internet.

### Route Table Configuration

If you intend to deploy worker nodes in public subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, create an internet gateway. Then create a worker node route table with a route rule that specifies the internet gateway as the target for the destination CIDR block 0.0.0.0/0.

If you intend to deploy worker nodes in private subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, create a NAT gateway. Then create a worker node route table with a route rule that specifies the NAT gateway as the target for the destination CIDR block 0.0.0.0/0.

If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you don't want to expose the data to the public internet, create a service gateway. Then create a worker node route table with a route rule that specifies the service gateway as the target for **All <region> Services in Oracle Services Network**.

Note that to avoid the possibility of asymmetric routing, a route table for a public subnet cannot contain both a route rule that targets an internet gateway as well as a route rule that targets a service gateway (for more information, see [Issues with access from Oracle services through a service gateway to your public instances](https://docs.oracle.com/en-us/oracle-cloud/instances-cloud-infrastructure/1.1.0/oracle-cloud-infrastructure-user-guide/content/issue-with-access-from-oracle-services-through-service-gateway-to-your-public-instances.html)).

### DHCP Options Configuration

The VCN in which you want to create and deploy clusters must have DHCP Options configured. The default value for **DNS Type** of Internet and VCN Resolver is acceptable.

### Security List Configuration

The VCN in which you want to create and deploy clusters must have security lists defined for worker node subnets and load balancer subnets (if specified). The security lists for worker node subnets and load balancer subnets must be different. The security list for load balancer subnets must be unique and for their exclusive use.

Worker nodes are created with public or private IP addresses, according to whether you specify public or private subnets when defining the node pools in a cluster. Container Engine for Kubernetes must be able to access worker nodes.

### Public Worker Node Subnet Security List Configuration

When configuring a security list for public worker node subnets, the security list must have:

- Stateless ingress and egress rules that allow all traffic between different worker node subnets. (Usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. Only in the rare case where no inter-pod communication is expected, is this not required.)
- Stateless ingress and egress rules that allow all traffic between worker node subnets and load balancer subnets (if specified).
- Stateful egress rules that allow traffic between worker node subnets and Container Engine for Kubernetes.
Optionally, you can include ingress rules for public worker node subnets to:

- Explicitly allow SSH access to worker nodes on port 22 (see Connecting to Worker Nodes in Public Subnets Using SSH on page 904).
- Allow inbound traffic to the worker nodes on the default NodePort range of 30000 to 32767 (see the Kubernetes documentation).

Optionally, you can include an egress rule that allows all outbound traffic to the internet.

**Private Worker Node Subnet Security List configuration**

When configuring a security list for private worker node subnets, the security list must have:

- Stateless ingress and egress rules that allow all traffic between the different worker node subnets. (Usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. Only in the rare case where no inter-pod communication is expected, is this not required.)
- Stateless ingress and egress rules that allow all traffic between worker node subnets and load balancer subnets.
- Stateful egress rules that allow traffic between worker node subnets and Container Engine for Kubernetes.

Optionally, you can include ingress rules for private worker node subnets to:

- Explicitly allow SSH access to worker nodes on port 22 from within the VCN CIDR block (see Connecting to Worker Nodes in Private Subnets Using SSH on page 905).
- Allow inbound traffic to the worker nodes on the default NodePort range of 30000 to 32767 from within the VCN CIDR block (see the Kubernetes documentation).

Optionally, you can include an egress rule that allows all outbound traffic to the internet.

**Subnet Configuration**

The characteristics of the cluster you want to create, and the number of availability domains in the region in which you want to deploy the cluster, will determine the number of subnets to configure. For example, to create a highly available cluster in a region with three availability domains will require:

- For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
- For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

Best practice is to use regional subnets to make failover across availability domains simpler to implement.

The VCN in which you want to create and deploy clusters must have at least one subnet defined in which to deploy worker nodes. Worker node subnets can be either public, or private for additional security (as specified by the Subnet access property). The number of worker node subnets to create depends on the region in which you are creating the cluster:

- If you are creating a cluster in a region with multiple availability domains, you can define a single regional subnet (recommended), or multiple AD-specific subnets (one in each of the availability domains).
- If you are creating a cluster in a region with a single availability domain, you can define a single regional subnet (recommended), or a single AD-specific subnet.

You have the option to define and use load balancers in clusters you create. If you want to define and use load balancers, the VCN in which you want to create and deploy clusters must have at least one subnet defined to host the load balancers. Load balancer subnets can be public or private (as specified by the Subnet access property). However, load balancers are optional, so you might not define load balancer subnets at all. The number of load balancer subnets to define depends on the region in which you are creating the cluster:

- If you are creating a cluster in a region with three availability domains, you can define:
  - zero or one load balancer regional subnet (recommended)
  - zero or two load balancer AD-specific subnets. If you define two load balancer AD-specific subnets, they must be in different availability domains.
• If you are creating a cluster in a region with a single availability domain, you can define zero or one load balancer subnet:
  • zero or one load balancer regional subnet (recommended)
  • zero or one load balancer AD-specific subnet.

In addition, all subnets must have the following properties set as shown:
• Route Table: The name of a route table, if one has been created, that has a route rule specifying an internet gateway (for public worker node subnets) or NAT gateway (for private worker node subnets) as the target for the destination CIDR block 0.0.0.0/0, and/or a route rule specifying a service gateway as the target for all `<region>` Services in Oracle Services Network.
• DHCP options: Default.

The CIDR blocks you specify for worker node and load balancer subnets must not overlap with CIDR blocks you specify for pods running in the cluster (see CIDR Blocks and Container Engine for Kubernetes on page 867).

Worker node subnets must have different security lists to load balancer subnets.

See VCNs and Subnets on page 2821 and Example Network Resource Configurations on page 840.

Example Network Resource Configurations

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy:
• Within the tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
• Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for a new 'quick cluster'. Alternatively, you can explicitly specify the existing network resources to use for a 'custom cluster'. If you specify existing network resources, you or somebody else must have already configured those resources appropriately. See Network Resource Configuration for Cluster Creation and Deployment on page 836.

This topic gives examples of how you might configure network resources for highly available 'custom cluster' creation and deployment in a region with three availability domains:
• for public clusters, where you want worker nodes hosted in public AD-specific subnets that can be accessed directly from the internet (see Example 1: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets on page 841)
• for private clusters, where you want worker nodes hosted in private AD-specific subnets that can only be accessed from within the VCN (see Example 2: Example Network Resource Configuration for a Highly Available Private Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets on page 852)
• for public clusters, where you want worker nodes hosted in a public regional subnet that can be accessed directly from the internet (see Example 3: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using a Regional Subnet on page 861)

Note that all the examples in this topic include a service gateway to enable worker nodes to access other Oracle Cloud Infrastructure resources in the same region (such as Oracle Cloud Infrastructure Registry) without exposing data to the public internet. However, you might be expecting applications deployed on the cluster to require access to public endpoints or services not supported by a service gateway. For example, to download updates or patches. If so, configure additional network resources (such as a NAT gateway) to access the internet.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.
Example 1: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets

This example assumes you want worker nodes hosted in three public AD-specific subnets that can be accessed directly from the internet.

Three worker node AD-specific subnets created manually, named, and defined as follows:

- **Name:** workers-1 with the following properties:
  - **Availability Domain:** AD1
  - **CIDR Block:** 10.0.10.0/25
  - **Route Table:** routetable-1
  - **Subnet access:** Public
  - **DNS Resolution:** Selected
  - **DHCP Options:** Default
  - **Security List:** workers

- **Name:** workers-2 with the following properties:
  - **Availability Domain:** AD2
  - **CIDR Block:** 10.0.11.0/25
  - **Route Table:** routetable-1
  - **Subnet access:** Public
  - **DNS Resolution:** Selected
  - **DHCP Options:** Default
  - **Security List:** workers

- **Name:** workers-3 with the following properties:
  - **Availability Domain:** AD3
  - **CIDR Block:** 10.0.12.0/25
  - **Route Table:** routetable-1
  - **Subnet access:** Public
  - **DNS Resolution:** Selected
  - **DHCP Options:** Default
  - **Security List:** workers

Two load balancer AD-specific subnets created, named, and defined as follows:

- **Name:** loadbalancers-1 with the following properties:
  - **Availability Domain:** AD1
  - **CIDR Block:** 10.0.20.0/24
  - **Route Table:** routetable-0
  - **Subnet access:** Public
  - **DNS Resolution:** Selected
  - **DHCP Options:** Default
  - **Security List:** loadbalancers

- **Name:** loadbalancers-2 with the following properties:
  - **Availability Domain:** AD2
  - **CIDR Block:** 10.0.21.0/24
  - **Route Table:** routetable-0
  - **Subnet access:** Public
  - **DNS Resolution:** Selected
  - **DHCP Options:** Default
  - **Security List:** loadbalancers

Example Security List Configurations for a Highly Available Public Cluster Using AD-Specific Subnets

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from the public worker node AD-specific subnets and the load balancer AD-specific subnets. The two security lists are named 'workers' and 'loadbalancers' respectively.

Note that two sets of alternative ingress and egress rules are given for the 'loadbalancers' security list, showing how to allow either unrestricted access to/from the cluster, and how to restrict access to/from a specific CIDR range.

Example Ingress Rules in the 'workers' Security List for Public Worker Node AD-Specific Subnets:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>State: Stateless Src. Type: CIDR</td>
<td>10.0.10.0/25</td>
<td>Protocol: All Src. Port Range: n/a Dest. Port Range: n/a</td>
<td>n/a</td>
<td>Allows: All traffic for all ports Description: This optional rule enables intra-VCN traffic. Although optional, this rule is usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. Only in the rare case where no inter-pod communication is expected, is this rule not required.</td>
</tr>
<tr>
<td>----</td>
<td>------------------</td>
<td>----------</td>
<td>---------------------------------------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>2</td>
<td>Stateless</td>
<td>10.0.11.0/25</td>
<td>Protocol: All Src. Port Range: n/a Dest. Port Range: n/a</td>
<td>n/a</td>
<td>Allows: All traffic for all ports</td>
</tr>
<tr>
<td>3</td>
<td>Stateless</td>
<td>10.0.12.0/25</td>
<td>Protocol: All Src. Port Range: n/a Dest. Port Range: n/a</td>
<td>n/a</td>
<td>Allows: All traffic for all ports</td>
</tr>
</tbody>
</table>
### Example Egress Rules in the 'workers' Security List for Public Worker Node AD-Specific Subnets:

Consider these egress rules as a minimum requirement. If applications deployed on worker nodes need to communicate with destinations outside of the Oracle Service Network, add additional egress rules. For example, if applications use Helm charts from the Helm stable repository, or Docker images from docker.io.

*Example Ingress Rules in the 'loadbalancers' Security List for Load Balancer AD-Specific Subnets:*

If you want to allow unrestricted incoming traffic through the load balancer from the public internet, set up the following security rule:
### Example Egress Rules in the 'loadbalancers' Security List for Load Balancer AD-Specific Subnets:

If you want to allow unrestricted outgoing response traffic through the load balancer to the public internet, set up the following security rules:

|---|------------------|-----------|-----------------------------|-------------------|-------------|---------|-------------|
| 1 | Stateful         | 160.34.126.216/30 | Protocol: TCP            | Src. Port Range: All | Dest. Port Range: All | n/a     | Allows: TCP traffic for all ports: all  
Description: This rule only allows incoming public traffic to service load balancers from a particular public CIDR range. |
<table>
<thead>
<tr>
<th>#</th>
<th>State:</th>
<th>Dest. Type:</th>
<th>Dest. CIDR</th>
<th>Protocol: Src. Port Range:</th>
<th>Type: Code:</th>
<th>Allows:</th>
<th>Description:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>State:</td>
<td>Stateless</td>
<td>0.0.0.0/0</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: all</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Dest. Type:</td>
<td></td>
<td>Src. Port Range: All</td>
<td></td>
<td>Description: This rule enables responses from a web application through the service load balancers.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CIDR</td>
<td></td>
<td></td>
<td>Dest. Port Range: All</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Alternatively, if you want to restrict outgoing response traffic through the load balancer to just that going to worker node subnets in the cluster, set up the following security rules:

<table>
<thead>
<tr>
<th>#</th>
<th>State:</th>
<th>Dest. Type:</th>
<th>Dest. CIDR</th>
<th>Protocol: Src. Port Range:</th>
<th>Type: Code:</th>
<th>Allows:</th>
<th>Description:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>State: Stateful</td>
<td>Dest. Type:</td>
<td>10.0.10.0/25</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: all</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>CIDR</td>
<td></td>
<td>Src. Port Range: All</td>
<td></td>
<td>Description: This rule restricts responses of the web application to the workers-1 subnet.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Dest. Port Range: All</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>State: Stateful</td>
<td>Dest. Type:</td>
<td>10.0.11.0/25</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: all</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>CIDR</td>
<td></td>
<td>Src. Port Range: All</td>
<td></td>
<td>Description: This rule restricts responses of the web application to the workers-2 subnet.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Dest. Port Range: All</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>State: Stateful</td>
<td>Dest. Type:</td>
<td>10.0.12.0/25</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: all</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>CIDR</td>
<td></td>
<td>Src. Port Range: All</td>
<td></td>
<td>Description: This rule restricts responses of the web application to the workers-3 subnet.</td>
<td></td>
</tr>
</tbody>
</table>
Example 2: Example Network Resource Configuration for a Highly Available Private Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets

This example assumes you want worker nodes hosted in three private AD-specific subnets that can only be accessed from within the VCN.

**Example Network Resource Configuration**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>VCN</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: acme-dev-vcn</td>
</tr>
<tr>
<td></td>
<td>• <strong>CIDR Block</strong>: 10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>• <strong>DNS Resolution</strong>: Selected</td>
</tr>
<tr>
<td>Internet Gateway</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: gateway-0</td>
</tr>
<tr>
<td>NAT Gateway</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: nat-gateway-0</td>
</tr>
<tr>
<td>Service Gateway</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: service-gateway-0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Services</strong>: All &lt;region&gt; Services in Oracle Services Network</td>
</tr>
<tr>
<td>Route Table</td>
<td>Two route tables created manually, named, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: routetable-0, with a route rule defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Destination CIDR block</strong>: 0.0.0.0/0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target Type</strong>: Internet Gateway</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target Internet Gateway</strong>: gateway-0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: routetable-1, with two route rules defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rule 1:</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Destination CIDR block</strong>: 0.0.0.0/0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target Type</strong>: NAT Gateway</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target NAT Gateway</strong>: nat-gateway-0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rule 2:</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Destination</strong>: All &lt;region&gt; Services in Oracle Services Network</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target Type</strong>: Service Gateway</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target</strong>: service-gateway-0</td>
</tr>
</tbody>
</table>

Note that to avoid the possibility of asymmetric routing, a route table for a public subnet cannot contain both a route rule that targets an internet gateway as well as a route rule that targets a service gateway (for more information, see Issues with access from Oracle services through a service gateway to your public instances).
### DHCP Options

Created automatically and defined as follows:
- **DNS Type** set to Internet and VCN Resolver

### Security Lists

Two created (in addition to the default security list) manually, named, and defined as follows:
- **Security List Name**: workers
- **Security List Name**: loadbalancers

For details of the ingress rules and egress rules defined for these security lists, see Example Security List Configurations for a Highly Available Private Cluster Using AD-Specific Subnets on page 855.
Three worker node AD-specific subnets created manually, named, and defined as follows:

- **Name**: workers-1 with the following properties:
  - **Availability Domain**: AD1
  - **CIDR Block**: 10.0.10.0/25
  - **Route Table**: routetable-1
  - **Subnet access**: Private
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: workers

- **Name**: workers-2 with the following properties:
  - **Availability Domain**: AD2
  - **CIDR Block**: 10.0.11.0/25
  - **Route Table**: routetable-1
  - **Subnet access**: Private
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: workers

- **Name**: workers-3 with the following properties:
  - **Availability Domain**: AD3
  - **CIDR Block**: 10.0.12.0/25
  - **Route Table**: routetable-1
  - **Subnet access**: Private
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: workers

Two load balancer AD-specific subnets created, named, and defined as follows:

- **Name**: loadbalancers-1 with the following properties:
  - **Availability Domain**: AD1
  - **CIDR Block**: 10.0.20.0/24
  - **Route Table**: routetable-0
  - **Subnet access**: Public
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: loadbalancers

- **Name**: loadbalancers-2 with the following properties:
  - **Availability Domain**: AD2
  - **CIDR Block**: 10.0.21.0/24
  - **Route Table**: routetable-0
  - **Subnet access**: Public
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: loadbalancers

Example Security List Configurations for a Highly Available Private Cluster Using AD-Specific Subnets

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from the private worker node AD-specific subnets and the load balancer AD-specific subnets. The two security lists are named 'workers' and 'loadbalancers' respectively.

Example Ingress Rules in the 'workers' Security List for Private Worker Node AD-Specific Subnets:

|----|------------------|--------------|---------------------------------------------|-------------|----------------------|
| 1  | State: Stateless Src. Type: CIDR | 10.0.10.0/25 | Protocol: All Src. Port Range: n/a Dest. Port Range: n/a | n/a         | Allows: All traffic for all ports
Description: This optional rule enables intra-VCN traffic. Although optional, this rule is usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. Only in the rare case where no inter-pod communication is expected, is this rule not required. |
|----|------------------|--------------|---------------------------|-------------------|-------------|---------------------|
| 2  | State: Stateless | 10.0.11.0/25 | Protocol: All Src. Port Range: n/a | Dest. Port Range: n/a | n/a         | Allows: All traffic for all ports
Description: This *optional* rule enables intra-VCN traffic. Although optional, this rule is usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. In the rare case where no inter-pod communication is expected, this rule is not required. |
| 3  | State: Stateless | 10.0.12.0/25 | Protocol: All Src. Port Range: n/a | Dest. Port Range: n/a | n/a         | Allows: All traffic for all ports
Description: This *optional* rule enables intra-VCN traffic. Although optional, this rule is usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. In the rare case where no inter-pod communication is expected, this rule is not required. |
### Example Egress Rules in the 'workers' Security List for Private Worker Node AD-Specific Subnets:

Consider these egress rules as a minimum requirement. If applications deployed on worker nodes need to communicate with destinations outside of the Oracle Service Network, add additional egress rules. For example, if applications use Helm charts from the Helm stable repository, or Docker images from docker.io.

Example 3: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using a Regional Subnet

This example assumes you want worker nodes hosted in a public regional subnet that can be accessed directly from the internet.

Example Network Resource Configuration

<table>
<thead>
<tr>
<th>Resource</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>VCN</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• Name: acme-dev-vcn</td>
</tr>
<tr>
<td></td>
<td>• CIDR Block: 10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>• DNS Resolution: Selected</td>
</tr>
<tr>
<td>Internet Gateway</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• Name: gateway-0</td>
</tr>
<tr>
<td>Service Gateway</td>
<td>Created manually, and defined as follows:</td>
</tr>
<tr>
<td></td>
<td>• Name: service-gateway-0</td>
</tr>
<tr>
<td></td>
<td>• Services: All &lt;region&gt; Services in Oracle Services Network</td>
</tr>
</tbody>
</table>
Two route tables created manually, named, and defined as follows:

- **Name**: routetable-0, with a route rule defined as follows:
  - **Destination CIDR block**: 0.0.0.0/0
  - **Target Type**: Internet Gateway
  - **Target Internet Gateway**: gateway-0

- **Name**: routetable-1, with a route rule defined as follows:
  - **Destination**: All <region> Services in Oracle Services Network
  - **Target Type**: Service Gateway
  - **Target**: service-gateway-0

Note that to avoid the possibility of asymmetric routing, a route table for a public subnet cannot contain both a route rule that targets an internet gateway as well as a route rule that targets a service gateway (for more information, see Issues with access from Oracle services through a service gateway to your public instances).

**DHCP Options**

Created automatically and defined as follows:

- **DNS Type** set to Internet and VCN Resolver

**Security Lists**

Two created (in addition to the default security list) manually, named, and defined as follows:

- **Security List Name**: workers
- **Security List Name**: loadbalancers

For details of the ingress rules and egress rules defined for the workers security list and the loadbalancers security list, see Example Security List Configurations for a Highly Available Public Cluster using Regional Subnets on page 863.

**Subnets**

One worker node regional subnet created manually, named, and defined as follows:

- **Name**: workers-rs with the following properties:
  - **CIDR Block**: 10.0.10.0/25
  - **Route Table**: routetable-1
  - **Subnet access**: Public
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: workers

One load balancer regional subnet created, named, and defined as follows:

- **Name**: loadbalancers-rs with the following properties:
  - **CIDR Block**: 10.0.20.0/24
  - **Route Table**: routetable-0
  - **Subnet access**: Public
  - **DNS Resolution**: Selected
  - **DHCP Options**: Default
  - **Security List**: loadbalancers
**Example Security List Configurations for a Highly Available Public Cluster using Regional Subnets**

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from a public worker node regional subnet and a load balancer regional subnet. The two security lists are named 'workers' and 'loadbalancers' respectively.

**Example Ingress Rules in the 'workers' Security List for a Public Worker Node Regional Subnet:**

|---|------------------|-----------|-----------------------------------------------|-------------|---------------------|
| 1 | **State**: Stateless  
**Src. Type**: CIDR | 10.0.10.0/25 | Protocol: All  
Src. Port Range: n/a  
Dest. Port Range: n/a | n/a | Allows: All traffic for all ports  
Description: This *optional* rule enables intra-VCN traffic. Although optional, this rule is usually necessary to enable pods on one worker node to communicate with pods on other worker nodes. Only in the rare case where no inter-pod communication is expected, is this rule not required. |
| 2 | **State**: Stateful  
**Src. Type**: CIDR | 0.0.0.0/0 | Protocol: ICMP  
Src. Port Range: n/a  
Dest. Port Range: n/a | 3  
Code: 4 | Allows: ICMP traffic for: 3, 4 Destination Unreachable: Fragmentation Needed and Don't Fragment was Set  
Description: This rule enables worker nodes to receive Path MTU Discovery fragmentation messages. |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>State: Stateful</td>
<td>0.0.0.0/0</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: 22 SSH Remote Login Protocol. Description: This optional rule enables inbound SSH traffic from the internet on port 22 to access worker nodes.</td>
</tr>
<tr>
<td>4</td>
<td>State: Stateful</td>
<td>0.0.0.0/0</td>
<td>Protocol: TCP</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: 30000 - 32767. Description: This optional rule enables inbound traffic to the worker nodes on the default NodePort range of 30000-32767 (see the Kubernetes documentation).</td>
</tr>
</tbody>
</table>

Example Egress Rules in the 'workers' Security List for a Public Worker Node Regional Subnet:

Consider these egress rules as a minimum requirement. If applications deployed on worker nodes need to communicate with destinations outside of the Oracle Service Network, add additional egress rules. For example, if applications use Helm charts from the Helm stable repository, or Docker images from docker.io.

</tbody>
</table>

CIDR Blocks and Container Engine for Kubernetes

When configuring the VCN and the worker node and load balancer subnets for use with Container Engine for Kubernetes, you specify CIDR blocks to indicate the network addresses that can be allocated to the resources. See Network Resource Configuration for Cluster Creation and Deployment on page 836.

When creating a cluster with Container Engine for Kubernetes, you specify:

- CIDR blocks for the Kubernetes services
- CIDR blocks that can be allocated to pods running in the cluster (see Creating a Kubernetes Cluster on page 871)

Note the following:

- The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for the Kubernetes services.
- The CIDR blocks you specify for pods running in the cluster must not overlap with CIDR blocks you specify for worker node and load balancer subnets.
- Each pod running on a worker node is assigned its own network address. Container Engine for Kubernetes allocates a /25 CIDR block of network addresses for each worker node in a cluster, to assign to pods running on that node. A /25 CIDR block equates to 128 distinct IP addresses, of which one is reserved. So a maximum of 127 network addresses are available to assign to pods running on each worker node (more than sufficient, given that the number of pods per node is capped at 110).
- When you create a cluster, you specify a value for the cluster's Pods CIDR Block property, either implicitly in the case of a 'quick cluster' or explicitly in the case of a 'custom cluster'. You cannot change the cluster's Pods CIDR Block property after the cluster has been created. The cluster's Pods CIDR Block property constrains the maximum total number of network addresses available for allocation to pods running on all the nodes in the cluster, and therefore effectively limits the number of nodes in the cluster. By default, the cluster's Pods CIDR Block property is set to a /16 CIDR block, making 65,536 network addresses available for all the nodes in the cluster. Since 128 network addresses are allocated for each node, specifying a /16 CIDR block for the cluster's Pods CIDR Block property limits the number of nodes in the cluster to 512. This is generally sufficient. To support more than 512 nodes in a cluster, create a 'custom cluster' and specify a larger value for the cluster's Pods CIDR Block property when you create the cluster. For example, specify a /14 CIDR block for the cluster's Pods CIDR Block property to create a cluster with 262,144 network addresses available for the nodes in the cluster (more than sufficient, given that the number of nodes per cluster is capped at 1000).
Policy Configuration for Cluster Creation and Deployment

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. If all the users that will be working with Container Engine for Kubernetes are already members of the Administrators group, there's no need to create additional policies. However, if you want to enable users that are not members of the Administrators group to use Container Engine for Kubernetes, you must create policies to enable the groups to which those users do belong to perform operations on resources in the tenancy or in individual compartments. Some policies are required, some are optional. See Create Required Policy for Groups on page 868 and Create One or More Additional Policies for Groups on page 869.

Note that in addition to the above policies managed by IAM, you can also use the Kubernetes RBAC Authorizer to enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. See About Access Control and Container Engine for Kubernetes on page 920.

Create Required Policy for Groups

To create, update, and delete clusters and node pools, users that are not members of the Administrators group must have permissions to work with cluster-related resources. To give users the necessary access, you must create a policy with a number of required policy statements for the groups to which those users do belong:

1. In the Console, open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click Create Policy.
4. Enter the following:

- **Name:** A name for the policy (for example, acme-dev-team-oke-required-policy) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
- **Description:** A friendly description. You can change this later if you want to.
- **Statement:** The following required policy statements to enable users to use Container Engine for Kubernetes to create, update, and delete clusters and node pools:

```
Allow group <group-name> to manage instance-family in <location>
Allow group <group-name> to use subnets in <location>
Allow group <group-name> to read virtual-network-family in <location>
Allow group <group-name> to use vnics in <location>
Allow group <group-name> to inspect compartments in <location>
```

The following required policy statement to enable users to perform any operation on cluster-related resources (this 'catch-all' policy effectively makes all users administrators insofar as cluster-related resources are concerned):

```
Allow group <group-name> to manage cluster-family in <location>
```

In the above policy statements, replace <location> with either tenancy (if you are creating the policy in the tenancy's root compartment) or compartment <compartment-name> (if you are creating the policy in an individual compartment).
- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more
information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create.

Create One or More Additional Policies for Groups

To enable users that are not members of the Administrators group to use Container Engine for Kubernetes, create additional policies to enable the groups to which those users do belong to perform operations on cluster-related resources as follows:

1. In the Console, open the navigation menu. Under Governance and Administration, go to Identity and click Policies. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click Create Policy.
4. Enter the following:

   • Name: A name for the policy (for example, acme-dev-team-oke-additional-policy) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   • Description: A friendly description. You can change this later if you want to.
   • Statement: A suitable policy statement to allow existing groups to perform operations on cluster-related resources. In the example policy statements below, replace <location> with either tenancy (if you are
creating the policy in the tenancy's root compartment) or **compartment <compartment-name>** (if you are creating the policy in an individual compartment):

- **To enable users in the acme-dev-team group to automatically create and configure associated new network resources when creating new 'quick clusters', policies must also grant the group:**
  - VCN_READ and VCN_CREATE permissions. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage vcns in <location>
    ```
  - SUBNET_READ and SUBNET_CREATE permissions. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage subnets in <location>
    ```
  - INTERNET_GATEWAY_CREATE permission. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage internet-gateways in <location>
    ```
  - NAT_GATEWAY_CREATE permission. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage nat-gateways in <location>
    ```
  - ROUTE_TABLE_UPDATE permission. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage route-tables in <location>
    ```
  - SECURITY_LIST_CREATE permission. Enter a policy statement like:
    
    ```
    Allow group acme-dev-team to manage security-lists in <location>
    ```

- **To enable users in the acme-dev-team-cluster-viewers group to simply list the clusters, enter a policy statement like:**
  
  ```
  Allow group acme-dev-team-cluster-viewers to inspect clusters in <location>
  ```

- **To enable users in the acme-dev-team-pool-admins group to list, create, update, and delete node pools, enter a policy statement like:**
  
  ```
  Allow group acme-dev-team-pool-admins to use cluster-node-pools in <location>
  ```

- **To enable users in the acme-dev-team-auditors group to see details of operations performed on clusters, enter a policy statement like:**
  
  ```
  Allow group acme-dev-team-auditors to read cluster-work-requests in <location>
  ```

- **To enable users in the acme-dev-team-sgw group to create a service gateway to enable worker nodes to access other resources in the same region without exposing data to the public internet, enter a policy statement like:**
  
  ```
  Allow group acme-dev-team-sgw to manage service-gateways in <location>
  ```

- **To enable users in the acme-dev-team group to access clusters using Cloud Shell, enter a policy statement like:**
  
  ```
  Allow group acme-dev-team to use cloud-shell in <location>
  ```

Note that to access clusters using Cloud Shell, you'll also need to set up the kubeconfig file appropriately (see Setting Up Cloud Shell Access to Clusters on page 876). For more information about Cloud Shell, see Cloud Shell.
Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

5. Click Create.

Creating a Kubernetes Cluster

You can use Container Engine for Kubernetes to create new Kubernetes clusters. To create a cluster, you must either belong to the tenancy's Administrators group, or belong to a group to which a policy grants the CLUSTER_MANAGE permission. See Policy Configuration for Cluster Creation and Deployment on page 868.

You first specify basic details for the new cluster (the cluster name, and the Kubernetes version to install on control plane nodes). You can then create the cluster in one of two ways:

- Using default settings to create a 'quick cluster' with new network resources as required. This approach is the fastest way to create a new cluster. If you accept all the default values, you can create a new cluster in just a few clicks. New network resources for the 'quick cluster' are created automatically, including one regional subnet for worker nodes, and another regional subnet for load balancers. The regional subnet for load balancers will be public, but you can specify whether the regional subnet for worker nodes will be public or private. Note that if you specify a private regional subnet for worker nodes in the 'quick cluster', a NAT gateway is also created (in addition to an internet gateway). To create a 'quick cluster', you must belong to a group to which a policy grants the necessary permissions to create the new network resources (see Create One or More Additional Policies for Groups on page 869).

- Using custom settings to create a 'custom cluster'. This approach gives you the most control over the new cluster. You can explicitly define the new cluster's properties. And you can explicitly specify which existing network resources to use, including the existing public or private subnets in which to create worker nodes and load balancers. The subnets can be regional subnets (recommended) or AD-specific subnets.

Note that although you will usually define node pools immediately when defining a new 'custom cluster', you don't have to. You can create a 'custom cluster' with no node pools, and add node pools later. One reason to create a 'custom cluster' that initially has no node pools is if you intend to install and configure a CNI network provider like Calico to support Kubernetes NetworkPolicy resources. If you install Calico on a cluster that has existing node pools in which pods are already running, you'll have to recreate the pods when the Calico installation is complete. For example, by running the kubectl rollout restart command. If you install Calico on a cluster before creating any node pools in the cluster (recommended), you can be sure that there will be no pods to recreate. See Example: Installing Calico and Setting Up Network Policies on page 960.

Regardless of how you create a cluster, Container Engine for Kubernetes gives names to worker nodes in the following format:

oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-
[slot]

where:

- oke is the standard prefix for all worker nodes created by Container Engine for Kubernetes
- c<part-of-cluster-OCID> is a portion of the cluster's OCID, prefixed with the letter c
- n<part-of-node-pool-OCID> is a portion of the node pool's OCID, prefixed with the letter n
- s<part-of-subnet-OCID> is a portion of the subnet's OCID, prefixed with the letter s
- <slot> is an ordinal number of the node in the subnet (for example, 0, 1)

For example, if you specified a cluster is to have two nodes in a node pool, the two nodes might be named:

- oke-cywiqripuyg-nsgagklgnst-st2qczvnmba-0
- oke-cywiqripuyg-nsgagklgnst-st2qczvnmba-1

Do not change the auto-generated names that Container Engine for Kubernetes gives to worker nodes.

To ensure high availability, Container Engine for Kubernetes:
• creates the Kubernetes Control Plane on multiple Oracle-managed control plane nodes (distributing the control plane nodes across different availability domains in a region, where supported)
• creates worker nodes in each of the fault domains in an availability domain (distributing the worker nodes as evenly as possible across the fault domains, subject to any other infrastructure restrictions)

Using the Console to create a ‘Quick Cluster’ with Default Settings

To create a ‘quick cluster’ with default settings and new network resources using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Kubernetes Clusters.
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click Create Cluster.
4. In the Create Cluster dialog, select Quick Create and click Launch Workflow.
5. On the Create Cluster page, either just accept the default configuration details for the new cluster, or specify alternatives as follows:

- **Name**: The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.
- **Compartment**: The compartment in which to create the new cluster and the associated network resources.
- **Kubernetes Version**: The version of Kubernetes to run on the control plane nodes and worker nodes of the cluster. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (see Supported Admission Controllers on page 924).
- **Visibility Type**: Whether to create a private or a public regional subnet to host worker nodes (note that a public regional subnet is always created to host load balancers in a ‘quick cluster’, regardless of your selection here):
  - **Private**: Select to create a private regional subnet to host worker nodes (along with the public regional subnet to host load balancers).
  - **Public**: Select to create a public regional subnet to host worker nodes (along with the public regional subnet to host load balancers).
- **Shape**: The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. If you select a flexible shape, you can explicitly specify the number of CPUs and the amount of memory. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 923.
- **Number of Nodes**: The number of worker nodes to create in the node pool, placed in the regional subnet created for the ‘quick cluster’. The nodes are distributed as evenly as possible across the availability domains in a region (or in the case of a region with a single availability domain, across the fault domains in that availability domain).

6. Either accept the default size of worker node boot volumes (as determined from the default image used for worker nodes) or click Specify a Custom Boot Volume Size and specify an alternative size for worker node boot volumes in **Boot Volume Size in GB**. If you do specify a custom boot volume size, it must be larger than the image’s default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively. See Custom Boot Volume Sizes on page 610.

7. Either accept the defaults for advanced cluster options, or click Show Advanced Options and specify alternatives as follows:

- **Public SSH Key**: (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don’t specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won’t have the corresponding private key, you will not have SSH access to the worker nodes. Note that if you specify that you want the worker nodes in the ‘quick cluster’ to be hosted in a private regional subnet, you cannot use SSH to access them directly (see Connecting to Worker Nodes in Private Subnets Using SSH on page 905).
- **Kubernetes Labels**: (Optional) One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.
8. Click **Next** to review the details you entered for the new cluster.

9. Click **Create Cluster** to create the new network resources and the new cluster.

   Container Engine for Kubernetes starts creating resources (as shown in the **Creating cluster and associated network resources** dialog):
   - the network resources (such as the VCN, internet gateway, NAT gateway, route tables, security lists, a regional subnet for worker nodes and another regional subnet for load balancers), with auto-generated names in the format `oke-<resource-type>-quick-<cluster-name>-<creation-date>`
   - the cluster, with the name you specified
   - the node pool, named pool1
   - worker nodes, with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`

   Do not change the resource names that Container Engine for Kubernetes has auto-generated. Note that if the cluster is not created successfully for some reason (for example, if you have insufficient permissions or if you’ve exceeded the cluster limit for the tenancy), any network resources created during the cluster creation process are not deleted automatically. You will have to manually delete any such unused network resources.

10. Click **Close** to return to the Console.

Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.

Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using `kubectl`.

### Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings

To create a 'custom cluster' with explicitly defined settings and existing network resources using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click **Create Cluster**.
4. In the **Create Cluster** dialog, select **Custom Create** and click **Launch Workflow**.
5. On the **Create Cluster** page, either just accept the default configuration details for the new cluster, or specify alternatives as follows:
   - **Name:** The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.
   - **Compartment:** The compartment in which to create the new cluster.
   - **Kubernetes Version:** The version of Kubernetes to run on the control plane nodes and worker nodes of the cluster. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (see **Supported Admission Controllers** on page 924).
6. Either accept the defaults for advanced cluster options, or click **Show Advanced Options** and set the options as follows:
   a. Specify whether to encrypt Kubernetes secrets at rest in the etcd key-value store for the cluster using the Vault service:
      - **No Encryption:** Kubernetes secrets at rest in the etcd key-value store are not encrypted.
      - **Encrypt Using Customer-Managed Keys:** Encrypt Kubernetes secrets in the etcd key-value store and specify:
         - **Choose a Vault in `<compartment-name>`:** The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, `<compartment-name>` is the compartment...
in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment.

- **Choose a Key in <compartment-name>:** The name of the master encryption key, from the list of keys in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment. Note that you cannot change the master encryption key after the cluster has been created.

Note that if you do want to use encryption, a suitable master encryption key, dynamic group, and policy must already exist before you can create the cluster. For more information, see Encrypting Kubernetes Secrets at Rest in Etcd on page 900.

b. Specify whether to control the operations that pods are allowed to perform on the cluster by enforcing pod security policies:

- **Not Enforced:** Do not enforce pod security policies.
- **Enforced:** Do enforce pod security policies, by enabling the PodSecurityPolicy admission controller. Only pods that meet the conditions in a pod security policy are accepted by the cluster. For more information, see Using Pod Security Policies with Container Engine for Kubernetes on page 905.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>It is very important to note that when you enable a cluster's PodSecurityPolicy admission controller, no application pods can start on the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. You will not be able to run application pods on a cluster with an enabled PodSecurityPolicy admission controller unless these prerequisites are met.</td>
</tr>
</tbody>
</table>

We strongly recommend you use PodSecurityPolicy admission controllers as follows:

- Whenever you create a new cluster, enable the Pod Security Admission Controller.
- Immediately after creating a new cluster, create pod security policies, along with roles (or clusterroles) and rolebindings (or clusterrolebindings).

7. Click **Next** and specify the existing network resources to use for the new cluster on the **Network Setup** page:

- **VCN in <compartment-name>:** The existing virtual cloud network that has been configured for cluster creation and deployment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment. See VCN Configuration on page 837.

- **Kubernetes Service LB Subnets:** Optionally, the existing subnets that have been configured to host load balancers. Load balancer subnets must be different from worker node subnets, can be public or private, and can be regional (recommended) or AD-specific. You don't have to specify any load balancer subnets. However, if you do specify load balancer subnets, the number of load balancer subnets to specify depends on the region in which you are creating the cluster and whether the subnets are regional or AD-specific.

If you are creating a cluster in a region with three availability domains, you can specify:

- Zero or one load balancer regional subnet (recommended).
- Zero or two load balancer AD-specific subnets. If you specify two AD-specific subnets, the two subnets must be in different availability domains.

If you are creating a cluster in a region with a single availability domain, you can specify:

- Zero or one load balancer regional subnet (recommended).
- Zero or one load balancer AD-specific subnet.

See Subnet Configuration on page 839.
8. Either accept the defaults for advanced cluster options, or click Show Advanced Options and specify alternatives as follows:

- **Kubernetes Service CIDR Block**: The available group of network addresses that can be exposed as Kubernetes services (ClusterIPs), expressed as a single, contiguous IPv4 CIDR block. For example, 10.96.0.0/16. The CIDR block you specify must not overlap with the CIDR block for the VCN. See CIDR Blocks and Container Engine for Kubernetes on page 867.
- **Pods CIDR Block**: The available group of network addresses that can be allocated to pods running in the cluster, expressed as a single, contiguous IPv4 CIDR block. For example, 10.244.0.0/16. The CIDR block you specify must not overlap with the CIDR blocks for subnets in the VCN, and can be outside the VCN CIDR block. See CIDR Blocks and Container Engine for Kubernetes on page 867.

9. Click Next and specify configuration details for the first node pool in the cluster on the Node Pools page:

- **Name**: A name of your choice for the new node pool. Avoid entering confidential information.
- **Version**: The version of Kubernetes to run on each worker node in the node pool. By default, the version of Kubernetes specified for the control plane nodes is selected. The Kubernetes version on worker nodes must be either the same version as that on the control plane nodes, or an earlier version that is still compatible. See Kubernetes Versions and Container Engine for Kubernetes on page 926.
- **Image**: The image to use on each node in the node pool. An image is a template of a virtual hard drive that determines the operating system and other software for the node. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 923.
- **Shape**: The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. If you select a flexible shape, you can explicitly specify the number of CPUs and the amount of memory. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 923.
- **Number of Nodes**: The number of worker nodes to create in the node pool, placed in the availability domains you select, and in the regional subnet (recommended) or AD-specific subnet you specify for each availability domain.
- **Availability Domain 1**:
  - **Availability Domain**: An availability domain in which to place worker nodes.
  - **Subnet**: A regional subnet (recommended) or AD-specific subnet configured to host worker nodes. If you specified load balancer subnets, the worker node subnets must be different. The subnets you specify can be public or private, and can be regional (recommended) or AD-specific. See Subnet Configuration on page 839.

Optionally click Add Availability Domain to select additional domains and subnets in which to place worker nodes.

When they are created, the worker nodes are distributed as evenly as possible across the availability domains you select (or in the case of a single availability domain, across the fault domains in that availability domain).

- **Specify a Custom Boot Volume Size**: Either accept the default size of worker node boot volumes (as determined from the image used for worker nodes) or click and specify an alternative size for worker node boot volumes in Boot Volume Size in GB:. If you do specify a custom boot volume size, it must be larger than the image's default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively. See Custom Boot Volume Sizes on page 610.
- **Public SSH Key**: (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that you cannot use SSH to access directly any worker nodes in private subnets (see Connecting to Worker Nodes in Private Subnets Using SSH on page 905).
- **Kubernetes Labels**: (Optional) One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.
10. (Optional) Click **Another node pool** and specify configuration details for a second and subsequent node pools in the cluster.

If you define multiple node pools in a cluster, you can host all of them on a single AD-specific subnet. However, it's best practice to host different node pools for a cluster on a regional subnet (recommended) or on different AD-specific subnets (one in each availability domain in the region).

11. Click **Next** to review the details you entered for the new cluster.

12. Click **Create Cluster** to create the new cluster.

Container Engine for Kubernetes starts creating the cluster with the name you specified.

If you specified details for one or more node pools, Container Engine for Kubernetes creates:

- node pools with the names you specified
- worker nodes with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`

Do not change the auto-generated names of worker nodes.

13. Click **Close** to return to the Console.

Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.

Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using kubectl.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the **CreateCluster** operation to create a cluster.

**Setting Up Cluster Access**

To access a cluster using kubectl, you have to set up a Kubernetes configuration file (commonly known as a 'kubeconfig' file) for the cluster. The kubeconfig file (by default named `config` and stored in the `$HOME/.kube` directory) provides the necessary details to access the cluster. Having set up the kubeconfig file, you can start using kubectl to manage the cluster.

The steps to follow when setting up the kubeconfig file depend on how you want to access the cluster:

- To access the cluster using kubectl in Cloud Shell, run an Oracle Cloud Infrastructure CLI command in the Cloud Shell window to set up the kubeconfig file.

  See Setting Up Cloud Shell Access to Clusters on page 876.

- To access the cluster using a local installation of kubectl:
  - Generate an API signing key pair (if you don't already have one).
  - Upload the public key of the API signing key pair.
  - Install and configure the Oracle Cloud Infrastructure CLI.
  - Set up the kubeconfig file.

  See Setting Up Local Access to Clusters on page 877.

**Setting Up Cloud Shell Access to Clusters**

To set up a kubeconfig file to enable access to a cluster using kubectl in Cloud Shell:

**Step 1: Set up the kubeconfig file**

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.

3. On the **Cluster List** page, click the name of the cluster you want to access using kubectl. The **Cluster** page shows details of the cluster.

4. Click the **Access Cluster** button to display the **Access Your Cluster** dialog box.

5. Click **Cloud Shell Access**.

6. Click **Launch Cloud Shell** to display the Cloud Shell window. For more information about Cloud Shell (including the required IAM policy), see **Cloud Shell**.

7. Run the Oracle Cloud Infrastructure CLI command to set up the kubeconfig file and save it in a location accessible to kubectl.

   For example, enter the following command (or copy and paste it from the **Access Your Cluster** dialog box) in the Cloud Shell window:

   ```bash
   oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.oc1.phx.aaaaaaaaae... --file $HOME/.kube/config --region us-phoenix-1 --token-version 2.0.0
   ```

   where ocid1.cluster.oc1.phx.aaaaaaaaae... is the OCID of the current cluster. For convenience, the command in the **Access Your Cluster** dialog box already includes the cluster's OCID.

   Note that if a kubeconfig file already exists in the location you specify, details about the cluster will be added as a new context to the existing kubeconfig file. The current-context: element in the kubeconfig file will be set to point to the newly-added context.

   **Tip:**

   For clipboard operations in the Cloud Shell window, Windows users can use Ctrl-C or Ctrl-Insert to copy, and Shift-Insert to paste. For Mac OS users, use Cmd-C to copy and Cmd-V to paste.

8. If you don't save the kubeconfig file in the default location ($HOME/.kube) or with the default name (config), set the value of the KUBECONFIG environment variable to point to the name and location of the kubeconfig file. For example, enter the following command in the Cloud Shell window:

   ```bash
   export KUBECONFIG=$HOME/.kube/config
   ```

**Step 2: Verify that kubectl can access the cluster**

Verify that kubectl can connect to the cluster by entering the following command in the Cloud Shell window:

```bash
$ kubectl get nodes
```

Information about the nodes in the cluster is shown.

You can now use kubectl to perform operations on the cluster.

**Setting Up Local Access to Clusters**

To set up a kubeconfig file to enable access to a cluster using a local installation of kubectl:

**Step 1: Generate an API signing key pair**

If you already have an API signing key pair, go straight to the next step. If not:

1. Use OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool. See **How to Generate an API Signing Key** on page 4180.

2. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later).
Step 2: Upload the public key of the API signing key pair

1. In the top-right corner of the Console, open the Profile menu () and then click User Settings to view the details.
2. Click Add Public Key.
3. Paste the public key's value into the window and click Add.

Step 3: Install and configure the Oracle Cloud Infrastructure CLI

1. Install the Oracle Cloud Infrastructure CLI version 2.6.4 (or later). See Quickstart on page 4195.
2. Configure the Oracle Cloud Infrastructure CLI. See Configuring the CLI on page 4202.

Step 4: Set up the kubeconfig file

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Kubernetes Clusters.
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster you want to access using kubectl. The Cluster page shows details of the cluster.
4. Click the Access Cluster button to display the Access Your Cluster dialog box.
5. Click Local Access.
6. Create a directory to contain the kubeconfig file. By default, the expected directory name is $HOME/.kube.

   For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:

   ```bash
   mkdir -p $HOME/.kube
   ```

7. Run the Oracle Cloud Infrastructure CLI command to set up the kubeconfig file and save it in a location accessible to kubectl.

   For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:

   ```bash
   oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.oc1.phx.aaaaaaaaae... --file $HOME/.kube/config --region us-phoenix-1 --token-version 2.0.0
   ```

   where ocid1.cluster.oc1.phx.aaaaaaaaae... is the OCID of the current cluster. For convenience, the command in the Access Your Cluster dialog box already includes the cluster's OCID.

   Note that if a kubeconfig file already exists in the location you specify, details about the cluster will be added as a new context to the existing kubeconfig file. The current-context: element in the kubeconfig file will be set to point to the newly-added context.

8. If you don't save the kubeconfig file in the default location ($HOME/.kube) or with the default name (config), set the value of the KUBECONFIG environment variable to point to the name and location of the kubeconfig file.

   For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:

   ```bash
   export KUBECONFIG=$HOME/.kube/config
   ```
**Step 5: Verify that kubectl can access the cluster**

1. Verify that kubectl is available by entering the following command in a local terminal window:

   ```
   kubectl version
   ```

   The response shows:
   - the version of kubectl installed and running locally
   - the version of Kubernetes (strictly speaking, the version of the kube-apiserver) running on the cluster's control plane nodes

   Note that the kubectl version must be within one minor version (older or newer) of the Kubernetes version running on the control plane nodes. If kubectl is more than one minor version older or newer, install an appropriate version of kubectl. See Kubernetes version and version skew support policy in the Kubernetes documentation.

   If the command returns an error indicating that kubectl is not available, install kubectl (see the kubectl documentation), and repeat this step.

2. Verify that kubectl can connect to the cluster by entering the following command in a local terminal window:

   ```
   kubectl get nodes
   ```

   Information about the nodes in the cluster is shown.

   You can now use kubectl to perform operations on the cluster.

**Notes about Kubeconfig Files**

Note the following about kubeconfig files:

- A single kubeconfig file can include the details for multiple clusters, as multiple contexts. The cluster on which operations will be performed is specified by the `current-context:` element in the kubeconfig file.
- A kubeconfig file includes an Oracle Cloud Infrastructure CLI command that dynamically generates an authentication token and inserts it when you run a kubectl command. The Oracle Cloud Infrastructure CLI must be available on your shell's executable path (for example, $PATH on Linux).
- The authentication tokens generated by the Oracle Cloud Infrastructure CLI command in the kubeconfig file are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters.
- The Oracle Cloud Infrastructure CLI command in the kubeconfig file uses your current CLI profile when generating an authentication token. If you have defined multiple profiles in different tenancies in the CLI configuration file (for example, in ~/.oci/config), specify which profile to use when generating the authentication token as follows. In both cases, `<profile-name>` is the name of the profile defined in the CLI configuration file:
  - Add `--profile` to the `args:` section of the kubeconfig file as follows:

    ```
    user:
    exec:
    apiVersion: client.authentication.k8s.io/v1beta1
    args:
    - ce
    - cluster
    - generate-token
    --cluster-id
    --profile
    - <cluster ocid>
    command: oci
    ```
• Set the OCI_CLI_PROFILE environment variable to the name of the profile defined in the CLI configuration file before running kubectl commands. For example:

```
export OCI_CLI_PROFILE=<profile-name>
```

```
kubectl get nodes
```

• The authentication tokens generated by the Oracle Cloud Infrastructure CLI command in the kubeconfig file are appropriate to authenticate individual users accessing the cluster using kubectl. However, the generated authentication tokens are unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the kubeconfig file. For more information, see Adding a Service Account Authentication Token to a Kubeconfig File on page 894.

## Upgrading Kubeconfig Files from Version 1.0.0 to Version 2.0.0
Container Engine for Kubernetes currently supports kubeconfig version 2.0.0 files, and no longer supports kubeconfig version 1.0.0 files.

Enhancements in kubeconfig version 2.0.0 files provide security improvements for your Kubernetes environment, including short-lived cluster-scoped tokens with automated refreshing, and support for instance principals to access Kubernetes clusters. Additionally, authentication tokens are generated on-demand for each cluster, so kubeconfig version 2.0.0 files cannot be shared between users to access Kubernetes clusters (unlike kubeconfig version 1.0.0 files).

Note that kubeconfig version 2.0.0 files are not compatible with kubectl versions prior to version 1.11.9. If you are currently running kubectl version 1.10.x or older, upgrade kubectl to version 1.11.9 or later. For more information about compatibility between different versions of kubernetes and kubectl, see the Kubernetes documentation.

Follow the instructions below to determine the current version of kubeconfig files, and how to upgrade any remaining kubeconfig version 1.0.0 files to version 2.0.0.

### Determine the kubeconfig file version
To determine the version of a cluster's kubeconfig file:

1. In a terminal window (the Cloud Shell window or a local terminal window as appropriate), enter the following command to see the format of the kubeconfig file currently pointed at by the KUBECONFIG environment variable:

```
kubectl config view
```

2. If the kubeconfig file is version 1.0.0, you see a response in the following format:

```
users:
  - name: <username>
    user:
      token: <token-value>
```

If you see a response in the above format, you have to upgrade the kubeconfig file. See Upgrading Kubeconfig Files from Version 1.0.0 to Version 2.0.0 on page 880.

3. If the kubeconfig file is version 2.0.0, you see a response in the following format:

```
user:
  exec:
    apiVersion: client.authentication.k8s.io/v1beta1
    args:
      - ce
```
Upgrade a kubeconfig version 1.0.0 file to version 2.0.0

To upgrade a kubeconfig version 1.0.0 file:

1. In the case of a local installation of kubectl, confirm that Oracle Cloud Infrastructure CLI version 2.6.4 (or later) is installed by entering:
   
   ```
   oci -version
   ```

   If the Oracle Cloud Infrastructure CLI version is earlier than version 2.6.4, upgrade the CLI to a later version. See Upgrading the CLI on page 4220.

2. Follow the appropriate instructions to set up the kubeconfig file for use in Cloud Shell or locally (see Setting Up Cloud Shell Access to Clusters on page 876 or Setting Up Local Access to Clusters on page 877). Running the `oci ce cluster create-kubeconfig` command shown in the Access Your Cluster dialog box upgrades the existing kubeconfig version 1.0.0 file. If you change the name or location of the kubeconfig file, set the KUBECONFIG environment variable to point to the new name and location of the file.

3. Confirm the kubeconfig file is now version 2.0.0:
   
a. In a terminal window (the Cloud Shell window or a local terminal window as appropriate), enter:
   
   ```
   kubectl config view
   ```

   b. Confirm that that the response is in the following format:

   ```
   user:
   exec:
     apiVersion: client.authentication.k8s.io/v1beta1
     args:
       - ce
       - cluster
       - generate-token
       - --cluster-id
       - <cluster ocid>
     command: oci
   env: []
   ```

Modifying Kubernetes Cluster Properties

You can use Container Engine for Kubernetes to modify the properties of existing Kubernetes clusters.

You can change:

- the number of node pools in a cluster by adding new node pools, or deleting existing node pools
- the version of Kubernetes to run on control plane nodes
- the enforcement of pod security policies
- some properties of node pools and worker nodes (see Modifying Node Pool and Worker Node Properties on page 883)

However, note that you cannot change:

- the name of the cluster
- the master encryption key (if specified when the cluster was created)
Also note that you must not change the auto-generated names of resources that Container Engine for Kubernetes has created (such as the names of worker nodes).

**Using the Console**

To modify an existing Kubernetes cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster you want to modify.
4. Use the buttons across the top of the **Cluster** page as follows:
   - If you want to set up the kubeconfig configuration file for the cluster, click the **Access Cluster** button (see **Setting Up Cluster Access** on page 876).
   - If you want to delete the cluster along with its control plane nodes and worker nodes, click the **Delete Cluster** button.
   - If a newer version of Kubernetes is available than the one running on the control plane nodes in the cluster, the **Upgrade** button is enabled. If you want to upgrade the control plane nodes to a newer version, click **Upgrade** (see **Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster** on page 930).
5. Use the **Cluster Details** tab to see information about the cluster, including:
   - The status of the cluster, and of the node pools in the cluster.
   - The cluster's OCID.
   - The Kubernetes version running on the control plane nodes in the cluster. If a newer version of Kubernetes is available than the one running on the control plane nodes in the cluster, the **Upgrade** link is shown. If you want to upgrade the control plane nodes to a newer version, click the **Upgrade** link (see **Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster** on page 930).
   - The address of the Kubernetes endpoint.
   - Whether pod security policies are being enforced (by enabling the cluster's PodSecurityPolicy admission controller). Note that you must create pod security policies before enabling the PodSecurityPolicy admission controller of an existing cluster that is already in production. We also strongly recommend you first verify the cluster's pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster. Also note that if you disable a cluster's PodSecurityPolicy admission controller, any pod security policies (along with roles, rolebindings, clusterroles, and clusterrolebindings) you've defined are not deleted, they are simply not enforced. See **Using Pod Security Policies with Container Engine for Kubernetes** on page 905.
6. Use the **Node Pools** tab to:
   - View information about each of the node pools in the cluster, including:
     - The status of the node pool.
     - The node pool's OCID.
     - The configuration currently used when starting new worker nodes in the node pool, including the Kubernetes version, the shape, and the image.
     - The availability domains, and different regional subnets (recommended) or AD-specific subnets hosting worker nodes.
   
   Note that you can change some of these node pool and worker node properties (see **Modifying Node Pool and Worker Node Properties** on page 883).
   - Add a new node pool to the cluster by clicking the **Add Node Pool** button and entering details for the new node pool.
   - Delete a node pool by selecting **Delete Node Pool** from the **Actions** menu.
7. Use the **Quick Start** tab to:
   - Set up access to the cluster (see **Setting Up Cluster Access** on page 876).
   - Download and deploy a sample Nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file (see **Deploying a Sample Nginx App on a Cluster Using Kubectl** on page 896).

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **Update Cluster** operation to modify an existing Kubernetes cluster.

**Modifying Node Pool and Worker Node Properties**

You can use Container Engine for Kubernetes to modify the properties of node pools and worker nodes in existing Kubernetes clusters.

You can change:
- the name of a node pool
- the version of Kubernetes to run on new worker nodes
- the number of worker nodes in a node pool, and the availability domains and subnets in which to place them
- the image to use for new worker nodes
- the shape to use for new worker nodes
- the boot volume size to use for new worker nodes
- the public SSH key to use to access new worker nodes

Note that you must not change the auto-generated names of resources that Container Engine for Kubernetes has created (such as the names of worker nodes).

Also note the following:
- Any changes you make to worker node properties will only apply to new worker nodes. You cannot change the properties of existing worker nodes.
- In some situations, you might want to update properties of all the worker nodes in a node pool simultaneously, rather than just the properties of new worker nodes that start in the node pool. For example, to upgrade all worker nodes to a new version of Oracle Linux. In this case, you can create a new node pool with worker nodes that have the required properties, and shift work from the original node pool to the new node pool using the `kubectl drain` command and pod disruption budgets. For more information, see **Updating Worker Nodes by Creating a New Node Pool** on page 885.
- If you use the **UpdateNodePool** API operation to modify properties of an existing node pool, be aware of the **Worker node properties out-of-sync with updated node pool properties** known issue and its workarounds.
- Do not use the `kubectl delete node` command to scale down or terminate worker nodes in a cluster that was created by Container Engine for Kubernetes. Instead, reduce the number of worker nodes by changing the corresponding node pool properties using the Console or the API. The `kubectl delete node` command does not change a node pool's properties, which determine the desired state (including the number of worker nodes). Also, although the `kubectl delete node` command removes the worker node from the cluster's etcd key-value store, the command does not delete the underlying compute instance.

**Using the Console**

To modify the properties of node pools and worker nodes of existing Kubernetes clusters:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster you want to modify.
4. On the Cluster page, click the name of the node pool that you want to modify.
5. Use the Node Pool Details tab to view information about the node pool, including:
   • The status of the node pool.
   • The node pool's OCID.
   • The configuration currently used when starting new worker nodes in the node pool, including:
     • the version of Kubernetes to run on worker nodes
     • the shape to use for worker nodes
     • the image to use on worker nodes
   • The availability domains, and different regional subnets (recommended) or AD-specific subnets hosting worker nodes.
6. (optional) Change properties of the node pool and worker nodes by clicking Edit and specifying:
   • Name: A different name for the node pool. Avoid entering confidential information.
   • Version: A different version of Kubernetes to run on new worker nodes in the node pool when performing an in-place upgrade. The Kubernetes version on worker nodes must be either the same version as that on the control plane nodes, or an earlier version that is still compatible (see Kubernetes Versions and Container Engine for Kubernetes on page 926). To start new worker nodes running the Kubernetes version you specify, 'drain' existing worker nodes in the node pool (to prevent new pods starting and to delete existing pods) and then terminate each of the existing worker nodes in turn.
     You can also specify a different version of Kubernetes to run on new worker nodes by performing an out-of-place upgrade. For more information about upgrading worker nodes, see Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 930.
   • Image: A different image to use on the nodes in the node pool. An image is a template of a virtual hard drive that determines the operating system and other software for the node. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 923.
   • Shape: A different shape to use for the nodes in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 923.
   • Boot Volume Size in GB: A different boot volume size for worker nodes. The default size of worker node boot volumes is determined from the image specified for worker nodes, but you can specify a custom boot volume size. If you do specify a custom boot volume size, it must be larger than the image's default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively (see Custom Boot Volume Sizes on page 610). If you change the boot volume size for worker nodes, consider extending the partition for the boot volume to take advantage of the larger size (see Extending the Partition for a Boot Volume on page 612).
   • Public SSH Key: (Optional) A different public key portion of the key pair you want to use for SSH access to the nodes in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that you cannot use SSH to access directly any worker nodes in private subnets (see Connecting to Worker Nodes in Private Subnets Using SSH on page 905).
7. (optional) Change the number and placement of worker nodes in the node pool by clicking Scale and specifying:
   • the number of worker nodes you want in the node pool after the scale operation is complete
   • the availability domains in which to place the worker nodes
   • the regional subnets (recommended) or AD-specific subnets to host the worker nodes
8. Use the Nodes tab to see information about specific worker nodes in the node pool. Optionally edit the configuration details of a specific worker node by clicking the worker node's name.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.
Use the `UpdateNodePool` operation to modify an existing node pool.

**Updating Worker Nodes by Creating a New Node Pool**

You can modify the properties of new worker nodes that start in an existing node pool (see Modifying Node Pool and Worker Node Properties on page 883). However, in some situations, you might want to update properties of all the worker nodes in a node pool simultaneously, rather than just the properties of new worker nodes that start in the node pool. For example, to upgrade all worker nodes to a new version of Oracle Linux.

In this case, you can create a new node pool with worker nodes that have the required properties, and shift work from the original node pool to the new node pool. Having 'drained' existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool.

To update the properties of all worker nodes in a node pool by creating a new node pool:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to update worker node properties.
4. On the **Cluster** page, display the **Node Pools** tab, and then click **Add Node Pool** to create a new node pool and specify the required properties for its worker nodes.
5. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then use the `kubectl label nodes` command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.
6. For each worker node in the original node pool, prevent new pods from starting and delete existing pods by entering `kubectl drain <node_name>` for each worker node.

For more information:
- about using `kubectl`, see Accessing a Cluster Using Kubectl on page 890
- about the `drain` command, see `drain` in the Kubernetes documentation

**Recommended:** Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.

After all the worker nodes have been drained from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.

7. On the **Cluster** page, display the **Node Pools** tab, and then select **Delete Node Pool** from the **Actions** menu beside the original node pool.

The original node pool and all its worker nodes are deleted.

**Deleting a Kubernetes Cluster**

You can delete a cluster along with its control plane nodes, worker nodes, and node pools.

Note the following:
- When you delete a cluster, no other resources created during the cluster creation process or associated with the cluster (such as VCNs, internet gateways, NAT gateways, route tables, security lists, load balancers, and block volumes) are deleted automatically. If you want to delete these resources, you have to do so manually.

Do not change the auto-generated names of worker nodes. If you do change the auto-generated name of a worker node and then delete the cluster, the renamed worker node is not deleted. You would have to delete the renamed worker node manually.
Using the Console

To delete a Kubernetes cluster using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the Delete icon beside the cluster to delete, and confirm that you want to delete it.

You can also delete a cluster using the **Delete Cluster** button on the **Cluster** page.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the **DeleteCluster** operation to delete a cluster.

Monitoring Clusters

Having created a cluster, you can monitor the overall status of the cluster itself, and the nodes and node pools within it.

In addition to monitoring the overall status of clusters, node pools, and nodes, you can monitor their health, capacity, and performance at a more granular level using **metrics**, **alarms**, and **notifications**. See Container Engine for Kubernetes Metrics on page 963.

Using the Console

To monitor a Kubernetes cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.

The **Status** column on the **Cluster List** page shows a summary status for each individual cluster and its control plane nodes. Clusters can have one of the following statuses:

<table>
<thead>
<tr>
<th>Cluster Status</th>
<th>Explanation</th>
<th>Possible Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Creating</strong></td>
<td>Cluster is in the process of being created.</td>
<td>Application is being deployed.</td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td>Cluster is running normally.</td>
<td>Control plane nodes are running normally.</td>
</tr>
</tbody>
</table>
| **Failed**     | Cluster is not running due to an unrecoverable error. | Possible reasons:  
• a problem setting up load balancers  
• conflicts in networking ranges |
| **Deleting**   | Cluster is in the process of being deleted. Application no longer required, so resources in the process of being released. | Application no longer required, so resources in the process of being released. |
| **Deleted**    | Cluster has been deleted. Application no longer required, so resources have been released. | Application no longer required, so resources have been released. |
Cluster Status | Explanation | Possible Reason
--- | --- | ---
**Updating** | Version of Kubernetes on the control plane nodes is in the process of being upgraded. | A newly supported version of Kubernetes has become available.

Note that the cluster's summary status is not necessarily directly related to the status of node pools and nodes within the cluster.

3. On the **Cluster List** page, click the name of the cluster for which you want to see detailed status.
4. Display the cluster's **Metrics** tab to see more granular information about the health, capacity, and performance of the cluster. See Container Engine for Kubernetes Metrics on page 963.
5. Display the **Node Pools** tab to see the summary status of each node pool in the cluster.
6. On the **Node Pools** tab, click the name of a node pool for which you want to see detailed status.
7. Display the node pool's **Metrics** tab to see more granular information about the health, capacity, and performance of the node pool. See Container Engine for Kubernetes Metrics on page 963.
8. Display the **Nodes** tab to see the summary status of each worker node in the node pool.

Worker nodes can have one of the following statuses:

| Node Status | Explanation | Possible Reason |
| --- | --- | ---
**Creating** | Node is being created. | Compute instance in the process of being created. |
**Active** | Node is running normally. | Node is running normally. |
**Updating** | Node is in the process of being updated. | Container Engine for Kubernetes is performing an operation on the node. |
**Deleting** | Node is in the process of being deleted. | Application no longer required, so resources in the process of being released. |
**Deleted** | Node has been deleted. | Application no longer required, so resources have been released. |
**Inactive** | Node still exists, but is not running. | Compute resource has a status of Stopped, Stopping, or Down For Maintenance. |

9. Click **View Metrics** beside a worker node to see more granular information about the health, capacity, and performance of that node. See Container Engine for Kubernetes Metrics on page 963.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the **GetCluster** and **GetNodePool** operations to monitor the status of Kubernetes clusters.
Viewing Work Requests and Kubernetes API Server Audit Logs

It's often useful to understand the context behind activities happening in a cluster. For example, to perform compliance checks, to identify security anomalies, and to troubleshoot errors by identifying who did what and when.

You can view operations performed by Container Engine for Kubernetes and the Kubernetes API server as follows:

- You can use the **Work Requests** tab of the cluster's **Summary** page to view and manage operations performed on a particular cluster by Container Engine for Kubernetes.
- You can use the Oracle Cloud Infrastructure Audit service to view all operations performed by:
  - Container Engine for Kubernetes, which emits audit events whenever you perform actions on a cluster, such as create and delete.
  - The Kubernetes API server, which emits audit events whenever you use tools like kubectl to make administrative changes to a cluster, such as creating a service. Kubernetes API server audit events are shown in the Oracle Cloud Infrastructure Audit service for clusters running Kubernetes version 1.13.x (or later). Note that events are only shown from 15 July, 2020 onward.

Note that in addition to viewing operations as described in this topic, you can also monitor the health, capacity, and performance of Kubernetes clusters themselves using metrics, alarms, and notifications. See Container Engine for Kubernetes Metrics on page 963.

**Using the Console**

To view and manage operations performed by Container Engine for Kubernetes on a particular cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster for which you want to view and manage operations.
   - The **Cluster** page shows information about the cluster.
4. Display the **Work Requests** tab, showing the recent operations performed on the cluster.

To view operations performed by Container Engine for Kubernetes and the Kubernetes API server as log events in the Oracle Cloud Infrastructure Audit service:

1. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Audit**.
2. Choose a **Compartment** you have permission to work in.
3. Search and filter to show the operations you're interested in:
   - To view operations performed by Container Engine for Kubernetes, enter **ClustersAPI** in the **Keywords** field and click **Search**.
   - To view operations performed by the Kubernetes API server, enter **OKE API Server Admin Access** in the **Keywords** field and click **Search**.

   For more information about using the Oracle Cloud Infrastructure Audit service, see Viewing Audit Log Events on page 494.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the GetWorkRequest, DeleteWorkRequest, ListWorkRequestErrors, ListWorkRequestLogs, and ListWorkRequests operations to view and manage operations performed by Container Engine for Kubernetes.

**Viewing Application Logs on Worker Nodes**

Having created a cluster using Container Engine for Kubernetes, you can use Oracle Cloud Infrastructure Logging to view and search the logs of applications running on worker node compute instances in the cluster.
Before you can collect and parse the application logs using Oracle Cloud Infrastructure Logging:

- You must have already:
  - Enabled monitoring for worker node compute instances (see Enabling Monitoring for Compute Instances on page 783).
  - Installed the Oracle Cloud Agent software on worker node compute instances. The agent enables you to specify which logs to collect and how to parse them. The agent is installed by default on worker node compute instances. To confirm that the agent is already installed, see Verify Agent Installation on page 2623.
- You must have already:
  - Created a dynamic group with a rule that includes worker nodes in the cluster's node pools as target hosts (see About Dynamic Groups on page 2422 and Selecting Target Hosts with Dynamic Groups on page 2625). For example:
    
    ```java
    instance.compartment.id = 'ocid1.tenancy.oc1..<unique-id>'
    ```
  - Created a policy for the dynamic group with a policy statement to allow the target hosts in the dynamic group to push logs to Oracle Cloud Infrastructure Logging (see Selecting Target Hosts with Dynamic Groups on page 2625). For example:
    
    ```java
    allow dynamic group <dynamic-group-name> to use log-content in tenancy
    ```

Having completed the above prerequisites, you can then define custom logs and associated agent configurations to view application logs on worker node compute instances. For more information about custom logs and agent configurations, see Custom Logs on page 2619.

Note that in addition to viewing application logs on worker node compute instances, you can also:

- Monitor the overall status of the cluster itself, node pools, and nodes. See Monitoring Clusters on page 886.
- Monitor the health, capacity, and performance of clusters, node pools, and nodes at a more granular level using *metrics*, *alarms*, and *notifications*. See Container Engine for Kubernetes Metrics on page 963.

**Using the Console**

To define a new custom log object and an associated agent configuration to enable you to view and search the logs of applications running on a cluster's worker node compute instances:

1. Open the navigation menu. Under *Solutions and Platform*, go to *Logging*, and then click *Logs*.
2. Choose a *Compartment* you have permission to work in.
3. Click *Create custom log* to create a new custom log.
4. On the *Create custom log* page, specify:
   - **Custom Log Name**: A name of your choosing for the new custom log. Avoid entering confidential information.
   - **Compartment**: The compartment in which to create the new custom log.
   - **Log Group**: The log group in which to place the custom log. Optionally, click *Create New Group* to create a new log group (see Managing Logs and Log Groups on page 2577).
5. Click *Create custom log*.
   
   A new custom log is created, and the *Create agent configuration* page is displayed.

   For convenience, these instructions now describe how to create a new agent configuration associated with the new custom log (although you can create a new agent configuration later if you prefer).

6. On the *Create agent configuration* page, select *Create new configuration* and specify:
   - **Configuration Name**: A name of your choosing for the new agent configuration. Avoid entering confidential information.
   - **Compartment**: The compartment in which to create the new agent configuration.
7. In the **Agent configuration** panel on the **Create agent configuration** page, specify:

   • **Choose host groups**: One or more host groups, as follows:
      
      • **Group type**: Select **Dynamic group**.
      
      • **Group**: An existing dynamic group that includes worker nodes in the cluster's node pools as target hosts. The dynamic group you select must have permission to access the compartment you specified for the agent configuration, and must also allow target hosts to push logs to Oracle Cloud Infrastructure Logging.
      
      • **Configure log inputs**: One or more locations from which to obtain application logs as inputs to the custom log, as follows:
         
         • **Input type**: Select **Log path**.
         
         • **Input name**: A name of your choosing for the new log input.
         
         • **File paths**: The path to application logs on the worker node compute instance. For example, `/var/log/containers/*`

     The **Select log destination** options are pre-populated with the custom log details you specified previously.

8. Click **Create custom log** to create the agent configuration associated with the custom log.

To view and search the contents of a custom log created for an application running on a cluster's worker node compute instances:

1. Open the navigation menu. Under **Solutions and Platform**, go to **Logging**, and then click **Logs**.
2. Click the name of the custom log that you want to view. You can sort log entries by age, and filter by time.
3. (Optional) Click **Explore with Log Search** to open the central logging **Search** page. You can apply filters, and explore and visualize the log data in different ways (see **Viewing Custom Logs in a Compute Instance** on page 2627).

### Accessing a Cluster Using Kubectl

You can use the Kubernetes command line tool kubectl to perform operations on a cluster you've created with Container Engine for Kubernetes. You can use the kubectl installation included in Cloud Shell, or you can use a local installation of kubectl. In both cases, before you can use kubectl to access a cluster, you have to specify the cluster on which to perform operations by setting up the cluster's kubeconfig file.

Note that an Oracle Cloud Infrastructure CLI command in the kubeconfig file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters. The generated authentication tokens are also unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the kubeconfig file. For more information, see **Adding a Service Account Authentication Token to a Kubeconfig File** on page 894.

Note also that the version of kubectl you use must be compatible with the version of Kubernetes running on clusters created by Container Engine for Kubernetes. In the case of Cloud Shell, kubectl is regularly updated so it is always compatible with the versions of Kubernetes currently supported by Container Engine for Kubernetes. In the case of a local installation of kubectl, it is your responsibility to update kubectl regularly. For more information about compatibility between different versions of Kubernetes and kubectl, see the **Kubernetes documentation**.

### Accessing a Cluster Using kubectl in Cloud Shell

To access a cluster using kubectl in Cloud Shell:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file for use in Cloud Shell, and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See **Setting Up Cloud Shell Access to Clusters** on page 876.
2. In the Cloud Shell window, enter `kubectl` followed by the command for the operation you want to perform on the cluster. For a list of available commands and options, see the **kubectl documentation**.

   Note that you must have the appropriate permissions to run the command you enter. See **About Access Control and Container Engine for Kubernetes** on page 920.
Accessing a Cluster Using kubectl Installed Locally

To access a cluster using kubectl installed locally:

1. If you haven't already done so, install kubectl (see the kubectl documentation).
2. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file for use locally, and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Local Access to Clusters on page 877.
3. In a local terminal window, enter `kubectl` followed by the command for the operation you want to perform on the cluster. For a list of available commands and options, see the kubectl documentation.

Note that you must have the appropriate permissions to run the command you enter. See About Access Control and Container Engine for Kubernetes on page 920.

Accessing a Cluster Using the Kubernetes Dashboard

The Kubernetes Dashboard is a web-based management interface that enables you to:

- deploy and edit containerized applications
- assess the status of containerized applications
- troubleshoot containerized applications

For more information about the Kubernetes Dashboard (sometimes called the Web UI or the Dashboard UI), see the Web UI (Dashboard) topic in the Kubernetes documentation.

The Kubernetes Dashboard is not deployed in clusters by default. However, you can deploy the Kubernetes Dashboard in clusters you create with Container Engine for Kubernetes in the following ways:

- To manually deploy the Kubernetes Dashboard on an existing cluster, see the Kubernetes documentation. When you follow the instructions to manually deploy the Kubernetes Dashboard, it is deployed in the `kube-dashboard` namespace (not the `kube-system` namespace). The URL to display a manually deployed Kubernetes Dashboard is:

  http://localhost:8001/api/v1/namespaces/kube-dashboard/services/
  https:kubernetes-dashboard:/proxy/#!/login

- To have Container Engine for Kubernetes automatically deploy the Kubernetes Dashboard during cluster creation, create the cluster using the API and set the isKubernetesDashboardEnabled attribute to true. When Container Engine for Kubernetes automatically deploys the Kubernetes Dashboard, it is deployed in the `kube-system` namespace. The URL to display an automatically deployed Kubernetes Dashboard is:

  http://localhost:8001/api/v1/namespaces/kube-system/services/
  https:kubernetes-dashboard:/proxy/#!/login

Note the following:

- You cannot run the Kubernetes Dashboard in Cloud Shell.
- You cannot use Container Engine for Kubernetes to deploy the Kubernetes Dashboard on existing clusters. You have to manually deploy the Kubernetes Dashboard on existing clusters.
- The commands to use to delete the Kubernetes Dashboard from a cluster will depend on the version of Kubernetes running on the cluster. See Notes about Deleting the Kubernetes Dashboard on page 893.
- An Oracle Cloud Infrastructure CLI command in the kubeconfig file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters. The generated authentication tokens are also unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the kubeconfig file. For more information, see Adding a Service Account Authentication Token to a Kubeconfig File on page 894.
### Accessing a Cluster using the Kubernetes Dashboard

To access a cluster using the Kubernetes Dashboard:

1. If you haven’t already done so, follow the steps to set up the cluster’s kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a text editor, create a file (for example, called oke-admin-service-account.yaml) with the following content:

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  name: oke-admin
  namespace: kube-system
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: oke-admin
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: cluster-admin
subjects:
- kind: ServiceAccount
  name: oke-admin
  namespace: kube-system
```

The file defines an administrator service account and a clusterrolebinding, both called oke-admin.

3. Create the service account and the clusterrolebinding in the cluster by entering:

   ```
   kubectl apply -f <filename>
   ```

   where `<filename>` is the name of the file you created earlier. For example:

   ```
   kubectl apply -f oke-admin-service-account.yaml
   ```

   The output from the above command confirms the creation of the service account and the clusterrolebinding:

   ```
   serviceaccount "oke-admin" created
   clusterrolebinding.rbac.authorization.k8s.io "oke-admin" created
   ```

   You can now use the oke-admin service account to view and control the cluster, and to connect to the Kubernetes dashboard.

4. Obtain an authentication token for the oke-admin service account by entering:

   ```
   kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep oke-admin | awk '{print $1}')
   ```

   The output from the above command includes an authentication token (a long alphanumeric string) as the value of the `token:` element, as shown below:

   ```
   Name:         oke-admin-token-gwbp2
   Namespace:    kube-system
   Labels:       <none>
   Annotations:  kubernetes.io/service-account.name: oke-admin
   kubernetes.io/service-account.uid: 3a7fcd8e-e123-11e9-81ca-0a580aed8570
   Type:         kubernetes.io/service-account-token
   ```
In the example above, eyJh________px1Q (abbreviated for readability) is the authentication token.

5. Copy the value of the token: element from the output. You will use this token to connect to the dashboard.

6. In a terminal window, enter `kubectl proxy` to make the Kubernetes Dashboard available.

7. Open a browser and go to the following URL to display the Kubernetes Dashboard that was deployed when cluster was created:

```
http://localhost:8001/api/v1/namespaces/kube-system/services/
https:kubernetes-dashboard:/proxy/#!/login
```

Note that if you followed the instructions in the Kubernetes documentation to manually deploy the Kubernetes Dashboard on an existing cluster, it is deployed in the `kube-dashboard` namespace rather than the `kube-system` namespace. As a result, the URL to display the manually deployed Kubernetes Dashboard is:

```
http://localhost:8001/api/v1/namespaces/kube-dashboard/services/
https:kubernetes-dashboard:/proxy/#!/login.
```

8. In the Kubernetes Dashboard, select **Token** and paste the value of the token: element you copied earlier into the **Token** field.

9. In the Kubernetes Dashboard, click **Sign In**, and then click **Overview** to see the applications deployed on the cluster.

### Notes about Deleting the Kubernetes Dashboard

If you want to delete the Kubernetes Dashboard from a cluster, the commands to use will depend on the version of Kubernetes running on the cluster:

- For clusters running Kubernetes versions prior to version 1.16.8, run the following kubectl commands to delete the Kubernetes Dashboard:

  ```
kubectl delete deployment kubernetes-dashboard -n kube-system
kubectl delete sa -n kube-system kubernetes-dashboard
kubectl delete svc -n kube-system kubernetes-dashboard
kubectl delete secret -n kube-system kubernetes-dashboard-cert
kubectl delete secret -n kube-system kubernetes-dashboard-key-holder
kubectl delete cm -n kube-system kubernetes-dashboard-settings
kubectl delete role -n kube-system kubernetes-dashboard-minimal
kubectl delete rolebinding -n kube-system kubernetes-dashboard-minimal
kubectl delete deploy -n kube-system kubernetes-dashboard
```

- For clusters running Kubernetes version 1.16.8 (or later), run the following kubectl commands to delete the Kubernetes Dashboard:

  ```
kubectl delete deployment kubernetes-dashboard -n kube-system
kubectl delete sa -n kube-system kubernetes-dashboard
kubectl delete svc -n kube-system kubernetes-dashboard
kubectl delete secret -n kube-system kubernetes-dashboard-cert
kubectl delete secret -n kube-system kubernetes-dashboard-csrf
kubectl delete secret -n kube-system kubernetes-dashboard-key-holder
kubectl delete cm -n kube-system kubernetes-dashboard-settings
kubectl delete role -n kube-system kubernetes-dashboard
kubectl delete rolebinding -n kube-system kubernetes-dashboard
kubectl delete clusterrole -n kube-system kubernetes-dashboard
kubectl delete clusterrolebinding -n kube-system kubernetes-dashboard
kubectl delete deploy -n kube-system kubernetes-dashboard
```
Adding a Service Account Authentication Token to a Kubeconfig File

When you set up the kubeconfig file for a cluster, by default it contains an Oracle Cloud Infrastructure CLI command to generate a short-lived, cluster-scoped, user-specific authentication token. The authentication token generated by the CLI command is appropriate to authenticate individual users accessing the cluster using kubectl and the Kubernetes Dashboard.

However, the generated authentication token is not appropriate to authenticate processes and tools accessing the cluster, such as continuous integration and continuous delivery (CI/CD) tools. To ensure access to the cluster, such tools require long-lived, non-user-specific authentication tokens.

One solution is to use a Kubernetes service account, as described in this topic. A service account has an associated service account authentication token, which is stored as a Kubernetes secret. Having created a service account, you bind it to a clusterrolebinding that has cluster administration permissions. You can then add the service account (and its service account authentication token) as a user definition in the kubeconfig file itself. Other tools can then use the service account authentication token when accessing the cluster.

Note that to run the commands in this topic, you must have the appropriate permissions. See About Access Control and Container Engine for Kubernetes on page 920.

To add a service account authentication token to a kubeconfig file:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a terminal window, create a new service account in the kube-system namespace by entering the following kubectl command:

   ```
   kubectl -n kube-system create serviceaccount <service-account-name>
   ```

   For example, to create a service account called kubeconfig-sa, enter:

   ```
   kubectl -n kube-system create serviceaccount kubeconfig-sa
   ```

   The output from the above command confirms the creation of the service account. For example:

   ```
   serviceaccount/kubeconfig-sa created
   ```

   Note that creating the service account in the kube-system namespace is recommended good practice, and is assumed in the instructions in this topic. However, if you prefer, you can create the service account in another namespace to which you have access.

3. Create a new clusterrolebinding with cluster administration permissions and bind it to the service account you just created by entering the following kubectl command:

   ```
   kubectl create clusterrolebinding <binding-name> --clusterrole=cluster-admin --serviceaccount=kube-system:<service-account-name>
   ```

   For example, to create a clusterrolebinding called add-on-cluster-admin and bind it to the kubeconfig-sa service account, enter:

   ```
   kubectl create clusterrolebinding add-on-cluster-admin --clusterrole=cluster-admin --serviceaccount=kube-system:kubeconfig-sa
   ```

   The output from the above command confirms the creation of the clusterrolebinding. For example:

   ```
   clusterrolebinding.rbac.authorization.k8s.io/add-on-cluster-admin created
   ```
4. Obtain the name of the service account authentication token and assign its value to an environment variable by entering the following command (these instructions assume you specify TOKENNAME as the name of the environment variable):

```
TOKENNAME=`kubectl -n kube-system get serviceaccount/<service-account-name> -o jsonpath='{.secrets[0].name}'`
```

For example:

```
TOKENNAME=`kubectl -n kube-system get serviceaccount/kubeconfig-sa -o jsonpath='{.secrets[0].name}'`
```

5. Obtain the value of the service account authentication token and assign its value (decoded from base64) to an environment variable. These instructions assume you specify TOKEN as the name of the environment variable. The commands to enter depend on the operating system:

- To obtain the value of the service account authentication token in a MacOS, Linux, or Unix environment, enter the following command:

```
TOKEN=`kubectl -n kube-system get secret $TOKENNAME -o jsonpath='{.data.token}'| base64 --decode`
```

- To obtain the value of the service account authentication token in a Windows environment:
  a. Enter the following command:

```
kubectl -n kube-system get secret $TOKENNAME -o jsonpath='{.data.token}'
```
  b. Copy the output from the above command and paste it into a base64 decoder (for example, https://www.base64decode.org, https://www.base64decode.net, or similar).
  c. Copy the output from the base64 decoder.
  d. Enter the following command:

```
TOKEN=`[<base64-decoded-output>]`
```

where `<base64-decoded-output>` is the output you copied from the base64 decoder.

6. Add the service account (and its authentication token) as a new user definition in the kubeconfig file by entering the following kubectl command:

```
kubectl config set-credentials <service-account-name> --token=$TOKEN
```

The service account (and its authentication token) is added to the list of users defined in the kubeconfig file. For example, to add the kubeconfig-sa service account and its authentication token to the kubeconfig file, enter:

```
kubectl config set-credentials kubeconfig-sa --token=$TOKEN
```

The output from the above command confirms the service account has been added to the kubeconfig file. For example:

```
User "kubeconfig-sa" set.
```
7. Set the user specified in the kubeconfig file for the current context to be the new service account user you created, by entering the following kubectl command:

```
kubectl config set-context --current --user=<service-account-name>
```

For example:

```
kubectl config set-context --current --user=kubeconfig-sa
```

The output from the above command confirms the current context has been changed. For example:

```
Context "context-ctdiztdhezd" modified.
```

8. (Optional) To verify that authentication works as expected, run a kubectl command to confirm that the service account user can be successfully authenticated using the service account authentication token.

For example, if you have previously deployed a sample Nginx application on the cluster (see Deploying a Sample Nginx App on a Cluster Using Kubectl on page 896), enter the following command:

```
kubectl get pods
```

The output from the above command shows the pods running on the cluster. If the command runs successfully, the service account user in the kubeconfig file has been successfully authenticated using the service account authentication token.

9. Distribute the kubeconfig file as necessary to enable other processes and tools (such as continuous integration and continuous delivery (CI/CD) tools) to access the cluster.

```
Note:

If you subsequently want to remove access to the cluster from the service account, delete the Kubernetes secret containing the service account authentication token by entering the following command:

```
kubectl -n kube-system delete secret $TOKENNAME
```
```

Deploying a Sample Nginx App on a Cluster Using Kubectl

Having created a Kubernetes cluster using Container Engine for Kubernetes, you'll typically want to try it out by deploying an application on the nodes in the cluster. For convenience, the Quick Start tab (available from the Cluster page) makes it easy to view and copy the commands to:

- set up access to the cluster
- download and deploy a sample Nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file

To deploy the sample nginx application:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a terminal window, deploy the sample Nginx application by entering:

```
kubectl create -f https://k8s.io/examples/application/deployment.yaml
```

```
Tip:

If the command fails to connect to https://k8s.io/examples/application/deployment.yaml, go to the url in a browser and
```

Oracle Cloud Infrastructure User Guide
download the manifest file `deployment.yaml` to a local directory.
Repeat the `kubectl create` command and specify the local location of the `deployment.yaml` file.

3. Confirm that the sample application has been deployed successfully by entering:

```
kubectl get pods
```

You can see the Nginx sample application has been deployed as two pods, on two nodes in the cluster.

### Pulling Images from Registry during Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry, you have to perform two steps:

- You have to use `kubectl` to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of `kubectl` (see the `kubectl` documentation).
- You have to specify the image to pull from Oracle Cloud Infrastructure Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a terminal window, enter:

```
kubectl create secret docker-registry <secret-name> --docker-server=<region-key>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>'
```

where:

- `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret. For example, `ocirsecret`
- `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region on page 3508.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older
tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).

- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-name>`. For example, `jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `oracleidentitycloudservice/<username>`.
- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, `k\j64r{1sJSSF-;)K8`.
- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, `jdoe@acme.com`.

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```bash
kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vru1zp/jdoe@acme.com' --docker-password='k\j64r{1sJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.

To specify the image to pull from Oracle Cloud Infrastructure Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Oracle Cloud Infrastructure Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Oracle Cloud Infrastructure Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: ngnix-image
spec:
  containers:
  - name: ngnix
    image: phx.ocir.io/ansh81vru1zp/project01/ngnix-lb:latest
    imagePullPolicy: Always
    ports:
    - name: ngnix
      containerPort: 8080
      protocol: TCP
    imagePullSecrets:
    - name: ocirsecret
```

3. Save and close the manifest file.

**Supported Labels for Different Usecases**

Container Engine for Kubernetes uses a number of different labels when creating and managing clusters, including:

- `failure-domain.beta.kubernetes.io/zone` on page 899
- `oci.oraclecloud.com/fault-domain` on page 899
- `node.kubernetes.io/exclude-from-external-load-balancers` on page 900

For more information about Kubernetes labels, see the Kubernetes documentation.
Container Engine for Kubernetes automatically adds the `failure-domain.beta.kubernetes.io/zone` label to each worker node (compute instance) in a cluster, according to the availability domain in which it is placed.

An availability domain is one or more data centers located within a region. A region is composed of one or more availability domains. Availability domains are isolated from each other, fault tolerant, and very unlikely to fail simultaneously. See Regions and Availability Domains on page 180.

You can use the `failure-domain.beta.kubernetes.io/zone` label in different ways:

- You can use the `failure-domain.beta.kubernetes.io/zone` label (in conjunction with the `oci.oraclecloud.com/fault-domain` label) to constrain the worker nodes on which to run a pod, in the case of a cluster with worker nodes in multiple availability domains. Include the `failure-domain.beta.kubernetes.io/zone` label in the pod specification to specify the availability domain in which worker nodes must have been placed.
- You can use the `failure-domain.beta.kubernetes.io/zone` label to specify the availability domain and region to provision persistent volume claims on the Block Volume service when using the FlexVolume plugin. See Creating a Persistent Volume Claim on page 947.

When you specify a value for the `failure-domain.beta.kubernetes.io/zone` label, you must use the correct shortened version of the availability domain name in an Oracle Cloud Infrastructure region. In most cases, the shortened versions of availability domain names are in the format `<region-identifier>-<availability-domain-number>`. For example, `UK-LONDON-1-AD-1`, `UK-LONDON-1-AD-2`, `UK-LONDON-1-AD-3`, `AP-MELBOURNE-1-AD-1`, `ME-JEDDAH-1-AD-1`. To find out the region identifiers and availability domains to use, see Availability by Region on page 836.

Note that the shortened versions of availability domain names in the Ashburn and Phoenix regions are exceptions, as shown below:

- For the Phoenix region, shortened versions of availability domain names are in the format `PHX-AD-<availability-domain-number>`. For example, `PHX-AD-1`, `PHX-AD-2`, `PHX-AD-3`.

Container Engine for Kubernetes automatically adds the `oci.oraclecloud.com/fault-domain` label to each worker node (compute instance) in a cluster, according to the fault domain in which it is placed.

A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. Each availability domain has three fault domains (named FAULT-DOMAIN-1, FAULT-DOMAIN-2, FAULT-DOMAIN-3). Every compute instance is placed in a fault domain. See Fault Domains on page 182.

You can constrain the worker nodes on which to run a pod by including the `oci.oraclecloud.com/fault-domain` label in the pod specification. Use the `oci.oraclecloud.com/fault-domain` label to specify the fault domain in which worker nodes must have been placed.

You'll typically use the `oci.oraclecloud.com/fault-domain` label to achieve high availability when a cluster is located in a region with a single availability domain.

For example:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
```
If you apply the above example pod spec to a cluster, an nginx pod is only created if the cluster has worker nodes in FAULT-DOMAIN-3 in the availability domain. If the cluster only has worker nodes in FAULT-DOMAIN-1 or FAULT-DOMAIN-2, the pod is not created and remains in a pending status.

If a cluster has worker nodes in multiple availability domains, include both the failure-domain.beta.kubernetes.io/zone label and the oci.oraclecloud.com/fault-domain label in a pod specification to specify both the availability domain and the fault domain of the worker nodes on which to run the pod.

### node.kubernetes.io/exclude-from-external-load-balancers

Container Engine for Kubernetes automatically enables the ServiceNodeExclusion feature gate on the clusters it creates. With the ServiceNodeExclusion feature gate enabled on a cluster, you can add a label to particular worker nodes to exclude them from the list of backend servers in an Oracle Cloud Infrastructure load balancer backend set. The fewer worker nodes included in a backend set, the faster the load balancer can be updated.

To exclude a worker node from the list of backend servers in a backend set, add the node.kubernetes.io/exclude-from-external-load-balancers label to the node by entering:

```bash
tool label nodes <node-name> node.kubernetes.io/exclude-from-external-load-balancers=true
```

For example:

```bash
tool label nodes 10.0.1.2 node.kubernetes.io/exclude-from-external-load-balancers=true
```

Note that having added the label to a node, the node is excluded from the list of backend servers regardless of the value of the label. For example, even if you specify node.kubernetes.io/exclude-from-external-load-balancers label=false, the worker node is still excluded from the list of backend servers.

To remove the label from the node, enter:

```bash
tool label nodes <node-name> node.kubernetes.io/exclude-from-external-load-balancers=
```

### Encrypting Kubernetes Secrets at Rest in Etcd

The control plane nodes in a Kubernetes cluster store sensitive configuration data (such as authentication tokens, passwords, and SSH keys) as Kubernetes secret objects in etcd. Etcd is an open source distributed key-value store that Kubernetes uses for cluster coordination and state management. In the Kubernetes clusters created by Container Engine for Kubernetes, etcd writes and reads data to and from block storage volumes in the Oracle Cloud Infrastructure Block Volume service. Although the data in block storage volumes is encrypted, Kubernetes secrets at rest in etcd itself are not encrypted by default.

For additional security, when you create a new cluster you can specify that Kubernetes secrets at rest in etcd are to be encrypted using the Oracle Cloud Infrastructure Vault service (see Overview of Vault on page 3952). Before you can create a cluster where Kubernetes secrets are encrypted in the etcd key-value store, you have to:

- know the name and OCID of a suitable master encryption key in Vault
- create a dynamic group that includes all clusters in the compartment in which you are going to create the new cluster
- create a policy authorizing the dynamic group to use the master encryption key
Having created the cluster and specified that you want Kubernetes secrets at rest in the etcd key-value store to be encrypted, you can optionally restrict the use of the master encryption key by modifying the dynamic group to include just that cluster.

Note the following:

- You can only select the option to encrypt the Kubernetes secrets in the cluster's etcd key-value store when creating a new 'custom cluster'. You cannot encrypt Kubernetes secrets in the etcd key-value stores of existing 'custom clusters', or in the etcd key-value stores of 'quick clusters'.
- You can only select the option to encrypt Kubernetes secrets in the cluster's etcd key-value store if you specify Kubernetes version 1.13.x or later as the version of Kubernetes to run on the control plane nodes of the cluster.
- Policies must have been defined to authorize Container Engine for Kubernetes to use the master encryption key, and to authorize users to delegate key usage to Container Engine for Kubernetes in the first place. For more information, see Let a user group delegate key usage in a compartment and Let Block Volume, Object Storage, File Storage, and Container Engine for Kubernetes services encrypt and decrypt volumes, buckets, file systems, and Kubernetes secrets in Common Policies on page 2142.
- Policies must have been defined to authorize Container Engine for Kubernetes to use the master encryption key, and to authorize users to delegate key usage to Container Engine for Kubernetes in the first place. For more information, see Let a user group delegate key usage in a compartment and Let Block Volume, Object Storage, File Storage, and Container Engine for Kubernetes services encrypt and decrypt volumes, buckets, file systems, and Kubernetes secrets in Common Policies on page 2142.
- After you've specified a master encryption key for a new cluster and created the cluster, do not subsequently delete the master encryption key in the Vault service. As soon as you schedule a key for deletion in Vault, the Kubernetes secrets stored for the cluster in etcd become inaccessible. If you have already scheduled the key for deletion, it might still be in the Pending Deletion state. If that is the case, cancel the scheduled key deletion (see To cancel the deletion of a key on page 3966) to restore access to the Kubernetes secrets. If you allow the scheduled key deletion operation to complete and the master encryption key to be deleted, the Kubernetes secrets stored for the cluster in etcd are permanently inaccessible. As a result, cluster upgrades will fail. In this situation, you have no choice but to delete and recreate the cluster.

Master Encryption Keys in Other Tenancies

You can create a cluster in one tenancy that uses a master encryption key in a different tenancy. In this case, you have to write cross-tenancy policies to enable the cluster in its tenancy to access the master encryption key in the Vault service’s tenancy. Note that if you want to create a cluster and specify a master encryption key that’s in a different tenancy, you cannot use the Console to create the cluster.

For example, assume the cluster is in the ClusterTenancy, and the master encryption key is in the KeyTenancy. Users belonging to a group (OKEAdminGroup) in the ClusterTenancy have permissions to create clusters. A dynamic group (OKEAdminDynGroup) has been created in the cluster, with the rule ALL {resource.type = 'cluster', resource.compartment.id = 'ocid1.compartment.oc1..<unique_ID>'}, so all clusters created in the ClusterTenancy belong to the dynamic group.

In the root compartment of the KeyTenancy, the following policies:

- use the ClusterTenancy's OCID to map ClusterTenancy to the alias OKE_Tenancy
- use the OCIDs of OKEAdminGroup and OKEAdminDynGroup to map them to the aliases RemoteOKEAdminGroup and RemoteOKEClusterDynGroup respectively
- give RemoteOKEAdminGroup and RemoteOKEClusterDynGroup the ability to list, view, and perform cryptographic operations with a particular master key in the KeyTenancy

```sh
Define tenancy OKE_Tenancy as ocid1.tenancy.oc1..<unique_ID>
Define dynamic-group RemoteOKEClusterDynGroup as ocid1.dynamicgroup.oc1..<unique_ID>
Define group RemoteOKEAdminGroup as ocid1.group.oc1..<unique_ID>
Admit dynamic-group RemoteOKEClusterDynGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
Admit group RemoteOKEAdminGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
```

In the root compartment of the ClusterTenancy, the following policies:

- use the KeyTenancy's OCID to map KeyTenancy to the alias KMS_Tenancy
- give OKEAdminGroup and OKEAdminDynGroup the ability to use master keys in the KeyTenancy

```sh
Define tenancy KMS_Tenancy as ocid1.tenancy.oc1..<unique_ID>
Define dynamic-group RemoteOKEClusterDynGroup as ocid1.dynamicgroup.oc1..<unique_ID>
Define group RemoteOKEAdminGroup as ocid1.group.oc1..<unique_ID>
Admit dynamic-group RemoteOKEClusterDynGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
Admit group RemoteOKEAdminGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
```

In the root compartment of the ClusterTenancy, the following policies:

- use the KeyTenancy's OCID to map KeyTenancy to the alias KMS_Tenancy
- give OKEAdminGroup and OKEAdminDynGroup the ability to use master keys in the KeyTenancy
• allow OKEAdminDynGroup to use a specific master key obtained from the KeyTenancy in the ClusterTenancy

Define tenancy KMS_Tenancy as ocid1.tenancy.oc1..<unique_ID>
Endorse group OKEAdminGroup to use keys in tenancy KMS_Tenancy
Endorse dynamic-group OKEAdminDynGroup to use keys in tenancy KMS_Tenancy
Allow dynamic-group OKEAdminDynGroup to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'

See Accessing Object Storage Resources Across Tenancies on page 3503 for more examples of writing cross-tenancy policies.

Having entered the policies, you can now run a command similar to the following to create a cluster in the ClusterTenancy that uses the master key obtained from the KeyTenancy:

oci ce cluster create --name oke-with-cross-kms --kubernetes-version v1.16.8 --vcn-id ocid1.vcn.oc1.iad.<unique_ID> --service-lb-subnet-ids '["ocid1.subnet.oc1.iad.<unique_ID>"]' --compartment-id ocid1.compartment.oc1..<unique_ID> --kms-key-id ocid1.key.oc1.iad.<unique_ID>

Using the Console

To create a new 'custom cluster' where Kubernetes secrets are encrypted in the cluster's etcd key-value store:

1. Log in to the Console.
2. If you know the OCID of the master encryption key to use to encrypt Kubernetes secrets, go straight to the next step. Otherwise:
   • If a suitable master encryption key already exists in Vault but you're not sure of its OCID, follow the instructions in To view key details on page 3963 and make a note of the master encryption key's OCID.
   • If a suitable master encryption key does not already exist in Vault, follow the instructions in To create a new master encryption key on page 3963 to create one. Having created a new master encryption key, make a note of its OCID.
3. Create a new dynamic group containing all the clusters in the compartment in which you intend to create the new cluster:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Dynamic Groups.
   b. Follow the instructions in To create a dynamic group on page 2423, and give the dynamic group a name (for example, acme-oke-kms-dyn-grp).
   c. Enter a rule that includes all clusters in the compartment in the format:

\[
\text{ALL \{resource.type = 'cluster', resource.compartment.id = 'ocid1.compartment.oc1..<unique_ID>'\}}
\]

where <compartment-ocid> is the OCID of the compartment in which you intend to create the new cluster.

For example:

\[
\text{ALL \{resource.type = 'cluster', resource.compartment.id = 'ocid1.compartment.oc1..aaaaaaaa23______smwa'\}}
\]

d. Click Create Dynamic Group.

Having created a dynamic group that includes all clusters in the compartment, you can now create a policy to give the dynamic group access to the master encryption key in Vault.
4. Create a new policy to enable use of the master encryption key:
   a. Open the navigation menu. Under Governance and Administration, go to Identity and click Policies.
   b. Follow the instructions in To create a policy on page 2454, and give the policy a name (for example, acme-oke-kms-dyn-grp-policy).
   c. Enter a policy statement to give the dynamic group access to the master encryption key, in the format:

   
   ```allow dynamic-group <dynamic-group-name> to use keys in compartment <compartment-name> where target.key.id = '<key-OCID>'
   
   where:
   
   • <dynamic-group-name> is the name of the dynamic group you created earlier.
   • <compartment-name> is the name of the compartment containing the master encryption key.
   • <key-OCID> is the OCID of the master encryption key in Vault.
   
   For example:

   ```allow dynamic-group acme-oke-kms-dyn-grp to use keys in compartment acme-kms-key-compartment where target.key.id = 'ocid1.key.oct1.iad.annrl______trfg'
   
   d. Click Create to create the new policy.

5. Follow the instructions to create a new 'custom cluster' in Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings on page 873, select the Encrypt Using Customer-Managed Keys option, and select:

   • Choose a Vault in <compartment-name>: The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment.
   
   • Choose a Key in <compartment-name>: The name of the master encryption key, from the list of keys in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment. Note that you cannot change the master encryption key after the cluster has been created.

6. (Optional) Having created the cluster, for additional security:
   a. Make a note of the OCID of the new cluster you just created.
   b. Restrict the use of the master encryption key by modifying the dynamic group rule you created earlier to explicitly specify the OCID of the new cluster, rather than all clusters in the compartment. For example:

   ```resource.id = 'ocid1.cluster.oct1.iad.aaaaaaaaaf______yg5q'
   
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use the CreateCluster operation to create a cluster.

Connecting to Worker Nodes Using SSH

If you provided a public SSH key when creating the node pool in a cluster, the public key is installed on all worker nodes in the cluster. On UNIX and UNIX-like platforms (including Solaris and Linux), you can then connect through SSH to the worker nodes using the ssh utility (an SSH client) to perform administrative tasks.

Note the following instructions assume the UNIX machine you use to connect to the worker node:

• Has the ssh utility installed.
• Has access to the SSH private key file paired with the SSH public key that was specified when the cluster was created.
How to connect to worker nodes using SSH depends on whether you specified public or private subnets for the worker nodes when defining the node pools in the cluster.

### Connecting to Worker Nodes in Public Subnets Using SSH

Before you can connect to a worker node in a public subnet using SSH, you must define an ingress rule in the subnet's security list to allow SSH access. The ingress rule must allow access to port 22 on worker nodes from source 0.0.0.0/0 and any source port, as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Source CIDR</th>
<th>IP Protocol</th>
<th>Source Port Range</th>
<th>Dest. Port Range</th>
<th>Type and Code</th>
<th>Allows: and Description:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>All</td>
<td>22</td>
<td>n/a</td>
<td>Allows: TCP traffic for ports: 22 SSH Remote Login Protocol Description: Enables SSH access.</td>
</tr>
</tbody>
</table>

To connect to a worker node in a public subnet through SSH from a UNIX machine using the ssh utility:

1. Find out the IP address of the worker node to which you want to connect. You can do this in a number of ways:
   - Using kubectl. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876. Then in a terminal window, enter `kubectl get nodes` to see the public IP addresses of worker nodes in node pools in the cluster.
   - Using the Console. In the Console, display the Cluster List page and then select the cluster to which the worker node belongs. On the Node Pools tab, click the name of the node pool to which the worker node belongs. On the Nodes tab, you see the public IP address of every worker node in the node pool.
   - Using the REST API. Use the ListNodePools operation to see the public IP addresses of worker nodes in a node pool.

2. In the terminal window, enter `ssh opc@<node_ip_address>` to connect to the worker node, where `<node_ip_address>` is the IP address of the worker node that you made a note of earlier. For example, you might enter `ssh opc@192.0.2.254`.

   Note that if the SSH private key is not stored in the file or in the path that the ssh utility expects (for example, the ssh utility might expect the private key to be stored in `~/.ssh/id_rsa`), you must explicitly specify the private key filename and location in one of two ways:
   - Use the `-i` option to specify the filename and location of the private key. For example, `ssh -i ~/.ssh/my_keys/my_host_key_filename opc@192.0.2.254`
   - Add the private key filename and location to an SSH configuration file, either the client configuration file (`~/.ssh/config`) if it exists, or the system-wide client configuration file (`/etc/ssh/ssh_config`). For example, you might add the following:

     ```
     Host 192.0.2.254
     IdentityFile ~/.ssh/my_keys/my_host_key_filename
     ```

For more about the ssh utility's configuration file, enter `man ssh_config`

Note also that permissions on the private key file must allow you read/write/execute access, but prevent other users from accessing the file. For example, to set appropriate permissions, you might enter `chmod 600 ~/.ssh/my_keys/my_host_key_filename`. If permissions are not set correctly and the private key file is accessible to other users, the ssh utility will simply ignore the private key file.
Connecting to Worker Nodes in Private Subnets Using SSH

Worker nodes in private subnets have private IP addresses only (they do not have public IP addresses). They can only be accessed by other resources inside the VCN. Oracle recommends using bastion hosts to control external access (such as SSH) to worker nodes in private subnets. A bastion host is in a public subnet, has a public IP address, and is accessible from the internet. For more information about bastion hosts, see the white paper Bastion Hosts: Protected Access for Virtual Cloud Networks.

Using Pod Security Policies with Container Engine for Kubernetes

You can control the operations that pods are allowed to perform on a cluster you have created with Container Engine for Kubernetes by setting up pod security policies for the cluster. Pod security policies are a way to ensure that pods meet security-related conditions before they can be accepted by a cluster. For example, you can use pod security policies to:

- limit the storage choices available to pods
- restrict the host networking and ports that pods can access
- prevent pods from running as the root user
- prevent pods from running in privileged mode

You can also use pod security policies to provide default values for pods, by 'mutating' the pod.

Having defined a pod security policy for a cluster, you have to authorize the requesting user or target pod's service account to use the policy. You do this by creating a role (or clusterrole) to access the pod security policy, and then creating a rolebinding (or clusterrolebinding) between the role (or clusterrole) and the requesting user or target pod's service account. For more information about roles, clusterroles, and bindings, see About Access Control and Container Engine for Kubernetes on page 920.

You specify whether a cluster enforces the pod security policies defined for it by enabling the cluster's PodSecurityPolicy admission controller. The PodSecurityPolicy admission controller acts on creation and modification of a pod and determines if the pod should be admitted to the cluster based on the requested security context in the pod spec and the cluster's pod security policies. If multiple pod security policies exist, the PodSecurityPolicy admission controller first compares the pod against non-mutating policies in alphabetical order and uses the first policy that successfully validates the pod. If no non-mutating pods validate the pod, the PodSecurityPolicy admission controller compares the pod against mutating policies in alphabetical order and uses the first policy that successfully validates the pod.

Caution:

Warning 1:

It is very important to note that when you enable a cluster's PodSecurityPolicy admission controller, no application pods can start on the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. You will not be able to run application pods on a cluster with an enabled PodSecurityPolicy admission controller unless these prerequisites are met.

We strongly recommend you use PodSecurityPolicy admission controllers as follows:

- Whenever you create a new cluster, enable the Pod Security Admission Controller.
- Immediately after creating a new cluster, create pod security policies, along with roles (or clusterroles) and rolebindings (or clusterrolebindings).

Warning 2:
You must create pod security policies before enabling the PodSecurityPolicy admission controller of an existing cluster that is already in production (that is, some time after you created it). If you decide to enable an existing cluster's PodSecurityPolicy admission controller, we strongly recommend you first verify the cluster's pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster.

When you enable the PodSecurityPolicy admission controller of a cluster you've created with Container Engine for Kubernetes, a pod security policy for Kubernetes system privileged pods is automatically created (along with the associated clusterrole and clusterrolebinding). This pod security policy, and the clusterrole and clusterrolebinding, enable the Kubernetes system pods to run. The pod security policy, clusterrole, and clusterrolebinding are defined in the kube-system.yaml file (see kube-system.yaml Reference on page 908).

Note that you can create pod security policies for a cluster before enabling the cluster's PodSecurityPolicy admission controller. Also note that you can disable a cluster's PodSecurityPolicy admission controller that was previously enabled. In this case, any previously created pod security policies, roles (or clusterroles), and rolebindings (or clusterrolebindings) are not deleted. The pod security policies are simply not enforced. Any application pod will be able to run on the cluster.

For more information about pod security policies and the PodSecurityPolicy admission controller, see the Kubernetes documentation.

Creating a Pod Security Policy for Application Pods

To create a pod security policy for application pods, create a role to access the pod security policy, and create a rolebinding to enable the application pods to use the pod security policy:

1. Create the pod security policy for application pods:

   **a.** Define and save the pod security policy in a file. For example, in `acme-app-psp.yaml`.

   For example, this policy (taken from the Kubernetes documentation) simply prevents the creation of privileged pods:

   ```yaml
   apiVersion: policy/v1beta1
   kind: PodSecurityPolicy
   metadata:
     name: acme-app-psp
   spec:
     privileged: false  # Don't allow privileged pods!
     # The rest fills in some required fields.
     seLinux:
       rule: RunAsAny
     supplementalGroups:
       rule: RunAsAny
     runAsUser:
       rule: RunAsAny
     fsGroup:
       rule: RunAsAny
     volumes:
       - '*'
   ```

   **b.** Enter the following command to create the pod security policy:

   ```bash
   kubectl create -f <filename>.yaml
   ```

   For example:

   ```bash
   kubectl create -f acme-app-psp.yaml
   ```
2. Create the role (or clusterrole) to access the pod security policy:
   a. Define and save a role (or clusterrole) in a file. For example, in `acme-app-psp-crole.yaml`.
      For example:

      ```yaml
      # Cluster role which grants access to the app pod security policy
      apiVersion: rbac.authorization.k8s.io/v1
      kind: ClusterRole
      metadata:
        name: acme-app-psp-crole
      rules:
        - apiGroups:
          - policy
          resourceNames:
            - acme-app-psp
          resources:
            - podsecuritypolicies
          verbs:
            - use
      
      b. Enter the following command to create the role (or clusterrole):

      ```bash
      kubectl create -f <filename>.yaml
      ```
      For example:

      ```bash
      kubectl create -f acme-app-psp-crole.yaml
      ```

3. Create the rolebinding (or clusterrolebinding) to authorize the application pods to use the pod security policy:
   a. Define and save the rolebinding (or clusterrolebinding) in a file. For example, in `acme-app-psp-crole-bind.yaml`.
      For example:

      ```yaml
      # Role binding which grants access to the app pod security policy
      apiVersion: rbac.authorization.k8s.io/v1
      kind: RoleBinding
      metadata:
        name: acme-app-psp-binding
        namespace: acme-namespace
      roleRef:
        apiGroup: rbac.authorization.k8s.io
        kind: ClusterRole
        name: acme-app-psp-crole
      subjects:
        # For all service accounts in acme-namespace
        - apiGroup: rbac.authorization.k8s.io
          kind: Group
          name: system:serviceaccounts:acme-namespace
      
      b. Enter the following command to create the rolebinding (or clusterrolebinding):

      ```bash
      kubectl create -f <filename>.yaml
      ```
      For example:

      ```bash
      kubectl create -f acme-app-psp-crole-bind.yaml
      ```
Having defined a pod security policy and authorized application pods to use it by creating a role and rolebinding (or a clusterrole and clusterrolebinding), enable the cluster's PodSecurityPolicy admission controller to enforce the pod security policy (if it's not enabled already).

**Using the Console to Enable the PodSecurityPolicy Admission Controller**

To enable the PodSecurityPolicy admission controller when creating new clusters using the Console:

1. **Log** in to the Console.
2. **Follow** the instructions to create a new 'custom cluster' in Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings on page 873, click **Show Advanced Options**, and select the **Pod Security Policies - Enforced** option. This option enables the PodSecurityPolicy admission controller.

   No application pods will be accepted into the new cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies.
3. **Follow** the instructions to set the remaining cluster details, and click **Create Cluster** to create the new cluster.
4. **Follow** the instructions in Creating a Pod Security Policy for Application Pods on page 906 to create pod security policies for the PodSecurityPolicy admission controller to enforce when accepting pods into the new cluster.

To enable the PodSecurityPolicy admission controller in existing clusters using the Console:

1. **Follow** the instructions in Creating a Pod Security Policy for Application Pods on page 906 to create pod security policies for the PodSecurityPolicy admission controller to enforce when accepting pods into the existing cluster.

   We strongly recommend you first verify the pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster.
2. **In** the Console, open the navigation menu. Under **Solutions and Platform**, go to Developer Services and click Kubernetes Clusters.
3. **Choose** a Compartment you have permission to work in.
4. **On** the Cluster List page, click the name of the cluster you want to modify.
5. **On** the Cluster Details tab, click **Not Enforced** beside **Pod Security Policies**.
6. **In** the Pod Security Policies window, select **Enforced**.

   From now on, no new application pods will be accepted into the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. Note that any currently running pods will continue to run regardless.
7. **Click** Save Changes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To enable the PodSecurityPolicy admission controller, use the:

- **CreateCluster** operation when creating new clusters
- **Update Cluster** operation when modifying existing clusters

**kube-system.yaml Reference**

The pod security policy, and the associated clusterrole and clusterrolebinding, for Kubernetes system privileged pods are automatically created when you enable a cluster's PodSecurityPolicy admission controller. These allow any pod in the kube-system namespace to run. They are created from definitions in the kube-system.yaml shown below:

```yaml
apiVersion: policy/v1beta1
kind: PodSecurityPolicy
```
metadata:
  annotations:
    # See https://kubernetes.io/docs/concepts/policy/pod-security-policy/
    # seccomp
    seccomp.security.alpha.kubernetes.io/allowedProfileNames: '*'
  name: oke-privileged
spec:
  allowedCapabilities:
    - '*'
  allowPrivilegeEscalation: true
  fsGroup:
    rule: 'RunAsAny'
  hostIPC: true
  hostNetwork: true
  hostPID: true
  hostPorts:
    - min: 0
      max: 65535
  privileged: true
  readOnlyRootFilesystem: false
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  volumes:
    - '*'

---

# Cluster role which grants access to the privileged pod security policy
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: oke-privileged-psp
rules:
  - apiGroups:
      - policy
    resourceNames:
      - oke-privileged
    resources:
      - podsecuritypolicies
    verbs:
      - use

---

# Role binding for kube-system - allow kube-system service accounts - should take care of CNI i.e. flannel running in the kube-system namespace
# Assumes access to the kube-system is restricted
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: kube-system-psp
  namespace: kube-system
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: oke-privileged-psp
subjects:
  # For all service accounts in the kube-system namespace
  - apiGroup: rbac.authorization.k8s.io
    kind: Group
Autoscaling Kubernetes Clusters

You can automatically scale the clusters you create using Container Engine for Kubernetes to optimize resource usage.

To enable autoscaling, you can deploy the Kubernetes Metrics Server to collect resource metrics from each worker node in the cluster (see Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 910).

Having deployed the Kubernetes Metrics Server, you can then use:

- the Kubernetes Horizontal Pod Autoscaler to adjust the number of pods in a deployment (see Using the Kubernetes Horizontal Pod Autoscaler on page 911)
- the Kubernetes Vertical Pod Autoscaler to adjust the resource requests and limits for containers running in a deployment's pods (see Using the Kubernetes Vertical Pod Autoscaler on page 915)

Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl

You can deploy the Kubernetes Metrics Server on clusters you create using Container Engine for Kubernetes to enable autoscaling.

The Kubernetes Metrics Server is a cluster-wide aggregator of resource usage data. The Kubernetes Metrics Server collects resource metrics from the kubelet running on each worker node and exposes them in the Kubernetes API server through the Kubernetes Metrics API. Other Kubernetes add-ons require the Kubernetes Metrics Server, including:

- the Horizontal Pod Autoscaler (see Using the Kubernetes Horizontal Pod Autoscaler on page 911)
- the Vertical Pod Autoscaler (see Using the Kubernetes Vertical Pod Autoscaler on page 915)

Note that the Kubernetes Metrics Server is not intended to be used for anything other than autoscaling. For example, it is not recommended that you use the Kubernetes Metrics Server to forward metrics to monitoring solutions, nor as a source of monitoring solution metrics. For more information, see the Kubernetes Metrics Server documentation.

To deploy the Kubernetes Metrics Server on a cluster you've created with Container Engine for Kubernetes:

1. If you haven't already done so, follow the steps to set up the cluster's kubectl configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.
2. If your Oracle Cloud Infrastructure user is a tenancy administrator or cluster administrator, skip the next step and go straight to the following step.
3. If your Oracle Cloud Infrastructure user is not a tenancy administrator or cluster administrator, ask a tenancy administrator or cluster administrator to grant your user the Kubernetes RBAC cluster-admin clusterrole on the cluster by entering:

   ```bash
   kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user-OCID>
   ```

   For more information, see About Access Control and Container Engine for Kubernetes on page 920.
4. In a terminal window, deploy the Kubernetes Metrics Server by entering:

```
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/download/<version-number>/components.yaml
```

where `<version-number>` is the Kubernetes Metrics Server version that you want to deploy. For example, v0.3.6.

Note that the Kubernetes Metrics Server is being actively developed, so the version number to specify will change over time. To find out the currently available versions, see the Kubernetes Metrics Server documentation.

**Tip:**

If the command fails to connect to https://github.com/kubernetes-sigs/metrics-server/releases/download/<version-number>/components.yaml, go to the url in a browser and download the manifest file components.yaml to a local directory. Repeat the `kubectl apply` command and specify the local location of the components.yaml file.

5. Confirm that the Kubernetes Metrics Server has been deployed successfully and is available by entering:

```
kubectl get deployment metrics-server -n kube-system
```

**Using the Kubernetes Horizontal Pod Autoscaler**

You can use the Kubernetes Horizontal Pod Autoscaler to automatically scale the number of pods in a deployment, replication controller, replica set, or stateful set, based on that resource's CPU or memory utilization, or on other metrics. The Horizontal Pod Autoscaler can help applications scale out to meet increased demand, or scale in when resources are no longer needed. You can set a target metric percentage for the Horizontal Pod Autoscaler to meet when scaling applications. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

The Horizontal Pod Autoscaler is a standard API resource in Kubernetes that requires the installation of a metrics source, such as the Kubernetes Metrics Server, in the cluster. For more information, see Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 910.

**Notes about the Horizontal Pod Autoscaler**

Note the following:

- The Kubernetes Metrics Server only supports scaling based on CPU and memory utilization. Other implementations of the Kubernetes Metrics API support scaling based on custom metrics. Refer to the Kubernetes documentation for a list of alternative implementations (see Implementations), and for more information about scaling based on custom metrics (see Autoscaling on multiple metrics and custom metrics).
- You can scale applications manually by updating manifest files, without using the Horizontal Pod Autoscaler.

**Working with the Horizontal Pod Autoscaler**

The instructions below are based on the Horizontal Pod Autoscaler Walkthrough topic in the Kubernetes documentation. They describe how to:

- Verify that the Kubernetes Metrics Server has been installed on a cluster.
- Deploy a sample php-apache web server.
- Create a Horizontal Pod Autoscaler resource that will scale based on CPU utilization.
- Start generation of a sample load.
- View the scaling operation in action.
- Stop the sample load generation.
- Clean up, by removing the php-apache web server and the Horizontal Pod Autoscaler.
Step 1: Verify the Kubernetes Metrics Server Installation

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. Confirm that the Kubernetes Metrics Server has been deployed successfully on the cluster and is available by entering:

   kubectl -n kube-system get deployment/metrics-server

   If the command returns a ‘Not Found’ error, then you must deploy the Kubernetes Metrics Server on the cluster before proceeding. See Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 910.

Step 2: Deploy a Sample Application

Deploy a simple Apache web server application by entering:

   kubectl apply -f https://k8s.io/examples/application/php-apache.yaml

The output from the above command confirms the deployment:

   deployment.apps/php-apache created
   service/php-apache created

The Apache web server pod that is created from the manifest file:

- Has a 500m CPU limit, which ensures the container will never use more than 500 millicores, or 1/2 of a core.
- Has a 200m CPU request allowance, which allows the container to use 200 millicores of CPU resources, or 1/5 of a core.

Step 3: Create a Horizontal Pod Autoscaler Resource

1. Create a Horizontal Pod Autoscaler resource to maintain a minimum of 1 and a maximum of 10 replicas, and an average CPU utilization of 50%, by entering:

   kubectl autoscale deployment php-apache --cpu-percent=50 --min=1 --max=10

   The output from the above command confirms the Horizontal Pod Autoscaler has been created.

   horizontalpodautoscaler.autoscaling/php-apache autoscaled

   The command creates a Horizontal Pod Autoscaler for the Apache web server deployment that:

   - Maintains a minimum of 1 and a maximum of 10 replicas of the previously created pods controlled by the Apache web server deployment.
   - Increases and decreases the number of replicas of the deployment to maintain an average CPU utilization of 50% across all pods.

   If the average CPU utilization falls below 50%, the Horizontal Pod Autoscaler tries to reduce the number of pods in the deployment to the minimum (in this case, 1). If the average CPU utilization goes above 50 percent, the Horizontal Pod Autoscaler tries to increase the number of pods in the deployment to the maximum (in this case, 10). For more information, see How does the Horizontal Pod Autoscaler work? in the Kubernetes documentation.

   For more information about the kubectl autoscale command, see autoscale in the Kubernetes documentation.
2. After a minute, confirm the current status of the Horizontal Pod Autoscaler by entering:

```bash
kubectl get hpa
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS MINPODS MAXPODS REPLICAS AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%  1 10 1 10s</td>
</tr>
</tbody>
</table>

The `TARGETS` column shows the average CPU utilization across all pods controlled by the Apache web server deployment. Since no requests are being sent to the server, the above example shows the current CPU utilization is 0%, compared to the target utilization of 50%. Note that you might see different numbers, depending on how long you wait before running the command.

**Step 4: Start Sample Load Generation**

1. Run a container with a busybox image to create a load for the Apache web server by entering:

```bash
kubectl run -it --rm load-generator --image=busybox /bin/sh --
generator=run-pod/v1
```

2. Generate a load for the Apache web server that will cause the Horizontal Pod Autoscaler to scale out the deployment by entering:

```bash
while true; do wget -q -O- http://php-apache; done
```

**Step 5: View the Scaling Operation**

1. After a minute, open a new terminal window and confirm the current status of the Horizontal Pod Autoscaler by entering:

```bash
kubectl get hpa
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS MINPODS MAXPODS REPLICAS AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>250%/50%  1 10 1 1m</td>
</tr>
</tbody>
</table>

In the above example, you can see the current CPU utilization has increased to 250%, compared to the target utilization of 50%. Note that you might see different numbers, depending on how long you wait before running the command.

To achieve the utilization target of 50%, the Horizontal Pod Autoscaler will have to increase the number of replicas to scale out the deployment.

2. After another few minutes, view the increased number of replicas by re-entering:

```bash
kubectl get hpa
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS MINPODS MAXPODS REPLICAS AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>50%/50%  1 10 5 5m</td>
</tr>
</tbody>
</table>

In the above example, you can see that the Horizontal Pod Autoscaler has resized the deployment to 5 replicas, and the utilization target of 50% has been achieved. Note that you might see different numbers, depending on how long you wait before running the command.
3. Verify the deployment has been scaled out by entering:

    kubectl get deployment php-apache

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>5/5</td>
<td>5</td>
<td>5</td>
<td>5m</td>
</tr>
</tbody>
</table>

Note that you might see different numbers, depending on how long you wait before running the command.

**Step 6: Stop Sample Load Generation**

1. In the terminal window where you created the container with the busybox image and generated the load for the Apache web server:
   a. Terminate the load generation by pressing Ctrl+C
   b. Close the command prompt by entering:

       exit

   The output from the above command confirms the session has ended:

   Session ended, resume using 'kubectl attach load-generator -c load-generator -i -t' command when the pod is running
   pod "load-generator" deleted

2. After a minute, confirm the current status of the Horizontal Pod Autoscaler by entering:

    kubectl get hpa

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>5</td>
<td>10m</td>
</tr>
</tbody>
</table>

In the above example, you can see the current CPU utilization has reduced to 0%, compared to the target utilization of 50%. However, there are still 5 replicas in the deployment. Note that you might see different numbers, depending on how long you wait before running the command.

3. After another few minutes, view the reduced number of replicas by re-entering:

    kubectl get hpa

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>15m</td>
</tr>
</tbody>
</table>

In the above example, you can see that the Horizontal Pod Autoscaler has resized the deployment to 1 replica.

Be aware that it will take time for the replica count to reduce to 1. Five minutes is the default timeframe for scaling in. Note that you might see different numbers, depending on how long you wait before running the command.
4. Verify the deployment has been scaled in by entering:

   ```bash
   kubectl get deployment php-apache
   ```

   The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>15m</td>
</tr>
</tbody>
</table>

   Note that you might see different numbers, depending on how long you wait before running the command.

**Step 7: Clean Up**

1. Delete the Horizontal Pod Autoscaler by entering:

   ```bash
   kubectl delete horizontalpodautoscaler.autoscaling/php-apache
   ```

   Note that when you delete a Horizontal Pod Autoscaler, the number of replicas remains the same. A deployment does not automatically revert back to the state it had prior to the creation of the Horizontal Pod Autoscaler.

2. Delete the Apache web server deployment by entering:

   ```bash
   kubectl delete deployment.apps/php-apache service/php-apache
   ```

**Using the Kubernetes Vertical Pod Autoscaler**

You can use the Kubernetes Vertical Pod Autoscaler to automatically adjust the resource requests and limits for containers running in a deployment's pods. The Vertical Pod Autoscaler can improve cluster resource utilization by:

- Setting the requests automatically based on usage to make sure the appropriate resource amount is available for each pod.
- Maintaining ratios between limits and requests that were specified in containers' initial configurations.
- Scaling down pods that are over-requesting resources, based on their usage over time.
- Scaling up pods that are under-requesting resources, based on their usage over time.

The Vertical Pod Autoscaler has three components:

- **Recommender**: Monitors the current and past resource consumption and provides recommended CPU and memory request values for a container.
- **Updater**: Checks for pods with incorrect resources and deletes them, so that the pods can be recreated with the updated request values.
- **Admission Plugin**: Sets the correct resource requests on new pods (that is, pods just created or recreated by their controller due to changes made by the Updater).

For more information, see [Vertical Pod Autoscaler](https://kubernetes.io/docs/concepts/workloads/pods/vpa/) and [Managing Resources for Containers](https://kubernetes.io/docs/concepts/workloads/pods/resource/) in the Kubernetes documentation.

You configure the Vertical Pod Autoscaler using the `VerticalPodAutoscaler` custom resource definition object. The `VerticalPodAutoscaler` object enables you to specify the pods to vertically autoscale, and which resource recommendations to apply (if any). For more information, see [VerticalPodAutoscaler](https://kubernetes.io/docs/concepts/workloads/pods/vpa/) and [Custom Resource Definition object](https://kubernetes.io/docs/concepts/extend-kubernetes/api-extension/custom-resources/) in the Kubernetes documentation.

The Vertical Pod Autoscaler requires the installation of a metrics source, such as the Kubernetes Metrics Server, in the cluster. For more information, see [Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl](https://kubernetes.io/docs/tasks/administer-cluster/deploy/metrics-server/) on page 910.

**Overriding Limit Ranges**

The Vertical Pod Autoscaler attempts to make recommendations within the minimum and maximum values specified by a limit range, if one has been defined. However, if the applicable limit range conflicts with the values specified in
the resourcePolicy section of the VerticalPodAutoscaler manifest, the Vertical Pod Autoscaler gives priority to the resource policy and makes recommendations accordingly (even if the values fall outside the limit range). For more information, see Limit Ranges and Resource Policy Overriding Limit Range in the Kubernetes documentation.

Creating Recommendations without Applying them

You can use the Vertical Pod Autoscaler to create and apply recommendations, or simply to create recommendations (without updating pods). To simply create recommendations without applying them, set updateMode: "Off" in the updatePolicy section of the VerticalPodAutoscaler manifest.

When pods are created, the Vertical Pod Autoscaler analyzes the CPU and memory needs of the containers and records those recommendations in its Status field. The Vertical Pod Autoscaler does not take any action to update the resource requests for the running containers.

Excluding Specific Containers

You can use the Vertical Pod Autoscaler to create and apply recommendations to all the containers in a pod, or you can selectively exclude particular containers. To turn off recommendations for a particular container, in the resourcePolicy section of the VerticalPodAutoscaler manifest, specify a containerName and set mode: "Off" in the containerPolicies section.

Notes about the Vertical Pod Autoscaler

Note the following:

• Currently, you are recommended not to use the Vertical Pod Autoscaler with the Horizontal Pod Autoscaler on CPU or memory utilization metrics. However, note that you can use the Vertical Pod Autoscaler with the Horizontal Pod Autoscaler on custom and external metrics. See Support for custom metrics in the Kubernetes documentation.

• The Vertical Pod Autoscaler recommendations might exceed available resources (for example, node size, available size, available quota). Note that applying the recommendations might cause pods to go into a pending status.

• Whenever the Vertical Pod Autoscaler updates pod resources, the pod is recreated, which causes all running containers to be restarted. Note that the pod might be recreated on a different node.

Working with the Vertical Pod Autoscaler

The instructions below walk you through deploying the Vertical Pod Autoscaler on a cluster. They describe how to:

• Verify that the Kubernetes Metrics Server has been installed on a cluster.
• Download and deploy the Vertical Pod Autoscaler.
• Deploy a sample application.
• View the scaling operation in action.
• View the recommendation.
• Clean up, by removing the sample application and the Vertical Pod Autoscaler.

Step 1: Verify the Kubernetes Metrics Server Installation

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.
2. Confirm that the Kubernetes Metrics Server has been deployed successfully on the cluster and is available by entering:

```
kubectl -n kube-system get deployment/metrics-server
```

If the command returns a `Not Found` error, then you must deploy the Kubernetes Metrics Server on the cluster before proceeding. See Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 910.

**Step 2: Download and Deploy the Vertical Pod Autoscaler**

1. Download the Vertical Pod Autoscaler source code from GitHub. For example, by entering:

```
git clone -b vpa-release-0.8 https://github.com/kubernetes/autoscaler.git
```
2. Change to the `vertical-pod-autoscaler` directory:

```
cd autoscaler/vertical-pod-autoscaler
```
3. If you have previously deployed the Vertical Pod Autoscaler, delete it by entering:

```
./hack/vpa-down.sh
```
4. Deploy the Vertical Pod Autoscaler by entering:

```
./hack/vpa-up.sh
```
5. Verify that the Vertical Pod Autoscaler pods have been created successfully by entering:

```
kubectl get pods -n kube-system
```

The output from the above command shows the pods:

```
vpa-admission-controller-59d9965cfb-bzs8l 1/1 Running 0 6m34s
vpa-recommender-5bcb58569-mqdds 1/1 Running 0 6m43s
vpa-updater-5979cbf757-scw2d 1/1 Running 0 6m46s
```

Note that you will probably see different names and numbers.

**Step 3: Deploy the Sample Application**

1. Deploy the sample hamster application to create a deployment and a corresponding Vertical Pod Autoscaler by entering:

```
kubectl apply -f examples/hamster.yaml
```

The output from the above command confirms the deployment and creation:

```
verticalpodautoscaler.autoscaling.k8s.io/hamster-vpa created
deployment.apps/hamster created
```

Deploying the hamster application creates a deployment with two pods and a Vertical Pod Autoscaler pointing at the deployment.
2. Verify that the hamster pods have been created successfully by entering:

```
kubectl get pods -l app=hamster
```

The output from the above command confirms the creation:

```
NAME                     READY STATUS  RESTARTS AGE
hamster-7cbfd64f57-mqqnk 1/1   Running 0 54s
```
Note that you will probably see different names for the hamster pods.

3. View the CPU and memory reservations using the `kubectl describe pod` command and one of the hamster pod names returned in the previous step. For example:

```
kubectl describe pod hamster-7cbfd64f57-rq6wv
```

Note that the above command is an example only. You must use one of the hamster pod names that was returned when you ran the `kubectl get pods -l app=hamster` command in the previous step.

In the requests section of the output, you can see the pod's current CPU and memory reservations. For example:

```
Requests:
cpu:        100m
memory:     50Mi
```

The Vertical Pod Autoscaler (specifically, the Recommender) analyzes the pods and observes their behavior to determine whether these CPU and memory reservations are appropriate. Note that you might see different CPU and memory reservations.

The reservations are not sufficient because the sample hamster application is deliberately under-resourced. Each pod runs a single container that:

- requests 100 millicores, but tries to utilize more than 500 millicores
- reserves much less memory than it needs to run

### Step 4: View the Scaling Operation

Having analyzed the original pods in the sample hamster application and determined that the CPU and memory reservations are inadequate, the Vertical Pod Autoscaler (specifically the Updater) relaunches the pods with different values as proposed by the Recommender. Note that the Vertical Pod Autoscaler does not modify the template in the deployment, but updates the actual requests of the pods.

1. Monitor the pods in the sample hamster application, and wait for the Updater to start a new hamster pod with a new name, by entering:

```
kubectl get --watch pods -l app=hamster
```

2. When you see that a new hamster pod has started, view its CPU and memory reservations using the `kubectl describe pod` command and the pod's name. For example:

```
kubectl describe pod hamster-7cbfd64f57-wmg4
```

In the requests section of the output, you can see the new pod's CPU and memory reservations:

```
Requests:
cpu:        587m
memory:     262144k
```

In the above example, notice that the CPU reservation has increased to 587 millicores and the memory reservation has increased to 262,144 Kilobytes. The original pod was under-resourced and the Vertical Pod Autoscaler has corrected the original reservations with more appropriate values. Note that you might see different CPU and memory reservations.
Step 5: View the Recommendation

View the recommendations made by the Vertical Pod Autoscaler (specifically, by the Recommender) by entering:

```
kubectl describe vpa/hamster-vpa
```

The output from the above command shows the recommendations:

```yaml
Name:         hamster-vpa
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
               {
                 "apiVersion": "autoscaling.k8s.io/v1beta2",
                 "kind": "VerticalPodAutoscaler",
                 "metadata": {
                   "annotations": {},
                   "name": "hamster-vpa",
                   "namespace": "default"
               }
API Version:  autoscaling.k8s.io/v1
Kind:         VerticalPodAutoscaler
Metadata:

       Lower Bound:
       Cpu:     519m
       Memory:  262144k
     Target:
       Cpu:     587m
       Memory:  262144k
     Uncapped Target:
       Cpu:     587m
       Memory:  262144k
     Upper Bound:
       Cpu:     1
       Memory:  500Mi
```
Note that you might see different recommendations.

**Step 6: Clean Up**

1. Remove the sample application by entering:

   ```bash
   kubectl delete -f examples/hamster.yaml
   ```

2. In the `vertical-pod-autoscaler` directory, delete the Vertical Pod Autoscaler deployment by entering:

   ```bash
   ./hack/vpa-down.sh
   ```

**About Access Control and Container Engine for Kubernetes**

To perform operations on a Kubernetes cluster, you must have appropriate permissions to access the cluster.

For most operations on Kubernetes clusters created and managed by Container Engine for Kubernetes, Oracle Cloud Infrastructure Identity and Access Management (IAM) provides access control. A user's permissions to access clusters comes from the groups to which they belong. The permissions for a group are defined by policies. Policies define what actions members of a group can perform, and in which compartments. Users can then access clusters and perform operations based on the policies set for the groups they are members of.

IAM provides control over:

- whether a user can create or delete clusters
- whether a user can add, remove, or modify node pools
- which Kubernetes object create/delete/view operations a user can perform on all clusters within a compartment or tenancy

See [Policy Configuration for Cluster Creation and Deployment](#) on page 868.

In addition to IAM, the Kubernetes RBAC Authorizer can enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. A Kubernetes RBAC role is a collection of permissions. For example, a role might include read permission on pods and list permission for pods. A Kubernetes RBAC clusterrole is just like a role, but can be used anywhere in the cluster. A Kubernetes RBAC rolebinding maps a role to a user or set of users, granting that role's permissions to those users for resources in that namespace. Similarly, a Kubernetes RBAC clusterrolebinding maps a clusterrole to a user or set of users, granting that clusterrole's permissions to those users across the entire cluster.

IAM and the Kubernetes RBAC Authorizer work together to enable users who have been successfully authorized by at least one of them to complete the requested Kubernetes operation.

When a user attempts to perform any operation on a cluster (except for create role and create clusterrole operations), IAM first determines whether the group to which the user belongs has the appropriate and sufficient permissions. If so, the operation succeeds. If the attempted operation also requires additional permissions granted via a Kubernetes RBAC role or clusterrole, the Kubernetes RBAC Authorizer then determines whether the user has been granted the appropriate Kubernetes role or clusterrole.

Typically, you'll want to define your own Kubernetes RBAC roles and clusterroles when deploying a Kubernetes cluster to provide additional fine-grained control. When you attempt to perform a create role or create clusterrole operation, the Kubernetes RBAC Authorizer first determines whether you have sufficient Kubernetes privileges. To create a role or clusterrole, you must have been assigned an existing Kubernetes RBAC role (or clusterrole) that has at least the same or higher privileges as the new role (or clusterrole) you're attempting to create.

By default, users are not assigned any Kubernetes RBAC roles (or clusterroles) by default. So before attempting to create a new role (or clusterrole), you must be assigned an appropriately privileged role (or clusterrole). A number of such roles and clusterroles are always created by default, including the cluster-admin clusterrole (for a full list, see [Default Roles and Role Bindings](#) in the Kubernetes documentation). The cluster-admin clusterrole essentially confers
super-user privileges. A user granted the cluster-admin clusterrole can perform any operation across all namespaces in a given cluster.

Note that Oracle Cloud Infrastructure tenancy administrators already have sufficient privileges, and do not require the cluster-admin clusterrole.

**Example: Granting the Kubernetes RBAC cluster-admin clusterrole**

**Note:**

The following instructions assume:

- You have the required access to create Kubernetes RBAC roles and clusterroles, either because you're in the tenancy's Administrators group, or because you have the Kubernetes RBAC cluster-admin clusterrole.
- The user to which you want to grant the RBAC cluster-admin clusterrole is not an OCI tenancy administrator. If they are an OCI tenancy administrator, they do not require the Kubernetes RBAC cluster-admin clusterrole.

Follow these steps to grant a user who is not a tenancy administrator the Kubernetes RBAC cluster-admin clusterrole on a cluster deployed on Oracle Cloud Infrastructure:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a terminal window, grant the Kubernetes RBAC cluster-admin clusterrole to the user by entering:

   ```
   kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user_OCID>
   ```

   where:

   - `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
   - `<user_OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

   For example:

   ```
   kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --user=ocid1.user.oc1..aaaaa...zutq
   ```

**Example: Giving a developer user the ability to read pods in a new cluster**

**Note:**

The following instructions assume you're in the tenancy's Administrators group, and therefore have:

- the required permissions to create clusters, and to manage users and groups
- the required access to create Kubernetes RBAC roles and clusterroles

Follow these steps to give a developer the necessary Oracle Cloud Infrastructure and Kubernetes RBAC permissions to use kubectl to view pods running on a cluster deployed on Oracle Cloud Infrastructure:
1. Create a new Oracle Cloud Infrastructure user for the developer to use (for example, called jdoe@acme.com), and make a note of the new user's OCID (for example, ocid1.user.oc1..aaaaa...tx5a, abbreviated for readability). See To create a user on page 2417.

2. Create a new Oracle Cloud Infrastructure group and add the new user to the group (for example, called acme-dev-pod-vwr). See To create a group on page 2420.

3. Create a new Oracle Cloud Infrastructure policy that grants the new group the CLUSTER_USE permission on clusters, with a policy statement like:

   Allow group acme-dev-pod-vwr to use clusters in <location>

   In the above policy statement, replace <location> with either tenancy (if you are creating the policy in the tenancy's root compartment) or compartment <compartment-name> (if you are creating the policy in an individual compartment).

   See To create a policy on page 2454.

5. Follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

6. In a text editor, create a file (for example, called role-pod-reader.yaml) with the following content. This file defines a Kubernetes RBAC role that enables users to read pod details.

   kind: Role
   apiVersion: rbac.authorization.k8s.io/v1
   metadata:
     namespace: default
     name: pod-reader
   rules:
   - apiGroups: ["" ] # "" indicates the core API group
     resources: ["pods"]
     verbs: ["get", "watch", "list"]

7. In a terminal window, create the new role in the cluster using kubectl. For example, if you gave the yaml file that defines the new role the name role-pod-reader.yaml, enter the following:

   kubectl create -f role-pod-reader.yaml

8. In a terminal window, bind the Kubernetes RBAC role you just created to the Oracle Cloud Infrastructure user account you created earlier by entering the following to create a new rolebinding (in this case, called pod-reader-binding):

   kubectl create rolebinding pod-reader-binding --role=pod-reader --user=ocid1.user.oc1..aaaaa...tx5a

9. Give the developer the credentials of the new Oracle Cloud Infrastructure user you created earlier, and tell the developer they can now see details of pods running on the cluster deployed on Oracle Cloud Infrastructure by:

   • Signing in to the Console using the new user's credentials.
   • Following the instructions in Setting Up Cluster Access on page 876 to set up their own copy of the cluster's kubeconfig file. If the file does not have the expected default name and location of $HOME/.kube/config, the developer will also have to set the KUBECONFIG environment variable to point to the file. Note that the developer must set up their own kubeconfig file. They cannot access a cluster using a kubeconfig file that you (or a different user) set up.
   • Using kubectl to see details of the pods by entering:

   kubectl get pods
Supported Images (Including Custom Images) and Shapes for Worker Nodes

When creating a cluster using Container Engine for Kubernetes, you can customize the worker nodes in the cluster by specifying:

- The operating system image to use for worker nodes. The image is a template of a virtual hard drive that determines the operating system and other software for the worker node.
- The shape to use for worker nodes. The shape is the number of CPUs and the amount of memory to allocate to each newly created compute instance to be used as a worker node.

This topic includes information about the images and shapes provided by Oracle Cloud Infrastructure that are supported by Container Engine for Kubernetes for use in node pools. Note that some of the shapes might not be available in your particular tenancy.

To see a list of the supported images and the shapes available in your tenancy, enter:

```
oci ce node-pool-options get --node-pool-option-id all
```

Supported Images

Container Engine for Kubernetes supports the provisioning of worker nodes using some, but not all, of the latest Oracle Linux images provided by Oracle Cloud Infrastructure.

To see the images supported by Container Engine for Kubernetes:

- When using the Console to create a 'custom cluster', view the list of values in the Image drop-down menu to see the list of supported images.
- When using the CLI, view the supported images (in the data: sources: section of the response) by entering:

```
oci ce node-pool-options get --node-pool-option-id all
```

Custom Images

When specifying the image that Container Engine for Kubernetes uses to provision worker nodes in a node pool, you can specify your own custom image rather than one of the explicitly supported Oracle Linux images returned by the `oci ce node-pool-options get --node-pool-option-id all` command. Worker nodes provisioned from a custom image include the customizations, configuration, and software that were present when the image was created. Note that Container Engine for Kubernetes only supports custom images that are based on one of the Oracle Linux images returned by the `oci ce node-pool-options get` command.

To provision worker nodes from a custom image, you must use the CLI or API and specify the custom image’s OCID when creating the node pool. For example, by running the `oci ce node-pool create` command and using the `--node-image-id` parameter to specify a custom image's OCID, as follows:

```
oci ce node-pool create \
--cluster-id ocid1.cluster.oc1.iad.aaaaaaaaaf______jrd \
--name my-custom-linux-image \
--node-image-id ocid1.image.oc1.iad.aaaaaaaa6______nha \
--compartment-id ocid1.compartment.oc1..aaaaaaaay______t6q \
--kubernetes-version v1.15.7 \
--node-shape VM.Standard2.1 \
--placement-configs "[ { "availabilityDomain": "nFuS:US-ASHBURN-AD-1", \
"subnetId": "ocid1subnet.oc1.iad.aaaaaaa3______a6q" } ]" \
--size 1 \
--region=us-ashburn-1
```

Note the following additional considerations when using custom images:

- Container Engine for Kubernetes installs Kubernetes on top of a custom image, and Kubernetes or the installation software might change certain kernel configurations.
- Custom images must have access to a yum repository (public or internal).
• Custom images must not use a customized cloud-init. You can perform post-provisioning customization using
SSH or Daemonset.
• For the best support, ensure you create a custom image from the most up-to-date base image.

For more information about custom images and Oracle Cloud Infrastructure, see Managing Custom Images on page 665.

**Supported Shapes**

Container Engine for Kubernetes supports the provisioning of worker nodes using many, but not all, of the shapes
provided by Oracle Cloud Infrastructure. More specifically:

• **Supported:** Flexible shapes; Bare Metal shapes, including standard shapes; HPC shapes, except in
  RDMA networks; VM shapes, including standard shapes; Dense I/O shapes.

• **Not Supported:** Dedicated VM host shapes; GPU shapes on VMs and Bare Metal instances; Micro VM shapes;
  HPC shapes on Bare Metal instances in RDMA networks.

Note that you might be unable to select some shapes in your particular tenancy due to service limits and compartment
quotas, even though those shapes are supported by Container Engine for Kubernetes.

To see the shapes that are supported by Container Engine for Kubernetes and available in your tenancy:

• When using the Console to create a 'custom cluster', view the list of values in the **Shape** drop-down menu to see
  the list of supported shapes.

• When using the CLI, view the supported shapes (in the **data: shapes:** section of the response) by entering:

  ```
  oci ce node-pool-options get --node-pool-option-id all
  ```

You might be able to use the Compute service's Console pages (or the Compute service's CLI or API) to subsequently
change the shape of a worker node after it has been created. However, bear in mind that Container Engine for
Kubernetes only supports those shapes shown in the **Shape** drop-down menu or returned by the `oci ce node-
pool-options get --node-pool-option-id all` command.

For more information about all the shapes provided by Oracle Cloud Infrastructure, see Compute Shapes on page 655.

**Supported Admission Controllers**

The Kubernetes version you select when you create a cluster using Container Engine for Kubernetes determines the
default set of admission controllers that are turned on in the created cluster. The set follows the recommendation
given in the Kubernetes documentation for that version. This topic shows the supported admission controllers, the
Kubernetes versions in which they are supported, and the order in which they run in the Kubernetes API server.

**Admission Controllers (sorted alphabetically)**

The table lists, in alphabetical order, the admission controllers that are turned on in the Kubernetes clusters you create
using Container Engine for Kubernetes. For each admission controller, the table shows the Kubernetes version in
which it is supported.

<table>
<thead>
<tr>
<th>Admission Controllers (in alphabetical order)</th>
<th>Supported in 1.16?</th>
<th>Supported in 1.17?</th>
<th>Supported in 1.18?</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultIngressClass</td>
<td>No</td>

</tbody>
</table>

Supported Admission Controllers (sorted by run order)

The table lists the admission controllers that are turned on in the Kubernetes clusters you create using Container Engine for Kubernetes. The table shows the order in which supported admission controllers run in the Kubernetes API server. Note that the run order is different in different Kubernetes versions.
Kubernetes Versions and Container Engine for Kubernetes

When you create a new Kubernetes cluster using Container Engine for Kubernetes, you specify:

- The version of Kubernetes to run on the control plane nodes in the cluster.
- The version of Kubernetes to run on the worker nodes in each node pool. Different worker nodes in the same node pool can run different versions of Kubernetes. Different node pools in a cluster can run different versions of Kubernetes.

The version of Kubernetes that you specify for the worker nodes in a node pool must be either the same Kubernetes version as that running on the control plane nodes, or an earlier Kubernetes version that is still compatible. In other words:

- The control plane nodes in a new cluster must run the same version of Kubernetes as the version running on worker nodes, or must be no more than two versions ahead.
- The worker nodes in a node pool must not run a more recent version of Kubernetes than the associated control plane nodes.

New Versions of Kubernetes

New Kubernetes versions are released periodically that contain new features and bug fixes. Kubernetes version numbers have the format x.y.z where x is a major release, y is a minor release, and z is a patch release. For example, 1.18.10.

Kubernetes itself is supported for three minor versions at a time (the current release version and two previous versions).

As described in the Kubernetes documentation, a certain amount of version variation is permissible between control plane nodes and worker nodes in a cluster:

- The Kubernetes version on worker nodes can lag behind the version on the control plane nodes by up to two versions, but no more. If the version on the worker nodes is more than two versions behind the version on the control plane nodes, the Kubernetes versions on the worker nodes and the control plane nodes are incompatible.
- The Kubernetes version on worker nodes must never be more recent than the version on the control plane nodes.

For the Kubernetes versions currently and previously supported by Container Engine for Kubernetes, see Supported Versions of Kubernetes on page 926.

Supported Versions of Kubernetes

When Container Engine for Kubernetes support for a new version of Kubernetes is announced, an older Kubernetes version ceases to be supported.

This topic lists:

- Kubernetes Versions Supported by Container Engine for Kubernetes on page 926
- Kubernetes Versions Previously Supported by Container Engine for Kubernetes on page 928

Kubernetes Versions Supported by Container Engine for Kubernetes

Container Engine for Kubernetes supports the following versions of Kubernetes:
<table>
<thead>
<tr>
<th>Kubernetes Version</th>
<th>Supported by Container Engine for Kubernetes?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.18.10</td>
<td>Yes</td>
<td>Support introduced: 1 December, 2020</td>
</tr>
<tr>
<td>1.17.13</td>
<td>Yes</td>
<td>Support for 1.17.x versions (initially 1.17.9) introduced: 3 November, 2020</td>
</tr>
<tr>
<td>1.16.15</td>
<td>Yes</td>
<td>Support for 1.16.x versions (initially 1.16.8) introduced: 22 June, 2020 See Notes about Container Engine for Kubernetes Support for Kubernetes Version 1.16 on page 927</td>
</tr>
</tbody>
</table>

**Notes about Container Engine for Kubernetes Support for Kubernetes Version 1.16**

Note that Kubernetes version 1.16 deprecates:

- A number of versions of the following Kubernetes APIs, in favor of more stable versions (as described in this [kubernetes.io blog post](#)):
  - NetworkPolicy
  - PodSecurityPolicy
  - DaemonSet
  - Deployment
  - StatefulSet
  - ReplicaSet

If a deprecated API version is used, workloads running on Kubernetes version 1.16 clusters are subject to disruption.

- Any labels in the k8s.io and kubernetes.io namespaces, except for the following:
  - kubernetes.io/hostname
  - kubernetes.io/instance-type
  - kubernetes.io/os
  - kubernetes.io/arch
  - beta.kubernetes.io/instance-type
  - beta.kubernetes.io/os
  - beta.kubernetes.io/arch
  - failure-domain.beta.kubernetes.io/zone
  - failure-domain.beta.kubernetes.io/region
  - failure-domain.kubernetes.io/zone
  - failure-domain.kubernetes.io/region
  - [*.]kubelet.kubernetes.io/*
  - [*.]node.kubernetes.io/*

If a disallowed label is used, errors occur when creating or updating node pools in Kubernetes version 1.16 clusters.

Before upgrading clusters to Kubernetes version 1.16, Oracle strongly recommends you prepare as follows:
Container Engine for Kubernetes

- Migrate to the stable API versions as soon as possible. Container Engine for Kubernetes already supports Kubernetes versions that support the stable API versions, so you can do this immediately. Depending on your use of the Kubernetes APIs, your migration tasks might include:
  - changing manifest files to reference the stable API versions
  - updating custom integrations and controllers to call the stable API versions
  - updating third party tools (ingress controllers, continuous delivery systems) to call stable API versions
  - verifying your version of kubectl adheres to the Kubernetes version skew support policy described in the Kubernetes documentation
  - making sure any references to documented Kubernetes examples are using stable API versions
- Update the Kubernetes labels in the k8s.io and kubernetes.io namespaces to just the following:
  - kubernetes.io/hostname
  - kubernetes.io/instance-type
  - kubernetes.io/os
  - kubernetes.io/arch
  - beta.kubernetes.io/instance-type
  - beta.kubernetes.io/os
  - beta.kubernetes.io/arch
  - failure-domain.beta.kubernetes.io/zone
  - failure-domain.beta.kubernetes.io/region
  - failure-domain.kubernetes.io/zone
  - failure-domain.kubernetes.io/region
  - [*]kubelet.kubernetes.io/*
  - [*]node.kubernetes.io/*

**Kubernetes Versions Previously Supported by Container Engine for Kubernetes**

Container Engine for Kubernetes previously supported the following versions of Kubernetes:

<table>
<thead>
<tr>
<th>Kubernetes Version</th>
<th>Supported by Container Engine for Kubernetes?</th>
<th>Support Ended</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.15.12</td>
<td>No</td>
<td>2 February, 2021</td>
</tr>
<tr>
<td>1.15.7</td>
<td>No</td>
<td>2 February, 2021</td>
</tr>
<tr>
<td>1.14.8</td>
<td>No</td>
<td>15 December 2020</td>
</tr>
<tr>
<td>1.13.x</td>
<td>No</td>
<td>21 March, 2020</td>
</tr>
<tr>
<td>1.12.7</td>
<td>No</td>
<td>29 January, 2020</td>
</tr>
<tr>
<td>1.12.6</td>
<td>No</td>
<td>15 April, 2019</td>
</tr>
<tr>
<td>1.11.9</td>
<td>No</td>
<td>9 September, 2019</td>
</tr>
<tr>
<td>1.11.8</td>
<td>No</td>
<td>15 April, 2019</td>
</tr>
<tr>
<td>1.11.x versions prior to 1.11.8</td>
<td>No</td>
<td>13 March, 2019</td>
</tr>
<tr>
<td>1.10.x</td>
<td>No</td>
<td>12 April, 2019</td>
</tr>
<tr>
<td>1.9.x</td>
<td>No</td>
<td>11 December, 2019</td>
</tr>
<tr>
<td>1.8.x</td>
<td>No</td>
<td>7 September, 2018</td>
</tr>
</tbody>
</table>
Upgrading Clusters to Newer Kubernetes Versions

After a new version of Kubernetes has been released and when Container Engine for Kubernetes supports the new version, you can upgrade the Kubernetes version running on control plane nodes and worker nodes in a cluster.

The control plane nodes and worker nodes that comprise the cluster can run different versions of Kubernetes, provided you follow the Kubernetes version skew support policy described in the Kubernetes documentation.

You upgrade control plane nodes and worker nodes differently:

• You upgrade control plane nodes by upgrading the cluster and specifying a more recent Kubernetes version for the cluster. Control plane nodes running older versions of Kubernetes are upgraded. Because Container Engine for Kubernetes distributes the Kubernetes Control Plane on multiple Oracle-managed control plane nodes to ensure high availability (distributed across different availability domains in a region where supported), you're able to upgrade the Kubernetes version running on control plane nodes with zero downtime.

Having upgraded control plane nodes to a new version of Kubernetes, you can subsequently create new node pools with worker nodes running the newer version. Alternatively, you can continue to create new node pools with worker nodes running older versions of Kubernetes (providing those older versions are compatible with the Kubernetes version running on the control plane nodes).

For more information about control plane node upgrade, see Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster on page 930.

• You upgrade worker nodes in one of two ways:
  • By performing an 'in-place' upgrade of a node pool in the cluster, specifying a more recent Kubernetes version for the existing node pool.
  • By performing an 'out-of-place' upgrade of a node pool in the cluster, replacing the original node pool with a new node pool for which you've specified a more recent Kubernetes version.

For more information about worker node upgrade, see Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 930.

To find out more about the Kubernetes versions currently and previously supported by Container Engine for Kubernetes, see Supported Versions of Kubernetes on page 926.

Notes about Upgrading Clusters

Note the following when upgrading clusters:

• Container Engine for Kubernetes only upgrades the Kubernetes version running on control plane nodes when you explicitly initiate the upgrade operation.

• After upgrading control plane nodes to a newer version of Kubernetes, you cannot downgrade the control plane nodes to an earlier Kubernetes version.

• Before you upgrade the version of Kubernetes running on the control plane nodes, it is your responsibility to test that applications deployed on the cluster are compatible with the new Kubernetes version. For example, before upgrading the existing cluster, you might create a new separate cluster with the new Kubernetes version to test your applications.

• The versions of Kubernetes running on the control plane nodes and the worker nodes must be compatible (that is, the Kubernetes version on the control plane nodes must be no more than two minor versions ahead of the Kubernetes version on the worker nodes). See the Kubernetes version skew support policy described in the Kubernetes documentation.

• If the version of Kubernetes currently running on the control plane nodes is more than one version behind the most recent supported version, you are given a choice of versions to upgrade to. If you want to upgrade to a version of Kubernetes that is more than one version ahead of the version currently running on the control plane nodes, you must upgrade to each intermediate version in sequence without skipping versions (as described in the Kubernetes documentation).

• To successfully upgrade control plane nodes in a cluster, the Kubernetes Dashboard service must be of type ClusterIP. If the Kubernetes Dashboard service is not of type ClusterIP (for example, if the service is of type NodePort), the upgrade will fail. In this case, change the type of the Kubernetes Dashboard service back to
ClusterIP (for example, by entering `kubectl -n kube-system edit service kubernetes-dashboard` and changing the type).

- Prior to Kubernetes version 1.14, Container Engine for Kubernetes created clusters with kube-dns as the DNS server. However, from Kubernetes version 1.14 onwards, Container Engine for Kubernetes creates clusters with CoreDNS as the DNS server. When you upgrade a cluster created by Container Engine for Kubernetes from an earlier version to Kubernetes 1.14 or later, the cluster's kube-dns server is automatically replaced with the CoreDNS server. Note that if you customized kube-dns behavior using the original kube-dns ConfigMap, those customizations are not carried forward to the CoreDNS ConfigMap. You will have to create and apply a new ConfigMap containing the customizations to override settings in the CoreDNS Corefile. For more information about upgrading to CoreDNS, see Configuring DNS Servers for Kubernetes Clusters on page 932.

**Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster**

When Container Engine for Kubernetes supports a newer version of Kubernetes than the version currently running on the control plane nodes in a cluster, you can upgrade the Kubernetes version running on the control plane nodes.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>After you’ve upgraded control plane nodes to a newer Kubernetes version, you can’t downgrade the control plane nodes to an earlier Kubernetes version. It’s therefore important that before you upgrade the Kubernetes version running on the control plane nodes, you test that applications deployed on the cluster are compatible with the new Kubernetes version.</td>
</tr>
</tbody>
</table>

**Using the Console**

To upgrade the version of Kubernetes running on the control plane nodes:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Kubernetes Clusters.
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster where you want to upgrade the Kubernetes version running on the control plane nodes.

   If a newer Kubernetes version is available than the one running on the control plane nodes in the cluster, the Upgrade button is enabled at the top of the Cluster page.
4. Click Upgrade to upgrade the control plane nodes to a newer version.
5. In the Upgrade Cluster Master dialog box, select the Kubernetes version to which to upgrade the control plane nodes, and click Upgrade.

The Kubernetes version running on the control plane nodes is upgraded. From now on, the new Kubernetes version will appear as an option when you’re defining new node pools for the cluster.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the UpdateCluster operation to upgrade the version of Kubernetes running on the control plane nodes.

**Upgrading the Kubernetes Version on Worker Nodes in a Cluster**

You can upgrade the version of Kubernetes running on the worker nodes in a cluster in two ways:

- Perform an ‘in-place’ upgrade of a node pool in the cluster, by specifying a more recent Kubernetes version for new worker nodes starting in the existing node pool. First, you modify the existing node pool's properties to specify the more recent Kubernetes version. Then, you 'drain' existing worker nodes in the node pool to prevent new pods starting, and to delete existing pods. Finally, you terminate each of the worker nodes in turn. When new worker nodes are started in the existing node pool, they run the more recent Kubernetes version you specified. See Performing an In-Place Worker Node Upgrade by Updating an Existing Node Pool on page 931.
• Perform an 'out-of-place' upgrade of a node pool in the cluster, by replacing the original node pool with a new node pool. First, you create a new node pool with a more recent Kubernetes version. Then, you 'drain' existing worker nodes in the original node pool to prevent new pods starting, and to delete existing pods. Finally, you delete the original node pool. When new worker nodes are started in the new node pool, they run the more recent Kubernetes version you specified. See Performing an Out-of-Place Worker Node Upgrade by Replacing an Existing Node Pool with a New Node Pool on page 932.

Note that in both cases:

• The more recent Kubernetes version you specify for the worker nodes in the node pool must be compatible with the Kubernetes version running on the control plane nodes in the cluster. See Upgrading Clusters to Newer Kubernetes Versions on page 929).
• You must drain existing worker nodes in the original node pool. If you don't drain the worker nodes, workloads running on the cluster are subject to disruption.

Performing an In-Place Worker Node Upgrade by Updating an Existing Node Pool

You can upgrade the version of Kubernetes running on worker nodes in a node pool by specifying a more recent Kubernetes version for the existing node pool. For each worker node, you first drain it to prevent new pods starting and to delete existing pods. You then terminate the worker node so that a new worker node is started, running the more recent Kubernetes version you specified. When new worker nodes are started in the existing node pool, they run the more recent Kubernetes version you specified.

To perform an in-place upgrade of a node pool in a cluster, by specifying a more recent Kubernetes version for the existing node pool:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Kubernetes Clusters.
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster where you want to change the Kubernetes version running on worker nodes.
4. On the Cluster page, display the Node Pools tab, and click the name of the node pool where you want to upgrade the Kubernetes version running on the worker nodes.
5. On the Node Pool page, click Edit and in the Version field, specify the required Kubernetes version for worker nodes.

The Kubernetes version you specify must be compatible with the version that is running on the control plane nodes.
6. Click Edit to save the change.

You now have to terminate existing worker nodes so that new worker nodes are started, running the Kubernetes version you specified.
7. For the first worker node in the node pool:
   a. Prevent new pods from starting and delete existing pods by entering:

```
  kubectl drain <node_name>
```

For more information:
• about using kubectl, see Accessing a Cluster Using Kubectl on page 890
• about the drain command, see drain in the Kubernetes documentation

Recommended: Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.

b. On the Node Pool page, display the Nodes tab and click the worker node’s name in the Node Name field.
c. On the Instances page, select Terminate from the More Actions menu.

The worker node is terminated and a new worker node is started in its place, running the Kubernetes version you specified.
8. Repeat the previous step for each remaining worker node in the node pool, until all worker nodes in the node pool are running the Kubernetes version you specified.

**Performing an Out-of-Place Worker Node Upgrade by Replacing an Existing Node Pool with a New Node Pool**

You can 'upgrade' the version of Kubernetes running on worker nodes in a node pool by replacing the original node pool with a new node pool that has new worker nodes running the appropriate Kubernetes version. Having drained existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool. When new worker nodes are started in the new node pool, they run the more recent Kubernetes version you specified.

To perform an 'out-of-place' upgrade of a node pool in a cluster, by creating a new node pool to 'upgrade' the Kubernetes version on worker nodes:

1. In the Console, open the navigation menu. Under Solutions and Platform, go to Developer Services and click Kubernetes Clusters.
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster where you want to change the Kubernetes version running on worker nodes.
4. On the Cluster page, display the Node Pools tab, and then click Add Node Pool to create a new node pool and specify the required Kubernetes version for its worker nodes.

   The Kubernetes version you specify must be compatible with the version that is running on the control plane nodes.
5. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then use the `kubectl label nodes` command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.
6. For the first worker node in the original node pool, prevent new pods from starting and delete existing pods by entering:

   ```
   kubectl drain <node_name>
   ```

   For more information:
   - about using kubectl, see Accessing a Cluster Using Kubectl on page 890
   - about the drain command, see drain in the Kubernetes documentation

   **Recommended**: Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.
7. Repeat the previous step for each remaining worker node in the node pool, until all the worker nodes have been drained from the original node pool.

   When you have drained all the worker nodes from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.
8. On the Cluster page, display the Node Pools tab, and then select Delete Node Pool from the Actions menu beside the original node pool.

   The original node pool and all its worker nodes are deleted.

**Configuring DNS Servers for Kubernetes Clusters**

**Configuring Built-in DNS Servers (kube-dns, CoreDNS)**

Clusters created by Container Engine for Kubernetes include a DNS server as a built-in Kubernetes service that is launched automatically. The kubelet process on each worker node directs individual containers to the DNS server to translate DNS names to IP addresses.
Prior to Kubernetes version 1.14, Container Engine for Kubernetes created clusters with kube-dns as the DNS server. However, from Kubernetes version 1.14 onwards, Container Engine for Kubernetes creates clusters with CoreDNS as the DNS server. CoreDNS is a general-purpose authoritative DNS server that is modular and pluggable.

Default CoreDNS behavior is controlled by a configuration file referred to as a Corefile. The Corefile is a Kubernetes ConfigMap, with a Corefile section that defines CoreDNS behavior. You cannot modify the Corefile directly. If you need to customize CoreDNS behavior, you create and apply your own ConfigMap to override settings in the Corefile (as described in this topic). Note that if you do customize CoreDNS default behavior, the customizations are periodically deleted during internal updates to the cluster.

When you upgrade a cluster created by Container Engine for Kubernetes from an earlier version to Kubernetes 1.14 or later, the cluster's kube-dns server is automatically replaced with the CoreDNS server. Note that if you customized kube-dns behavior using the original kube-dns ConfigMap, those customizations are not carried forward to the CoreDNS ConfigMap. You will have to create and apply a new ConfigMap containing the customizations to override settings in the CoreDNS Corefile.

For more information about CoreDNS customization and Kubernetes, see the Kubernetes documentation and the CoreDNS documentation.

To create a ConfigMap to override the settings in the CoreDNS Corefile:

1. Define a ConfigMap in a yaml file, in the format:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: coredns-custom
     namespace: kube-system
   data:
     <customization-options>
   ```

   For example:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: coredns-custom
     namespace: kube-system
   data:
     example.server: | # All custom server files must have a "server" file extension.
                      # Change example.com to the domain you wish to forward.
               example.com {
                      # Change 1.1.1.1 to your customer DNS resolver.
               forward 1.1.1.1
        }
   ```

   For more information about the ConfigMap options to use to customize CoreDNS behavior, see the Kubernetes documentation and the CoreDNS documentation.

2. Create the ConfigMap by entering:

   ```bash
   kubectl apply -f <filename>.yaml
   ```

3. Verify the customizations have been applied by entering:

   ```bash
   kubectl get configmaps --namespace=kube-system coredns-custom -o yaml
   ```

4. Force CoreDNS to reload the ConfigMap by entering:

   ```bash
   kubectl delete pod --namespace kube-system -l k8s-app=kube-dns
   ```
Configuring ExternalDNS to use Oracle Cloud Infrastructure DNS

ExternalDNS is an add-on to Kubernetes that can create DNS records for services in DNS providers external to Kubernetes. It sets up DNS records in an external DNS provider to make Kubernetes services discoverable via that DNS provider, and enables you to control DNS records dynamically. See ExternalDNS for more information.

Having deployed ExternalDNS on a cluster, you can expose a service running on the cluster by adding the external-dns.alpha.kubernetes.io/hostname annotation to the service. ExternalDNS creates a DNS record for the service in the external DNS provider you've configured for the cluster.

ExternalDNS is not itself a DNS server like CoreDNS, but a way to configure other external DNS providers. Oracle Cloud Infrastructure DNS is one such external DNS provider. See Overview of the DNS Service on page 1674.

For convenience, instructions are included below to set up ExternalDNS on a cluster and configure it to use Oracle Cloud Infrastructure DNS. These instructions are a summary based on the Setting up ExternalDNS for Oracle Cloud Infrastructure (OCI) tutorial, which is available on GitHub.

To set up ExternalDNS on a cluster and configure it to use Oracle Cloud Infrastructure DNS:

1. Create a new DNS zone in Oracle Cloud Infrastructure DNS to contain the DNS records that ExternalDNS will create for the cluster. See Creating a Zone on page 1677.
2. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.
3. Create a Kubernetes secret containing the Oracle Cloud Infrastructure user authentication details for ExternalDNS to use when connecting to the Oracle Cloud Infrastructure API to insert and update DNS records in the DNS zone you just created.

   a. In a text editor, create a credentials file containing the Oracle Cloud Infrastructure user credentials to use to access the DNS zone:

   ```
   auth:
     region: <region-identifier>
     tenancy: <tenancy-ocid>
     user: <user-ocid>
     key: |
       -----BEGIN RSA PRIVATE KEY-----
       <private-key>
       -----END RSA PRIVATE KEY-----
     fingerprint: <fingerprint>
     # Omit if there is not a password for the key
     passphrase: <passphrase>
     compartment: <compartment-ocid>
   ```

   where:
   * `<region-identifier>` identifies the user's region. For example, us-phoenix-1
   * `<tenancy-ocid>` is the OCID of the user's tenancy. For example, ocid1.tenancy.oc1..aaaaaaaap...keq (abbreviated for readability).
   * `<user-ocid>` is the OCID of the user. For example, ocid1.user.oc1..aaaaa...zutq (abbreviated for readability).
   * `<private-key>` is an RSA key, starting with -----BEGIN RSA PRIVATE KEY----- and ending with -----END RSA PRIVATE KEY-----
   * `<passphrase>` optionally provides the passphrase for the key, if one exists
   * `<compartment-ocid>` is the OCID of the compartment to which the DNS zone belongs

For example:

```
auth:
  region: us-phoenix-1
```
b. Save the credentials file with a name of your choosing (for example, `oci-creds.yaml`).

c. Create a Kubernetes secret from the credentials file you just created, by entering:

```
kubectl create secret generic <secret-name> --from-file=<credential-filename>
```

For example:

```
kubectl create secret generic external-dns-config --from-file=oci-creds.yaml
```

4. Deploy ExternalDNS on the cluster.

a. In a text editor, create a configuration file (for example, called `external-dns-deployment.yaml`) to create the ExternalDNS deployment, and specify the name of the Kubernetes secret you just created. For example:

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  name: external-dns
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: external-dns
rules:
- apiGroups: ["" ]
  resources: ["services","endpoints","pods"]
  verbs: ["get","watch","list"]
- apiGroups: ["extensions","networking.k8s.io"]
  resources: ["ingresses"]
  verbs: ["get","watch","list"]
- apiGroups: [""]
  resources: ["nodes"]
  verbs: ["list"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: external-dns-viewer
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: external-dns
subjects:
- kind: ServiceAccount
  name: external-dns
  namespace: default
---
apiVersion: apps/v1
kind: Deployment
```
metadata:
    name: external-dns
spec:
    strategy:
        type: Recreate
    selector:
        matchLabels:
            app: external-dns
    template:
        metadata:
            labels:
                app: external-dns
        spec:
            serviceAccountName: external-dns
            containers:
                - name: external-dns
                    image: k8s.gcr.io/external-dns/external-dns:v0.7.3
                    args:
                        - --source=service
                        - --source=ingress
                        - --provider=oci
                        - --policy=upsert-only # prevent ExternalDNS from deleting any
                        records, omit to enable full synchronization
                        - --txt-owner-id=my-identifier
                    volumeMounts:
                        - name: config
                            mountPath: /etc/kubernetes/
                - name: config
                    secretName: external-dns-config

b. Save and close the configuration file.
c. Apply the configuration file to deploy ExternalDNS by entering:

```
kubectl apply -f <filename>
```

where `<filename>` is the name of the file you created earlier. For example:

```
kubectl apply -f external-dns-deployment.yaml
```

The output from the above command confirms the deployment:

```
serviceaccount/external-dns created
clusterrole.rbac.authorization.k8s.io/external-dns created
clusterrolebinding.rbac.authorization.k8s.io/external-dns-viewer created
deployment.apps/external-dns created
```

5. Verify that ExternalDNS has been deployed successfully and can insert records in the DNS zone you created earlier in Oracle Cloud Infrastructure by creating an nginx deployment and an nginx service:

a. In a text editor, create a configuration file (for example, called `nginx-externaldns.yaml`) to create an nginx deployment and an nginx service that includes the `external-dns.alpha.kubernetes.io/hostname` annotation. For example:

```
apiVersion: v1
kind: Service
metadata:
    name: nginx
    annotations:
        external-dns.alpha.kubernetes.io/hostname: example.com
spec:
```
Creating Load Balancers to Distribute Traffic Between Cluster Nodes

When you create a deployment, you can optionally create a load balancer service in the same compartment as the cluster to distribute traffic between the nodes assigned to the deployment. The key fields in the configuration of a load balancer service are the type of service being created and the ports that the load balancer will listen to.

Note:

Load balancer services you create appear in the Console. However, do not use the Console (or the Oracle Cloud Infrastructure CLI or API) to modify load balancer services. Any modifications you make will either be reverted by Container Engine for Kubernetes or will conflict with its operation and possibly result in service interruption.
Creating Load Balancers to Distribute HTTP Traffic

Consider the following configuration file, nginx_lb.yaml. It defines a deployment (kind: Deployment) for the nginx app, followed by a service definition with a type of LoadBalancer (type: LoadBalancer) that balances http traffic on port 80 for the nginx app.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-nginx
  labels:
    app: nginx
spec:
  replicas: 3
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - name: nginx
        image: nginx:1.7.9
        ports:
        - containerPort: 80
---
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx
```

The first part of the configuration file defines an Nginx deployment, requesting that it be hosted on 3 pods running the nginx:1.7.9 image, and accept traffic to the containers on port 80.

The second part of the configuration file defines the Nginx service, which uses type LoadBalancer to balance Nginx traffic on port 80 amongst the available pods.

To create the deployment and service defined in nginx_lb.yaml while connected to your Kubernetes cluster, enter the command:

```
kubectl apply -f nginx_lb.yaml
```

This command outputs the following upon successful creation of the deployment and the load balancer:

```
deployment "my-nginx" created
service "my-nginx-svc" created
```

The load balancer may take a few minutes to go from a pending state to being fully operational. You can view the current state of your cluster by entering:

```
kubectl get all
```
The output from the above command shows the current state:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>po/my-nginx-431080787-0m4m8</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
<tr>
<td>po/my-nginx-431080787-hqqcr</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
<tr>
<td>po/my-nginx-431080787-n8125</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>203.0.113.1</td>
<td>&lt;NONE&gt;</td>
<td>443/TCP</td>
<td>3d</td>
</tr>
<tr>
<td>svc/my-nginx-svc</td>
<td>203.0.113.7</td>
<td>192.0.2.22</td>
<td>80:30269/TCP</td>
<td>3m</td>
</tr>
</tbody>
</table>

The output shows that the **my-nginx** deployment is running on 3 pods (the po/my-nginx entries), that the load balancer is running (svc/my-nginx-svc) and has an external IP (192.0.2.22) that clients can use to connect to the app that's deployed on the pods.

**Creating Load Balancers with SSL Support to Distribute HTTPS Traffic**

You can create a load balancer with SSL termination, allowing https traffic to an app to be distributed among the nodes in a cluster. This example provides a walkthrough of the configuration and creation of a load balancer with SSL support.

Consider the following configuration file, nginx-demo-svc-ssl.yaml, which defines an Nginx deployment and exposes it via a load balancer that serves http on port 80, and https on port 443. This sample creates an Oracle Cloud Infrastructure load balancer, by defining a service with a type of LoadBalancer (type: LoadBalancer).

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: nginx-deployment
spec:
  replicas: 2
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - name: nginx
        image: nginx
        ports:
        - containerPort: 80
---
kind: Service
apiVersion: v1
metadata:
  name: nginx-service
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-ssl-ports: "443"
    service.beta.kubernetes.io/oci-load-balancer-tls-secret: ssl-certificate-secret
spec:
  selector:
```
The Load Balancer's annotations are of particular importance. The ports on which to support https traffic are defined by the value of `service.beta.kubernetes.io/oci-load-balancer-ssl-ports`. You can declare multiple SSL ports by using a comma-separated list for the annotation's value. For example, you could set the annotation's value to "443, 3000" to support SSL on ports 443 and 3000.

The required TLS secret, `ssl-certificate-secret`, needs to be created in Kubernetes. This example creates and uses a self-signed certificate. However, in a production environment, the most common scenario is to use a public certificate that's been signed by a certificate authority.

The following command creates a self-signed certificate, `tls.crt`, with its corresponding key, `tls.key`:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj "/CN=nginxsvc/O=nginxsvc"
```

Now that you created the certificate, you need to store both it and its key as a secret in Kubernetes. The name of the secret must match the name from the `service.beta.kubernetes.io/oci-load-balancer-tls-secret` annotation of the load balancer's definition. Use the following command to create a TLS secret in Kubernetes, whose key and certificate values are set by `--key` and `--cert`, respectively.

```
kubectl create secret tls ssl-certificate-secret --key tls.key --cert tls.crt
```

You must create the Kubernetes secret before you can create the service, since the service references the secret in its definition. Create the service using the following command:

```
kubectl create -f manifests/demo/nginx-demo-svc-ssl.yaml
```

Watch the service and wait for a public IP address (EXTERNAL-IP) to be assigned to the Nginx service (nginx-service) by entering:

```
kubectl get svc --watch
```

The output from the above command shows the load balancer IP to use to connect to the service.
The load balancer is now running, which means the service can now be accessed as follows:

- using http, by entering:
  
  ```
  curl http://198.51.100.1
  ```

- using https, by entering:
  
  ```
  curl --insecure https://198.51.100.1
  ```

The "--insecure" flag is used to access the service using https due to the use of self-signed certificates in this example. Do not use this flag in a production environment where the public certificate was signed by a certificate authority.

**Note**: When a cluster is deleted, a load balancer that's dynamically created when a service is created will not be removed. Before deleting a cluster, delete the service, which in turn will result in the cloud provider removing the load balancer. The syntax for this command is:

```
kubectl delete svc SERVICE_NAME
```

For example, to delete the service from the previous example, enter:

```
kubectl delete svc nginx-service
```

### Updating the TLS Certificates of Existing Load Balancers

To update the TLS certificate of an existing load balancer:

1. Obtain a new TLS certificate. In a production environment, the most common scenario is to use a public certificate that's been signed by a certificate authority.
2. Create a new Kubernetes secret. For example, by entering:

```
kubectl create secret tls new-ssl-certificate-secret --key new-tls.key --cert new-tls.crt
```

3. Modify the service definition to reference the new Kubernetes secret by changing the `service.beta.kubernetes.io/oci-load-balancer-tls-secret` annotation in the service configuration. For example:

```json
apiVersion: v1
kind: Service
metadata:
  name: nginx-service
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-ssl-ports: "443"
    service.beta.kubernetes.io/oci-load-balancer-tls-secret: new-ssl-certificate-secret
spec:
  selector:
    app: nginx
  type: LoadBalancer
  ports:
  - name: http
    port: 80
    targetPort: 80
  - name: https
    port: 443
    targetPort: 80
```
4. Update the service. For example, by entering:

```bash
kubectl apply -f new-nginx-demo-svc-ssl.yaml
```

## Creating Internal Load Balancers in Public and Private Subnets

You can create Oracle Cloud Infrastructure load balancers to control access to services running on a cluster:

- When you create a `custom` cluster, you select an existing VCN that contains the network resources to be used by the new cluster. If you want to use load balancers to control traffic into the VCN, you select existing public or private subnets in that VCN to host the load balancers.
- When you create a `quick` cluster, the VCN that's automatically created contains a public regional subnet to host a load balancer. If you want to host load balancers in private subnets, you can add private subnets to the VCN later.

Alternatively, you can create an internal load balancer service (often referred to simply as an 'internal load balancer') in a cluster to enable other programs running in the same VCN as the cluster to access services in the cluster. An internal load balancer is an Oracle Cloud Infrastructure private load balancer. A private load balancer has a private IP address assigned by the Load Balancing service, which serves as the entry point for incoming traffic. For more information about Oracle Cloud Infrastructure private load balancers, see Private Load Balancer on page 2481.

You can host internal load balancers in public subnets and private subnets.

To create an internal load balancer hosted on a public subnet, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-internal: "true"
```

To create an internal load balancer hosted on a private subnet, add both following annotations in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-internal: "true"

service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
```

where `ocid1.subnet.oc1..aaaaaa....vdfw` is the OCID of the private subnet.

For example:

```yaml
apiVersion: v1
class: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-internal: "true"
    service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
spec:
  type: LoadBalancer
  ports:
  - port: 8100
    selector:
      app: nginx
```
Specifying Alternative Load Balancer Shapes

The shape of an Oracle Cloud Infrastructure load balancer specifies its maximum total bandwidth (that is, ingress plus egress). By default, load balancers are created with a shape of 100Mbps. Other shapes are available, including 400Mbps and 8000Mbps.

To specify an alternative shape for a load balancer, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-shape: <value>
```

where `<value>` is the bandwidth of the shape (for example, 100Mbps, 400Mbps, 8000Mbps).

For example:

```
apiVersion: v1
class: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-shape: 400Mbps
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

**Note:** Sufficient load balancer quota must be available in the region for the shape you specify. Enter the following `kubectl` command to confirm that load balancer creation did not fail due to lack of quota:

```
kubectl describe service <service-name>
```

Specifying Flexible Load Balancer Shapes

The shape of an Oracle Cloud Infrastructure load balancer specifies its maximum total bandwidth (that is, ingress plus egress). As described in Specifying Alternative Load Balancer Shapes on page 943, you can specify different load balancer shapes.

In addition, you can also specify a flexible shape for an Oracle Cloud Infrastructure load balancer, by defining a minimum and a maximum bandwidth for the load balancer.

To specify a flexible shape for a load balancer, add the following annotations in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-shape: "flexible"
service.beta.kubernetes.io/oci-load-balancer-shape-flex-min: <min-value>
service.beta.kubernetes.io/oci-load-balancer-shape-flex-max: <max-value>
```

where:

- `<min-value>` is the minimum bandwidth for the load balancer, in Mbps (for example, 10)
- `<max-value>` is the maximum bandwidth for the load balancer, in Mbps (for example, 100)

Note that you do not include a unit of measurement when specifying bandwidth values for flexible load balancer shapes (unlike for pre-defined shapes). For example, specify the minimum bandwidth as 10 rather than as 10Mbps.
For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-shape: "flexible"
    service.beta.kubernetes.io/oci-load-balancer-shape-flex-min: 10
    service.beta.kubernetes.io/oci-load-balancer-shape-flex-max: 100
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

### Specifying Load Balancer Connection Timeout

You can specify the maximum idle time (in seconds) allowed between two successive receive or two successive send operations between the client and backend servers.

To explicitly specify a maximum idle time, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-connection-idle-timeout: <value>
```

where `value` is the number of seconds.

For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-connection-idle-timeout: 100
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

Note that if you don't explicitly specify a maximum idle time, a default value is used. The default value depends on the type of listener:

- for TCP listeners, the default maximum idle time is 300 seconds
- for HTTP listeners, the default maximum idle time is 60 seconds

### Specifying Load Balancer Security List Management Options

You can use the security list management feature in Kubernetes to manage security list rules. This feature is useful if you are new to Kubernetes, or for basic deployments.
Note:
You might encounter scalability and other issues if you use the Kubernetes security list management feature in complex deployments, and with tools like Shepherd and Terraform. For these reasons, Oracle does not recommend using the Kubernetes security list management feature in production environments.

To specify how the Kubernetes security list management feature manages security lists, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-security-list-management-mode: <value>
```

where `<value>` is one of:

- **"All"**: All required security list rules for load balancer services are managed.
- **"Frontend"**: Only security list rules for ingress to load balancer services are managed. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges.
- **"None"**: No security list management is enabled. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges. Additionally, you have to set up rules to allow inbound traffic to load balancers.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-security-list-management-mode: "Frontend"
spec:
  type: LoadBalancer
  ports:
  - port: 80
    selector:
      app: nginx
```

Note that if you specify an invalid value for `oci-load-balancer-security-list-management-mode`, the value "All" is used instead.

### Specifying Load Balancer Listener Protocol

You can define the type of traffic accepted by the load balancer listener by specifying the protocol on which the listener accepts connection requests.

To explicitly specify the load balancer listener protocol, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-backend-protocol: <value>
```

where `<value>` is the protocol that defines the type of traffic accepted by the listener. For example, "HTTP". To get a list of valid protocols, use the `ListProtocols` operation.
For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-backend-protocol: "HTTP"
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

Note that if you don't explicitly specify a protocol, "TCP" is used as the default value.

### Specifying Load Balancer Health Check Parameters

An Oracle Cloud Infrastructure load balancer applies a health check policy to continuously monitor backend servers. A health check is a test to confirm backend server availability, and can be a request or a connection attempt. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

Health check policies include a number of parameters, which have default values. When you create a load balancer, you can override health check parameter default values by including annotations in the metadata section of the manifest file. Having created a load balancer, you can later add, modify, and delete those annotations. If you delete an annotation that specified a value for a health check parameter, the load balancer uses the parameter's default value instead.

To specify how many unsuccessful health check requests to attempt before a backend server is considered unhealthy, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-health-check-retries: <value>
```

where `<value>` is the number of unsuccessful health check requests.

To specify the interval between health check requests, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-health-check-interval: <value>
```

where `<value>` is a numeric value in milliseconds. The minimum is 1000.

To specify the maximum time to wait for a response to a health check request, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-health-check-timeout: <value>
```

where `<value>` is a numeric value in milliseconds. A health check is successful only if the load balancer receives a response within this timeout period.

For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
```
labels:
  app: nginx
annotations:
  service.beta.kubernetes.io/oci-load-balancer-health-check-retries: 5
  service.beta.kubernetes.io/oci-load-balancer-health-check-interval: 15000
  service.beta.kubernetes.io/oci-load-balancer-health-check-timeout: 4000
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx

Note that if you don’t explicitly specify health check parameter values by including annotations in the metadata section of the manifest file, the following defaults are used:

<table>
<thead>
<tr>
<th>Annotation Not Included</th>
<th>Default Value Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>service.beta.kubernetes.io/oci-load-balancer-health-check-retries</td>
<td>3</td>
</tr>
<tr>
<td>service.beta.kubernetes.io/oci-load-balancer-health-check-interval</td>
<td>10000</td>
</tr>
<tr>
<td>service.beta.kubernetes.io/oci-load-balancer-health-check-timeout</td>
<td>3000</td>
</tr>
</tbody>
</table>

For more information about Oracle Cloud Infrastructure load balancer health check policies, see Working with Health Check Policies on page 2558.

**Preventing Nodes from Handling Load Balancer Traffic**

You can exclude particular worker nodes from the list of backend servers in an Oracle Cloud Infrastructure load balancer backend set. For more information, see node.kubernetes.io/exclude-from-external-load-balers on page 900.

**Creating a Persistent Volume Claim**

Container storage via a container’s root file system is ephemeral, and can disappear upon container deletion and creation. To provide a durable location to prevent data from being lost, you can create and use persistent volumes to store data outside of containers.

A persistent volume offers persistent storage that enables your data to remain intact, regardless of whether the containers to which the storage is connected are terminated.

A persistent volume claim (PVC) is a request for storage, which is met by binding the PVC to a persistent volume (PV). A PVC provides an abstraction layer to the underlying storage. For example, an administrator could create a number of static persistent volumes that can later be bound to one or more persistent volume claims. If none of the static persistent volumes match the user's PVC request, the cluster may attempt to dynamically create a new PV that matches the PVC request.

With Oracle Cloud Infrastructure as the underlying IaaS provider, you can provision persistent volume claims by attaching volumes from the Oracle Cloud Infrastructure Block Volume service. The volumes are connected to clusters created by Container Engine for Kubernetes using FlexVolume and CSI (Container Storage Interface) volume plugins deployed on the clusters.

The minimum amount of persistent storage that a PVC can request is 50 gigabytes. If the request is for less than 50 gigabytes, the request is rounded up to 50 gigabytes.

For more information about persistent volumes, persistent volume claims, and volume plugins, see the Kubernetes documentation.
Provisioning Persistent Volume Claims on the Block Volume Service

The Oracle Cloud Infrastructure Block Volume service (the Block Volume service) provides persistent, durable, and high-performance block storage for your data. You can use the CSI volume plugin or the FlexVolume volume plugin to connect clusters to volumes from the Block Volume service. Using the CSI volume plugin has several advantages:

- In future, new functionality will only be added to the CSI volume plugin, not to the FlexVolume volume plugin (although Kubernetes developers will continue to maintain the FlexVolume volume plugin).
- The CSI volume plugin does not require access to underlying operating system and root file system dependencies.

The StorageClass specified for a PVC controls which volume plugin to use to connect to Block Volume service volumes. If you don’t explicitly specify a value for storageClassName in the yaml file that defines the PVC, the cluster’s default StorageClass is used. In clusters created by Container Engine for Kubernetes, the oci StorageClass is initially set up as the default. The oci StorageClass is used by the FlexVolume volume plugin.

In the case of the CSI volume plugin, the CSI topology feature ensures that worker nodes and volumes are located in the same availability domain. In the case of the FlexVolume volume plugin, you can use the matchLabels element to select the availability domain in which a persistent volume claim is provisioned. Note that you do not use the matchLabels element with the CSI volume plugin.

Regardless of the volume plugin you choose to use, if a cluster is in a different compartment to its worker nodes, you must create an additional policy to enable access to Block Volume service volumes. This situation arises when the subnet specified for a node pool belongs to a different compartment to the cluster. To enable the worker nodes to access Block Volume service volumes, create the additional policy with both the following policy statements:

- ALLOW any-user to manage volumes in TENANCY where request.principal.type = 'cluster'
- ALLOW any-user to manage volume-attachments in TENANCY where request.principal.type = 'cluster'

Note:

In the FlexVolume examples in this topic, the PVCs request storage in availability domains in the Ashburn region using the failure-domain.beta.kubernetes.io/zone label. For more information about using this label (and the shortened versions of availability domain names to specify), see failure-domain.beta.kubernetes.io/zone on page 899.

Specifying the Volume plugin used by a Persistent Volume Claim

To explicitly specify the volume plugin to use to connect to the Block Volume service when provisioning a persistent volume claim, specify a value for storageClassName in the yaml file that defines the PVC:

- to use the CSI volume plugin, specify storageClassName: "oci-bv"
- to use the FlexVolume volume plugin, specify storageClassName: "oci"

Example 1: Dynamically Creating a Persistent Volume on the Block Volume Service for Use by the CSI Volume Plugin

In this example, the cluster administrator has not created any suitable PVs that match the PVC request. As a result, a block volume is dynamically provisioned using the CSI plugin specified by the oci-bv StorageClass's definition (provisioner: blockvolume.csi.oraclecloud.com).

You define a PVC in a file called csi-bvs-pvc.yaml. For example:

```yaml
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mynginxclaim
spec:
```
Enter the following command to create the PVC from the csi-bvs-pvc.yaml file:

```bash
kubectl create -f csi-bvs-pvc.yaml
```

The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "mynginxclaim" created
```

Verify that the PVC has been created by running `kubectl get pvc`:

```bash
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESSMODES</th>
<th>STORAGECLASS</th>
</tr>
</thead>
<tbody>
<tr>
<td>mynginxclaim</td>
<td>Pending</td>
<td></td>
<td></td>
<td></td>
<td>oci-bv</td>
</tr>
</tbody>
</table>

4m

The PVC has a status of `Pending` because the `oci-bv` StorageClass's definition includes `volumeBindingMode: WaitForFirstConsumer`.

You can use this PVC when creating other objects, such as pods. For example, you could create a new pod from the following pod definition, which instructs the system to use the `mynginxclaim` PVC as the nginx volume, which is mounted by the pod at /data.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
      image: nginx:latest
      ports:
        - name: http
          containerPort: 80
      volumeMounts:
        - name: data
          mountPath: /usr/share/nginx/html
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: mynginxclaim
```

Having created the new pod, you can verify that the PVC has been bound to a new persistent volume by entering:

```bash
kubectl get pvc
```

The output from the above command confirms that the PVC has been bound:
You can verify that the pod is using the new persistent volume claim by entering:

```
kubectl describe pod nginx
```

### Example 2: Dynamically Creating a Persistent Volume on the Block Volume Service for Use by the FlexVolume Volume Plugin

In this example, the cluster administrator has not created any suitable PVs that match the PVC request. As a result, a block volume is dynamically provisioned using the FlexVolume volume plugin specified by the `oci` StorageClass's definition (`provisioner: oracle.com/oci`).

You define a PVC in a file called `flex-bvs-pvc.yaml`. For example:

```yaml
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mynginxclaim
spec:
  storageClassName: "oci"
  selector:
    matchLabels:      
    failure-domain.beta.kubernetes.io/zone: "US-ASHBURN-AD-1"
  accessModes:
    - ReadWriteOnce
  resources:
    requests:      
    storage: 50Gi
```

Note that the `flex-bvs-pvc.yaml` file includes the `matchLabels` element, which is only applicable in the case of the FlexVolume volume plugin.

Enter the following command to create the PVC from the `flex-bvs-pvc.yaml` file:

```
kubectl create -f flex-bvs-pvc.yaml
```

The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "mynginxclaim" created
```

Verify that the PVC has been created and bound to a new persistent volume by entering:

```
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

```
NAME               STATUS    VOLUME                               CAPACITY
ACCESSMODES   STORAGECLASS   AGE
mynginxclaim       Bound     ocid1.volume.oc1.iad.<unique_ID> 50Gi
RWO             oci-bv        4m
```

The PVC already has a status of `Bound` because the `oci` StorageClass’s definition includes `volumeBindingMode: Immediate`. 
You can use this PVC when creating other objects, such as pods. For example, the following pod definition instructs the system to use the mynginxclaim PVC as the nginx volume, which is mounted by the pod at /data.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
  - name: nginx
    image: nginx:latest
    ports:
    - name: http
      containerPort: 80
    volumeMounts:
    - name: data
      mountPath: /usr/share/nginx/html
  volumes:
  - name: data
    persistentVolumeClaim:
      claimName: mynginxclaim
```

Having created the new pod, you can verify that it is running and using the new persistent volume claim by entering:

```bash
kubectl describe pod nginx
```

**Example 3: Creating a Persistent Volume from a Backup on the Block Volume Service for Use by the FlexVolume Volume Plugin**

In this example, the cluster administrator has created a block volume backup for you to use when provisioning a new persistent volume claim. The block volume backup comes with data ready for use by other objects such as pods.

You define a PVC in a file called flex-pvcfrombackup.yaml file. You use the `volume.beta.kubernetes.io/oci-volume-source` annotation element to specify the source of the block volume to use when provisioning a new persistent volume claim using the FlexVolume volume plugin. You can specify the OCID of either a block volume or a block volume backup as the value of the annotation. In this example, you specify the OCID of the block volume backup created by the cluster administrator. For example:

```yaml
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: myvolume
  annotations:
    volume.beta.kubernetes.io/oci-volume-source: ocidi.volumebackup.ocl.iad.abuw...
spec:
  selector:
    matchLabels:
      failure-domain.beta.kubernetes.io/zone: US-ASHBURN-AD-1
  accessModes:
  - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
```

Note that the flex-pvcfrombackup.yaml file includes the `matchLabels` element, which is only applicable in the case of the FlexVolume volume plugin.

Enter the following command to create the PVC from the flex-pvcfrombackup.yaml file:

```bash
kubectl create -f flex-pvcfrombackup.yaml
```
The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "myvolume" created
```

Verify that the PVC has been created and bound to a new persistent volume created from the volume backup by entering:

```
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESSMODES</th>
<th>STORAGECLASS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>myvolume</td>
<td>Bound</td>
<td>ocid1.volume.oc1.iad.&lt;unique_ID&gt;</td>
<td>50Gi</td>
<td>RWO</td>
<td>oci</td>
<td>4m</td>
</tr>
</tbody>
</table>

You can use the new persistent volume created from the volume backup when defining other objects, such as pods. For example, the following pod definition instructs the system to use the myvolume PVC as the nginx volume, which is mounted by the pod at /data.

```
apiVersion: v1
group: apps
kind: StatefulSet
metadata:
  name: nginx
spec:
  replicas: 1
  serviceName: nginx
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
        - name: nginx
          image: nginx:latest
          ports:
            - containerPort: 80
          volumeMounts:
            - name: data
              mountPath: /data
          volumes:
            - name: data
              persistentVolumeClaim:
                claimName: myvolume
```

Having created the new pod, you can verify that it is running and using the new persistent volume claim by entering:

```
kubectl describe pod nginx
```

Adding OCI Service Broker for Kubernetes to Clusters

Service brokers offer a catalog of backing services to workloads running on cloud native platforms. The Open Service Broker API is a commonly-used standard for interactions between service brokers and platforms. The Open Service Broker API specification describes a simple set of API endpoints that platforms use to provision, gain access to, and manage service offerings. For more information about the Open Service Broker API, see resources available online including those at openservicebrokerapi.org.

OCI Service Broker for Kubernetes is an implementation of the Open Service Broker API. OCI Service Broker for Kubernetes is specifically for interacting with Oracle Cloud Infrastructure services from Kubernetes clusters. It includes service broker adapters to bind to the following Oracle Cloud Infrastructure services:

- Object Storage
- Autonomous Transaction Processing
- Autonomous Data Warehouse
- Streaming
You can add OCI Service Broker for Kubernetes to clusters you've created with Oracle Cloud Infrastructure Container Engine for Kubernetes to interact with the Oracle Cloud Infrastructure services listed above. Having added OCI Service Broker for Kubernetes to a cluster, you don't have to manually provision and de-provision the Oracle Cloud Infrastructure services each time you deploy or un-deploy an application on the cluster. Instead, you interact with the Oracle Cloud Infrastructure services by using kubectl to call the Open Service Broker APIs implemented by OCI Service Broker for Kubernetes.

OCI Service Broker for Kubernetes is available as a Helm chart, a Docker container, and as source code from Github. For more information about OCI Service Broker for Kubernetes, see the OCI Service Broker for Kubernetes documentation in the Github repository.

**Adding OCI Service Broker for Kubernetes to a Cluster**

To add OCI Service Broker for Kubernetes to a cluster, follow the detailed instructions in the Github repository. For convenience, here's a high-level summary of the steps involved:

1. **Install OCI Service Broker for Kubernetes.** During this step, you will typically:
   - Install the Service Catalog.
   - Install the svcat tool.
   - Deploy OCI Service Broker for Kubernetes.
   - Grant RBAC permissions and roles.
   - Register OCI Service Broker for Kubernetes.
   
   For more information about installation, see the OCI Service Broker for Kubernetes documentation in the Github repository.

2. **Secure OCI Service Broker for Kubernetes.** During this step, you will typically:
   - Restrict access to Service Catalog resources using RBAC permissions and roles.
   - Configure TLS for OCI Service Broker for Kubernetes.
   - Set up an Oracle Cloud Infrastructure user for use by OCI Service Broker for Kubernetes.
   - Set up appropriate policies to control access to resources (according to the Oracle Cloud Infrastructure services to be used).
   - Limit access to the OCI Service Broker for Kubernetes endpoint using NetworkPolicy.
   - Stand up an etcd cluster for Service Catalog and OCI Service Broker for Kubernetes.
   - Protect sensitive values by creating secrets.
   
   The security configuration to choose will depend on your particular requirements. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.

3. **Provision and bind to the required Oracle Cloud Infrastructure services.** During this step, you will typically:
   - Provide service provision request parameters.
   - Provide service binding request parameters.
   - Provide service binding response credentials.
   
   The details to provide will depend on the Oracle Cloud Infrastructure service to bind to. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.

**Example: Setting Up an Ingress Controller on a Cluster**

You can set up different open source ingress controllers on clusters you have created with Container Engine for Kubernetes.

This topic explains how to set up an example ingress controller along with corresponding access control on an existing cluster. Having set up the ingress controller, this topic describes how to use the ingress controller with an example hello-world backend, and how to verify the ingress controller is working as expected.
Example Components

The example includes an ingress controller and a hello-world backend.

Ingress Controller Components

The ingress controller comprises:

- An ingress controller deployment called `nginx-ingress-controller`. The deployment deploys an image that contains the binary for the ingress controller and Nginx. The binary manipulates and reloads the `/etc/nginx/nginx.conf` configuration file when an ingress is created in Kubernetes. Nginx upstreams point to services that match specified selectors.
- An ingress controller service called `ingress-nginx`. The service exposes the ingress controller deployment as a LoadBalancer type service. Because Container Engine for Kubernetes uses an Oracle Cloud Infrastructure integration/cloud-provider, a load balancer will be dynamically created with the correct nodes configured as a backend set.

Backend Components

The hello-world backend comprises:

- A backend deployment called `docker-hello-world`. The deployment handles default routes for health checks and 404 responses. This is done by using a stock hello-world image that serves the minimum required routes for a default backend.
- A backend service called `docker-hello-world-svc`. The service exposes the backend deployment for consumption by the ingress controller deployment.

Setting Up the Example Ingress Controller

In this section, you create the access rules for ingress. You then create the example ingress controller components, and confirm they are running.

Creating the Access Rules for the Ingress Controller

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.
2. If your Oracle Cloud Infrastructure user is a tenancy administrator, skip the next step and go straight to Creating the Service Account, and the Ingress Controller on page 955.
3. If your Oracle Cloud Infrastructure user is not a tenancy administrator, in a terminal window, grant the user the Kubernetes RBAC cluster-admin clusterrole on the cluster by entering:

```
kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user-OCID>
```

where:

- `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
- `<user-OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

For example:

```
kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --user=ocid1.user.oc1..aaaaa...zutq
```
Creating the Service Account, and the Ingress Controller

1. Run the following command to create the `nginx-ingress-controller` ingress controller deployment, along with the Kubernetes RBAC roles and bindings:

   ```bash
   kubectl apply -f https://raw.githubusercontent.com/kubernetes/ingress-nginx/nginx-0.30.0/deploy/static/mandatory.yaml
   ```

2. Create and save the file `cloud-generic.yaml` containing the following code to define the `ingress-nginx` ingress controller service as a load balancer service:

   ```yaml
   kind: Service
   apiVersion: v1
   metadata:
     name: ingress-nginx
     namespace: ingress-nginx
     labels:
       app.kubernetes.io/name: ingress-nginx
       app.kubernetes.io/part-of: ingress-nginx
   spec:
     type: LoadBalancer
     selector:
       app.kubernetes.io/name: ingress-nginx
       app.kubernetes.io/part-of: ingress-nginx
     ports:
       - name: http
         port: 80
         targetPort: http
       - name: https
         port: 443
         targetPort: https
   ```

3. Using the file you just saved, create the `ingress-nginx` ingress controller service by running the following command:

   ```bash
   kubectl apply -f cloud-generic.yaml
   ```

Verifying the `ingress-nginx` Ingress Controller Service is Running as a Load Balancer Service

1. View the list of running services by entering:

   ```bash
   kubectl get svc -n ingress-nginx
   ```

The output from the above command shows the services that are running:

```
NAME            TYPE           CLUSTER-IP     EXTERNAL-IP    PORT(S)
AGE
```
The EXTERNAL-IP for the ingress-nginx ingress controller service is shown as <pending> until the load balancer has been fully created in Oracle Cloud Infrastructure.

2. Repeat the kubectl get svc command until an EXTERNAL-IP is shown for the ingress-nginx ingress controller service:

```
kubectl get svc -n ingress-nginx
```

The output from the above command shows the EXTERNAL-IP for the ingress-nginx ingress controller service:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ingress-nginx</td>
<td>LoadBalancer</td>
<td>10.96.229.38</td>
<td>129.146.214.219</td>
<td>80:30756/TCP</td>
</tr>
</tbody>
</table>

### Creating the TLS Secret

A TLS secret is used for SSL termination on the ingress controller.

1. Output a new key to a file. For example, by entering:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj "/CN=nginxsvc/O=nginxsvc"
```

To generate the secret for this example, a self-signed certificate is used. While this is okay for testing, for production, use a certificate signed by a Certificate Authority.

**Note:**

Under Windows, you may need to replace "/CN=nginxsvc/O=nginxsvc" with "//CN=nginxsvc\O=nginxsvc". For example, this is necessary if you run the openssl command from a Git Bash shell.

2. Create the TLS secret by entering:

```
kubectl create secret tls tls-secret --key tls.key --cert tls.crt
```

### Setting Up the Example Backend

In this section, you define a hello-world backend service and deployment.

### Creating the docker-hello-world Service Definition

1. Create the file hello-world-ingress.yaml containing the following code. This code uses a publicly available hello-world image from Docker Hub. You can substitute another image of your choice that can be run in a similar manner.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: docker-hello-world
  labels:
    app: docker-hello-world
spec:
```

Container Engine for Kubernetes

```yaml
selector:
  matchLabels:
    app: docker-hello-world
replicas: 3

template:
  metadata:
    labels:
      app: docker-hello-world
  spec:
    containers:
      - name: docker-hello-world
        image: scottsbaldwin/docker-hello-world:latest
        ports:
          - containerPort: 80
---

apiVersion: v1
kind: Service
metadata:
  name: docker-hello-world-svc
spec:
  selector:
    app: docker-hello-world
  ports:
    - port: 8088
      targetPort: 80
  type: ClusterIP

```

Note the docker-hello-world service's type is ClusterIP, rather than LoadBalancer, because this service will be proxied by the ingress-nginx ingress controller service. The docker-hello-world service does not need public access directly to it. Instead, the public access will be routed from the load balancer to the ingress controller, and from the ingress controller to the upstream service.

2. Create the new hello-world deployment and service on nodes in the cluster by running the following command:

```
kubectl create -f hello-world-ingress.yaml
```

### Using the Example Ingress Controller to Access the Example Backend

In this section you create an ingress to access the backend using the ingress controller.

#### Creating the Ingress Resource

1. Create the file `ingress.yaml` and populate it with this code:

```yaml
apiVersion: networking.k8s.io/v1beta1
kind: Ingress
metadata:
  name: hello-world-ing
  annotations:
    kubernetes.io/ingress.class: "nginx"
spec:
  tls:
    - secretName: tls-secret
  rules:
    - http:
        paths:
          - backend:
              serviceName: docker-hello-world-svc
              servicePort: 8088
```

Oracle Cloud Infrastructure User Guide
2. Create the resource by entering:

```
kubectl create -f ingress.yaml
```

## Verifying that the Example Components are Working as Expected

In this section, you confirm that all of the example components have been successfully created and are operating as expected. The `docker-hello-world-svc` service should be running as a ClusterIP service, and the `ingress-nginx` service should be running as a LoadBalancer service. Requests sent to the ingress controller should be routed to nodes in the cluster.

### Obtaining the External IP Address of the Load Balancer

To confirm the `ingress-nginx` service is running as a LoadBalancer service, obtain its external IP address by entering:

```
kubectl get svc --all-namespaces
```

The output from the above command shows the services that are running:

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>docker-hello-world-svc</td>
<td>ClusterIP</td>
<td>10.96.83.247</td>
</tr>
<tr>
<td></td>
<td>8088/TCP</td>
<td>16s</td>
<td></td>
</tr>
<tr>
<td>default</td>
<td>kubernetes</td>
<td>ClusterIP</td>
<td>10.96.0.1</td>
</tr>
<tr>
<td></td>
<td>443/TCP</td>
<td>1h</td>
<td></td>
</tr>
<tr>
<td>ingress-nginx</td>
<td>ingress-nginx</td>
<td>LoadBalancer</td>
<td>10.96.229.38</td>
</tr>
<tr>
<td>129.146.214.219</td>
<td>80:30756/TCP,443:30118/TCP</td>
<td>5m</td>
<td></td>
</tr>
<tr>
<td>kube-system</td>
<td>kube-dns</td>
<td>ClusterIP</td>
<td>10.96.5.5</td>
</tr>
<tr>
<td></td>
<td>53/UDP,53/TCP</td>
<td>1h</td>
<td></td>
</tr>
</tbody>
</table>

### Sending cURL Requests to the Load Balancer

1. Use the external IP address of the `ingress-nginx` service (for example, 129.146.214.219) to curl an http request by entering:

```
curl -I http://129.146.214.219
```

Example output from the above command:

```
HTTP/1.1 301 Moved Permanently
Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
Date: Thu, 07 Sep 2017 15:20:16 GMT
Server: nginx/1.13.2
Location: https://129.146.214.219/
Content-Type: text/html
Content-Length: 185
Proxy-Connection: Keep-Alive
```
Strict-Transport-Security: max-age=15724800; includeSubDomains;

The output shows a 301 redirect and a Location header that suggest that http traffic is being redirected to https.

2. Either cURL against the https url or add the `-L` option to automatically follow the location header. The `-k` option instructs cURL to not verify the SSL certificates. For example, by entering:

```
curl -ikL http://129.146.214.219
```

Example output from the above command:

```
HTTP/1.1 301 Moved Permanently
Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
Date: Thu, 07 Sep 2017 15:22:29 GMT
Server: nginx/1.13.2
Location: https://129.146.214.219/
Content-Type: text/html
Content-Length: 185
Proxy-Connection: Keep-Alive
Strict-Transport-Security: max-age=15724800; includeSubDomains;

HTTP/1.1 200 Connection established
HTTP/1.1 200 OK
Server: nginx/1.13.2
Date: Thu, 07 Sep 2017 15:22:30 GMT
Content-Type: text/html
Content-Length: 71
Connection: keep alive
Last-Modified: Thu, 07 Sep 2017 15:17:24 GMT

<h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
```

The last line of the output shows the HTML that is returned from the pod whose hostname is `docker-hello-world-1732906117-0ztkm`.

3. Issue the cURL request several times to see the hostname in the HTML output change, demonstrating that load balancing is occurring:

```
$ curl -k https://129.146.214.219
<h1>Hello webhook world from: docker-hello-world-1732906117-6115l</h1>

$ curl -k https://129.146.214.219
<h1>Hello webhook world from: docker-hello-world-1732906117-7r89v</h1>

$ curl -k https://129.146.214.219
<h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
```
Inspecting nginx.conf

The nginx-ingress-controller ingress controller deployment manipulates the nginx.conf file in the pod within which it is running.

1. Find the name of the pod running the nginx-ingress-controller ingress controller deployment by entering:

   ```bash
   kubectl get po -n ingress-nginx
   ```

   The output from the above command shows the name of the pod running the nginx-ingress-controller ingress controller:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>nginx-ingress-controller-110676328-h86xg</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>1h</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Use the name of the pod running the nginx-ingress-controller ingress controller deployment to show the contents of nginx.conf by entering the following kubectl exec command:

   ```bash
   kubectl exec -n ingress-nginx -it nginx-ingress-controller-110676328-h86xg -- cat /etc/nginx/nginx.conf
   ```

3. Look for `proxy_pass` in the output. There will be one for the default backend and another that looks similar to:

   ```text
   proxy_pass http://upstream_balancer;
   ```

   This shows that Nginx is proxying requests to an upstream called `upstream_balancer`.

4. Locate the upstream definition in the output. It will look similar to:

   ```text
   upstream upstream_balancer {
       server 0.0.0.1:1234; # placeholder
       balancer_by_lua_block {
           tcp_udpBalancer.balance()
       }
   }
   ```

   The upstream is proxying via Lua.

Example: Installing Calico and Setting Up Network Policies

The Kubernetes networking model assumes containers (pods) have unique and routable IP addresses within a cluster. In the Kubernetes networking model, containers communicate with each other using those IP addresses, regardless of whether the containers are deployed on the same node in a cluster or on a different node. The Container Networking Interface (CNI) is the API that enables containers to communicate with the network using IP addresses.

By default, pods accept traffic from any source. To enhance cluster security, pods can be 'isolated' by selecting them in a network policy (the Kubernetes NetworkPolicy resource). A network policy is a specification of how groups of pods are allowed to communicate with each other and other network endpoints. NetworkPolicy resources use labels to select pods and to define rules that specify what traffic is allowed to the selected pods. If a NetworkPolicy in a cluster namespace selects a particular pod, that pod will reject any connections that are not allowed by any NetworkPolicy. Other pods in the namespace that are not selected by a NetworkPolicy will continue to accept all traffic. For more information about network policies, see the Kubernetes documentation.

Network policies are implemented by the CNI network provider. Simply creating the NetworkPolicy resource without a CNI network provider to implement it will have no effect. Note that not all CNI network providers implement the NetworkPolicy resource.
Clusters you create with Container Engine for Kubernetes have flannel installed as the default CNI network provider. Flannel is a simple overlay virtual network that satisfies the requirements of the Kubernetes networking model by attaching IP addresses to containers. For more information about flannel, see the flannel documentation.

Although flannel satisfies the requirements of the Kubernetes networking model, it does not support NetworkPolicy resources. If you want to enhance the security of clusters you create with Container Engine for Kubernetes by implementing network policies, you have to install and configure a network provider that does support NetworkPolicy resources. One such provider is Calico (refer to the Kubernetes documentation for a list of other network providers). Calico is an open source networking and network security solution for containers, virtual machines, and native host-based workloads. For more information about Calico, see the Calico documentation.

You can manually install Calico alongside flannel in clusters you have created using Container Engine for Kubernetes.

### Note:
- Only the use of open source Calico is supported. Use of Calico Enterprise is not supported.
- If you install Calico on a cluster that has existing node pools in which pods are already running, you will have to recreate the pods when the Calico installation is complete. For example, by running the `kubectl rollout restart` command. If you install Calico on a cluster before creating any node pools in the cluster (recommended), you can be sure that there will be no pods to recreate.

### Installing Calico manually

Having created a cluster using Container Engine for Kubernetes (using either the Console or the API), you can subsequently install Calico on the cluster (alongside flannel) to support network policies.

For convenience, Calico installation instructions are included below, based on Calico version 3.10. Note that Calico installation instructions vary between Calico versions. For information about installing different versions of Calico, always refer to the Calico documentation for installing Calico for network policy enforcement only.

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 876.

2. In a terminal window, download the Calico policy-only manifest for the Kubernetes API datastore by entering:

   ```
curl https://docs.projectcalico.org/v3.10/manifests/calico-policy-only.yaml -o calico.yaml
   
   Note that the url differs, according to the version of Calico that you want to install. Refer to the Calico documentation for instructions to install a particular version of Calico.

3. The calico.yaml file includes multiple references to the pod CIDR block value. In the downloaded calico.yaml file, the pod CIDR block value is initially set to 192.168.0.0/16. If the pod CIDR block value of the cluster created by Container Engine for Kubernetes is 192.168.0.0/16, skip this step. However, if the pod CIDR block value of the cluster created by Container Engine for Kubernetes is a different value (such as the default value of
10.244.0.0/16), you have to change the initial value in the calico.yaml file. The steps below show one way to do that:

a. Set the value of an environment variable to the pod CIDR block value. For example, by entering a command like:

```bash
echo $POD_CIDR
```

b. Replace the default value 192.168.0.0/16 in the calico.yaml file with the actual pod CIDR block value of the cluster created by Container Engine for Kubernetes. For example, by entering a command like:

```bash
sed -i -e "s?192.168.0.0/16?$POD_CIDR?g" calico.yaml
```

4. The calico.yaml file defines a deployment named calico-typha, which has a replica count of 1 by default. You might want to consider changing this default replica count for large clusters or production environments. Calico recommends:

- At least one replica for every 200 nodes, up to a maximum of 20.
- A minimum of three replicas in production environments to reduce the impact of rolling upgrades and failures (the number of replicas should always be less than the number of nodes, otherwise rolling upgrades will stall).

To change the replica count, open the calico.yaml file in a text editor and change the value of the `replicas` setting:

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: calico-typha
...
spec:
...
  replicas: <number-of-replicas>
```

Note that the way to set the replica count differs, according to the Calico version you've installed. Refer to the Calico documentation to find out how to set the replica count for the version you've installed.

5. Install and configure Calico by entering the following command:

```bash
kubectl apply -f calico.yaml
```

### Setting up Network Policies

Having installed Calico on a cluster you've created with Container Engine for Kubernetes, you can create Kubernetes NetworkPolicy resources to isolate pods as required.

For NetworkPolicy examples and how to use them, see the Calico documentation and specifically:

- Kubernetes policy, demo
- Kubernetes policy, basic tutorial
- Kubernetes policy, advanced tutorial

Note that the examples vary, according to the Calico version you've installed.

### Frequently Asked Questions About Container Engine for Kubernetes

This topic provides answers to some frequently asked questions about Container Engine for Kubernetes.
Does Container Engine for Kubernetes Support Alpha and Beta Features in Kubernetes?

Periodically, Kubernetes releases new features. New Kubernetes features are introduced in the following stages, as described in the Kubernetes documentation and summarized below:

- **Alpha stage**: An Alpha feature is disabled by default, might contain bugs, and might change or be dropped at any time. The feature is recommended for short-lived testing clusters only.
- **Beta stage**: A Beta feature is usually enabled by default, has been well-tested, and will not be dropped. However, details of the feature might change in incompatible ways, and is recommended for non-business-critical use only.
- **General Availability stage**: A Generally Available (or Stable) feature is always enabled, and will appear in released software for many subsequent versions.

Container Engine for Kubernetes supports the use of Kubernetes Beta features that are enabled by default in Kubernetes. Container Engine for Kubernetes does not support Alpha features, nor Beta features that are disabled by default.

For more information about Kubernetes Alpha and Beta features, see the Kubernetes documentation.

Container Engine for Kubernetes Metrics

You can monitor the health, capacity, and performance of Kubernetes clusters managed by Container Engine for Kubernetes using metrics, alarms, and notifications.

This topic describes the metrics emitted by Container Engine for Kubernetes in the `oci_oke` metric namespace.

Resources: clusters, worker nodes

Overview of the Container Engine for Kubernetes Service Metrics

Container Engine for Kubernetes metrics help you monitor Kubernetes clusters, along with node pools and individual worker nodes. You can use metrics data to diagnose and troubleshoot cluster and node pool issues.

To view a default set of metrics charts in the Console, navigate to the cluster you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: `oci_oke`

The metrics listed in the following tables are automatically available for any Kubernetes clusters you create. You do not need to enable monitoring on the resource to get these metrics.

Container Engine for Kubernetes metrics include the following dimensions:

**RESOURCEID**

- The OCID of the resource to which the metric applies.

**RESOURCEDisplayNAME**

- The name of the resource to which the metric applies.

**RESPONSECODE**

- The response code sent from the Kubernetes API server.
RESPONSEGROUP

The response code group, based on the response code's first digit (for example, 2xx, 3xx, 4xx, 5xx).

CLUSTERID

The OCID of the cluster to which the metric applies.

NODEPOOLID

The OCID of the node pool to which the metric applies.

NODESTATE

The state of the compute instance hosting the worker node. For example, ACTIVE, CREATING, DELETING, DELETED, FAILED, UPDATING, INACTIVE.

NODECONDITION

The condition of the worker node, as indicated by the Kubernetes API server. For example, Ready, MemoryPressure, PIDPressure, DiskPressure, NetworkUnavailable.

AVAILABILITYDOMAIN

The availability domain where the compute instance resides.

FAULTDOMAIN

The fault domain where the compute instance resides.

### Using the Console

#### To view default metric charts for a single cluster

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Kubernetes Clusters**.

2. Select the region you are using with Container Engine for Kubernetes.

3. Select the compartment containing the cluster for which you want to view metrics.

   The **Clusters** page shows all the clusters in the compartment you selected.

4. Click the name of the cluster for which you want to view metrics.

5. Under **Resources**, click **Metrics**.

   The **Metrics** tab displays a chart for each metric for the cluster that is emitted by the Container Engine for Kubernetes metric namespace. To see metrics for a node pool in the cluster, display the **Node Pools** tab, click the name of the node pool, and display the **Metrics** tab. To see metrics for a worker node in the node pool, display the **Nodes** tab and click the **View Metrics** link beside the name of the worker node. For more information about the emitted metrics, see **Available Metrics: oci_oke** on page 963.

   For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**Not seeing the cluster metrics data you expect?**

If you don't see the metrics data for a cluster that you expect, see the following possible causes and resolutions.
## Container Engine for Kubernetes

### Problem

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>I know the Kubernetes API server returned some error responses but the API Server Response Count chart doesn't show them.</td>
<td>The responses might have been returned outside the time period covered by the API Server Response Count chart.</td>
<td>Confirm the Start Time and End Time cover the period when the responses were returned.</td>
<td>Adjust the Start Time and End Time as necessary.</td>
</tr>
<tr>
<td>I know the Kubernetes API server returned some error responses but the API Server Response Count chart doesn't show them, even though the responses were returned between the Start Time and End Time.</td>
<td>Although the responses were returned between the Start Time and End Time, the x-axis (window of data display) might be excluding the responses.</td>
<td>Confirm the x-axis (window of data display) covers the period when the responses were returned.</td>
<td>Adjust the x-axis (window of data display) as necessary.</td>
</tr>
<tr>
<td>I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>This is expected behavior. If there is no metrics data to show in the selected interval, the data line is discontinuous.</td>
<td>Increase the Interval (for example, from 1 minute to 5 minutes, or from 1 minute to 1 hour).</td>
<td>Adjust the Interval as necessary.</td>
</tr>
</tbody>
</table>

### Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter
13

Data Transfer

This chapter explains how to migrate data to Oracle Cloud Infrastructure using Disk-Based Data Import and Data Transfer Appliance.

Overview of Data Transfer Service

Oracle offers offline data transfer solutions that let you migrate data to Oracle Cloud Infrastructure. You can also export data currently residing in Oracle Cloud Infrastructure to your data center offline. Moving data over the public internet is not always feasible because of high network costs, unreliable network connectivity, long transfer times, and security concerns. Our transfer solutions address these pain points, are easy to use, and provide faster data upload compared to over-the-wire data transfer.

Note:

To simplify this Data Transfer documentation, we generically refer to Object Storage to mean that you can transfer data into a bucket in either the Object Storage tier or Archive Storage tier.

DISK-BASED DATA TRANSFER

You send your data as files on encrypted commodity disk to an Oracle transfer site. Operators at the Oracle transfer site upload the files into your designated Object Storage bucket in your tenancy.

This transfer solution requires you to source and purchase the disk used to transfer data to Oracle Cloud Infrastructure. The disk is shipped back to you after the data is successfully uploaded.

See Data Import - Disk on page 970 for details.

APPLIANCE-BASED DATA TRANSFER

You send your data as files on secure, high-capacity, Oracle-supplied storage appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the data into your designated Object Storage bucket in your tenancy.

This solution supports data transfer when you are migrating a large volume of data and when using a transfer disk is not a practical alternative. You do not need to write any code or purchase any hardware. Oracle supplies the transfer appliance and software required to manage the transfer.

See Data Import - Appliance on page 1015 for details.

APPLIANCE-BASED DATA EXPORT

You export your data from your Oracle Cloud Infrastructure Object Storage bucket to your data center using an Oracle-provided appliance.

This solution is useful if you have media content or processed datasets you need to share with a customer or business partner.

See Appliance Data Export on page 1082 for details.

Supported Regions

Data transfer and export are supported in the following regions:
• US East (Ashburn)
• US West (Phoenix)
• US DoD East (Ashburn)
• US DoD North (Chicago)
• US DoD West (Phoenix)
• Germany Central (Frankfurt)
• UK South (London)
• Japan East (Tokyo)
• Japan Central (Osaka)

Limits on Data Transfer Service Resources

When you sign up for Oracle Cloud Infrastructure, a set of service limits is configured for your tenancy. The service limit is the quota or allowance set on a resource. Verify that your service limits are set appropriately before you begin the data transfer process.

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Tagging Resources

Apply tags to your resources to help organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 211.

Automation for Objects Using the Events Service

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Notifications

You can set up different types of notifications to alert you when any change happens to during your data transfer. See Notifications Overview on page 3350.

Note:

To fully utilize notifications, setup events that trigger the notifications. See Overview of Events on page 1784 for more information.

You can also set up notifications for appliance-based import and export jobs using a CLI command. The notifications run from the CLI provides a more convenient process than using the Notifications and Events services. Instructions for setting these CLI-based notifications are in the Preparation topics for appliance-based import and export.

Inputting Text into Data Transfer

You must use only ASCII text for all inputs to Data Transfer. This requirement applies to the browser-based Console and CLIs.

What's Next

Now you are ready to prepare for your data transfer or export. See the following pages for more information on each of the data transfer or export methods:

• Data Import - Disk on page 970
Data Import - Disk

Disk-Based Data Import is one of Oracle's offline data transfer solutions that lets you migrate data to Oracle Cloud Infrastructure. You send your data as files on an encrypted disk to an Oracle transfer site. Operators at the Oracle transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

Note:
Oracle does not certify or test disks you intend to use for disk import jobs. Calculate your disk capacity requirements and disk I/O to determine what USB 2.0/3.0 disk works best for your data transfer needs.

Disk-Based Data Import Concepts

IMPORT DISK
An import disk is a user-supplied storage device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You copy your data to the import disk and ship it in a parcel to Oracle to upload your data.

Disk-Based Data Import supports external USB 2.0/3.0 hard disk drives.

Note:
Pin-code protected devices and physical-key protected devices are currently not supported.

TRANSFER DISK
A transfer disk is the logical representation of an import disk that has been prepared to copy and upload data to Oracle Cloud Infrastructure.

Note:
The terms transfer disk and import disk both represent the disk being used to move your data to Oracle Cloud Infrastructure. Transfer disk is used in the context of configuring the disk within the transfer job and transfer package. Import disk is used when physically handling the disk, such as connecting it to the Data Host or mailing it to Oracle.

TRANSFER JOB
A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job consists of one or more transfer packages that each contain a single transfer disk.

DATA TRANSFER UTILITY
The Data Transfer Utility is the command line software that Oracle provides for you to prepare the transfer disk for your data and for shipment to Oracle. In addition, you can use this software to manage transfer jobs and packages.

Note:
You can only run Data Transfer Utility tasks for a supported Linux machine. Windows-based machines are not supported in disk-based transfer jobs.
DATA HOST

The host computer on your site that stores the data you intend to copy to the disk for migration to Oracle Cloud Infrastructure.

Note:

Only Linux machines can be used as Data Hosts.

TRANSFER PACKAGE

A transfer package is the logical representation of the parcel containing the transfer disk that you ship to Oracle to upload to Oracle Cloud Infrastructure.

BUCKET

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy whose policies determine what actions a user can perform.

DATA TRANSFER ADMINISTRATOR

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs.

DATA TRANSFER UPLOAD USER

A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from your transfer disk to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure.

Roles and Responsibilities

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

- **Project Sponsor**: Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project. The Project Sponsor is also responsible for signing legal documentation and setting up notifications for the data import.

- **Infrastructure Engineer**: Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

- **Data Administrator**: Responsible for identifying and preparing the data to be transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.

Task Flow for Disk-Based Data Import

Here is a high-level overview of the tasks involved in transferring data to Oracle Cloud Infrastructure using Data Transfer Disk. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.
Secure Disk Data Transfer to Oracle Cloud Infrastructure

This section highlights the security details of the Data Transfer Service process.

- The Data Transfer Utility uses the standard Linux dm-crypt and LUKS utilities to encrypt block devices.
- The dm-crypt software generates a master AES-256 bit encryption key that is used for all data written to or read from the disk. That key is protected by an encryption passphrase that the user must know to access the encrypted data.
- When the data transfer administrator uses the Data Transfer Utility to create a disk, Oracle Cloud Infrastructure creates a strong encryption passphrase that is displayed to the user and passed to dm-crypt. The passphrase is displayed to standard output only once and cannot be retrieved again. Copy this passphrase to a durable, secure location for future reference.
• For extra security, you can also encrypt your own data with your own encryption keys. Before copying your data to the transfer disk, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
• All network communication between the Data Transfer Utility and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).
• After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the config_upload_user configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the config_upload_user file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

| Note: |
| Data Transfer Service Does Not Support Passphrases on Private Keys |
| While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the config_upload_user. If you use a passphrase, Oracle personnel cannot upload your data. |

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See Installing the Data Transfer Utility on page 974 for more information about the required configuration files.

• When you disconnect or lock a transfer disk using the Data Transfer Utility, the original encryption passphrase is required to once again access the disk. If the encryption passphrase is not known or lost, you cannot access the data on the transfer disk. To reuse a transfer disk, you must reformat the disk. Reformatting a disk removes all the data.
• Oracle retrieves the encryption passphrase for a transfer disk from Oracle Cloud Infrastructure. Oracle uses the passphrase to decrypt, mount the transfer disk, and upload the data to the designated bucket in the tenancy.
• After processing a transfer package, Oracle returns the transfer disk attached to the transfer package using the return shipping label you provide.
• To protect your data, we make the data on the disk unrecoverable before shipping the transfer disk back to you. To comply with customs regulations, we wipe the disk completely before shipping it back to international shipping addresses.

Ways to Manage Disk Data Transfers

We provide two ways to manage disk-based data transfers:

• The Data Transfer Utility is a full-featured command line tool for disk-based data transfers only (appliance-based data transfers use a different command line tool). For more information and installation instructions, see Installing the Data Transfer Utility on page 974.
• The Console is an easy-to-use, partial-featured browser-based interface. For more information, see Signing In to the Console on page 41.

| Note: |
| You can perform many data transfer tasks using either the Console or the Data Transfer Utility. However, there are some tasks you can only perform using the Data Transfer Utility (for example, creating and locking the transfer disk). describes the management tasks in detail and guides you to the appropriate management interface to use for each task. |

What's Next

You are now ready to begin preparation for the Disk-Based Data Import. See Preparing for Disk Data Transfers on page 974 for more information.
Preparing for Disk Data Transfers

This topic describes the tasks associated with preparing for the Disk-Based Data Import. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 971.

Import Disk Requirements

You are responsible for performing following tasks in order:

• Purchasing the required number of hard drives to migrate your data to Oracle Cloud Infrastructure. Use USB 2.0/3.0 external hard disk drives (HDD) with a single partitioned file system containing your data.

  Note:
  Oracle does not certify or test disks you intend to use for disk import jobs. Calculate your disk capacity requirements and disk I/O to determine what USB 2.0/3.0 disk works best for your data transfer needs.

• Copying the data to the HDDs following the procedures described in this import disk documentation.

• Shipping the disks to the specified Oracle data transfer site.

After the data is copied successfully to Oracle Cloud Infrastructure Object Storage, the hard drives are shipped back to you in the same encrypted state that they were received.

Installing the Data Transfer Utility

This topic describes how to install and configure the Data Transfer Utility for use in disk-based data transfers. In addition, this topic describes the syntax for the Data Transfer Utility commands.

Important:

With this release, the Data Transfer Utility only supports disk-based data transfers. Use of the Data Transfer Utility for appliance-based transfers has been replaced with the Oracle Cloud Infrastructure command line interface (CLI).

The Data Transfer Utility is licensed under the Universal Permissive License 1.0 and the Apache License 2.0. Third-party content is separately licensed as described in the code.

Note:

The Data Transfer Utility must be run as the root user.

Prerequisites

To install and use the Data Transfer Utility, obtain the following:

• An Oracle Cloud Infrastructure account.

• The required Oracle Cloud Infrastructure users and groups with the required IAM policies.

  See Creating the Required IAM Users, Groups, and Policies on page 980 for details.
• A Data Host machine with the following installed:
  • Oracle Linux 6 or greater, Ubuntu 14.04 or greater, or SUSE 11 or greater. All Linux operating systems must have the ability to create an EXT file system.

  Note:
  Windows-based machines are not supported in disk-based transfer jobs.

  • Java 1.8 or Java 1.11
  • hdparm 9.0 or later
  • Cryptsetup 1.2.0 or greater
  • Firewall access: If you have a restrictive firewall in the environment where you are using the Data Transfer Utility, you may need to open your firewall configuration to the following IP address ranges: 140.91.0.0/16. You also need to open access to the object storage IP address ranges: 134.70.0.0/17.

Installation
Download and install the Data Transfer Utility installer that corresponds to your Data Host's operating system.

To install the Data Transfer Utility on Debian or Ubuntu
1. Download the installation .deb file.
2. Issue the apt install command as the root user that has write permissions to the /opt directory.

   ```
   sudo apt install ./dts-X.Y.Z.x86_64.deb
   ```

   X.Y.Z represents the version numbers that match the installer you downloaded.

3. Confirm that the Data Transfer Utility installed successfully.

   ```
   sudo dts --version
   ```

   Your Data Transfer Utility version number is returned.

To install the Data Transfer Utility on Oracle Linux or Red Hat Linux
1. Download the installation .rpm file.
2. Issue the yum install command as the root user that has write permissions to the /opt directory.

   ```
   sudo yum localinstall ./dts-X.Y.Z.x86_64.rpm
   ```

   X.Y.Z represents the version numbers that match the installer you downloaded.

3. Confirm that the Data Transfer Utility installed successfully.

   ```
   sudo dts --version
   ```

   Your Data Transfer Utility version number is returned.

Configuration
Before using the Data Transfer Utility, you must create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials. One configuration file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The other configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Base Data Transfer Directory
Create a base Oracle Cloud Infrastructure directory:

```bash
mkdir /root/.oci/
```
Configuration File for the Data Transfer Administrator

Create a data transfer administrator configuration file /root/.oci/config with the following structure:

```ini
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user’s private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `##profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1

[PROFILE1]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1
```

By default, the `DEFAULT` profile is used for all Data Transfer Utility commands. For example:

```
dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name> --device-type <disk>
```

Instead, you can issue any Data Transfer Utility command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name> --device-type <disk> --profile <profile_name>
```

Using the example configuration file above, the `<profile_name>` would be `profile1`.

Configuration File for the Data Transfer Upload User

Create a data transfer upload user /root/.oci/config_upload_user configuration file with the following structure:

```ini
[DEFAULT]
user=<The OCID for the data transfer upload user>
```
fingerprint=<The fingerprint of the above user's public key>  
key_file=<The _absolute_ path to the above user's private key file on the host machine>  
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>  
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>

For example:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

**Important:**

Creating an upload user configuration file with multiple profiles is *not* supported.

**Configuration File Entries**

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

**Note:**

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>key_file</td>
<td>Full path and filename of the private key.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 4179.
### Entry

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenancy</td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 180. Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London).</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can verify the data transfer upload user credentials using the following command:

```
dts job verify-upload-user-credentials --bucket <bucket_name>
```

### Configuration File Location

The location of the configuration files is `~/oci/config`.

### Using the Data Transfer Utility

This section provides an overview of the syntax for the Data Transfer Utility.

**Important:**

The Data Transfer Utility must be run as the root user.

You can specify Data Transfer Utility command options using the following commands:

- `--option <value>`
- `--option=<value>`

### Syntax

The basic Data Transfer Utility syntax is:

```
dts <resource> <action> <options>
```

This syntax is applied to the following:

- `dts` is the shortened utility command name
- `job` is an example of a `<resource>`
- `create` is an example of an `<action>`
- Other utility strings are `<options>`

The following examples show typical Data Transfer Utility commands to create a transfer job:

```
dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name "mycompany transfer1" --bucket mybucket --device-type disk
```
Or:

```bash
dts job create --compartment-id=compartment-id 
  ocid.compartment.oc1..exampleuniqueID --display-name="mycompany transfer1"
  --bucket=mybucket --device-type=disk
```

**Note:**
In the previous examples, provide a friendly name for the transfer job using the `--display-name` option. Avoid entering confidential information.

### Finding Out the Installed Version of the Data Transfer Utility

You can get the installed version of the Data Transfer Utility using `--version` or `-v`. For example:

```bash
dts --version
0.6.183
```

### Accessing Data Transfer Utility Help

All Data Transfer Utility help commands have an associated help component you can access from the command line. To view the help, enter any command followed by the `--help` or `-h` option. For example:

```bash
dts job --help
```

**Usage:** `job [COMMAND]`
Transfer disk or appliance job operations — `{job <action> [options]}`

**Commands:**
- `create job` Creates a new transfer disk or appliance job.
- `show details` Shows the transfer disk or appliance job details.
- `update details` Updates the transfer disk or appliance job details.
- `delete` Deletes the transfer disk or appliance job.
- `close` Closes the transfer disk or appliance job.
- `list` Lists all transfer disk or appliance jobs.
- `verify-upload-user-credentials` Verifies the transfer disk or appliance upload user credentials.

When you run the help option (`--help` or `-h`) for a specified command, all the subordinate commands and options for that level of the Data Transfer Utility are displayed. If you want to access the Data Transfer Utility help for a specific subordinate command, include it in the Data Transfer Utility string, for example:

```bash
dts job create --help
```

**Usage:** `job create --bucket=<bucket> --compartment-id=<compartmentId>
  [--defined-tags=<definedTags>] --device-type=<deviceType>
  --display-name=<displayName>
  [--freeform-tags=<freeformTags>] [--profile=<profile>]`

Creates a new transfer disk or appliance job.

- `--bucket=<bucket>` Upload bucket for the job.
- `--compartment-id=<compartmentId>` Compartment OCID.
- `--defined-tags=<definedTags>` Defined tags for the new transfer job in JSON format.
- `--device-type=<deviceType>` Device type for the job: DISK or APPLIANCE.
- `--display-name=<displayName>` Display name for the job.
Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- **Data transfer administrators** who can create and manage transfer jobs.
- **Data transfer upload users** who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups on page 2419.

An administrator creates these groups with the following policies:

- **The data transfer administrator group** requires an authorization policy that includes the following:

  ```
  Allow group <group_name> to manage data-transfer-jobs in compartment <compartment_name>
  Allow group <group_name> to manage objects in compartment <compartment_name>
  Allow group <group_name> to manage buckets in compartment <compartment_name>
  ```

  Alternatively, you can consolidate the `manage buckets` and `manage objects` policies into the following:

  ```
  Allow group <group_name> to manage object-family in compartment <compartment_name>
  ```

- **The data transfer upload user group** requires an authorization policy that includes the following:

  ```
  Allow group <group_name> to manage buckets in compartment <compartment_name> where all
  { request.permission='BUCKET_READ', target.bucket.name='<bucket_name>' }
  ```

  ```
  Allow group <group_name> to manage objects in compartment <compartment_name> where all
  { target.bucket.name='<bucket_name>', any
  { request.permission='OBJECT_CREATE', request.permission='OBJECT_OVERWRITE', request.permission='OBJECT_INSPECT' }}
  ```

To enable notifications, add the following policies:

- **Allow group <group name> to manage ons-topics in tenancy**
- **Allow group <group name> to manage ons-subscriptions in tenancy**
- **Allow group <group name> to manage cloudevents-rules in tenancy**
- **Allow group <group name> to inspect compartments in tenancy**

See Notifications Overview on page 3350 and Overview of Events on page 1784 for more information.
The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see Managing Users on page 2414.

**Important:**
For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

### Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a *compartment* in your tenancy. For details on creating the bucket to store uploaded data, see Managing Buckets on page 3398.

### Configuring Firewall Settings

Ensure that your local environment's firewall can communicate with the Data Transfer Service running on the IP address ranges: 140.91.0.0/16. You also need to open access to the Object Storage IP address ranges: 134.70.0.0/17.

### Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See Transfer Jobs on page 999 for complete details on all tasks related to transfer jobs.

**Tip:**
You can use the Console or the Data Transfer Utility to create a transfer job.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least one transfer disk with a transfer package. Identify which compartment and Object Storage bucket that Oracle is to upload your data to. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

**Note:**
It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

**To create a transfer job using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Select the designated compartment you are to use for data transfers from the list.
   A list of transfer jobs that have already been created is displayed.
3. Click Create Transfer Job.
   The Create Transfer Job dialog appears.
4. Enter a Job Name. Avoid entering confidential information. Then, select the Upload Bucket from the list.
5. Select Disk for the Transfer Device Type.
6. Click Create Transfer Job.

**To create a transfer job using the Data Transfer Utility**

```
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name>
```

<display_name> is the name of the transfer job. Avoid entering confidential information.
For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocidd.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob
```

```
Transfer Job : 
ID : ocidd.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocidd.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
freeformTags : *** none ***
definedTags : *** none ***
Packages :

Status : PREPARING
Devices : [*** none ***]
UnattachedDevices : [*** none ***]
Appliances : [*** none ***]
```

When you use the `dts job describe` command to display the details of a job, tagging details are also included in the output if you specified tags.

Optional, you can specify one or more defined or free-form tags when you create a transfer job. For more information about tagging, see Resource Tags on page 211.

**Defined Tags**

To specify defined tags when creating a job:

```
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --defined-tags '{ "<tag_namespace>": { "<tag_key>": "<value>" }}'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocidd.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

```
Transfer Job :
ID : ocidd.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocidd.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
freeformTags : *** none ***
definedTags :
  Operations :
    CostCenter : 01
Packages :
[1] :
  Label : PBNZOX9RU
```
TransferSiteShippingAddress : Oracle Data Transfer Service;
Job:JZM9PAVWH Package:PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor : FedEx
DeliveryTrackingNumber : *** none ***
ReturnDeliveryTrackingNumber : *** none ***
Status : PREPARING
Devices : [*** none ***]
UnattachedDevices : [*** none ***]
Appliances : [*** none ***]

When you use the to display the details of a job, tagging details are also included in the output if you specified tags.

Note:
Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags on page 3914 for details.

Freeform Tags
To specify freeform tags when creating a job:

dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --freeform-tags '{ "<tag_key>"":"<value>" }'

For example:

oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'

Transfer Job :
ID : ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocid.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
freeformTags :
Pittsburg_Team : brochures
definedTags : [*** none ***]
Packages :
[1] :
Label : PBNZOX9RU
TransferSiteShippingAddress : Oracle Data Transfer Service;
Job:JZM9PAVWH Package:PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor : FedEx
DeliveryTrackingNumber : *** none ***
ReturnDeliveryTrackingNumber : *** none ***
Status : PREPARING
Devices : [*** none ***]
UnattachedDevices : [*** none ***]
Appliances : [*** none ***]

When you use the to display the details of a job, tagging details are also included in the output if you specified tags.

Multiple Tags
To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type disk --freeform-tags '{ "<tag_key>":"<value>" }', '{ "<tag_key>":"<value>" }'
```

**Getting Transfer Job IDs**

Each transfer job you create has a unique ID within Oracle Cloud Infrastructure. For example:

```
ocid1.datatransferjob.region1.phx..<unique_ID>
```

You will need to forward this transfer job ID to the Data Administrator.

*To get the transfer job ID using the Console*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.
   
The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job whose details you want to view.
   
   Alternatively, you can click the **Actions** icon (⋮), and then click **View Details**.
   
The Details page for that transfer job appears.
4. Find the **OCID** field in the Details page and click **Show** to display it or **Copy** to copy it to your computer.

*To get the transfer job ID using the CLI*

```
dts job list --compartment-id <compartment_id>
```

For example:

```
dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID
```

**Transfer Job List**:

```
[1] :
   ID : ocid1.datatransferjob.oc1..exampleuniqueID
   Name : MyDiskImportJob
   Label : JVWK5YWPU
   BucketName : MyBucket1
   CreationDate : 2020/06/01 17:33:16 EDT
   Status : INITIATED
   FreeformTags : *** none ***
   DefinedTags :
   Financials :
      key1 : nondefault
```

The ID for each transfer job is returned:

```
ID : ocid1.datatransferjob.oc1..exampleuniqueID
```

**Tip:**

When you create a transfer job using the `dts job create` CLI, the transfer job ID is displayed in the CLI's return.
Creating Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the transfer appliance. Send these configuration files to the Data Administrator where they can be placed in the Data Host. The `config` file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The `config_upload_user` file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.

Creating the Data Transfer Directory

Create an Oracle Cloud Infrastructure directory (`.oci`) on the same Data Host where the CLI is installed. For example:

```bash
mkdir /root/.oci/
```

The two configuration files (`config` and `config_upload_user`) are placed in this directory.

Creating the Data Transfer Administrator Configuration File

Create the data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `##profile` option to specify which profile to use in the command.

Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1

[PROFILE1]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1
```

By default, the `DEFAULT` profile is used for all CLI commands. For example:

```bash
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type disk
```

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```bash
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type disk --profile MyProfile
```

Using the example configuration file above, the `<profile_name>` would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```bash
oci dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name>
```

### Creating the Data Transfer Upload User Configuration File

The `config_upload_user` configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

```ini
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user’s private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

### Adding Object Storage Endpoints

Include the line `endpoint=<url>` for the Object Storage API endpoint in the upload user configuration file.

For example:

```ini
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

Click here to view a list of endpoints.

A complete configuration including the Object Storage endpoint might look like this:

```ini
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

**Important:**

Creating an upload user configuration file with multiple profiles is not supported.
### Configuration File Entries

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

**Note:**
Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>

</tbody>
</table>

Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London).

You can verify the data transfer upload user credentials using the following command:

```
dts job verify-upload-user-credentials --bucket <bucket_name>
```
Creating Transfer Packages

A transfer package is the virtual representation of the physical disk package that you are shipping to Oracle for upload to Oracle Cloud Infrastructure. See Transfer Packages on page 1012 for complete details on all tasks related to transfer packages.

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID```

To create a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to create a transfer package.
3. Click the Actions icon ( chặn ), and then click View Details.

   Alternatively, click the hyperlinked name of the transfer job.

   A list of transfer packages that have already been created is displayed.
4. Click Create Transfer Package.

   The Create Transfer Package dialog appears.
5. Select a Vendor from the list.
6. Click Create Transfer Package.

   The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run dts package create to create a transfer package.

```
dts package create --job-id <job_id>```

The following information is returned:

```
Transfer Package :
Label :
TransferSiteShippingAddress :
DeliveryVendor :
DeliveryTrackingNumber :
ReturnDeliveryTrackingNumber :
Status :
Devices :
```

Getting Transfer Package Labels

To get the transfer package label using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon ( chặn ), and then click View Details.

   Alternatively, click the hyperlinked name of the transfer job.
4. Click Transfer Packages under Resources.

   A list of transfer packages associated with the transfer job is displayed.
To get the transfer package label using the Data Transfer Utility

```
dts job show --job-id <job_id>
```

For example:

```
dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Transfer Job :

<table>
<thead>
<tr>
<th>ID</th>
<th>ocid1.datatransferjob.oc1..exampleuniqueID</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompartmentId</td>
<td>ocid.compartment.oc1..exampleuniqueID</td>

</tr>
</tbody>
</table>

The transfer package label is displayed as part of the job details.

Getting Shipping Labels

You can find the shipping address in the transfer package details. Use this information to get a shipping label for the transfer package that is used to send the disk to Oracle.

After getting the shipping labels from the Console or Data Transfer Utility, go to the supported carrier you are using (UPS, FedEx, or DHL) and manually create both the SHIP TO ORACLE and RETURN TO CUSTOMER labels. See Shipping Import Disks on page 995 and Monitoring the Import Disk Shipment and Data Transfer on page 997 for information.

To get the shipping address for a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
   A list of transfer packages that have already been created is displayed.
4. Find the transfer package for which you want to see the details.
5. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
**Data Transfer**

To get the shipping address for a transfer package using the Data Transfer Utility

```
dts package show --job-id <job_id> --package-label <package_label>
```

For example:

```
dts package show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8067MI
```

Transfer Package:
```
Label : PWA8067MI
TransferSiteShippingAddress : Oracle Data Transfer Service;
Job:JZM9PAVWH Package:PWA8067MI ; 21111 Ridgetop Circle; Dock B; Sterling,
VA 20166; USA
DeliveryVendor : *** none ***
DeliveryTrackingNumber : *** none ***
ReturnDeliveryTrackingNumber : *** none ***
Status : PREPARING
Devices : [*** none ***]
```

**Notifying the Data Administrator**

When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Data Transfer Utility configuration files
- Transfer job ID
- Package label

**What’s Next**

You are now ready to configure your system for the data transfer. See Configuring Import Disk Data Transfers on page 990.

### Configuring Import Disk Data Transfers

This topic describes the tasks associated with configuring the Disk-Based Data Import. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 971.

Configuration for the Disk-Based Data Import consists of the following tasks:

- Attaching the import disk to the Data Host. Remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the host as block devices and must provide a valid response to the `hdparm -i <device>` Linux command.
- Sending the block device path to the Data Administrator.

**What’s Next**

You are now ready to load your data to the transfer disk. See Copying the Data to the Import Disk on page 990.

### Copying the Data to the Import Disk
This topic describes the tasks associated with running the data transfer from the Data Host to the import disk. The Data Administrator role typically performs these tasks. See Roles and Responsibilities on page 971.

**Information Prerequisites**

Before performing any disk copying tasks, you must obtain the following information:

- Disk block device path. The Infrastructure Engineer typically provides this information.
- IAM login information, Data Transfer Utility configuration files, transfer job ID, and package label. The Project Sponsor typically provides this information.

**Creating the Transfer Disk**

The transfer disk is the logical representation of the physical import disk that has been configured for use for receiving data as part of the disk-based data transfer. See Transfer Disks on page 1008 for complete details on all tasks related to transfer disks.

**Note:**
You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk for use with the disk on which you are copying your files, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase
- Creates a file system on the disk
- Mounts the file system at `/mnt/orcdts_<label>`

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the contents on the disk. The encryption passphrase is displayed to standard output to the data transfer administrator user and cannot be retrieved again. Create a local, secure copy of the encryption passphrase, so you can reference the passphrase again.

Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example, `/dev/sdb`).

**To create a transfer disk using the Data Transfer Utility**

At the command prompt on the host, run `dts disk create` to create a transfer disk.

```
dts disk create --job-id <job_id> --block-device <block_device>
```

**Copying Files to the Disk**

You can only copy regular files to the disk. You cannot copy special files, such as symbolic links, device special, sockets, and pipes, directly to the disk. See the following section for instructions on how to prepare special files.

**Important:**

- Individual files being copied to the disk cannot exceed 9.76 TB.
- Do not fill up the disk to 100% capacity. There must be space available to generate metadata and for the manifest file to perform the upload to Object Storage. At least 1 GB of free disk space is needed for this area.

Attach the disk to the Data Host and copy files to the mount point created by `disk` through the Data Transfer Utility.

**Note:**

Only Linux machines can be used as Data Hosts.
**Note:**

Copy all Files Before Disconnecting the Disk

Do not disconnect the disk until you copy all files from the Data Host and generate the manifest file. If you accidentally disconnect the disk before copying all files, you must unlock the disk using the encryption passphrase. The encryption passphrase was generated and displayed when you created the transfer disk. If the generated encryption passphrase is not available, you must delete the transfer disk from the transfer job and re-create the transfer disk. All data previously copied to that disk is lost.

**Copying Special Files**

To transfer special files, create a tar archive of these files and copy the tar archive to the Data Transfer Appliance. We recommend copying many small files using a tar archive. Copying a single compressed archive file should also take less time than running copy commands such as `cp -r` or `rsync`.

Here are some examples of creating a tar archive and getting it onto the Data Transfer Appliance:

- Running a simple tar command:

  ```
tar -cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/
  ```

- Running a command to create a file with md5sum hashes for each file in addition to the tar archive:

  ```
tar cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/ | xargs -I '{}' sh -c "test -f '{}' && md5sum '{}"" | tee tarzip_md5
  ```

The tar archive file `filesystem.tgz` has a base64 md5sum once it is uploaded to OCI Object Storage. Store the `tarzip_md5` file where you can retrieve it. After the compressed tar archive file is downloaded from Object Storage and unpacked, you can compare the individual files against the hashes in the file.

**Generating the Manifest File**

**Note:**

You can only use the Data Transfer Utility to generate a manifest file. The amount of time to generate the manifest file depends on the size of the upload files, disk speed, and available processing power.

After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the `config_upload_user` configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

**Note:**

Data Transfer Service Does Not Support Passphrases on Private Keys

While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the `config_upload_user`. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See [Installing the Data Transfer Utility](#) on page 974 for more information about the required configuration files.
To create a manifest file using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk manifest` to create a manifest file.

```
dts disk manifest --job-id <job_id> --disk-label <disk_label>[--object-name-prefix <object_name_prefix>]
```

**Note:**

Do You Need to Regenerate the Manifest File?

If you add, remove, or modify any files on the disk after generating the manifest file, you must regenerate the file. If the manifest file does not match the contents of the target bucket, Oracle cannot upload the data.

Locking the Transfer Disk

**Note:**

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

To lock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk lock` to lock a transfer disk.

```
dts disk lock --job-id <job_id> --disk-label <disk_label> --block-device <block_device>
```

Unlocking the Transfer Disk

**Note:**

You can only use the Data Transfer Utility to unlock a transfer disk.

When unlocking the transfer disk, you are prompted for the encryption passphrase that was generated when you created the transfer disk.

To unlock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk unlock` to unlock a transfer disk.

```
dts disk unlock --job-id <job_id> --disk-label <disk_label> --block-device <block_device> --encryption-passphrase <encryption_passphrase>
```

Attaching the Transfer Disk to the Transfer Package

Attach a transfer disk to a transfer package after you have performed the following tasks:

1. Copied your data onto the disk
2. Generated the required manifest file
3. Run and reviewed the dry-run report
4. Locked the transfer disk in preparation for shipment

A disk can be attached to one package, detached, and then attached to another package. In some cases, you have attached a transfer disk to a transfer package, but have changed your mind about shipping that disk with the transfer package. You can also detach a transfer disk from one transfer package and attach that disk to a different transfer package.

To attach a transfer disk to a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job associated with the transfer package that you want to attach a disk to.
3. Click the **Actions** icon ( ), and then click **View Details**.
   A list of transfer packages is displayed.
4. Find the transfer package that you want to attach a disk to.
5. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   A list of transfer disks is displayed.
6. Click **Attach Transfer Disks**.
   The Attach Transfer Disks dialog appears.
7. Select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

To attach a transfer disk to a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk attach` to attach a disk to a transfer package.

```bash
dts disk attach --job-id <job_id> --package-label <package_label> --disk-label <disk_label>
```

**Detaching the Transfer Disk from the Transfer Package**

To detach a transfer disk from a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer package for which you want to detach a transfer disk.
3. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   A list of transfer disks that have already been attached is displayed.
4. Find the transfer disk that you want to detach.
5. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer disk.
6. Click **Detach Transfer Disk**.

To detach a transfer disk from a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk detach` to detach a disk from a transfer package.

```bash
dts disk detach --job-id <job_id> --package-label <package_label> --disk-label <disk_label>
```

**Setting Tracking Details on the Transfer Package**

After delivering the transfer package to the shipping vendor, update the transfer package with the tracking information.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle cannot process a transfer package until you update the tracking information.</td>
</tr>
</tbody>
</table>

To update the transfer package with tracking information using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the Actions icon (‡), and then click View Details.
   A list of transfer packages that have already been created is displayed.
4. Find the transfer package that you want to update.
5. Click the Actions icon (‡), and then click View Details.
6. Click Edit.
7. Enter the Tracking ID and the Return Tracking ID.
8. Click Edit Transfer Package.

To update the transfer package with tracking information using the Data Transfer Utility

At the command prompt on the host, run `dts package ship` to update the transfer package tracking information.

```bash
dts package ship --job-id <job_id> --package-label <package_label> --package-vendor <vendor_name> --tracking-number <tracking_number> --return-tracking-number <return_tracking_number>
```

Notifying the Infrastructure Engineer

After completing the tasks listed in this topic, notify the Infrastructure Engineer of the following:

- Disconnect the physical disk from the Data Host
- Package the disk for shipment

What’s Next

You are now ready to ship your disk with the copied data to Oracle. See Shipping Import Disks on page 995.

Shipping Import Disks

![Flowchart](flowchart.png)

This topic describes the tasks associated with shipping the import disk containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 971.

Disconnecting the Transfer Disk from the Data Host

Do not disconnect the import disk until you copy all files from the Data Host and generate the manifest file. See Copying the Data to the Import Disk on page 990 for more information.

Printing Shipping Labels

You should receive the shipping labels electronically from the Project Sponsor. Print them on the appropriate labels for shipping the import disk. See Getting Shipping Labels on page 989 for more information.

Packaging and Shipping the Import Disk

General

Include the required return shipping label in the box when packaging the import disk for shipment.

**Note:**

If you do not include the return shipping label inside the box, Oracle cannot process the transfer package.

Ensure that the transfer job and transfer package label are clearly readable on the outside of the box containing the import disk.
**Important:**

If you are shipping transfer disks to London or Frankfurt, request that the shipping vendor requires a signature delivery.

**Listing Disk Delivery Vendors**

You can view the vendors available for delivery of your import disk to Oracle Cloud Infrastructure.

**Note:**

Available vendors for transfer disk delivery to Oracle Cloud Infrastructure can vary over time. Have the latest version of the Data Transfer Utility installed to view the current list.

**Note:**

You can only use the Data Transfer Utility to lock an transfer disk.

To list the vendors available for delivering the transfer disk to Oracle Cloud Infrastructure

At the command prompt on the Data Host, run `dts package list-delivery-vendors` to list the available delivery vendors.

```
dts package list-delivery-vendors

Delivery Vendors :
[1] : FedEx
[3] : UPS
```

**Shipping Import Disks Internationally**

Create a commercial invoice when shipping transfer disks internationally. To ensure that packages are not held up in customs, follow these guidelines when creating the commercial invoice:

- Show a unique reference number.
- Show the "bill-to party" as follows:
  - For shipments to the European Union (Frankfurt) location:
    ORACLE Deutschland B.V. & Co. KG Riesstrasse 25 Munich, 80992 GERMANY
  - For shipments to the United States location:
    Oracle America, Inc. 500 Oracle Parkway REDWOOD CITY CA 94065 UNITED STATES
- Show the "ship-to party" as the address provided in the transfer package details. See Getting Shipping Labels on page 989 for details.
- State that "The value shown includes the value of software and data recorded onto the hard drive unit."
- State that the "Goods are free of charge - no payment required."
- State that the type of export is "Temporary."
- Ensure that the commodity code shows the correct HS code for a hard drive unit as specified in the source country's HS code list.
- State the description as the manufacture's description of the hard drive unit and include the words "Hard Disk Drive."
- Ensure that the invoice is signed and includes the printed name of the signer.
What's Next

Now you can track your transfer disk shipment and review post transfer logs and summaries. See Monitoring the Import Disk Shipment and Data Transfer on page 997.

Monitoring the Import Disk Shipment and Data Transfer

This topic describes the monitoring tasks to do after sending the import disk with the copied data to Oracle for data transfer to Oracle Cloud Infrastructure. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 971.

Tracking the Import Disk Shipment

When Oracle has processed the transfer (import) disk associated with a transfer package, the status of the transfer package changes to Processed. When Oracle has shipped the disk, the status of the transfer package changes to Returned.

To check the status of a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Choose the data transfer package for which you want to display the details.
3. Click the Actions icon ( ), and then click View Details.
4. Look at the Status.

To check the status of a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run dts package show to show the status of a transfer package.

\[ dts \text{ package show \ --job-id <job_id> \ --package-label <package_label>} \]

For example:

\[ dts \text{ package show \ --job-id ocid1.datatransferjob.oci1..exampleuniqueID \ --package-label PWA8067MI} \]

Transfer Package :
Label : PWA8067MI
TransferSiteShippingAddress : Oracle Data Transfer Service; Job:JZM9PAVWH Package:PWA8067MI ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor : *** none ***
DeliveryTrackingNumber : *** none ***
ReturnDeliveryTrackingNumber : *** none ***
Status : PREPARING
Devices : [*** none ***]

Reviewing the Upload Summary

Oracle creates upload summary log files for each uploaded import disk. These logs are placed in the bucket where the data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the import disk's manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

The top of the log report summarizes the overall file processing status:

P - Present: The file is present in both the disk and the target bucket
M - Missing: The file is present in the disk but not the target bucket. It was likely uploaded and then deleted by another user before the summary was generated.
C - Name Collision: The file is present in the manifest but a file with the same name but different contents is present in the target bucket.
U - Unreadable: The file is not readable from the disk
N - Name Too Long: The file name on disk is too long and could not be uploaded

Complete file upload details follow the summary.

Viewing Data Transfer Metrics

After the import disk with your copied data is received by Oracle and the data transfer begins, you can view the metrics associated with the transfer job in the Transfer Appliance Details page in chart or table format.

Tip:
Set up your notifications to alert you when the data transfer from the import disk to Oracle Cloud Infrastructure is occurring. When the state changes from ORACLE_RECEIVED to PROCESSING, you can start viewing data transfer metrics.

Select **Metrics** under **Resources** to display each of these measures:

- **Import Files Uploaded** - Total number of files uploaded for import.
- **Import Bytes Uploaded** - Total number of bytes uploaded for import.
- **Import Files Remaining** - Total number of files remaining for import upload.
- **Import Bytes Remaining** - Total number of bytes remaining for import upload.
- **Import Files in Error** - Total number of files in error for import.
- **Import Upload Verification Progress** - Progress of verification of files that have already been uploaded for import.

Select the **Start Time** and **End Time** for these measures, either by manually entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. As an alternative to selecting a start and end time, you can also select from a list of standard times (last hour, last 6 hours, and so forth) from the **Quick Selects** list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.

Tip:
Mean is the most useful statistic for data transfer as it reflects an absolute value of the metric.

Choose additional actions from the **Options** list, including viewing the query in the **Metrics Explorer**, capturing the URL for the measure, and switching between chart and table view.

Click **Reset Charts** to delete any existing information in the charts and begin recording new metrics.

See **Monitoring Overview** on page 2660 for general information on monitoring your Oracle Cloud Infrastructure services.
**Closing the Transfer Job**

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of the associated transfer disk must be complete, in error, missing, canceled, or deleted.

*To close a transfer job using the Console*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the data transfer package for which you want to display the details.
3. Click the **Actions** icon (.), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click **Close Transfer Job**.

*To close a transfer job using the Data Transfer Utility*

At the command prompt on the host, run `dts job close` to close a transfer job.

```
dts job close --job-id <job_id>
```

**What's Next**

You have completed the process of setting up, running, and monitoring the import disk-based data transfer. After the disk contents is successfully migrated to Oracle Cloud Infrastructure, your physical disk is erased and returned to you.

If you determine that another disk-based data transfer is required, repeat the procedure from the beginning.

**Disk Import Reference**

This topic provides complete task details for certain components associated with Disk-Based Data Imports. Use this topic as a reference to learn and use commands associated with components included in the Disk-Based Data Import procedure.

**Transfer Jobs**

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least one transfer disk with a transfer package. Identify which compartment and Object Storage bucket to which Oracle will upload your data.

**Tip:**

Create a compartment for each transfer job to minimize the required access your tenancy.

*Creating Transfer Jobs*

Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..<unique_ID>
```

*To create a transfer job using the Console*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the designated compartment you are to use for data transfers from the list.
   A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
   
   The Create Transfer Job dialog appears.

4. Enter a **Job Name**. Avoid entering confidential information. Then, select the **Upload Bucket** from the list.

5. Select **Disk** for the **Transfer Device Type**.

6. Click **Create Transfer Job**.

To create a transfer job using the Data Transfer Utility

```
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name>
```

<display_name> is the name of the transfer job. Avoid entering confidential information.

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob
```

Transfer Job:

<table>

</table>

When you use the `oci dts job create` command to display the details of a job, tagging details are also included in the output if you specified tags.

Optionally, you can specify one or more defined or free-form tags when you create a transfer job. For more information about tagging, see **Resource Tags** on page 211.

**Defined Tags**

To specify defined tags when creating a job:

```
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --defined-tags '{ "<tag_namespace>": { ";<tag_key>": "<value>" } }'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

Transfer Job:
To specify freeform tags when creating a job:

```bash
dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --freeform-tags '{ "<tag_key>":"<value>" }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

Transfer Job:
- ID: ocid1.datatransferjob.oc1..exampleuniqueID
- CompartmentId: ocid.compartment.oc1..exampleuniqueID
- UploadBucket: MyBucket1
- Name: MyDiskImportJob
- Label: JZM9PAVWH
- CreationDate: 2019/06/04 17:07:05 EDT
- Status: PREPARING
- freeformTags: Pittsburg_Team: brochures
- definedTags: *** none ***
- Packages:
  - [1]:
    - Label: PBNZOX9RU
    - TransferSiteShippingAddress: Oracle Data Transfer Service; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
    - DeliveryVendor: FedEx
    - DeliveryTrackingNumber: *** none ***
    - ReturnDeliveryTrackingNumber: *** none ***
    - Status: PREPARING
    - Devices: [*** none ***]
    - UnattachedDevices: [*** none ***]
    - Appliances: [*** none ***]

When you use the `dts job show` command to display the details of a job, tagging details are also included in the output if you specified tags.

**Note:**

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags on page 3914 for details.
TransferSiteShippingAddress : Oracle Data Transfer Service;  
Job:JZM9PAVWH Package:PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA

When you use the to display the details of a job, tagging details are also included in the output if you specified tags.

Multiple Tags

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type disk --freeform-tags '{ "<tag_key>":"<value>" }', '{ "<tag_key>":"<value>" }'

Listing Transfer Jobs

To display the list of transfer jobs using the Console

Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.

To display the list of transfer jobs using the Data Transfer Utility

dts job list --compartment-id <compartment_id>

For example:

dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

Transfer Job List :  
[1] :  
ID : ocid1.datatransferjob.oc1..exampleuniqueID  
Name : MyDiskImportJob  
Label : JVWK5YWPU  
BucketName : MyBucket1  
CreationDate : 2020/06/01 17:33:16 EDT  
Status : INITIATED  
FreeformTags : *** none ***  
DefinedTags :  
Financials :  
key1 : nondefault

When you use the Data Transfer Utility to list jobs, tagging details are also included in the output if you specified tags.

Displaying Transfer Job Details

To display the details of a transfer job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to display the details.
3. Click the Actions icon ( ), and then click View Details.
To display the details of a transfer job using the Data Transfer Utility

dts job show --job-id <job_id>

For example:

dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID

Transfer Job :
| ID                | ocid1.datatransferjob.oc1..exampleuniqueID |
| CompartmentId     | ocid.compartment.oc1..exampleuniqueID      |
| UploadBucket      | MyBucket1                                  |
| Name              | MyDiskImportJob                            |
| Label             | JZM9PAVWH                                  |
| CreationDate      | 2019/06/04 17:07:05 EDT                    |
| Status            | PREPARING                                  |

| Label             | PBNZOX9RU                                   |
| TransferSiteShippingAddress | Oracle Data Transfer Service; |
| Job:JZM9PAVWH Package:PBNZOX9RU | 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA |
| DeliveryVendor     | FedEx                                      |
| DeliveryTrackingNumber | *** none ***                               |
| ReturnDeliveryTrackingNumber | *** none ***                               |
| Status             | PREPARING                                  |
| Devices            | [*** none ***]                              |
| UnattachedDevices  | [*** none ***]                              |
| Appliances         | [*** none ***]                              |

When you use the Data Transfer Utility to display the details of a job, tagging details are also included in the output if you specified tags.

Editing Transfer Jobs
To edit the name of a transfer job using the Console

Note:
You can only change the name of a transfer job using the Console. If you want to change other attributes of the transfer job, use the Data Transfer Utility instead.

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the data transfer job that you want to edit.
3. Click the Actions icon (.), and then click Edit.
4. Edit the name of the transfer job. Avoid entering confidential information.
5. Click Save.

To edit the name of a transfer job using the Data Transfer Utility

dts job update --job-id <job_id> --display-name <display_name>

<display_name> is the new name of the transfer job. Avoid entering confidential information.

For example:
To edit the tags associated with a transfer job using the Data Transfer Utility

The Data Transfer Utility replaces any existing tags with the new key/value pairs you specify.

To edit defined tags, provide the replacement key value pairs:

dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>" : { "<tag_key>" : "<value>" }}'

For example:

dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --
defined-tags '{"Operations" : {"CostCenter" : "42"}}'

To edit free-form tags, provide the replacement key/value pairs:

dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>" : "<value>", }'

For example:

dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --
freeform-tags '{"Chicago_Team" : "marketing_videos"}'}
To delete the tags associated with a transfer job using the Data Transfer Utility

The Data Transfer Utility replaces any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, you would specify new tag string that does not contain the key/value pair you want to delete.

Partial tag deletion is handled in the same way as you edit tags:

- To edit free-form tags, provide the replacement key/value pairs:

  ```
  dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>" : "<value>" }'
  ```

- To edit defined tags, provide the replacement key value pairs:

  ```
  dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>" : {
  "<tag_key>" : "<value>" }}'
  ```

To delete all free-form tags:

```
 dts job update --job-id <job_id> --freeform-tags '{}'
```  

To delete all defined tags:

```
 dts job update --job-id <job_id> --defined-tags '{}'
```  

Moving Transfer Jobs Between Compartments

**Note:**

You can only use the Console to move disk-based data transfer jobs between compartments.

To move a transfer job to a different compartment using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Select the Compartment from the list.

   The transfer jobs in that compartment are displayed.
3. Click the link under Transfer Jobs for the transfer job that you want to move.

   The Details page for that transfer job appears.
   
   Alternatively, you can click the Actions icon (⋮), and then click Move Resource.
4. Click Move Resource in the Details page.

   The Move Resource to a Different Compartment dialog appears.
5. Choose the compartment you want to which you want to move the transfer job from the list.
6. Click Move Resource.

You are returned to the Details page for that transfer job.
To move a transfer job to a different compartment using the Data Transfer Utility

```
dts job move --job-id <job_id> compartment-id <compartment_id> <options>
```

<compartment_id> is the compartment to which the data transfer job is being moved.

<options> are:

- `--if-match`: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object's tag matches the tag specified in the request.
- `--from-json`: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The `--generate-full-command-json-input` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. `compartment-id` -> `compartmentId`), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

To confirm the transfer, display the list of transfer jobs in the new compartment. See Listing Transfer Jobs on page 1002 for more information.

**Verifying Upload User Credentials**

```
Note:
You can only use the CLI command to verify upload user credentials.
```

You can verify the current upload user credentials to see if there are any problems or updates required. If any configuration file is incorrect or invalid, the upload fails.

**To verify the upload user credentials of a transfer job using the CLI**

```
dts job verify-upload-user-credentials --bucket <bucket>
```

<bucket> is the upload bucket for the transfer job.

For example:

```
dts job verify-upload-user-credentials --bucket MyBucket1
```

created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in bucket MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1

Depending on your user configuration, you may get an error message returned similar to the following:

```
ERROR : key_file /root/.oci/oci_api_key.pem is not a valid file
```

If a user credential issue is identified, fix it and rerun the `verify-upload-user-credentials` CLI to ensure that all problems are addressed. Then you can proceed with transfer job activities.

**Deleting Transfer Jobs**

Typically, you would delete a transfer job early in the transfer process and before you create any transfer packages or their associated disks. For example, you initiated the data transfer by creating a transfer job, but changed your mind. If you want to delete a transfer job later in the transfer process, you must first delete all transfer packages and their associated disks from the transfer job.
To delete a transfer job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the data transfer job that you want to delete.
3. Click the Actions icon ( ), and then click Delete.
   Alternatively, you can delete a transfer job from the View Details page.
4. Confirm the deletion when prompted.

To delete a transfer job using the Data Transfer Utility

```
dts job delete --job-id <job_id>
```

For example:

```
dts job delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Confirm the deletion when prompted. The transfer job is deleted with no further action or return. To confirm the deletion, display the list of transfer jobs in the compartment. See Listing Transfer Jobs on page 1002 for more information.

Closing Transfer Jobs

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click Close Transfer Job.

To close a transfer job using the Data Transfer Utility

```
dts job close --job-id <job_id>
```

For example:

```
dts job close --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Transfer Job:

<table>
<thead>
<tr>
<th>ID</th>

</tbody>
</table>
Transfer Disks

The section describes the creation and management transfer disks.

**Important:**

Before creating a transfer disk from an attached disk, remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the Data Host as block devices and must provide a valid response to the `hdparm -I <device>` Linux command.

Creating Transfer Disks

**Note:**

You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase
- Creates a file system on the disk
- Mounts the file system at `/mnt/orcdts_<label>`

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the transfer disk. This passphrase is displayed in the return when you run the command. Create a local, secure copy of the encryption passphrase so you can reference the passphrase again. You cannot retrieve the passphrase after it is shown here. This passphrase is used to encrypt this disk and normally will not be needed again. However, if the system is restarted before all files are copied to the filesystem and the disk is then finalized through this CLI, you will need to provide the passphrase.

Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example `/dev/sdb`).

**To create a transfer disk using the Data Transfer Utility**

```
dts disk create --job-id <job_id> --block-device <block_device>
```

When the run the disk create command, the CLI displays information regarding the creation of the disk, and prompts you to continue in several places. When the disk is created the following disk information is displayed:

```
dts disk create --job-id ocid1.datatransferjob.oci1..exampleuniqueID -- block-device /dev/sdb
...
Transfer Disk :
  Label:             : DNKZQ1XKC
  SerialNumber:      : VB6fc3b4a1-5d90f001
  Status             : PREPARING
  EncryptionPassphrase : passphrase
```

**Important:**

Record the passphrase in a secure, local location.
**Displaying Transfer Disk Details**

**Note:**
You can only use the Data Transfer Utility to display details for a specified transfer disk.

To display the details of a disk using the Data Transfer Utility

```bash
dts disk show --job-id <job_id> --disk-label <disk_label>
```

For example:

```bash
dts disk show --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC
```

Transfer Disk:
- **Label:** DNKZQ1XKC
- **SerialNumber:** VB6fc3b4a1-5d90f001
- **UploadStatusLogUrl:** JVPWPV6U/DNKZQ1XKC/upload_summary.txt
- **Status:** PREPARING

The path syntax for the upload status log URL is `<transfer_job_label>/<disk_label>/upload_summary.txt`.

**Deleting Transfer Disks**

**Note:**
You can only use the Data Transfer Utility to delete a transfer disk.

Typically, you would delete a transfer disk during the disk preparation process. You created, attached, and copied data to the transfer disk, but have changed your mind about shipping the disk. If you want to reuse the disk, remove all file systems and create the disk again.

To delete a transfer disk using the Data Transfer Utility

```bash
dts disk delete --job-id <job_id> --disk-label <disk_label>
```

For example:

```bash
dts disk delete --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC
```

Deleted Disk: DNKZQ1XKC

**Canceling Transfer Disks**

**Note:**
You can only use the Data Transfer Utility to cancel a transfer disk.

If you shipped a disk to Oracle, but have changed your mind about uploading the files, you can cancel the transfer disk.

Oracle cannot process canceled transfer disks. Oracle returns canceled transfer disks to the sender.

To cancel a transfer disk using the Data Transfer Utility

```bash
dts disk cancel --job-id <job_id> --disk-label <disk_label>
```
For example:

dts disk cancel --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC

Canceled Disk: DNKZQ1XKC

Locking Transfer Disks

**Note:**

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

**To lock a transfer disk using the Data Transfer Utility**

dts disk lock --job-id <job_id> --disk-label <disk_label> --block-device <block_device>

For example:

dts disk lock --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC --block-device /dev/sdb

Copying upload user credentials.
created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1
Scanning filesystem to validate manifest. If special files are encountered, they will be listed below.
validated manifest
/dev/sdb DNKZQ1XKC is encrypted and locked
Locked disk.

Unlocking Transfer Disks

If you need to unlock the transfer disk, you are prompted for the encryption passphrase that was generated when you created the transfer disk.

**To unlock a transfer disk using the Data Transfer Utility**

dts disk unlock --job-id <job_id> --disk-label <disk_label> --block-device <block_device> --encryption-passphrase <encryption_passphrase>

For example:

dts disk unlock --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC --block-device /dev/sdb --encryption-passphrase passphrase

Encryption passphrase ('q' to quit):
enabled cleartext read/write on device
Unlocked and mounted disk.

Attaching Transfer Disks to Transfer Packages

Attach a transfer disk to a transfer package after you have done the following tasks in order:

- Copied your data onto the disk
- Generated the required manifest file
• Run and reviewed the dry-run report
• Locked the transfer disk in preparation for shipment

**Note:**
You can only attach a single disk to each transfer package.

**To attach a transfer disk to a transfer package using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer job associated with the transfer package having the disk attached.
3. Click the **Actions** icon (🔍), and then click **View Details**.
   A list of transfer packages is displayed.
4. Find the transfer package that you want to attach a disk to.
5. Click the **Actions** icon (🔍), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   The transfer disk is displayed.
6. Click **Attach Transfer Disks**.
   The Attach Transfer Disks dialog appears.
7. Select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

**To attach a transfer disk to a transfer package using the Data Transfer Utility**

```bash
dts disk attach --job-id <job_id> --package-label <package_label> --disk-label <disk_label>
```

For example:

```bash
dts attach --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8O67MI --disk-label DNKZQ1XKC
```

Attached disk: DNKZQ1XKC to package: PWA8O67MI

See **Transfer Packages** on page 1012 for more information, including how to obtain the package label.

**Detaching Transfer Disks from Transfer Packages**

**To detach a transfer disk to a transfer package using the Console**

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer package for which you want to detach a transfer disk.
3. Click the **Actions** icon (🔍), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   The attached transfer disk is displayed.
4. Click the **Actions** icon (🔍), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer disk.
5. Click **Detach Transfer Disk**.
To detach a transfer disk to a transfer package using the Data Transfer Utility

```
dts disk detach --job-id <job_id> --package-label <package_label> --disk-label <disk_label>
```

For example:

```
dts detach --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8O67MI --disk-label DNKZQ1XKC
```

Detached disk: DNKZQ1XKC from package: PWA8O67MI

**Querying Transfer Disks**

You can query the transfer disk for information regarding the physical transfer disk such as the loops, sizes, and mountpoints.

**Note:**

You can only use the Data Transfer Utility to query the transfer disk.

To query the transfer disk using the Data Transfer Utility

```
dts disk query
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>SIZE</th>
<th>UUID</th>
<th>LABEL</th>
</tr>
</thead>

</table>

**Transfer Packages**

A transfer package is the virtual representation of the physical disk package that you are shipping to Oracle for upload to Oracle Cloud Infrastructure.

**Creating Transfer Packages**

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer job for which you want to create a transfer package.
3. Click the **Actions** icon (★), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.
   A list of transfer packages that have already been created is displayed.
4. Click **Create Transfer Package**.
   The Create Transfer Package dialog appears.
5. Select a **Vendor** from the list.
6. Click **Create Transfer Package**.
The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

```
dts package create --job-id <job_id>
```

For example:
```
dts package create --job-id ocid1.datatransferjob.oci1..exampleuniqueID
```

Transfer Package :
Label : PWA8067MI

Displaying Transfer Package Details

To display the details of a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
   A list of transfer packages that have already been created is displayed.

To display the details of a transfer package using the Data Transfer Utility

```
dts package show --job-id <job_id> --package-label <package_label>
```

For example:
```
dts package show --job-id ocid1.datatransferjob.oci1..exampleuniqueID --package-label PWA8067MI
```

Transfer Package :
Label : PWA8067MI
TransferSiteShippingAddress : Oracle Data Transfer Service; Job:JZM9PAVWH Package:PWA8067MI ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor : *** none ***
DeliveryTrackingNumber : *** none ***
ReturnDeliveryTrackingNumber : *** none ***
Status : PREPARING
Devices : [*** none ***]

Editing Transfer Packages

Edit the transfer package and supply the tracking information when you ship the package.

To edit a transfer package using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the **Actions** icon (⋮), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the **Actions** icon (⋮), and then click **View Details**.
6. Click **Edit**.

   Change the vendor and supply the tracking information as needed.
7. Click **Edit Transfer Package**.

**Deleting Transfer Packages**

Typically, you would delete a transfer package early in the transfer process and before you create its associated transfer disk. You initiated the transfer job and package, but have changed your mind. If you delete a transfer package later in the transfer process, you must first detach the associated transfer disk. You cannot delete a transfer package once the package has been shipped to Oracle.

To delete a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the **Actions** icon (⋮), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the **Actions** icon (⋮), and then click **View Details**.
6. Click **Edit**.

   Change the vendor and supply the tracking information as needed.
7. Click **Edit Transfer Package**.

**To delete a transfer package using the Data Transfer Utility**

    dts package delete --job-id <job_id> --package-label <package_label>

For example:

    dts package delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8067MI

    Deleted package with label: PWA8067MI

**Canceling Transfer Packages**

If you shipped a transfer package, but have changed your mind about uploading the data, you can cancel a transfer package. Before canceling a transfer package, you must first cancel the transfer disk associated with that transfer package. Oracle cannot process canceled transfer packages. Oracle returns canceled transfer packages to the sender.

To cancel a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Find the transfer job for which you want to see associated transfer packages.
3. Click the **Actions** icon (⋮), and then click **View Details**.
4. Find the transfer package that you want to cancel.
5. Click the **Actions** icon (⋮), and then click **View Details**.
6. Click **Cancel Transfer Package**.
To cancel a transfer package using the Data Transfer Utility

dts package cancel --job-id <job_id> --package-label <package_label>

For example:

dts package cancel --job-id ocid1.datatransferjob.oci1..exampleuniqueID --package-label PWA8067MI

Canceled package with label: PWA8067MI

Data Import - Appliance

Appliance-Based Data Import is one of Oracle's offline data transfer solutions that lets you migrate petabyte-scale datasets to Oracle Cloud Infrastructure. You send your data as files on one or more secure, high-capacity, Oracle-supplied Data Transfer Appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

Note:
Appliance-Based Data Import is not available for free trial or Pay As You Go accounts.

Appliance-Based Data Import Concepts

TRANSFER JOB

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job is associated with one or more import appliances.

DATA TRANSFER APPLIANCE

The Data Transfer Appliance (import appliance) is a high-storage capacity device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You request an import appliance from Oracle, copy your data onto it, and then ship it back to Oracle for upload.

COMMAND LINE INTERFACE

The command line interface (CLI) is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks, including Appliance-Based Data Import jobs.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

HOST

A physical computer at the customer site on which one or more of the logical hosts (Control, Data, Terminal Emulation) is running. Depending on your computing environment, you can have any of the following:

- A separate physical host for each logical host
- All three logical hosts consolidated onto a single physical host
- Two logical hosts on one physical host and the third logical host on a separate physical host

All physical hosts must be on network used for the data transfer.
**CONTROL HOST**

The logical representation of the host computer at your site from which you perform Data Transfer Service tasks. Depending on your needs, you may use one or more separate hosts (Control and Data) to run your Appliance-Based Data Import job.

**Note:**
You can only run Oracle Cloud Infrastructure CLI commands from a Linux-based Control Host machine. You can run Console tasks from a browser running on a Windows machine.

**DATA HOST**

The logical representation of the host computer on your site that stores the data you intend to copy to Oracle Cloud Infrastructure.

**Note:**
Only Linux machines can be used as Data Hosts.

**TERMINAL EMULATION HOST**

The logical representation of the host computer that uses terminal emulation software to communicate with, and allow you to command, the import appliance.

**BUCKET**

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy whose policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

**DATA TRANSFER ADMINISTRATOR**

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs.

**DATA TRANSFER UPLOAD USER**

A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from the import appliance to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure.

**APPLIANCE MANAGEMENT SERVICE**

Software running on the import appliance that provides management functions. Users interact with this service though the Oracle Cloud Infrastructure CLI.

**Appliance Specifications**

Use NFS versions 3, 4, or 4.1 to copy your data onto the appliance. Here are some details about the appliance:

<table>
<thead>
<tr>
<th>Item Description</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage Capacity</td>
<td>150 TB of protected usable space</td>
</tr>
<tr>
<td>Network Interfaces</td>
<td>- 10 GbE - RJ45</td>
</tr>
<tr>
<td></td>
<td>- 10 GbE - SFP+</td>
</tr>
<tr>
<td></td>
<td>You are responsible for providing all network cables. If you want to use SFP+, your transceivers must be compatible with Intel X520 NICs.</td>
</tr>
<tr>

</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Provided Cables**     | - NEMA 5–15 type B to C13  
- C13 - 14 power  
- USB - DB9 serial |
| **Environmental**       | - Operational temperature: 50–95°F (10–35°C)  
- Operational relative humidity: 8–90% non-condensing  
- Acoustics: < 75 dB @ 73°F (23°C)  
- Operational altitude: -1,000 ft - 10,000 ft (approx. -300–3048 m) |
| **Power**               | - Consumption: 554 W  
- Voltage: 100–240 VAC  
- Frequency: 47–63 Hz  
- Conversion efficiency: 89% |
| **Weight**              | - Unit: 38 lbs (approx. 17 kg)  
- Unit + Transit Case: 64 lbs (approx. 29 kg) |
| **Height**              | 3.5" (approx. 9 cm) (2U) |
| **Width**               | 17" (approx. 43 cm) |
| **Depth**               | 24" (approx. 61 cm) |
| **Shipping Case**       | 11" x 25" x 28" (approx. 28 x 63.5 x 71 cm) |

**Import File Constraints**

All files being imported using the Data Transfer Appliance must conform to the following:

- Maximum file size - 10 TB
- Maximum file name length - 1024 characters

**Roles and Responsibilities**

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

- **Project Sponsor**: Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project. The Project Sponsor is also responsible for signing legal documentation and setting up notifications for the data import.

- **Infrastructure Engineer**: Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

- **Data Administrator**: Responsible for identifying and preparing the data to be transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.
Task Flow for Appliance-Based Data Import

Here is a high-level overview of the tasks involved in the Appliance-Based Data Import to Oracle Cloud Infrastructure. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.
Secure Appliance Data Transfer to Oracle Cloud Infrastructure

This section highlights the security details of the Data Transfer Appliance process.

- Appliances are shipped from Oracle to you with a tamper-evident security tie on the transit case. A second tamper-evident security tie is included in the import appliance transit case for you to secure the case when you ship the case back to Oracle. The number on the physical security ties must match the numbers logged by Oracle in the import appliance details.
- When you configure the import appliance for the first time:
  - The import appliance generates a master AES-256 bit encryption key that is used for all data written to or read from the device. The encryption key never leaves the device.
  - The encryption key is protected by an encryption passphrase that you must know to access the encrypted data. The system securely fetches a provided encryption passphrase from Oracle Cloud Infrastructure and registers that passphrase on the import appliance.

  **Note:**
  The encryption passphrase is never stored on the import appliance

- All data is encrypted as the data is copied to an import appliance.
- For more security, you can also encrypt your own data with your own encryption keys. Before copying your data to the import appliance, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
- All network communication between your appliance-based data transfer environment and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).
- After copying your data to a transfer appliance, the data transfer system generates a manifest file. The manifest contains an index of all of the copied files and generated data integrity hashes. The system also encrypts and copies the `config_upload_user` configuration file to the transfer appliance. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer appliance and uploading files to Oracle Cloud Infrastructure Object Storage.

  **Note:**
  Data Transfer Service Does Not Support Passphrases on Private Keys
  While we recommend encrypting a private key with a passphrase when generating API signing keys, the Data Transfer Service does not support passphrases on the key file required for the `config_upload_user` configuration file. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer appliance without the correct credentials defined in this configuration file. See Preparing Upload Configuration Files on page 1031 for more information about the required configuration files.

- Oracle erases all of your data from the import appliance after it has been processed. The erasure process follows the NIST 800-88 standards.
- Keep possession of the security tie after you have finished unpacking and connecting the import appliance. Include it when returning the import appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

**What's Next**

You are now ready to prepare the host for the Appliance-Based Data Import. See Preparing for Appliance Data Transfers on page 1021 for more information.
Preparing for Appliance Data Transfers

This topic describes the tasks associated with preparing for the Appliance-Based Data Import job. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1017.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Installing and Using the Oracle Cloud Infrastructure Command Line Interface

The Oracle Cloud Infrastructure Command Line Interface (CLI) provides a set of command line-based tools for configuring and running Appliance-Based Data Import jobs. Use the Oracle Cloud Infrastructure CLI as an alternative to running commands from the Console. Sometimes you must use the CLI to complete certain tasks as there is no Console equivalent.

Minimum Required CLI Version

The minimum CLI version required for Appliance-Based Data Import is 2.12.1.

Determining CLI Versions

Access the following URL to see the currently available version of the CLI:

https://github.com/oracle/oci-cli/blob/master/CHANGELOG.rst

Enter the following command at the prompt to see the version of the CLI currently installed on your machine:

oci --version

If you have a version on your machine older than the version currently available, install the latest version.

Note:
Always update to the latest version of the CLI. The CLI is not updated automatically, and you can only access new or updated CLI features by installing the current version.

Linux Operating System Requirements

See Requirements on page 4193 for a list of the Linux operating systems that support the CLI.

Installing the CLI

Installation and configuration of the CLIs is described in detail in Command Line Interface (CLI) on page 4192.

Using the CLI

You can specify CLI options using the following commands:

• --option <value> or
• --option=<value>
The basic CLI syntax is:

```
oci dts <resource> <action> <options>
```

This syntax is applied to the following:

- `oci dts` is the shortened CLI command name
- `job` is an example of a `<resource>`
- `create` is an example of an `<action>`
- Other strings are `<options>`

The following command to create a transfer job shows a typical CLI command construct.

```
oci dts job create --compartment-id ocid1.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyApplianceImportJob --device-type appliance
```

**Note:**
In the previous examples, provide a friendly name for the transfer job using the `##display#name` option. Avoid entering confidential information.

### Accessing Command Line Interface Help

All CLI help commands have an associated help component you can access from the command line. To view the help, enter any command followed by the `--help` or `-h` option. For example:

```
oci dts job --help
```

**NAME**

dts_job -

**DESCRIPTION**

Transfer disk or appliance job operations

**AVAILABLE COMMANDS**

- change-compartment
- close
- create
- delete
- detach-devices-details
  ...

When you run the help option (`--help` or `-h`) for a specified command, all the subordinate commands and options for that level of CLI are displayed. If you want to access the CLI help for a specific subordinate command, include it in the CLI string. For example:

```
oci dts job create --help
```

**NAME**

dts_job_create -

**DESCRIPTION**

Creates a new transfer disk or appliance job.

**USAGE**

oci dts job create [OPTIONS]

**REQUIRED PARAMETERS**
Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- **Data transfer administrators** who can create and manage transfer jobs.
- **Data transfer upload users** who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups on page 2419.

An administrator creates these groups with the following policies:

- **The data transfer administrator group** requires an authorization policy that includes the following:

  ```
  Allow group <group_name> to manage data-transfer-jobs in
  compartment <compartment_name>
  Allow group <group_name> to manage objects in
  compartment <compartment_name>
  Allow group <group_name> to manage buckets in
  compartment <compartment_name>
  ```

  Alternatively, you can consolidate the manage buckets and manage objects policies into the following:

  ```
  Allow group <group_name> to manage object-family in
  compartment <compartment_name>
  ```

- **The data transfer upload user group** requires an authorization policy that includes the following:

  ```
  Allow group <group_name> to manage buckets
  in compartment <compartment_name> where all
  { request.permission='BUCKET_READ', target.bucket.name='<bucket_name>' }
  Allow group <group_name> to manage objects
  in compartment <compartment_name> where all
  { target.bucket.name='<bucket_name>', any
  { request.permission='OBJECT_CREATE',
  request.permission='OBJECT_OVERWRITE',
  request.permission='OBJECT_INSPECT' })
  ```

  To enable notifications, add the following policies:

  ```
  Allow group <group name> to manage ons-topics in tenancy
  ```
Allow group <group name> to manage ons-subscriptions in tenancy
Allow group <group name> to manage cloudevents-rules in tenancy
Allow group <group name> to inspect compartments in tenancy

See Notifications Overview on page 3350 and Overview of Events on page 1784 for more information.

The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see Managing Users on page 2414.

**Important:**
For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

**Requesting Appliance Entitlement**

If your tenancy is not entitled to use the Data Transfer Appliance, you must request the Data Transfer Appliance Entitlement before creating an appliance-based transfer job.

**Important:**
The main buyer or administrator, who is at a VP level or higher, receives an email notification and is required to e-sign a Terms and Conditions document. After Oracle has confirmed signature of the document, you can create an appliance-based transfer job. The email for the DocuSign does not go to the requester unless they are the main buyer or administrator who is at least at a VP level.

It can take up to 24 hours before the Terms and Conditions are sent.

To request the Data Transfer Appliance Entitlement using the Console

Open the Transfer Job page and click Request at the top. Otherwise, you are prompted to request the entitlement when attempting to create your first appliance-based transfer job.

Once requested, the status of your request is visible at the top of the Transfer Job page. For example:

**Data Transfer Appliance Entitlement:** Granted

It can take a while to get the Data Transfer Appliance Entitlement approved. After Oracle receives your request, a Terms and Conditions Agreement is sent to the account owner via DocuSign to use the appliance. The entitlement request is approved once the signature is received. The Data Transfer Appliance Entitlement is a tenancy-wide entitlement that you need to request once for each tenancy.

To request the Data Transfer Appliance Entitlement using the CLI

```
oci dts appliance request-entitlement --compartment-id <compartment_id> --name <name> --email <email>
```

<name> is the name of the requester.
<email> is the email address of the requester.

For example:

```
oci dts appliance request-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID --name "John Doe" --email jdoe@mycompany.com
```

```json
{
    "data": {
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2019-12-18T18:29:15+00:00",
        "defined-tags": {}
    }
}```
To show the status of a Data Transfer Appliance Entitlement request using the CLI

```
oci dts appliance show-entitlement --compartment-id <compartment_id>
```

For example:

```
oci dts appliance show-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID
```

Establishing the Data Transfer Appliance Entitlement Policy

Use the following policy to enable users in a specific group to request a Data Transfer Appliance Entitlement in your tenancy.

```
Allow group <group_name> to {DTA_ENTITLEMENT_CREATE} in tenancy
```

Appliance Entitlement Eligibility

Your request for a Data Transfer Appliance Entitlement in your tenancy may be denied if you are a free trial customer. If your request is denied, upgrade to a full account. You can also contact your Oracle Customer Support Manager or Oracle Support to determine your options for obtaining the entitlement.

Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a compartment in your tenancy. For details on creating the bucket to store uploaded data, see Managing Buckets on page 3398.

Configuring Firewall Settings

Ensure that your local environment's firewall can communicate with the Data Transfer Service running on the IP address ranges: 140.91.0.0/16. You also need to open access to the Object Storage IP address ranges: 134.70.0.0/17.

Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See Transfer Jobs on page 1060 for complete details on all tasks related to transfer jobs.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. Identify which compartment and Object Storage bucket to which Oracle is to upload
your data. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

**Note:**
It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a transfer job ID that you specify in other transfer tasks. For example:

```
oci1.datatransferjob.region1.phx..<unique_ID>
```

To create a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the designated compartment you are to use for data transfers from the list.
   - A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
   - The Create Transfer Job dialog appears.
4. Enter a **Job Name**. Avoid entering confidential information. Then, select the **Upload Bucket** from the list.
5. Select **Appliance** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the CLI

```
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type <device_type>
```

- `<display_name>` is the name of the transfer job. Avoid entering confidential information.
- `<device_type>` should always be appliance for Appliance-Based Data Import jobs.

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance
```

```json
{
    "data": {
        "attached-transfer-appliance-labels": [],
        "attached-transfer-device-labels": [],
        "attached-transfer-package-labels": [],
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2019-12-18T19:43:58+00:00",
        "defined-tags": {},
        "device-type": "APPLIANCE",
        "display-name": "MyApplianceImportJob",
        "freeform-tags": {},
        "id": "oci1.datatransferjob.oc1..exampleuniqueID",
        "label": "JAKQVAGJF",
        "lifecycle-state": "INITIATED",
        "upload-bucket-name": "MyBucket1"
    },
    "etag": "2--gzip"
}
```

 Optionally, you can specify one or more defined or freeform tags when you create a transfer job. For more information about tagging, see [Resource Tags](#) on page 211.
Defined Tags

To specify defined tags when creating a job:

```
oci dts job create --bucket <bucket> --compartment-id <compartment_id>
   --display-name <display_name> --device-type appliance --defined-tags
   '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID
   --display-name MyApplianceImportJob --device-type appliance --defined-tags
   '{"Operations": {"CostCenter": "01"}}'
```

```
{
   "data": {
      "attached-transfer-appliance-labels": [],
      "attached-transfer-device-labels": [],
      "attached-transfer-package-labels": [],
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "creation-time": "2019-12-18T19:43:58+00:00",
      "defined-tags": {
         "operations": {
            "costcenter": "01"
         }
      },
      "device-type": "APPLIANCE",
      "display-name": "MyApplianceImportJob",
      "freeform-tags": {
         "Operations": {"CostCenter": "01"}
      },
      "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "label": "JAKQVAGJF",
      "lifecycle-state": "INITIATED",
      "upload-bucket-name": "MyBucket1"
   },
   "etag": "2--gzip"
}
```

Freeform Tags

To specify freeform tags when creating a job:

```
oci dts job create --bucket <bucket> --compartment-id <compartment_id>
   --display-name <display_name> --device-type appliance --freeform-tags
   '{ "<tag_key>":"<value>" }'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID
   --display-name MyApplianceImportJob --device-type appliance --freeform-tags
   '{"Pittsburg_Team":"brochures"}'
```

```
{
   "data": {
      "attached-transfer-appliance-labels": [],
      "attached-transfer-device-labels": [],
      "attached-transfer-package-labels": [],
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "creation-time": "2019-12-18T19:43:58+00:00",
      "defined-tags": {
         "Pittsburg_Team": "brochures",
      },
      "device-type": "APPLIANCE",
      "display-name": "MyApplianceImportJob",
      "freeform-tags": {
```
"Pittsburg_Team": "brochures"},
  "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
  "label": "JAKQVAGJF",
  "lifecycle-state": "INITIATED",
  "upload-bucket-name": "MyBucket1"
},
  "etag": "2--gzip"
}

**Note:**
Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See [Working with Defined Tags](#) for details.

### Multiple Tags
To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```bash
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type appliance --freeform-tags '{ "<tag_key>": "<value>" }', '{ "<tag_key>": "<value>" }'
```

### Notifications
To include notifications, include the `--setup-notifications` option. See [Setting Up Transfer Job Notifications from the CLI](#) for more information on this feature.

### Getting Transfer Job IDs
Each transfer job you create has a unique ID within Oracle Cloud Infrastructure. For example:

```
ocid1.datatransferjob.oc1.phx.exampleuniqueID
```

You will need to forward this transfer job ID to the Data Administrator.

*To get the transfer job ID using the Console*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.
   The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job whose details you want to view.
   Alternatively, you can click the **Actions** icon (●), and then click **View Details**.
   The Details page for that transfer job appears.
4. Find the **OCID** field in the Details page and click **Show** to display it or **Copy** to copy it to your computer.

*To get the transfer job ID using the CLI*

```
oci dts job list --compartment-id <compartment_id>
```

For example:

```
oci dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

{
  "data": [
    {
      "creation-time": "2019-12-18T19:43:58+00:00",
```
The ID for each transfer job is included in the return:

```
"id": "ocid.compartment.oc1..exampleuniqueID"
```

**Tip:**
When you create a transfer job using the `oci dts job create` CLI, the transfer job ID is displayed in the CLI's return. You can also run the `oci dts job show` CLI for that specific job to get the ID.

### Setting Up Transfer Job Notifications from the CLI

You can generate notifications that send messages regarding changes to a new or existing appliance-based transfer job through the CLI. Using this feature creates a topic, subscription for a list of email addresses, and a rule that notifies you on all events related to the export job's activities and changes in state. This method provides a more convenient way to generate notifications tailored to appliance-based transfer jobs.

The CLI command to set up transfer job notifications is different depending on whether you are creating a new transfer job or updating an existing transfer job. In both cases, running the CLI command prompts you to enter the email addresses of each notification subscriber as a comma separated list. Each recipient is sent an email with a link to confirm they want to receive the notifications.

You are prompted to enter those email addresses you want included in the notifications, separated by commas (","). When your list is complete, add a colon (":") followed by your own email address:

```
user1@mycompany.com,user2@mycompany.com : myemail@mycompany.com
```

For both of the notification commands, the following is returned:

```
If the commands fail to run, you can use the OCI CLI to do the setup manually:
export ROOT_COMPARTMENT_OCID=ocidv1:tenancy:oc1:exampleuniqueID
oci ons topic create --compartment-id $ROOT_COMPARTMENT_OCID --name
DTSExportTopic --description "Topic for data transfer service export jobs"
oci ons subscription create --protocol EMAIL --compartment-id
$ROOT_COMPARTMENT_OCID --topic-id $TOPIC_OCID --endpoint $EMAIL_ID
oci events rule create --display-name DTSExportRule --is-enabled
true --compartment-id $ROOT_COMPARTMENT_OCID --actions '{"actions":
[{{"actionType":"ONS","topicId":"$TOPIC_OCID","isEnabled":true}}]}' --condition
'{{"eventType":"com.oraclecloud.datatransferservice.addapplianceexportjob","com.oraclecloud.datatransferservice.updateapplianceexportjob","com.oraclecloud.datatransferservice.moveapplianceexportjob"}}'
```

Oracle Cloud Infrastructure User Guide 1029
To set up notifications when creating a transfer job using the CLI

To set up notifications when creating a transfer job, include the --setup-notifications option in the CLI:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id>
    --display-name <display_name> --device-type appliance ... --setup-notifications
```

To set up notifications for an existing transfer job using the CLI

To set up notifications for an existing transfer job:

```
oci dts job setup-notifications --job-id <job_id>
```

For example:

```
oci dts job setup-notifications --job-id
    ocid1.datatransferjob.oc1..exampleuniqueID

If the commands fail to run, you can use the OCI CLI to do the setup manually:
oci ons topic create --compartment-id ocid1.tenancy.oc1..exampleuniqueID
    --name MyImportJob --description "Topic for data transfer service import job
    with OCID ocid1.datatransferjob.oc1..exampleuniqueID"
oci ons subscription create --protocol EMAIL --compartment-id
    $ROOT_COMPARTMENT_OCID --topic-id $TOPIC_OCID --subscription_endpoint
    $EMAIL_ID
oci events rule create --display-name MyImportJob --is-enabled true--
    compartment-id ocid1.tenancy.oc1..exampleuniqueID --actions '{"actions":
    [{"actionType":"ONS","topicId":"$TOPIC_OCID","isEnabled":true}]}
    --condition
    '{"eventType":"com.oraclecloud.datatransferservice.*transferjob","data":
    {"resourceId":"ocid1.datatransferjob.oc1..exampleuniqueID"})' --description
    "Rule for data transfer service to send notifications for an import job
    with OCID ocid1.datatransferjob.oc1..exampleuniqueID"
Creating topic DTSImportJobTopic_2pwaqq
{
    "data": {
        "api-endpoint": "https://cell1.notification.us-phoenix-1.oraclecloud.com",
        "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",
        "defined-tags": {},
        "description": "Topic for data transfer service import job with OCID
        ocid1.datatransferjob.oc1..exampleuniqueID",
        "etag": "null",
        "freeform-tags": {},
        "lifecycle-state": "ACTIVE",
        "name": "DTSImportJobTopic_2pwaqq",
        "time-created": "2020-07-15T18:26:07.179000+00:00",
        "topic-id": "ocid1.onstopic.oc1..exampleuniqueID"
    },
    "etag": "2e5a567d"
}
```

Enter email addresses to subscribe to as a comma separated list. Example:

```
jdoe@mycompany.com,rroe@mycompany.com : jsmith@mycompany.com
```

Creating subscription for jsmith@mycompany.com
Preparing Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the import appliance. Send these configuration files to the Data Administrator where they can be placed in the Control Host (if there are separate Control and Data Hosts). The config file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The config_upload_user file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.
Creating the Data Transfer Directory

Create a Oracle Cloud Infrastructure directory (.oci) on the same Control Host machine where the Oracle Cloud Infrastructure CLI is installed. For example:

```bash
mkdir /root/.oci/
```

The two configuration files (config and config_upload_user) are placed in whatever location you choose.

**Note:**
You can store the configuration files anywhere on your Control Host. The root directory is only given as an example.

Creating the Data Transfer Administrator Configuration File

The data transfer administrator configuration file contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup CLI or manually using a text editor.

**Using the Setup CLI**

Run the `oci setup config` command line utility to walk through the first-time setup process. The command prompts you for the information required for the configuration file and the API public/private keys. The setup dialog generates an API key pair and creates the configuration file.

For more information about how to find the required information, see:

- Where to Get the Tenancy's OCID and User's OCID on page 4184
- Regions and Availability Domains on page 180

**Manual Setup**

If you want to set up the API public/private keys yourself and write your own configuration file, see SDK and Tool Configuration.

**Tip:**
Use the `oci setup keys` command to generate a key pair to include in the config file.

Create the data transfer administrator configuration file `/root/.oci/config` with the following structure:

```ini
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1, and ap-osaka-1.>
```

For example:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<exampleuniqueID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```
For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```ini
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1

[PROFILE1]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1
```

By default, the DEFAULT profile is used for all CLI commands. For example:

```bash
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type appliance
```

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```bash
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type appliance --profile MyProfile
```

Using the example configuration file above, the `<profile_name>` would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```bash
oci dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name> --config
```

Creating the Data Transfer Upload User Configuration File

The `config_upload_user` configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

```ini
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1, and ap-osaka-1.>
```

Adding Object Storage Endpoints

Include the line `endpoint=<url>` for the Object Storage API endpoint in the upload user configuration file.
For example:

```
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

Click [here](https://example.com) to view a list of endpoints.

A complete configuration including the Object Storage endpoint might look like this:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
region=us-phoenix-1
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

**Important:**

Creating an upload user configuration file with multiple profiles is *not* supported.

### Configuration File Entries

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

**Note:**

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>key_file</td>
<td>Full path and filename of the private key. <strong>Important:</strong> The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
You can verify the data transfer upload user credentials using the following command:

```
oci dts job verify-upload-user-credentials --bucket <bucket_name>
```

### Requesting the Import Appliance

This section describes how to request an import appliance from Oracle for copying your data to Oracle Cloud Infrastructure. See Import Appliances on page 1069 for complete details on all tasks related to transfer jobs.

Oracle Cloud Infrastructure customers can use import appliances to migrate data for free. You are only charged for Object Storage usage once the data is successfully transferred to your designated bucket. All appliance requests still require approval from Oracle.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenancy</td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 4179.</td>
<td>Yes</td>
</tr>
<tr>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 180.</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London).</td>
<td></td>
</tr>
</tbody>
</table>

Tip:

To save time, identify the data you intend to upload and make data copy preparations before requesting the import appliance.

Creating an appliance request returns an Oracle-assigned appliance label. For example:

```
XA8XM27EH
```

**To request an appliance using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.

   Choose the transfer job that for which you want to request an import appliance.

2. Click Request Transfer Appliance under Transfer Appliances.

   The Request Transfer Appliance dialog appears.
3. Provide the shipping address details where you want the import appliance sent.

- **Company Name**: Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
- **Recipient Name**: Required. Specify the name of the recipient of the import appliance.
- **Recipient Phone Number**: Required. Specify the recipient's phone number.
- **Recipient Email Address**: Required. Specify the recipient's email address.
- **Care Of**: Optional intermediary party responsible for transferring the import appliance shipment from the delivery vendor to the intended recipient.
- **Address Line 1**: Required. Specify the street address to where the import appliance is sent.
- **Address Line 2**: Optional identifying address details like building, suite, unit, or floor information.
- **City/Locality**: Required. Specify the city or locality.
- **State/Province/Region**: Required. Specify the state, province, or region.
- **Zip/Postal Code**: Specify the zip code or postal code.
- **Country**: Required. Select the country.

4. Click **Request Transfer Appliance**.

*To request an appliance using the CLI*

```
oci dts appliance request --job-id <job_id> --addressee <addressee>
--care-of <care_of> --address1 <address_line1> --city-or-locality <city_or_locality>
--state-province-region <state_province_region> --country <country> --zip-postal-code <zip_postal_code>
--phone-number <phone_number> --email <email> <options>
```

*<options>* are:

- **--address2**: Optional address of the addressee (line 2).
- **--address3**: Optional address of the addressee (line 3).
- **--address4**: Optional address of the addressee (line 4).
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The **--generate-full-command-json-input** option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: [https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions](https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions).

For example:

```
oci dts appliance request --job-id ocid1.datatransferjob.oc1..exampleuniqueID --addressee MyCompany --care-of "John Doe" --address1 "123 Main Street" --city-or-locality Anytown --state-province-region NY --country USA --zip-postal-code 12345 --phone-number 8005551212 --email john.doe@mycompany.com
```

```json
{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
```
When you submit an appliance request, Oracle generates a unique label (label: "XAKWEGKZ5T") to identify the import appliance and your request is sent to Oracle for approval and processing.

**Setting Up Import Appliance Request Notifications from the CLI**

You can generate notifications that send messages regarding changes to your import appliance request by using the `setup-notifications` command through the CLI. Running this command creates a topic, subscription for list of email addresses, and also a rule that notifies you on all events related to the import appliance request's activities and changes in state. This method provides a more convenient way to generate notifications tailored to import appliance requests.

Running the CLI command prompts you to enter the email addresses of each notification subscriber as a comma separated list. Each recipient is sent an email with a link to confirm they want to receive the notifications.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setting up notifications from the CLI affects all import appliances in your tenancy. You cannot specify notifications for individual appliances.</td>
</tr>
</tbody>
</table>

**Setting Up Notifications for a New Import Appliance Request**

To include job notifications when requesting an import appliance, include the `--setup-notifications` option in the CLI:

```
oci dts appliance request --job-id <job_id> --addressee <addressee> --address1 <address_line1> --city-or-locality <city_or_locality> --state-or-region <state_or_region> --country <country> --zip-code <zip> ... --setup-notifications
```

**Setting up Notifications for an Existing Import Appliance Request**

To set up notifications for an existing import appliance request, run the `appliance setup-notifications` CLI on the appliance:

```
oci dts appliance setup-notifications --appliance-label <appliance_label>
```

**Notifying the Data Administrator**

When you have completed all the tasks in this topic, provide the Data Administrator of the following:
Data Transfer

- IAM login credentials
- Oracle Cloud Infrastructure CLI configuration files
- Transfer job ID
- Appliance label

What’s Next

You are now ready to configure your system for the data transfer. See Configuring Appliance Data Imports on page 1038.

Configuring Appliance Data Imports

This topic describes the tasks associated with configuring the Appliance-Based Data Import. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1017.

Unpacking and Connecting the Import Appliance to the Network

When the shipping vendor delivers your import appliance, Oracle updates the status as Delivered and provides the date and time the appliance was received in the Transfer Appliance Details.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your import appliance arrives in a transit case with a telescoping handle and wheels. The case amenities allow for easy movement to the location where you intend to place the appliance to upload your data.</td>
</tr>
</tbody>
</table>

| Retain all packaging materials! When shipping the import appliance back to Oracle, you must package the appliance in the same manner and packaging in which the appliance was received. |

Here are the tasks involved in unpacking and getting your import appliance ready to configure.

1. Inspect the tamper-evident security tie on the transit case.

   If the appliance was tampered with during transit, the tamper-evident security tie serves to alert you.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the security tie is damaged or is missing, do not plug the appliance into your network! Immediately file a Service Request (SR).</td>
</tr>
</tbody>
</table>
2. Remove and compare the number on the security tie with the number logged by Oracle.

To see the security tie number logged by Oracle using the Console

a. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
b. Find the transfer job and import appliance associated with the removed security tie.
c. Click the **Actions** icon ( ), and then click **View Details**.
d. Look at the contents of the **Send Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

To see the security tie number logged by Oracle using the CLI

```
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```

For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```json
{
  "data": {
    "delivery-security-tie-id": "exampleuniqueID",
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "PROCESSING",
    "next-billing-time": null,
    "return-security-tie-id": "exampleuniqueID",
    "serial-number": "exampleuniqueserialnumber",
    "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```
Compare the value of the `delivery-security-tie-id` attribute with the number on the physical tag to ensure they match.

**Caution:**
If the number on the physical security tie does not match the number logged by Oracle, do not plug the appliance into your network! Immediately file a Service Request (SR).

**Note:**
Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

3. Open the transit case and ensure that the case contains the following items:
   - Appliance unit and power cable (two types of power cables provided: C14 and C13 to 14)
   - USB to DB-9 serial cable
   - Return shipping instructions (retain these instructions)
   - Return shipping label, label sleeve, tie-on tag, and zip tie
   - Return shipment tamper-evident security tie (use this tie to ensure secure transit case back to Oracle)

4. Compare the number on the return shipment security tie with the number logged by Oracle.

To see the security tie number logged by Oracle using the Console

a. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.  
b. Find the transfer job and import appliance associated with the return shipment security tie.  
c. Click the actions icon (⃣), and then click **View Details**.
   d. Look at the contents of the **Return Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

To see the security tie number logged by Oracle using the CLI

```bash
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```

For example:

```bash
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```json
{
    "data": {
        "appliance-delivery-tracking-number": null,
        "appliance-delivery-vendor": null,
        "appliance-return-delivery-tracking-number": null,
        "creation-time": "2020-05-20T22:08:13+00:00",
        "customer-received-time": null,
        "customer-returned-time": null,
        "customer-shipping-address": {
            "address1": "123 Main Street",
            "address2": null,
            "address3": null,
            "address4": null,
            "addressee": "MyCompany",
            "care-of": "John Doe",
        }...
    }
}
```
Compare the value of the `return-security-tie-id` attribute with the number on the physical tag to ensure they match.

**Caution:**
If the number on the return security tie does not match the number logged by Oracle, file a Service Request (SR). These security tie numbers must match or Oracle cannot upload data from your returned appliance.

5. Remove the import appliance from the case and place the appliance on a solid surface or in a rack.

**Caution:**
We recommend assistance lifting the appliance out of the transit case and placing the appliance in a rack or on a desk top. The total shipping weight is about 64 lbs (29.0299 kg) and appliance weight is 38 lbs (17.2365 kg).

6. Connect the appliance to your local network using one of the following:
   - 10GBase-T: Standard RJ-45
   - SFP+: The transceiver must be compatible with Intel X520 NICs.

7. Attach one of the provided power cords to the appliance and plug the other end into a grounded power source.

8. Turn on the appliance by flipping the power switch on the back of the appliance.

**Connecting the Import Appliance to the Terminal Emulation Host**

Connect the import appliance to your designated Terminal Emulation Host computer using the provided USB to DB-9 serial cable.

**Note:**
You might need to download the driver for this cable on your Terminal Emulation Host: [https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support](https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support)

**Setting Up Terminal Emulation**

Appliance-based transfers require you to set up your host for terminal emulation so you can communicate with the appliance through the appliance's serial console. This communication requires installing serial console terminal emulator software. We recommend using the following:

- PuTTY for Windows
- ZOC for OS X
- PuTTY or Minicom for Linux

Configure the following terminal emulator software settings:
• Baud Rate: 115200
• Emulation: VT102
• Handshaking: Disabled/off
• RTS/DTS: Disabled/off

Note:
PuTTY does not allow you to configure all of these settings individually. However, you can configure the PuTTY default settings by selecting the Serial connection type and specifying "115200" for the Serial Line baud speed. This configuration is sufficient to use PuTTY as a terminal emulator for the appliance.

Configuring the Import Appliance Networking

When the import appliance boots up, an appliance serial console configuration menu is displayed on the Terminal Emulation Host to which the appliance is connected.

Oracle Cloud Data Transfer Appliance
   - For use with minimum dts version: dts-0.4.140
   - See "Help" for determining your dts version

1) Configure Networking
2) Show Networking
3) Reset Authentication
4) Show Authentication
5) Show Status
6) Collect Appliance Diagnostic Information
7) Generate support bundle
8) Shutdown Appliance
9) Reboot Appliance
10) Help

Select a command:

Note:
It can take up to 5 minutes for the serial console menu to display. Press Enter if you do not see the serial console configuration menu after this amount of time.

The appliance supports a single active network interface on any of the 10-Gbps network ports. If only one interface is cabled and active, that interface is chosen automatically. When multiple interfaces are active, you are given the choice to select the interface to use.

To configure your import appliance networking

1. From the Terminal Emulation Host, select Configure Networking from the appliance serial console menu.
2. Provide the required networking information when prompted:

   • **IP Address**: IP address of the appliance.
   • **Subnet Mask Length**: The count of leading 1 bit in the subnet mask. For example, if the subnet mask is 255.255.255.0 then the length is 24.
   • **Default Gateway**: Default gateway for network communications.

For example:

Configure Networking:
^C to cancel

Configuring IP address, subnet mask length, gateway

Example:
### Data Transfer

- **IP Address**: 10.0.0.2
- **Subnet Mask Length**: 24
- **Gateway**: 10.0.0.1

- **Address**: 10.0.0.1
- **Subnet Mask Length**: 24
- **Gateway**: 10.0.0.1

**Configuring IP address 10.0.0.1 netmask 255.255.255.0 default gateway 10.0.0.1**

**Enabling enp0s3**

**Now trying to restart the network**

**Network configuration is complete**

**New authentication material created.**

- **Client access token**: 4iH1gw1lokPJ0

Press ENTER to return...

---

When you configure a network interface, the appliance software generates a new client access token and appliance X.509/SSL certificate. The access token is used to authorize your Control Host to communicate with the Data Transfer Appliance's Management Service. The x.509/SSL certificate is used to encrypt communications with the Data Transfer Appliance's Management Service over the network. Provide the access token and SSL certificate fingerprint values displayed here when you use the CLI commands to **initialize authentication on your host machine**.

You can change the selected interface, network information, and reset the authentication material at any time by selecting **Configure Networking** again from the appliance serial console menu.

### Notifying the Data Administrator

After completing the tasks in this topic, send the following import appliance information to the Data Administrator:

- Appliance IP address
- Access token
- SSL certificate fingerprint

### What's Next

You are now ready to load your data to the disk. See **Copying Data to the Import Appliance** on page 1043.

### Copying Data to the Import Appliance

This topic describes the tasks associated with copying data from the Data Host to the import appliance using the Control Host. The Data Administrator role typically performs these tasks. See **Roles and Responsibilities** on page 1017.

**Note:**

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

### Information Prerequisites

Before performing any import appliance copying tasks, you must obtain the following information:
• Appliance IP address - typically is provided by the Infrastructure Engineer.
• IAM login information, Data Transfer Utility configuration files, transfer job ID, and appliance label - typically is provided by the Project Sponsor.

**Setting Up an HTTP Proxy Environment**

You might need to set up an HTTP proxy environment on the Control Host to allow access to the public internet. This proxy environment allows the Oracle Cloud Infrastructure CLI to communicate with the Data Transfer Appliance Management Service and the import appliance over a local network connection. If your environment requires internet-aware applications to use network proxies, configure the Control Host to use your environment's network proxies by setting the standard Linux environment variables on your Control Host.

Assume that your organization has a corporate internet proxy at http://www-proxy.myorg.com and that the proxy is an HTTP address at port 80. You would set the following environment variable:

```
export HTTPS_PROXY=http://www-proxy.myorg.com:80
```

If you configured a proxy on the Control Host and the appliance is directly connected to that host, the Control Host tries unsuccessfully to communicate with the appliance using a proxy. Set a `no_proxy` environment variable for the appliance. For example, if the appliance is on a local network at 10.0.0.1, you would set the following environment variable:

```
export NO_PROXY=10.0.0.1
```

**Setting Firewall Access**

If you have a restrictive firewall in the environment where you are using the Oracle Cloud Infrastructure CLI, you may need to open your firewall configuration to the following IP address ranges: 140.91.0.0/16.

**Initializing Authentication to the Import Appliance**

**Note:**

You can only use the Oracle Cloud Infrastructure CLI to initialize authentication.

Initialize authentication to allow the host machine to communicate with the import appliance. Use the values returned from the `Configure Networking` command. See Configuring the Transfer Appliance Networking for details.

**To initialize authentication using the CLI**

Perform this task using the following CLI. There is no Console equivalent.

```
oci dts physical-appliance initialize-authentication --job-id <job-id> --appliance-cert-fingerprint <fingerprint> --appliance-ip <ip_address> --appliance-label <appliance-label>
```

For example:

```
```

When prompted, supply the access token and system. For example:

```
```

Retrieving the Appliance serial id from Oracle Cloud Infrastructure.
Access token ('q' to quit):
Found an existing appliance. Is it OK to overwrite it? [y/n] y
Registering and initializing the authentication between the dts CLI and the appliance
Appliance Info:
  encryptionConfigured: false
  lockStatus: NA
  finalizeStatus: NA
  totalSpace: Unknown
  availableSpace: Unknown

The Control Host can now communicate with the import appliance.

To show details about the connected appliance using the CLI

At the command prompt on the host, run `oci dts physical-appliance show` to show the status of the connected import appliance.

```
oci dts physical-appliance show
```

For example:

```
Appliance Info:
  encryptionConfigured: false
  lockStatus: NA
  finalizeStatus: NA
  totalSpace: Unknown
  availableSpace: Unknown
```

Configuring Import Appliance Encryption

Configure the import appliance to use encryption. Oracle Cloud Infrastructure creates a strong passphrase for each appliance. The command securely collects the strong passphrase from Oracle Cloud Infrastructure and sends that passphrase to the Data Transfer service.

If your environment requires Internet-aware applications to use network proxies, ensure that you set up the required Linux environment variables. See for more information.

**Important:**

If you are working with multiple appliances at the same time, be sure the job ID and appliance label you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

**Note:**

You can only use the Oracle Cloud Infrastructure CLI to configure encryption.

To configure import appliance encryption using the CLI

At the command prompt on the host, run `oci dts physical-appliance configure-encryption` to configure import appliance encryption.

```
oci dts physical-appliance configure-encryption --job-id <job_id> --appliance-label <appliance_label>
```
Data Transfer

For example:

```
oci dts physical-appliance configure-encryption --job-id
ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-label
XA8XM27EVH
```

Moving the state of the appliance to preparing...
Passphrase being retrieved...
Configuring encryption...
Encryption configured. Getting physical transfer appliance info...

```
{
  "data": {
    "availableSpaceInBytes": "Unknown",
    "encryptionConfigured": true,
    "finalizeStatus": "NA",
    "lockStatus": "LOCKED",
    "totalSpaceInBytes": "Unknown"
  }
}
```

Unlocking the Import Appliance

You must unlock the appliance before you can write data to it. Unlocking the appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance. Unlocking can be accomplished in two different ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

**Important:**

It can take up to 10 minutes to unlock an appliance the first time. Subsequent unlocks are not as time consuming.

**Note:**

You can only use the Oracle Cloud Infrastructure CLI to unlock the import appliance.

To unlock the appliance and send the passphrase to the appliance using the CLI

```
oci dts physical-appliance unlock --job-id <job_id> --appliance-label <label>
```

For example:

```
oci dts physical-appliance unlock --job-id
ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Retrieving the passphrase from Oracle Cloud Infrastructure

```
{
  "data": {
    "availableSpaceInBytes": "64.00GB",
    "encryptionConfigured": true,
    "finalizeStatus": "NOT_FINALIZED",
    "lockStatus": "NOT_LOCKED",
    "totalSpaceInBytes": "64.00GB"
  }
}
```
To query Oracle Cloud Infrastructure for the passphrase to unlock the import appliance using the CLI

```bash
oci dts appliance get-passphrase --job-id <job_id> --appliance-label <label>
```

For example:

```bash
oci dts appliance get-passphrase --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
{
  "data": {
    "encryption-passphrase": "passphrase"
  }
}
```

Run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted to complete the task:

```bash
oci dts physical-appliance unlock
```

Creating NFS Datasets

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the import appliance for migration to Oracle Cloud Infrastructure. We currently support one dataset per appliance. Appliance-Based Data Import supports NFS versions 3, 4, and 4.1 to write data to the appliance. In preparation for writing data, create and configure a dataset to write to. See Datasets on page 1077 for complete details on all tasks related to datasets.

To create a dataset using the CLI

```bash
oci dts nfs-dataset create --name <dataset_name>
```

For example:

```bash
oci dts nfs-dataset create --name nfs-ds-1
```

Creating dataset with NFS export details nfs-ds-1

```json
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": null,
      "state": "INITIALIZED"
    }
  }
}
```

Configuring Export Settings on the Dataset

To configure export settings on a dataset using the CLI

```bash
oci dts nfs-dataset set-export --name <dataset_name> --rw true --world true
```

For example:

```bash
oci dts nfs-dataset set-export --name nfs-ds-1 --rw true --world true
```

Settings NFS exports to dataset nfs-ds-1

```json
{
  "data": {
    "datasetType": "NFS",
```

Oracle Cloud Infrastructure User Guide
Here is another example of creating the export to give read/write access to a subnet:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --ip 10.0.0.0 --subnet-mask-length 24 --rw true --world false
```

Settings NFS exports to dataset nfs-ds-1
```
{
    "data": {
        "datasetType": "NFS",
        "name": "nfs-ds-1",
        "nfsExportDetails": {
            "exportConfigs": [
                {
                    "hostname": null,
                    "ipAddress": "10.0.0.0",
                    "readWrite": true,
                    "subnetMaskLength": "24",
                    "world": false
                }
            ],
            "state": "INITIALIZED"
        }
    }
}
```

Activating the Dataset

Activation creates the NFS export, making the dataset accessible to NFS clients.

To activate the dataset using the CLI

```
oci dts nfs-dataset activate --name <dataset_name>
```

For example:

```
oci dts nfs-dataset activate --name nfs-ds-1
```

Fetching all the datasets
Activating dataset small-files
Dataset nfs-ds-1 activated

Setting Your Data Host as an NFS Client

**Note:**

Only Linux machines can be used as Data Hosts.
Set up your Data Host as an NFS client:

- For Debian or Ubuntu, install the `nfs-common` package. For example:
  
  ```bash
  sudo apt-get install nfs-common
  ```

- For Oracle Linux or Red Hat Linux, install the `nfs-utils` package. For example:
  
  ```bash
  sudo yum install nfs-utils
  ```

### Mounting the NFS Share

**To mount the NFS share**

At the command prompt on the Data Host, create the mountpoint directory:

```bash
mkdir -p /mnt/<mountpoint>
```

For example:

```bash
mkdir -p /mnt/nfs-ds-1
```

Next, use the `mount` command to mount the NFS share.

```bash
mount -t nfs <appliance_ip>:/data/<dataset_name> <mountpoint>
```

For example:

```bash
mount -t nfs 10.0.0.1:/data/nfs-ds-1 /mnt/nfs-ds-1
```

**Note:**

The appliance IP address in this example (10.0.0.1) may be different than the one you use for your appliance.

After the NFS share is mounted, you can write data to the share.

### Copying Files to the NFS Share

You can only copy regular files to transfer appliances. You cannot copy special files, such as symbolic links, device special, sockets, and pipes, directly to the Data Transfer Appliance. See the following section for instructions on how to prepare special files.

**Important:**

- Individual files being copied to the transfer appliance cannot exceed 9.76 TB.
- Do not fill up the transfer appliance to 100% capacity. There must be space available to generate metadata and for the manifest file to perform the upload to Object Storage. At least 1 GB of free disk space is needed for this area.

### Copying Special Files

To transfer special files, create a tar archive of these files and copy the tar archive to the Data Transfer Appliance. We recommend copying many small files using a tar archive. Copying a single compressed archive file should also take less time than running copy commands such as `cp -r` or `rsync`.

Here are some examples of creating a tar archive and getting it onto the Data Transfer Appliance:

- Running a simple tar command:
  
  ```bash
tar -cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/
  ```
Running a command to create a file with md5sum hashes for each file in addition to the tar archive:

```bash
tar cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/ | xargs -I '{}' sh -c "test -f '{}' && md5sum '{}''" | tee tarzip_md5
```

The tar archive file `filesystem.tgz` has a base64 md5sum once it is uploaded to OCI Object Storage. Store the `tarzip_md5` file where you can retrieve it. After the compressed tar archive file is downloaded from Object Storage and unpacked, you can compare the individual files against the hashes in the file.

**Deactivating the Dataset**

**Note:**

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Import, you can skip this step and proceed to Sealing the Dataset on page 1050.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

*To deactivate the dataset using the CLI*

At the command prompt on the host, run `dts nfs-dataset deactivate` to deactivate the NFS dataset.

```bash
oci dts nfs-dataset deactivate --name <dataset_name>
```

For example:

```bash
oci dts nfs-dataset deactivate --name nfs-ds-1
```

**Sealing the Dataset**

Sealing a dataset stops all writes to the dataset. This process can take some time to complete, depending upon the number of files and total amount of data copied to the import appliance.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. Running the `seal` command with the `--wait` option results in the seal operation being triggered and continues to provide status updates until sealing completion.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.

*To seal the dataset using the CLI*

```bash
oci dts nfs-dataset seal --name <dataset_name> [--wait]
```

For example:

```bash
oci dts nfs-dataset seal --name nfs-ds-1
```

**Seal initiated. Please use seal-status command to get progress.**

*To monitor the dataset sealing process using the CLI*

```bash
oci dts nfs-dataset seal-status --name <dataset_name>
```

For example:

```bash
oci dts nfs-dataset seal-status --name nfs-ds-1
```
Downloading the Dataset Seal Manifest

After sealing the dataset, you can optionally download the dataset’s seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.

To download the dataset seal manifest file using the CLI

```
oci dts nfs-dataset get-seal-manifest --name <dataset_name> --output-file <file_path>
```

For example:

```
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

Finalizing the Import Appliance

```
Note:

You can only use the CLI commands to finalize the import appliance.
```

Finalizing an appliance tests and copies the following to the appliance:

- Upload user configuration credentials
- Private PEM key details
- Name of the upload bucket

The credentials, API key, and bucket are required for Oracle to be able to upload your data to Oracle Cloud Infrastructure Object Storage. When you finalize an appliance, you can no longer access the appliance for dataset operations unless you unlock the appliance. See Reopening a Dataset on page 1080 if you need to unlock an appliance that was finalized.

```
Important:

If you are working with multiple appliances at the same time, be sure the job ID and appliance label you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.
```
**To finalize the import appliance**

1. Seal the dataset before finalizing the import appliance. See Sealing the Dataset on page 1050.
2. Open a command prompt on the host and run `oci dts physical-appliance finalize` to finalize an appliance.

   ```
   oci dts physical-appliance finalize --job-id <job_id> --appliance-label <appliance_label>
   
   For example:
   
   oci dts physical-appliance finalize --job-id ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-label XAKWEGKZ5T
   
   Retrieving the upload summary object name from Oracle Cloud Infrastructure
   Retrieving the upload bucket name from Oracle Cloud Infrastructure
   Validating the upload user credentials
   Create object BulkDataTransferTestObject in bucket MyBucket using upload user
   Overwrite object BulkDataTransferTestObject in bucket MyBucket using upload user
   Inspect object BulkDataTransferTestObject in bucket MyBucket using upload user
   Read bucket metadata MyBucket using upload user
   Storing the upload user configuration and credentials on the transfer appliance
   Finalizing the transfer appliance...
   
   The transfer appliance is locked after finalize. Hence the finalize status will be shown as NA. Please unlock the transfer appliance again to see the correct finalize status
   Changing the state of the transfer appliance to FINALIZED
   
   ```

   ```json
   {  
     "data": {  
       "availableSpaceInBytes": "Unknown",  
       "encryptionConfigured": true,  
       "finalizeStatus": "NA",  
       "lockStatus": "LOCKED",  
       "totalSpaceInBytes": "Unknown"  
     }  
   }
   ```

   **Note:**

   If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. See Reopening a Dataset on page 1080.

**What's Next**

You are now ready to ship your import appliance with the copied data to Oracle. See Shipping the Import Appliance on page 1052.

**Shipping the Import Appliance**

This topic describes the tasks associated with shipping the import appliance containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1017.
Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Shutting Down the Import Appliance

Shut down the import appliance before packing up and shipping the appliance back to Oracle.

To shut down the import appliance

Using the terminal emulator on the host machine, select Shutdown from the appliance serial console.

Important:
The shutdown does not power off the appliance. Wait 10 minutes after issuing the shutdown, then turn the power switch off and disconnect the power cable.

Packing and Shipping the Import Appliance to Oracle

Return the import appliance to Oracle within 30 days. If you need the appliance beyond the standard 30-day window, you can file a service request to ask for an extension of up to 60 days.

Important:
Review and follow the instructions that were provided in the transit case with the appliance.

To pack and ship the import appliance

1. Unplug the power cord from the power source and detach the other end of the cord from the appliance.
2. Disconnect the appliance from your network.
3. Remove the return shipment tamper-evident security tie from the transit case.
4. Place the appliance, power cord, and serial cable in the transit case.
5. Close and secure the transit case with the return tamper-evident security tie.
6. Loop the top of the plastic tie-on tag with return shipping label through the handle of the transit case. Remove the protective tape from the back of the tie-on tag, exposing the adhesive area on which to secure the tag onto itself. Use the provided zip tie to secure the tie-on tag to the handle.
7. Return the transit case:
   • If a return label was included with the import appliance, attach the label and arrange with the shipping vendor to drop off or pick up the appliance.
   • If a return label was not included, open a service request with Oracle to arrange for the appliance's return. See Creating a Service Request Using the Console on page 126.

The shipping vendor notifies Oracle when the appliance is shipped back to Oracle for upload to Oracle Cloud Infrastructure Object Storage.

What's Next

Now you can track your return import appliance shipment to Oracle and review post transfer logs and summaries. See Monitoring the Import Appliance and Data Transfer on page 1054.
Monitoring the Import Appliance and Data Transfer

This topic describes the monitoring tasks to do after sending the import appliance with the copied data back to Oracle for data transfer to Oracle Cloud Infrastructure. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1017.

**Note:**
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Monitoring the Status of Your Import Appliance Return Shipment

The shipping vendor notifies Oracle when your import appliance is picked up and shipped back for upload to Oracle Cloud Infrastructure Object Storage.

**To monitor the status of your import appliance return shipment using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the transfer job and associated import appliance that you shipped back to Oracle for data upload.
3. Under Transfer Appliances, look at the Status field.

**To monitor the status of your import appliance return shipment using the CLI**

```
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```

For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```json
{
"data": {
"appliance-delivery-tracking-number": null,
"appliance-delivery-vendor": null,
"appliance-return-delivery-tracking-number": null,
"creation-time": "2020-05-20T22:08:13+00:00",
"customer-received-time": null,
"customer-returned-time": null,
"customer-shipping-address": {
"address1": "123 Main Street",
"address2": null,
"address3": null,
"address4": null,
"addressee": "MyCompany",
"care-of": "John Doe",
"city-or-locality": "Anytown",
"country": "USA",
"email": "john.doe@mycompany.com",
"phone-number": "3115551212",
"state-or-region": "NY",
"zipcode": "12345"
},
"delivery-security-tie-id": "exampleuniqueID",
"label": "XAKWEGKZ5T",
"lifecycle-state": "PROCESSING",
```
The import appliance status is indicated by the `lifecycle-state` attribute.

**Import Appliance Status Values**

Here are the import appliance status values, listed in alphabetic order:

**CANCELLED**
You can change your mind about uploading your data to Oracle Cloud Infrastructure Object Storage and cancel your import appliance. Ship the appliance back to Oracle and then cancel the appliance. Oracle always uses secure wipe tools on the boot and data areas whenever an appliance is returned.

**COMPLETE**
Oracle completed your import appliance data upload. Your data is available in your designated bucket in Oracle Cloud Infrastructure Object Storage.

**CUSTOMER LOST**
You have not returned the import appliance within the required 90 days.

**DELIVERED**
Oracle received a delivery confirmation from the shipping vendor that your import appliance was delivered. When the appliance is delivered, Oracle provides the date and time it was received in the appliance details. Appliance usage tracking begins.

**ERROR**
Oracle encountered an unrecoverable error trying to process your import appliance. Oracle cannot upload your data from the appliance. To protect your data, Oracle uses secure wipe tools on the boot and data areas any transfer appliance that cannot be processed. Complete another request for an appliance.

**ORACLE PREPARING**
Oracle approved your import appliance request. The status displays "Preparing" until the appliance is shipped to you.

**ORACLE RECEIVED**
Oracle received your import appliance shipment. The status displays "Oracle Received" until Oracle begins processing and uploading your data from the appliance.

**ORACLE RECEIVED CANCELED**
You canceled your import appliance after you shipped the appliance back to Oracle. Oracle received your canceled appliance does not upload any data from it.

**PREPARING**
You activated your import appliance. You can now copy your data onto the appliance. The status displays "Preparing" until you ship the appliance back to Oracle.

**PROCESSING**
Oracle is processing and uploading the data from your import appliance. The status displays "Processing" until Oracle completes uploading your data from the appliance.
REJECTED

Oracle denied your import appliance request.

**Important:**

If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

REQUESTED

You successfully completed your request for an import appliance. The status displays requested until Oracle approves your appliance request.

RETURN SHIPPED

Oracle received confirmation from the shipping vendor that you shipped your import appliance back to Oracle. The status displays "Return Shipped" until Oracle receives your appliance.

RETURN SHIPPED CANCELLED

You canceled your import appliance after the appliance was delivered to you or after you shipped the appliance back to Oracle. Oracle received confirmation from the shipping vendor that your canceled transfer appliance is on the way back to Oracle. The status displays "Return shipped cancelled" until Oracle receives your appliance.

SHIPPING

Oracle completed the necessary preparations and shipped your import appliance. When the appliance is shipped, Oracle provides the serial number of the appliance, the shipping vendor, and the tracking number in the appliance details. The status displays shipping until the appliance is delivered to you.

**Reviewing the Upload Summary**

Oracle creates upload summary log files for each uploaded appliance. These log files are placed in the bucket where data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the appliance's manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

**Note:**

If you chose to upload your data to an Archive Storage bucket, you must first restore the log file object before you can download that file for review.

The top of the log report summarizes the overall file processing status:

| P | Present: The file is present in both the device and the target bucket |
| M | Missing: The file is present in the device but not the target bucket. It was likely uploaded and then deleted by another user before the summary was generated. |
| C | Name Collision: The file is present in the manifest but a file with the same name but different contents is present in the target bucket. |
| U | Unreadable: The file is not readable from the disk |
| N | Name Too Long: The file name on disk is too long and could not be uploaded |

Complete file upload details follow the summary.
If you upload more than 100,000 files, the upload details are broken into multiple pages. You can only download the first page from the Console. Download the rest of the pages directly from the Object Storage bucket. The subsequent pages have the same object name as the first page, but have an enumerated suffix.

Verifying Uploaded File Integrity

To verify object data integrity of files uploaded to Object Storage from the Data Transfer Appliance, a cryptographic hash using MD5 is provided for all objects uploaded to Object Storage from the Data Transfer Appliance. Oracle Cloud Infrastructure provides the object hash value in base64 encoding.

To download files imported into Object Storage and verify their integrity, run the following CLI command:

```
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location>
```

For example:

```
oci os object get --namespace MyNamespace --bucket-name MyBucket1 --name JLA12B3C/XAABC12EFG/upload_summary.txt --file upload_summary.txt
```

Downloading object [####################################] 100%

Open the file and match the file names of the uploaded files with the MD5 column:

```
# SUMMARY FOR DEVICE [cloudstorage-appliance-1]
Generated at 2020-05-18 21:51:13
TOTAL: 10
### P present: 10
### M missing: 0
### C name collision: 0
### U unreadable: 0
### N nameTooLong: 0

<table>
<thead>
<tr>
<th>STATUS</th>
<th>NAME</th>
<th>LAST_MODIFIED</th>
<th>SIZE (MB)</th>
<th>MD5</th>
</tr>
</thead>
<tbody>
<tr>
<td>present</td>
<td>file_5.txt</td>
<td>Mon May 18 21:51:13 UTC 2020</td>
<td>0.00</td>
<td>8gCSOiPiShA==</td>
</tr>
<tr>
<td>present</td>
<td>file_1.txt</td>
<td>Mon May 18 21:51:13 UTC 2020</td>
<td>0.00</td>
<td>EcN8s6dgT/9pGYA7Yxk1Q==</td>
</tr>
</tbody>
</table>
```

In this example, `file_1.txt` has the MD5 sum of: EcN8s6dgT/9pGYA7Yxk1Q==

To download `file_1.txt`, run the following CLI command:

```
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location>
```

For example:

```
oci os object get --namespace example_namespace --bucket-name bucket-1 --name file_1.txt --file file_1.txt
```

Downloading object [####################################] 100%

Covert the base64 encoded hash value to hexadecimal, use the following command:

```
python -c 'print "BASE64-ENCODED-MD5-VALUE".decode("base64").encode("hex")'
```
For example:

```
python -c 'print "EoN8s6dgT/9pGYA7Yx1klQ==".decode("base64").encode("hex")'
12837cb3a7604fff6919803b631d6495
```

Now generate the md5sum on Linux and verify both values match:

```
md5sum <file_name>
```

For example:

```
md5sum file_1.txt
12837cb3a7604fff6919803b631d6495  file_1.txt
```

### Verifying Multipart Uploaded Files

Large files are split into 1 GB parts when they are uploaded from the Data Transfer Appliance to Object Storage. You can verify the md5sum after downloading a file that was transferred in multiple parts using one of several available scripts. See the following for more information and links to these scripts:

### Viewing Data Transfer Metrics

After the import appliance with your copied data is received by Oracle and the data transfer begins, you can view the metrics associated with the transfer job in the Transfer Appliance Details page in chart or table format.

**Tip:**

Set up your notifications to alert you when the data transfer from the appliance to Oracle Cloud Infrastructure is occurring. When the state changes from ORACLE_RECEIVED to PROCESSING, you can start viewing data transfer metrics. If you included the `--setup-notification` option when you made your appliance request from the CLI, this alert occurs automatically. See [Notifications Overview](#) on page 3350 for more information.

Select **Metrics** under **Resources** to display each of these measures:

- **Import Files Uploaded** - Total number of files uploaded for import.
- **Import Bytes Uploaded** - Total number of bytes uploaded for import.
- **Import Files Remaining** - Total number of files remaining for import upload.
- **Import Bytes Remaining** - Total number of bytes remaining for import upload.
- **Import Files in Error** - Total number of files in error for import.
- **Import Upload Verification Progress** - Progress of verification of files that have already been uploaded for import.

Select the **Start Time** and **End Time** for these measures, either by manually entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. As an alternative to selecting a start and end time, you can also select from a list of standard times (last hour, last 6 hours, and so forth) from the **Quick Selects** list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.
Data Transfer

Tip:
Mean is the most useful statistic for data transfer as it reflects an absolute value of the metric.

Choose additional actions from the Options list, including viewing the query in the Metrics Explorer, capturing the URL for the measure, and switching between chart and table view.

Click Reset Charts to delete any existing information in the charts and begin recording new metrics.

See Monitoring Overview on page 2660 for general information on monitoring your Oracle Cloud Infrastructure services.

Closing the Transfer Job

Close the transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated import appliances be returned, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click Close Transfer Job.

To close a transfer job using the CLI

oci dts job close --job-id <job_id>

For example:

oci dts job close --job-id ocid1.datatransferjob.oc1..exampleuniqueID
{
    "data": {
        "attached-transfer-appliance-labels": [],
        "attached-transfer-device-labels": [],
        "attached-transfer-package-labels": [],
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2020-05-20T22:00:43+00:00",
        "defined-tags": {},
        "device-type": "APPLIANCE",
        "display-name": "MyApplianceImportJob",
        "freeform-tags": {},
        "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
        "label": "JGX4N1XLI",
        "lifecycle-state": "CLOSED",
        "upload-bucket-name": "MyBucket"
    },
    "etag": "1"
}

The lifecycle-state attribute value is "CLOSED."

What’s Next

You have completed the process of setting up, running, and monitoring the Appliance-Based Data Import. If you determine that another appliance-based data transfers is required, repeat the procedure from the beginning.
Appliance Import Reference

This topic provides complete task details for certain components associated with Appliance-Based Data Imports. Use this topic as a reference to learn and use commands associated with components included in the Appliance-Based Data Import procedure.

Transfer Jobs

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job is associated with one or more import appliances.

**Note:**

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating Transfer Jobs

Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

Creating a transfer job returns a job OCID that you specify in other transfer tasks. For example:

```
oci1.datatransferjob.oci1..exampleuniqueID
```

To create a transfer job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Select the Compartment you are to use for data transfers from the list.
   A list of transfer jobs that have already been created is displayed.
3. Click Create Transfer Job.
   The Create Transfer Job dialog appears.
4. Enter a **Job Name**. Avoid entering confidential information. Then, select the **Upload Bucket** from the list.
5. Select Disk for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the CLI

```
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type <device_type>
```

<display_name> is the name of the transfer job. Avoid entering confidential information.
<device_type> should always be appliance for Appliance-Based Data Import jobs.

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance
```

```json
{
"data": {
"attached-transfer-appliance-labels": [],
"attached-transfer-device-labels": [],
"attached-transfer-package-labels": [],
"compartment-id": "ocid.compartment.oc1..exampleuniqueID",
"creation-time": "2019-12-18T19:43:58+00:00",
"defined-tags": {},
"device-type": "APPLIANCE",
"display-name": "MyApplianceImportJob",
```
Optionally, you can specify one or more defined or freeform tags when you create a transfer job. For more information about tagging, see Resource Tags on page 211.

**Defined Tags**

To specify defined tags when creating a job:

```bash
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type appliance --defined-tags '{ "<tag_namespace>": { "<tag_key>": "<value>" } }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

```json
{
   "data": {
      "attached-transfer-appliance-labels": [],
      "attached-transfer-device-labels": [],
      "attached-transfer-package-labels": [],
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "creation-time": "2019-12-18T19:43:58+00:00",
      "defined-tags": {
         "operations": {
            "costcenter": "01"
         }
      },
      "device-type": "APPLIANCE",
      "display-name": "MyApplianceImportJob",
      "freeform-tags": {},
      "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "label": "JAKQVAGJF",
      "lifecycle-state": "INITIATED",
      "upload-bucket-name": "MyBucket1"
   },
   "etag": "2--gzip"
}
```

**Freeform Tags**

To specify freeform tags when creating a job:

```bash
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type appliance --freeform-tags '{ "<tag_key>": "<value>" }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance --freeform-tags '{"Pittsburg_Team": "brochures"}'
```
Data Transfer

```json
{
"data": {
"attached-transfer-appliance-labels": [],
"attached-transfer-device-labels": [],
"attached-transfer-package-labels": [],
"compartment-id": "ocid.compartment.oc1..exampleuniqueID",
"creation-time": "2019-12-18T19:43:58+00:00",
"defined-tags": {},
"device-type": "APPLIANCE",
"display-name": "MyApplianceImportJob",
"freeform-tags": {
"Pittsburg_Team": "brochures"
},
"id": "ocid1.datatransferjob.oc1..exampleuniqueID",
"label": "JAKQVAGJF",
"lifecycle-state": "INITIATED",
"upload-bucket-name": "MyBucket1"
},
"etag": "2--gzip"
}
```

**Note:**

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See [Working with Defined Tags](#) on page 3914 for details.

### Multiple Tags

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
oci dts job create --bucket <bucket> --compartment-id <compartment_id> --display-name <display_name> --device-type appliance --freeform-tags "{"<tag_key>"":<value>" },{ "<tag_key>"":<value>" }
```

### Notifications

To include notifications, include the `--setup-notifications` option. See [Setting Up Transfer Job Notifications from the CLI](#) on page 1029 for more information on this feature.

### Listing Transfer Jobs

To display the list of transfer jobs using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list. The transfer jobs in that compartment are displayed.

To display the list of transfer jobs using the CLI

```
oci dts job list --compartment-id <compartment_id>
```

For example:

```
oci dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

```

Oracle Cloud Infrastructure User Guide 1062
When you use the CLI to list jobs, tagging details are also included in the output if you specified tags.

**Displaying Transfer Job Details**

To display the details of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.

   The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job whose details you want to view.

   Alternatively, you can click the **Actions** icon (⋮), and then click **View Details**.

The Details page for that transfer job appears.

To display the details of a transfer job using the CLI

```
oci dts job show --job-id <job_id>
```

For example:

```
oci dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```
When you use the CLI command to display the details of a job, tagging details are also included in the output if you specified tags.

**Editing Transfer Jobs**

To edit the name of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.
   The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job whose name you want to edit.
   The Details page for that transfer job appears.

   Alternatively, you can click the **Actions** icon (⋮), and then click **View Details**.
4. Click **Edit** in the Details page.
   The Edit Transfer Job dialog appears.
5. Edit the name of the transfer job. Avoid entering confidential information.
6. Click **Edit Transfer Job**.
   You are returned to the Details page for that transfer job.

To edit the name of a transfer job using the CLI

```
oci dts job update --job-id <job_id> --display-name <display_name>
```

<display_name> is the new name of the transfer job. Avoid entering confidential information.

For example:

```
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --display-name MyRenamedJob
```

```
{
   "data": {
      "attached-transfer-appliance-labels": [],
      "attached-transfer-device-labels": [],
      "attached-transfer-package-labels": [],
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "creation-time": "2019-12-18T19:43:58+00:00",
      "defined-tags": {},
      "device-type": "APPLIANCE",
      "display-name": "MyRenamedJob",
      "freeform-tags": {},
      "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "label": "JAKQVAGJE",
      "lifecycle-state": "INITIATED",
      "upload-bucket-name": "MyBucket1"
   },
   "etag": "3"
}
```

**Editing Transfer Job Tags**

To edit the tags associated with a transfer job using the CLI

The CLI command replaces any existing tags with the new key/value pairs you specify. For more information about tagging, see **Resource Tags** on page 211.
To edit defined tags, provide the replacement key value pairs:

```bash
oci dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>": {
  "<tag_key>": "<value>"
}}'
```

For example:

```bash
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --
defined-tags '{"Operations": {"CostCenter": "42"}}'
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```

To edit free-form tags, provide the replacement key/value pairs:

```bash
oci dts job update --job-id <job_id> --freeform-tags
'{ "<tag_key>": "<value>" }'
```

For example:

```bash
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --
freeform-tags '{"Chicago_Team":"marketing_videos"}'
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```
### Deleting Transfer Job Tags

To delete the tags associated with a transfer job using the CLI

The CLI command replaces any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, specify a new tag string that does not contain the unwanted key/value pairs.

To delete all free-form tags:

```
oci dts job update --job-id <job_id> --freeform-tags '{}'
```

To delete all defined tags:

```
oci dts job update --job-id <job_id> --defined-tags '{}'
```

### Moving Transfer Jobs Between Compartments

#### To move transfer job to a different compartment using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.
   
   The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job that you want to move.
   
   The Details page for that transfer job appears.

   Alternatively, you can click the **Actions** icon (⋮), and then click **Move Resource**.
4. Click **Move Resource** in the Details page.
   
   The Move Resource to a Different Compartment dialog appears.
5. Choose the compartment you want to which you want to move the transfer job from the list.
6. Click **Move Resource**.

   You are returned to the Details page for that transfer job.

#### To move a transfer job to a different compartment using the CLI

```
oci dts job move --job-id <job_id> compartment-id <compartment_id> <options>
```

<compartment_id> is the compartment to which the data transfer job is being moved.

<options> are:

- **--if-match**: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object's tag matches the tag specified in the request.
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The **--generate-full-command-json-input** option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id -> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

For example:

```
oci dts job move --job-id ocid1.datatransferjob.oc1..exampleuniqueID compartment-id ocid.compartment.oc1..exampleuniqueID
```
To confirm the transfer, display the list of transfer jobs in the new compartment. See Listing Transfer Jobs on page 1062 for more information.

**Verifying Upload User Credentials**

*Note:* You can only use the CLI command to verify upload user credentials.

You can verify the current upload user credentials to see whether there are any problems or updates required. If any configuration file is incorrect or invalid, the upload fails.

To verify the upload user credentials using the CLI:

```bash
oci dts job verify-upload-user-credentials --bucket <bucket>
```

*bucket* is the upload bucket for the transfer job.

For example:

```bash
oci dts job verify-upload-user-credentials --bucket MyBucket1
```

created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in bucket MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1

Depending on your user configuration, you may get an error message returned similar to the following:

```bash
WARNING: Permissions on /home/user/.oci/config_upload_user are too open.
To fix this please try executing the following command:
ocli setup repair-file-permissions --file /home/user/.oci/config_upload_user
Alternatively to hide this warning, you may set the environment variable,
OCI_CLI_SUPPRESS_FILE_PERMISSIONS_WARNING:
export OCI_CLI_SUPPRESS_FILE_PERMISSIONS_WARNING=True
```

ERROR: The config file at /home/user/.oci/config_upload_user is invalid:

```
+Config Errors+--------------+
| Key                | Error       | Hint |
+--------------------+-------------+------+
| fingerprint         | malformed   | openssl rsa -pubout -outform DER -in path to your private key | openssl md5 -c |
```

If a user credential issue is identified, fix it and rerun the `verify-upload-user-credentials` CLI to ensure that all problems are addressed. Then you can proceed with transfer job activities.

**Deleting Transfer Jobs**

You can delete transfer jobs when they are in the Initiated, Preparing, and Close states.

To delete a transfer job using the Console:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.
2. Select the **Compartment** from the list.
   
   The transfer jobs in that compartment are displayed.

3. Find the data transfer job that you want to delete.

4. Click the **Actions** icon (\(\text{\text{\textsuperscript{}}\text{\text{\textsuperscript{}}}}\)), and then click **Delete**.

   Alternatively, you can delete a transfer job from the **View Details** page.

5. Confirm the deletion when prompted.

To delete a transfer job using the CLI

```
oci dts job delete --job-id <job_id>
```

For example:

```
oci dts job delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Confirm the deletion when prompted. The transfer job is deleted with no further action or return. To confirm the deletion, display the list of transfer jobs in the compartment. See **Listing Transfer Jobs** on page 1062 for more information.

**Closing Transfer Jobs**

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

When you close the transfer job, the status changes to **Closed**.

To close a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.

2. Select the **Compartment** from the list.

   The transfer jobs in that compartment are displayed.

3. Find the data transfer package for which you want to display the details.

4. Click the **Actions** icon (\(\text{\text{\textsuperscript{}}\text{\text{\textsuperscript{}}}}\)), and then click **View Details**.

   Alternatively, click the hyperlinked name of the transfer job.

5. Click **Close Transfer Job**.

To close a transfer job using the CLI

```
oci dts job close --job-id <job_id>
```

For example:

```
oci dts job close --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],

Import Appliances

This section describes tasks associated with the Oracle-provided import appliance.

**Requesting Appliances**

**Tip:**

To save time, identify the data you intend to upload and make data copy preparations before requesting the import appliance.

Creating an import appliance request returns an Oracle-assigned appliance label. For example:

XAKWEGKZ5T

To request an appliance using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.

   Choose the transfer job for which you want to request an import appliance.

2. Under **Transfer Appliances**, click **Request Transfer Appliance**.

   The Request Transfer Appliance dialog appears.

3. Enter the shipping address details where you want the import appliance sent.

   - **Company Name**: Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
   - **Recipient Name**: Required. Specify the name of the recipient who receives the import appliance.
   - **Recipient Phone Number**: Required. Specify the recipient's phone number.
   - **Recipient Email Address**: Required. Specify the recipient's email address.
   - **Care Of**: Optional intermediary party responsible for transferring the import appliance shipment from the delivery vendor to the intended recipient.
   - **Address Line 1**: Required. Specify the street address where the import appliance is being sent.
   - **Address Line 2**: Optional identifying address details like building, suite, unit, or floor information.
   - **City/Locality**: Required. Specify the city or locality.
   - **State/Province/Region**: Required. Specify the state, province, or region.
   - **Zip/Postal Code**: Specify the zip code or postal code.
   - **Country**: Required. Select the country.

4. Click **Request Transfer Appliance**.

To request an appliance using the CLIs

```bash
oci dts appliance request --job-id <job_id> --addressee <addressee> 
--care-of <care_of> --address1 <address_line1> --city-or-
locality <city_or_locality> --state-province-region <state_province_region>
--country <country> --zip-postal-code <zip_postal_code> --phone-
number <phone_number> --email <email> <options>
```

<options> are:

- **--address2**: Optional address of the addressee (line 2).
- **--address3**: Optional address of the addressee (line 3).
- **--address4**: Optional address of the addressee (line 4).
--from-json: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The --generate-full-command-json-input option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

For example:

```bash
oci dts appliance request --job-id ocid1.datatransferjob.oc1..exampleuniqueID --addressee MyCompany --care-of "John Doe" --address1 "123 Main Street" --city-or-locality Anytown --state-province-region NY --country USA --zip-postal-code 12345 --phone-number 8005551212 --email john.doe@mycompany.com

{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",
      "city-or-locality": "Anytown",
      "country": "USA",
      "email": "john.doe@mycompany.com",
      "phone-number": "3115551212",
      "state-or-region": "NY",
      "zipcode": "12345"
    },
    "delivery-security-tie-id": null,
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "REQUESTED",
    "next-billing-time": null,
    "return-security-tie-id": null,
    "serial-number": null,
    "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```

When you submit an appliance request, Oracle generates a unique label (label": "XAKWEGKZ5T") to identify the import appliance and your request is sent to Oracle for approval and processing.

**Monitoring the Appliance Request Status**

The time it takes to approve, prepare, and ship your appliance request varies and depends on various factors, including current available inventory. Oracle provides status updates daily throughout the appliance request and ship process.

To monitor the status of your appliance request using the Console
1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Imports**.

2. Select the **Compartment** from the list. The transfer jobs in that compartment are displayed.

3. Find and select the transfer job for which you want to monitor associated appliance requests.

4. Under **Transfer Appliances**, find the appliance label Oracle assigned to your appliance request and look at the **Status** field.

Here are the key status values to look for when monitoring your appliance request:

- **Requested**: You successfully completed your request for an import appliance. The status displays **Requested** until Oracle approves your appliance request.
- **Rejected**: Oracle denied your appliance request.

**Important:** If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

- **Oracle Preparing**: Oracle approved your appliance request. The status displays **Oracle Preparing** until the import appliance is shipped to you.

- **Shipping**: Oracle completed the necessary preparations and shipped your import appliance. When the import appliance is shipped, Oracle provides the serial number of the import appliance, the shipping vendor, and the tracking number in the **Transfer Appliance Details**. The status displays **Shipping** until the import appliance is delivered to you.

- **Delivered**: The shipping vendor delivered your import appliance. When the import appliance is delivered, Oracle provides the date and time the import appliance was received in the **Transfer Appliance Details**. The status displays **Delivered**.

To monitor the status of your appliance request using the CLI:

```
oci dts appliance show --job-id <job_id> --appliance-label <appliance label>
```

For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```
{
    "data": {
        "appliance-delivery-tracking-number": null,
        "appliance-delivery-vendor": null,
        "appliance-return-delivery-tracking-number": null,
        "creation-time": "2020-05-20T22:08:13+00:00",
        "customer-received-time": null,
        "customer-returned-time": null,
        "customer-shipping-address": {
            "address1": "123 Main Street",
            "address2": null,
            "address3": null,
            "address4": null,
            "addressee": "MyCompany",
            "care-of": "John Doe",
            "city-or-locality": "Anytown",
            "country": "USA",
            "email": "john.doe@mycompany.com",
            "phone-number": "3115551212",
            "state-or-region": "NY",
            "zipcode": "12345"
        },
        "delivery-security-tie-id": null,
```

Oracle Cloud Infrastructure User Guide 1071
The request status is displayed as the value for lifecycle-state.

### Displaying the List of Appliances

To display the list of appliances using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Select the Compartment from the list.

   The transfer jobs in that compartment are displayed.
3. Choose the transfer job for which you want to display the list of associated import appliances.

   The list of import appliances is displayed below the transfer job details.

To display the list of appliances using the CLI

```bash
oci dts appliance list --job-id <job_id>
```

For example:

```json
oci dts appliance list --job-id ocid1.datatransferjob.oc1..exampleuniqueID
{
  "data": {
    "transfer-appliance-objects": [
      {
        "creation-time": "2020-05-20T22:08:13+00:00",
        "label": "XAKWEGKZ5T",
        "lifecycle-state": "PROCESSING",
        "serial-number": null
      }
    ]
  }
}
```

### Displaying Appliance Details

To display the details of an appliance using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Select the Compartment from the list.

   The transfer jobs in that compartment are displayed.
3. Find the transfer job for which you want to display the details of an associated import appliance.

   The list of appliances is displayed below the transfer job details.
4. Find the import appliance for which you want to display the details.
5. Click the Actions icon (giene), and then click View Details.

To display the details of an appliance using the CLI

```bash
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```
For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```
{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",
      "city-or-locality": "Anytown",
      "country": "USA",
      "email": "john.doe@mycompany.com",
      "phone-number": "3115551212",
      "state-or-region": "NY",
      "zipcode": "12345"
    },
    "delivery-security-tie-id": "exampleuniqueID",
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "PROCESSING",
    "next-billing-time": null,
    "return-security-tie-id": "exampleuniqueID",
    "serial-number": "exampleuniqueserialnumber",
    "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```

**Editing the Appliance Request Shipping Information**

You can only edit the shipping information when the status is **Requested**.

To edit the appliance request shipping information using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the **Requested** import appliance that you want to edit the shipping information.
3. Click the Actions icon (†), and then click Edit.
4. Edit the shipping information for the import appliance.
5. Click Save.

To edit the appliance request shipping information using the CLI

```
oci dts appliance update-shipping-address --job-id <job_id> --appliance-label <appliance_label> --addressee <addressee> <changed_fields>
```

Include the addressee field even if it has not changed.
Data Transfer

<changed_fields> represents one or more of the following shipping address fields that you want to update:

--care-of <care_of> --address1 <address> --city <city> --state <addressee> --zip <zip> --country <country> --phone-number <phone_number> email <email>

You only need to include those fields that are being updated. For example:

oci dts appliance update-shipping-address --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T --addressee MyCompany --care-of "Richard Roe" --phone-number 3115559876 --email richard.roe@mycompany.com

Confirm the update of the appliance request shipping information when prompted. The appliance details are displayed with the updated information.

```
{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "Richard Roe",
      "city-or-locality": "Anytown",
      "country": "USA",
      "email": "john.doe@oracle.com",
      "phone-number": "3115559876",
      "state-or-region": "NY",
      "zipcode": "12345"
    },
    "delivery-security-tie-id": null,
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "REQUESTED",
    "next-billing-time": null,
    "return-security-tie-id": null,
    "serial-number": null,
    "transfer-job-id": "ocid1.datatransferjob.oct1..exampleuniqueID",
    "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```

Deleting an Appliance Request

You can delete an appliance request before Oracle approves the request—the status must be Requested. For example, you initiated the transfer by creating a transfer job and requested an appliance, but changed your mind.

To delete an appliance request using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Imports.
2. Find the data transfer job and appliance request that you want to delete.
3. Click the Actions icon ( ), and then click Delete.

Alternatively, you can delete an appliance request from the Transfer Appliance Details page.
4. Confirm the deletion when prompted.

To delete an appliance request using the CLI

```
oci dts appliance delete --job-id <job_id> --appliance-label <appliance_label>
```

For example:

```
oci dts appliance delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Confirm the deletion when prompted.

**Displaying Registered Appliances**

You can display a list of all appliances registered through the initialize authentication command. See Initializing Authentication to the Import Appliance on page 1044 for more information.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only use the CLI command to display a list of all appliances registered through the initialize authentication command.</td>
</tr>
</tbody>
</table>

To display the list of all registered appliances using the CLI

```
oci dts physical-appliance list
```

For example:

```
oci dts physical-appliance list
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Unregistering Appliances**

You can unregister an appliance previously registered through the initialize authentication command. See Initializing Authentication to the Import Appliance on page 1044 for more information.

To unregister an appliance using the CLI

```
oci dts physical-appliance unregister
```

**Configuring Import Appliance Encryption**

Configure the import appliance to use encryption. Oracle Cloud Infrastructure creates a strong passphrase for each appliance. The command securely collects the strong passphrase from Oracle Cloud Infrastructure and sends that passphrase to the Data Transfer service.

If your environment requires Internet-aware applications to use network proxies, ensure that you set up the required Linux environment variables. See for more information.
Important:

If you are working with multiple appliances at the same time, be sure the job ID and appliance label you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

Note:

You can only use the Oracle Cloud Infrastructure CLI to configure encryption.

Configuring Appliance Encryption

Note:

You can only use the CLI command to configure encryption for appliances.

To configure appliance encryption using the CLI

At the command prompt on the host, run `oci dts physical-appliance configure-encryption` to configure import appliance encryption.

```bash
oci dts physical-appliance configure-encryption --job-id <job_id> --appliance-label <appliance_label>
```

For example:

```bash
oci dts physical-appliance configure-encryption --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Moving the state of the appliance to preparing...
Passphrase being retrieved...
Configuring encryption...
Encryption configured. Getting physical transfer appliance info...
{
    "data": {
        "availableSpaceInBytes": "Unknown",
        "encryptionConfigured": true,
        "finalizeStatus": "NA",
        "lockStatus": "LOCKED",
        "totalSpaceInBytes": "Unknown"
    }
}

Initializing Authentication to the Appliance

Note:

You can only use the Oracle Cloud Infrastructure CLI to initialize authentication.

Initialize authentication to allow the host machine to communicate with the import appliance. Use the values returned from the Configure Networking command. See Configuring the Transfer Appliance Networking for details.

Initializing Authentication

Note:

You can only use the CLI command to initialize authentication for appliances.
To initialize authentication using the CLI

```bash
oci dts physical-appliance initialize-authentication --job-id <job-id> --appliance-cert-fingerprint <fingerprint> --appliance-ip <ip_address> --appliance-label <appliance-label>
```

For example:

```bash
```

Retrieving the Appliance serial id from Oracle Cloud Infrastructure

Access token:

Registering and initializing the authentication between the CLI and the appliance

```json
{
  "data": {
    "availableSpaceInBytes": "Unknown",
    "encryptionConfigured": false,
    "finalizeStatus": "NA",
    "lockStatus": "NA",
    "totalSpaceInBytes": "Unknown"
  }
}
```

When prompted, supply the access token and system. The Control Host can now communicate with the import appliance.

**Datasets**

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the appliance for import. We currently support one dataset per appliance.

**Note:**

You can only use the CLI to run dataset tasks.

**Creating the Dataset**

Appliance data transfer supports NFS version 3, 4, and 4.1 to write data to the import appliance. In preparation for writing data, create and configure a dataset to write to.

To create a dataset using the CLI

```bash
oci dts nfs-dataset create --name <dataset_name>
```

For example:

```bash
oci dts nfs-dataset create --name nfs-ds-1
```

Creating dataset with NFS export details nfs-ds-1

```json
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": null
    },
    "state": "INITIALIZED"
  }
}
```
**Activating the Dataset**

Activation creates the NFS export, making the dataset accessible to NFS clients.

To activate the dataset using the CLI

```
oci dts nfs-dataset activate --name <dataset_name>
```

For example:

```
oci dts nfs-dataset activate --name nfs-ds-1
```

Fetching all the datasets
Activating dataset small-files
Dataset nfs-ds-1 activated

**Configuring Export Settings on the Dataset**

To configure export settings on a dataset using the CLI

```
oci dts nfs-dataset set-export --name <dataset_name> --rw true --world true
```

For example:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --rw true --world true
```

Settings NFS exports to dataset nfs-ds-1

```
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": [
        {
          "hostname": null,
          "ipAddress": null,
          "readWrite": true,
          "subnetMaskLength": null,
          "world": true
        }
      ],
      "state": "INITIALIZED"
    }
  }
}
```

Here is another example of creating the export to give read/write access to a subnet:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --ip 10.0.0.0 --subnet-mask-length 24 --rw true --world false
```

Settings NFS exports to dataset nfs-ds-1

```
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": [
        {
          "hostname": null,
          "ipAddress": "10.0.0.0",
          "readWrite": true,
          "subnetMaskLength": "24",
          "world": true
        }
      ],
      "state": "INITIALIZED"
    }
  }
}
```
Deactivating the Dataset

**Note:**

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Import, you can skip this step and proceed to Sealing the Dataset on page 1079.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

To deactivate the dataset using the CLI

```
dts nfs-dataset deactivate --name <dataset_name>
```

For example:

```
dts nfs-dataset deactivate --name nfs-ds-1
```

Sealing the Dataset

Sealing a dataset stops all writes to the dataset. This process can take some time to complete, depending upon the number of files and total amount of data copied to the import appliance.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. Running the `seal` command with the `--wait` option results in the seal operation being triggered and continues to provide status updates until sealing completion.

**Important:**

You can only copy regular files to transfer appliances. Special files (for example, symbolic links, device special, sockets, and pipes) cannot be copied directly. To transfer special files, create a tar archive of these files and copy the tar archive to the transfer appliance.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.

To seal the dataset using the CLI

```
oci dts nfs-dataset seal --name <dataset_name> [--wait]
```

For example:

```
oci dts nfs-dataset seal --name nfs-ds-1
```

Seal initiated. Please use seal-status command to get progress.

Monitoring the Dataset Sealing Process

To monitor the dataset sealing process using the CLI

```
oci dts nfs-dataset seal-status --name <dataset_name>
```
For example:

```
oci dts nfs-dataset seal-status --name nfs-ds-1
{
  "data": {
    "bytesProcessed": 2803515612507,
    "bytesToProcess": 2803515612507,
    "completed": true,
    "endTimeInMs": 1591990408804,
    "failureReason": null,
    "numFilesProcessed": 182,
    "numFilesToProcess": 182,
    "startTimeInMs": 1591987136180,
    "success": true
  }
}
```

### Downloading the Dataset Seal Manifest

After sealing the dataset, you can optionally download the dataset’s seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.

To download the dataset seal manifest file using the CLI

```
oci dts nfs-dataset get-seal-manifest --name <dataset_name> --output-file <file_path>
```

For example:

```
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

### Reopening a Dataset

If changes are necessary after sealing a dataset or finalizing an import appliance, you must reopen the dataset to modify the contents. Make the required changes and again seal the dataset. Resealing the dataset generates a new manifest.

**Note:**

If an import appliance is rebooted or power cycled, follow the instructions in this topic to reopen the dataset.

### Step 1: Unlocking the Appliance

You must unlock the appliance before you can write data to it. Unlocking the appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance. Unlocking can be accomplished in two different ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

To unlock the appliance and send the passphrase to the appliance

```
oci dts physical-appliance unlock --job-id <job_id> --appliance-label <label>
```
For example:

```
oci dts physical-appliance unlock --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Retrieving the passphrase from Oracle Cloud Infrastructure

```
{
  "data": {
    "availableSpaceInBytes": "64.00GB",
    "encryptionConfigured": true,
    "finalizeStatus": "NOT_FINALIZED",
    "lockStatus": "NOT_LOCKED",
    "totalSpaceInBytes": "64.00GB"
  }
}
```

To query Oracle Cloud Infrastructure for the passphrase to provide to unlock the appliance

```
oci dts appliance get-passphrase --job-id <job_id> --appliance-label <label>
```

For example:

```
oci dts appliance get-passphrase --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
{
  "data": {
    "encryption-passphrase": "passphrase"
  }
}
```

Then, run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted.

```
oci dts physical-appliance unlock
```

Step 2: Reopening the Appliance

Reopen the dataset to write data to the import appliance again.

To reopen an NFS dataset

```
oci dts nfs-dataset reopen --name <dataset_name>
```

Step 3: Repeat Steps to Write Data to the Appliance

Repeat the same tasks you performed when you originally wrote data to the import appliance beginning with activating the dataset in the Copying Files to the NFS Share on page 1049 section.

Displaying the List of Datasets

To display the list of datasets using the CLI

```
oci dts nfs-dataset list
```

For example:

```
oci dts nfs-dataset list
```

Listing NFS datasets

```
{
  "data": [
  {
    "datasetType": "NFS",
```
"name": "nfs-ds-1",
"nfsExportDetails": {
  "exportConfigs": [
    {
      "hostname": null,
      "ipAddress": null,
      "readWrite": true,
      "subnetMaskLength": null,
      "world": true
    }
  ],
  "state": "ACTIVE"
}

Displaying Dataset Details
To display the details of a transfer job using the CLI

oci dts nfs-dataset show --name <dataset_name>

For example:

oci dts nfs-dataset show --name MyDataset

{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": [
        {
          "hostname": null,
          "ipAddress": null,
          "readWrite": true,
          "subnetMaskLength": null,
          "world": true
        }
      ],
      "state": "ACTIVE"
    }
  }
}

Deleting a Dataset
To delete a dataset using the CLI

oci dts nfs-dataset delete --name <dataset_name>

For example:

oci dts nfs-dataset delete --name nfs-ds-1

Confirm the deletion when prompted. The dataset is deleted with no further action or return. To confirm the deletion, display the list of datasets. See Displaying the List of Datasets on page 1081 for more information.

Appliance Data Export

Data Export is Oracle's offline data export solution that lets you migrate petabyte-scale datasets from your Oracle Cloud Infrastructure Object Storage bucket to your data center using an Oracle-provided Data Transfer Appliance.
Use Data Export when you have stored terabytes or petabytes of data in Oracle Cloud Infrastructure and need to retrieve it from Object Storage more quickly than using the public internet. For example, you may have media content or processed datasets you need to share with a customer or business partner.

You cannot export data from multiple Object Storage buckets to the same export job. If you want to export data from more than one bucket, you must create an export job for each of the buckets.

**Note:**

Data Export does not support exporting files from an Archive Storage bucket. Move your data from the Archive Storage bucket to an Object Storage bucket and then create an export job specifying the Object Storage bucket. See Overview of Archive Storage on page 484 for more information.

**Note:**

Data Export is not available for free trial or Pay As You Go accounts.

**Data Export Concepts**

**EXPORT JOB**

An export job is the logical representation of an offline export of data from your Oracle Cloud Infrastructure Object Storage bucket to your data center. Exporting your data does not remove it from the original storage bucket on Oracle Cloud Infrastructure.

**Note:**

An export job is associated with a single export appliance. If your data export needs exceed the capacity of the appliance (150 TB), you need to create additional export jobs with their own dedicated appliances.

**DATA TRANSFER APPLIANCE**

The Data Transfer Appliance (export appliance) is a high-storage capacity device used to export data from Oracle Cloud Infrastructure to your data center. You request an export appliance from Oracle, specify the data files to be copied from your Object Storage bucket to the export appliance, and then have the export appliance containing the data shipped to you. After you receive the export appliance, copy your data to your data center. When you complete the copying of data, completely delete all the data from the export appliance before sending it back to Oracle.

**COMMAND LINE INTERFACE**

The command line interface (CLI) is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks, including Appliance-Based Data Import jobs. See Command Line Interface (CLI) on page 4192 for more information.

**Note:**

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

**HOST**

A physical computer at the customer site on which one or more of the logical hosts (Control, Data, Terminal Emulation) is running. Depending on your computing environment, you can have any of the following:

- A separate physical host for each logical host
- All three logical hosts consolidated onto a single physical host
- Two logical hosts on one physical host and the third logical host on a separate physical host
All physical hosts must be on the network used for the data transfer.

**CONTROL HOST**

The logical representation of the host computer at your site from which you perform data export tasks. Depending on your needs, you may use one or more separate hosts (Control and Data) to configure your export job.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only run Oracle Cloud Infrastructure CLI commands from a Linux-based Control Host machine. You can run Console tasks from a browser running on a Windows machine.</td>
</tr>
</tbody>
</table>

**DATA HOST**

The logical representation of the host computer on your site that receives the data exported from Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only Linux machines can be used as Data Hosts.</td>
</tr>
</tbody>
</table>

**TERMINAL EMULATION HOST**

The logical representation of the host computer that uses terminal emulation software to communicate with, and allow you to command, the appliance.

**BUCKET**

The logical container in the Object Storage from where your data is copied to the appliance before it is shipped to you. A bucket is associated with a single compartment in your tenancy whose policies determine what actions a user can perform.

**APPLIANCE MANAGEMENT SERVICE**

Software running on the appliance that provides management functions. Users interact with this service through the Oracle Cloud Infrastructure CLI.

### Appliance Specifications

Use NFS versions 3, 4, or 4.1 to copy your data onto the appliance. Here are some details about the appliance:

<table>
<thead>
<tr>
<th>Item Description</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage Capacity</td>
<td>150 TB of protected usable space</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Network Interfaces</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>- 10 GbE - RJ45</td>
<td></td>
</tr>
<tr>
<td>- 10 GbE - SFP+</td>
<td></td>
</tr>
<tr>
<td>You are responsible for providing all network cables. If you want to use SFP+, your transceivers must be compatible with Intel X520 NICs.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Provided Cables</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>- NEMA 5–15 type B to C13</td>
<td></td>
</tr>
<tr>
<td>- C13 - 14 power</td>
<td></td>
</tr>
<tr>
<td>- USB - DB9 serial</td>
<td></td>
</tr>
</tbody>
</table>
### Environmental
- Operational temperature: 50–95°F (10–35°C)
- Operational relative humidity: 8–90% non-condensing
- Acoustics: < 75 dB @ 73°F (23°C)
- Operational altitude: -1,000 ft - 10,000 ft (approx. -300–3048 m)

### Power
- Consumption: 554 W
- Voltage: 100–240 VAC
- Frequency: 47–63 Hz
- Conversion efficiency: 89%

### Weight
- Unit: 38 lbs (approx. 17 kg)
- Unit + Transit Case: 64 lbs (approx. 29 kg)

### Height
3.5” (approx. 9 cm) (2U)

### Width
17” (approx. 43 cm)

### Depth
24” (approx. 61 cm)

### Shipping Case
11” x 25” x 28” (approx. 28 x 63.5 x 71 cm)

## Roles and Responsibilities

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data export.

- **Project Sponsor:** Responsible for the overall success of the data export. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of the data export. The Project Sponsor is also responsible for signing legal documentation and setting up notifications for the data export.

- **Infrastructure Engineer:** Responsible for integrating the export appliance into the organization's IT infrastructure where the data is being copied. Tasks associated with this role include connecting the export appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

- **Data Administrator:** Responsible for identifying and preparing the data to be exported from Oracle Cloud Infrastructure to your data center. This person usually has access to, and expertise with, the data being exported.

These roles correspond to the various phases of the data export described in the following section. A specific role can be responsible for one or more phases.

## Task Flow for Data Export

Here is a high-level overview of the tasks involved in the data export from Oracle Cloud Infrastructure to your data center. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.
Secure Appliance Data Export from Oracle Cloud Infrastructure

This section highlights the security details of the data export process.

- Appliances are shipped from Oracle to you with a tamper-evident security tie on the transit case. A second tamper-evident security tie is included in the appliance transit case for you to secure the case when you ship the case back to Oracle. The number on the physical security ties must match the numbers logged by Oracle in the appliance details.
- The AES-256 encryption key is created by Oracle when the files are copied the export appliance.
- When you configure the appliance for the first time:
  - The encryption key is protected by an encryption passphrase that you must know to access the encrypted data. The system securely fetches a provided encryption passphrase from Oracle Cloud Infrastructure and registers that passphrase on the appliance.
  - All data copied to the appliance is encrypted.
  - Oracle erases all of your data from the transfer appliance after it has been returned. The erasure process follows the NIST 800-88 standards.
  - Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the completion of the export job.

What's Next

You are now ready to prepare the host for the data export. See Preparing for Data Export on page 1087 for more information.

Preparing for Data Export

This topic describes the tasks associated with preparing for the Data Export job. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1085.

Installing and Using the Oracle Cloud Infrastructure Command Line Interface

The Oracle Cloud Infrastructure Command Line Interface (CLI) provides a set of command line-based tools for configuring and running Data Export jobs. Use the Oracle Cloud Infrastructure CLI as an alternative to running commands from the Console. Sometimes you must use the CLI to complete certain tasks as there is no Console equivalent.

Minimum Required CLI Version

The minimum CLI version required for Data Export is 2.12.1.

Determining CLI Versions

Access the following URL to see the currently available version of the CLI:
Enter the following command at the prompt to see the version of the CLI currently installed on your machine:

```bash
oci --version
```

If you have a version on your machine older than the version currently available, install the latest version.

**Note:**

Always update to the latest version of the CLI. The CLI is not updated automatically, and you can only access new or updated CLI features by installing the current version.

### Linux Operating System Requirements

See Requirements on page 4193 for a list of the Linux operating systems that support the CLI.

### Installing the CLI

Installation and configuration of the CLIs is described in detail in Command Line Interface (CLI) on page 4192.

### Using the CLI

You can specify CLI options using the following commands:

- `--option <value>`
- `--option= <value>`

The basic CLI syntax is:

```bash
oci dts <resource> <action> <options>
```

This syntax is applied to the following:

- `oci dts` is the shortened CLI command name
- `job` is an example of a `<resource>`
- `create` is an example of an `<action>`
- Other strings are `<options>`

The following command to create an export job shows a typical CLI command construct.

```bash
oci dts export create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket-name MyBucket1 --display-name MyExportJob --addressee "MyCompany Corp" --care-of "John Doe" --address1 "123 Main St." --city-or-locality Anytown --state-province-region CA --country USA --zip-postal-code 12345 --phone-number "555.555.1212" --email jdoe@mycompany.com
```

**Note:**

In the previous examples, provide a friendly name for the export job using the `##display#name` option. Avoid entering confidential information.

### Accessing Command Line Interface Help

All CLI help commands have an associated help component you can access from the command line. To view the help, enter any command followed by the `--help` or `-h` option. For example:

```bash
oci dts export --help
```
When you run the help option (\(--\text{help} \) or \(-h\)) for a specified command, all the subordinate commands and options for that level of CLI are displayed. If you want to access the CLI help for a specific subordinate command, include it in the CLI string, for example:

```
oci dts export create --help
```

NAME
dts_export_create -

DESCRIPTION
Creates a new Appliance Export Job that corresponds with customer's logical dataset

USAGE
oci dts export create [OPTIONS]

REQUIRED PARAMETERS
- --address1 [text]
  Address line 1.
- --addressee [text]
  Company or person to send the appliance to
- --bucket-name [text]
  Name of the object storage bucket for this export job
- --care-of [text]
  Place/person to direct the package to.
--city-or-locality [text]
:

**Setting Up the Oracle Cloud Infrastructure Configuration File**

Before using the command line utility, create a configuration file that contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup dialog or manually using a text editor.

**Using the Setup CLI**

Run the `oci setup config` command line utility to walk through the first-time setup process. The command prompts you for the information required for the configuration file and the API public/private keys. The setup dialog generates an API key pair and creates the configuration file.

For more information about how to find the required information, see:

- [Where to Get the Tenancy's OCID and User's OCID on page 4184](#)
- [Regions and Availability Domains on page 180](#)

**Manual Setup**

If you want to set up the API public/private keys yourself and write your own config file, see [SDK and Tool Configuration](#).

**Tip:**

Use the `oci setup keys` command to generate a key pair to include in the config file.

Create the configuration file `/root/.oci/config` with the following structure:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For example:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `##profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```ini
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `##profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:
By default, the DEFAULT profile is used for all CLI commands. For example:

```
oci dts export create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket-name MyBucket --display-name MyDisplay ...
```

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
oci dts export create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket-name MyBucket --display-name MyDisplay ... --profile MyProfile
```

Using the example configuration file above, the `<profile_name>` would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```
oci dts export create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name>
```

### Creating the Required IAM Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

You provide resource access to the data export administrators group using policies. See Managing Groups on page 2419 for more information.

Create this group using the following policies:

```
Allow group <group-name> to manage appliance-export-jobs in compartment <compartment-name>
Allow group <group-name> to manage buckets in compartment <compartment name>
Allow group <group-name> to manage objects in compartment <compartment name>
```

To enable notifications, add the following policies:

```
Allow group <group name> to manage ons-topics in tenancy
Allow group <group name> to manage ons-subscriptions in tenancy
Allow group <group name> to manage cloudevents-rules in tenancy
Allow group <group name> to inspect compartments in tenancy
```

See Getting Started with Policies on page 2135 for more information.

### Requesting Appliance Entitlement

If your tenancy is not entitled to use the Data Transfer Appliance, you must request the Data Transfer Appliance Entitlement before creating an export job.

*To request the Data Transfer Appliance Entitlement using the Console*

Open the Transfer Job page and click Request at the top. Otherwise, you are prompted to request the entitlement when attempting to create your first export job.
Once requested, the status of your request is visible at the top of the Transfer Job page. For example:

**Data Transfer Appliance Entitlement:** Granted

It can take a while to get the Data Transfer Appliance Entitlement approved. After Oracle receives your request, a Terms and Conditions Agreement is sent to the account owner via DocuSign to use the appliance. The entitlement request is approved once the signature is received. The Data Transfer Appliance Entitlement is a tenancy-wide entitlement that you need to request once for each tenancy.

**To request the Data Transfer Appliance Entitlement using the CLI**

```
oci dts appliance request-entitlement --compartment-id <compartment_id> --name <name> --email <email>
```

 `<name>` is the name of the requester.

 `<email>` is the email address of the requester.

For example:

```
oci dts appliance request-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID --name "John Doe" --email jdoe@mycompany.com
```

```
{
 "data": {
 "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
 "creation-time": "2019-12-18T18:29:15+00:00",
 "defined-tags": {},
 "display-name": null,
 "freeform-tags": {},
 "id": "ocid1.datatransferapplianceentitlement.oc1..exampleuniqueID",
 "lifecycle-state": "CREATING",
 "lifecycle-state-details": "REQUESTED",
 "requestor-email": "jdoe@mycompany.com",
 "requestor-name": "John Doe",
 "update-time": "2019-12-20T19:04:09+00:00"
 }
}
```

**To show the status of a Data Transfer Appliance Entitlement request using the CLI**

```
oci dts appliance show-entitlement --compartment-id <compartment_id>
```

For example:

```
oci dts appliance show-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```
{
 "data": {
 "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
 "defined-tags": null,
 "display-name": null,
 "freeform-tags": null,
 "id": null,
 "lifecycle-state": "ACTIVE",
 "lifecycle-state-details": "APPROVED",
 "requestor-email": null,
 "requestor-name": null
 }
}
```
Establishing the Data Transfer Appliance Entitlement Policy

Use the following policy to enable users in a specific group to request a Data Transfer Appliance Entitlement in your tenancy.

```
Allow group <group_name> to {DTA_ENTITLEMENT_CREATE} in tenancy
```

Entitlement Eligibility

Your request for a Data Transfer Appliance Entitlement in your tenancy may be denied if you are a free trial customer. If your request is denied, upgrade to a full account. You can also contact your Oracle Customer Support Manager or Oracle Support to determine your options for obtaining the entitlement.

Appliance Entitlement Eligibility

Your request for a Data Transfer Appliance Entitlement in your tenancy may be denied if you are a free trial customer. If your request is denied, upgrade to a full account. You can also contact your Oracle Customer Support Manager or Oracle Support to determine your options for obtaining the entitlement.

Setting Up Notifications

Set up rules for the Export Job notification resource that notify the appropriate administrators of the tenancy of events such as when someone creates an export job and when Oracle ships the export appliance.

The types of events you can set up are:

- CREATE
- DELETE
- UPDATE

See Notifications Overview on page 3350 and Overview of Events on page 1784 for more information.

You can also set up notifications for your export job using the CLI. See Setting Up Export Job Notifications on page 1097 for more information on this feature.

Notification Policies

Set up the following policies to support notifications for export jobs:

```
Allow group <group_name> to manage ons-topics in tenancy
Allow group <group_name> to manage ons-subscriptions in tenancy
Allow group <group_name> to manage cloudevents-rules in tenancy
Allow group <group_name> to inspect compartments in tenancy
```

Configuring Firewall Settings

Ensure that your local environment’s firewall can communicate with the Data Transfer Service running on the IP address ranges: 140.91.0.0/16. You also need to open access to the Object Storage IP address ranges: 134.70.0.0/17.

Creating Export Jobs

This section describes how to create an export job as part of the preparation for the data export. See Export Jobs on page 1113 for complete details on all tasks related to export jobs.

An export job represents the collection of files that you want to export and signals the intention to copy those files from your Oracle Cloud Infrastructure Object Storage or Archive Storage bucket to your data center using an Oracle-provided export appliance. Create the export job in the same compartment as the bucket and supply a human-readable name for the export job.

**Note:**

It is recommended that you create a compartment for each export job to minimize the required access your tenancy.
Creating an export job returns a job ID that you specify in other export tasks. For example:

ocid.compartment.oc1..exampleuniqueID

To create an export job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the Compartment you are to use for data exports from the list.
3. A list of export jobs that have already been created is displayed in the Export Jobs page.
4. Click Create Export Job.
5. Enter a Job Name. Avoid entering confidential information. Then, select the Bucket Name from the list.
6. Complete the following fields:
   - Company Name
   - Recipient Phone
   - Recipient Email
   - Care of - Optional intermediary party responsible for transferring the appliance from the delivery vendor to the intended recipient.
   - Address 1
   - Address 2
   - City/Locality
   - State/Province/Region
   - Zip/Postal Code
   - Country
7. (Optional) Add any tagging information, including the tag namespace, key, and value in the associated fields.
8. Click Create.

The export job you created is added to the list of export jobs.

To create an export job using the CLI

oci dts export create --compartment-id <compartment_id> --bucket-name <bucket_name> --display-name <display_name> --addressee <addressee> --care-of <care_of> --address <address> --city-or-locality <city_or_locality> --state-province-region <state_province_region> --country <country> --zip-postal-code <zip_postal_code> --phone-number <phone_number> --email <email> <options>

<display_name> is the name of the export job as it appears. Avoid entering confidential information.
<addressee> is the company or person to receiving the appliance.
<care_of> is the contact associated with the addressee.
<address> is the required address of the addressee.
<city_or_locality> is city or locality of the addressee.
<state_province_region> is the state, province, or region of the addressee.
<country> is the country of the addressee.
<zip_postal_code> is the zip or postal code of the addressee.
<phone_number> is the phone number of the addressee or contact.
<email> is the email address of the addressee or contact.
<options> are:
• **--prefix**: List of objects with names matching this prefix would be part of this export job.
• **--range-start**: Object names returned by a list query must be greater or equal to this parameter.
• **--range-end**: Object names returned by a list query must be strictly less than this parameter.
• **--freeform-tags**: Free-form tags for this resource. Each tag is a simple key-value pair with no predefined name, type, or namespace. Example: `{"Department": "Finance"}` This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The **--generate-param-json-input** option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
• **--defined-tags**: Defined tags for this resource. Each key is predefined and scoped to a namespace. For more information, see [Resource Tags]. Example: `{"Operations": {"CostCenter": "42"}}` This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The **--generate-param-json-input** option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
• **--wait-for-state**: This operation creates, modifies or deletes a resource that has a defined lifecycle state: CREATING, ACTIVE, IN PROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED. Specify this option to perform the action and then wait until the resource reaches a given lifecycle state. Multiple states can be specified, returning on the first state. For example, **--wait-for-state SUCCEEDED --wait-for-state FAILED** would return on whichever lifecycle state is reached first. If timeout is reached, a return code of 2 is returned. For any other error, a return code of 1 is returned.
• **--max-wait-seconds**: The maximum time in seconds to wait for the resource to reach the lifecycle state defined by the **--wait-for-state** attribute. Default is 1200.
• **--wait-interval-seconds**: The check interval in seconds to determine whether the resource to see if it has reached the lifecycle state defined by the **--wait-for-state**. Default is 30.
• **--address2**: Optional address line 2.
• **--address3**: Optional address line 3.
• **--address4**: Optional address line 4.
• **--from-json**: Provide input to this command as a JSON document from a file using the file://path/to/file syntax. The **--generate-full-command-json-input** option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: [https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions].

For example:

```bash
oci dts export create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket-name MyBucket1 --display-name MyExportJob1 --addressee "MyCompany Corp" --care-of "John Doe" --address1 "123 Main St." --city-or-locality Anytown --state-province-region CA --country USA --zip-postal-code 12345 --phone-number "4085551212" --email jdoe@mycompany.com
```

```json
{
  "data": {
    "appliance-decryption-passphrase": "********",
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "appliance-serial-number": null,
    "bucket-access-policies": [
      "POLICIES CREATION IN PROGRESS"
    ],
    "bucket-name": "MyExportJobs",
```

Oracle Cloud Infrastructure User Guide 1095
Notifications To include notifications, include the `--setup-notifications` option. See Setting Up Export Job Notifications on page 1097 for more information on this feature.

Getting Export Job IDs

Each export job you create has a unique ID within Oracle Cloud Infrastructure. For example:

```
ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID
```

You will need to forward this export job ID to the Data Administrator.

To get the export job ID using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the Compartment from the list.
   The export jobs in that compartment are displayed.
3. Find the export job for which you want to display the details.
4. Click the Actions icon (agle), and then click View Details.

To get the export job ID using the CLI

```
oci dts export list --compartment-id <compartment_id>
```
For example:

```shell
oci dts export list --compartment-id ocid.compartment.oc1..exampleuniqueID
```

```
{
  "data": [
    {
      "bucket-name": "MyExportJobs",
      "creation-time": "2020-06-18T17:24:13+00:00",
      "defined-tags": {},
      "display-name": "MyExportJob1",
      "freeform-tags": {},
      "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
      "lifecycle-state": "CREATING",
      "lifecycle-state-details": "PENDING_MANIFEST_GENERATION"
    },
    {
      "bucket-name": "MyTestExportJobs",
      "creation-time": "2020-06-18T18:07:59+00:00",
      "defined-tags": {},
      "display-name": "MyTestExportJob",
      "freeform-tags": {},
      "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
      "lifecycle-state": "CREATING",
      "lifecycle-state-details": "PENDING_MANIFEST_GENERATION"
    }
  ]
}
```

The ID for each export job is included in the return:

```
"id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID"
```

**Tip:**

When you create an export job using the `oci dts export create` CLI, the export job ID is displayed in the CLI's return. You can also run the `oci dts export show` CLI for that specific job to get the ID.

### Setting Up Export Job Notifications

You can generate notifications that send messages regarding changes to a new or existing export job through the CLI. Using this feature creates a topic, subscription for a list of email addresses, and a rule that notifies you on all events related to the export job's activities and changes in state. This method provides a more convenient way to generate notifications tailored to export jobs.

The CLI command to set up export job notifications is different depending on whether you are creating a new export job or updating an existing export job. In both cases, running the CLI command prompts you to enter the email addresses of each notification subscriber as a comma separated list. Each recipient is sent an email with a link to confirm they want to receive the notifications.

You are prompted to enter those email addresses you want included in the notifications, separated by commas (","). When your list is complete, add a colon (";") followed by your own email address: `user1@mycompany.com, user2@mycompany.com : myemail@mycompany.com`.

For both of the notification commands, the following is returned:

If the commands fail to run, you can use the OCI CLI to do the setup manually:

```shell
export ROOT_COMPARTMENT_OCID=ocidv1:tenancy:oc1:exampleuniqueID
oci ons topic create --compartment-id $ROOT_COMPARTMENT_OCID --name DTSEExportTopic --description "Topic for data transfer service export jobs"
```
oci ons subscription create --protocol EMAIL --compartment-id $ROOT_COMPARTMENT_OCID --topic-id $TOPIC_OCID --endpoint $EMAIL_ID
oci events rule create --display-name DTExportRule --is-enabled true --compartment-id $ROOT_COMPARTMENT_OCID --actions '[{"actionType":"ONS","topicId":"$TOPIC_OCID","isEnabled":true}]' --condition '["eventType": ["com.oraclecloud.datatransferservice.addapplianceexportjob","com.oraclecloud.datatransferservice.deleteapplianceexportjob","com.oraclecloud.datatransferservice.updateapplianceexportjob","com.oraclecloud.datatransferservice.moveapplianceexportjob"]]' --description "Rule for data transfer service to send notifications for export jobs"
Creating topic for export

To set up notifications when creating an export job using the CLI

To set up notifications when creating an export job, include the --setup notifications option as part of the CLI:

oci dts export create --compartment-id <compartment_id> --bucket-name <bucket_name> --display-name <display_name> --addressee <addressee> --care-of <care_of> --address <address> --city-or-locality <city_or_locality> --state-province-region <state_province_region> --country <country> --zip-postal-code <zip_postal_code> --phone-number <phone_number> --email <email> <options> --setup-notifications

To set up notifications for an existing export job using the CLI

To set up notifications for an existing export job:

oci dts export setup-notifications

Generating the Export Manifest File

The data export job requires that you generate a manifest file for the files you want to be exported to you in the Data Transfer Appliance. This manifest file is stored in your export job's bucket. Oracle uses the manifest file to download from that bucket all the files that are listed in the manifest. When the Data Transfer Appliance is sent to you, the download summary is available at the root of the Data Transfer Appliance's mount point, allowing you to compare the manifest against the download summary.

Note:
You can only use the CLI command to generate the export manifest file.

To generate an export manifest file using the CLI

oci dts export generate-manifest --compartment-id <compartment_id> --job-id <job_id> --bucket <bucket> <options>

<options> are:
• --prefix: The subset of objects that needs to be exported whose names start with this prefix.
• --start: The subset of objects that needs to be exported starting with this object (inclusive).
• --end: The subset of objects that needs to be exported up to this object (inclusive).

Creating the Data Export Policy

Data export requires you to add the provided policy language to authorize a secure Oracle IAM user to have read-only access to the bucket for export. You must have administrator privileges in your tenancy to create the data export policy.

To create an export policy using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
Data Transfer

2. Select the Compartment from the list.
The export jobs in that compartment are displayed.
3. Click the export job link whose data export policies you want to access.
The Details page for that export job appears.
4. Find the export policies under Policy Language in the Details page.
5. Copy and use these policy statements in the policy you create in the Console.
See Getting Started with Policies on page 2135 for more information.
To create an export policy using the CLI
The export create-policy CLI automates the process of generating policies for export job. You do not need to use the
Console to create individual policies if you run this CLI.
oci dts export create-policy --job-id <job_id>
For example:
oci dts export create-policy --job-id
ocid1.datatransferapplianceentitlement.oc1..exampleuniqueID
Setting up the following policies in the root compartment. If the following
operation fails it means that you do not have enough privileges to create
policies. Re-run the below command with the correct user
NOTE: Sometimes you will need to replace a single quote with '"'"'
oci iam policy create --name e2e-export-test-af3df5176d46_Policy
--compartment-id $ROOT_COMPARTMENT --statements '["DEFINE TENANCY
OCI_TENANCY AS ocid1.tenancy.oc1..exampleuniqueID", "DEFINE GROUP
OCI_EXPORT_GROUP AS ocid1.group.region1..exampleuniqueID", "ADMIT GROUP
OCI_EXPORT_GROUP OF TENANCY OCI_TENANCY TO read objects IN TENANCY where
target.bucket.name='dtsTestBucket'", "ADMIT GROUP OCI_EXPORT_GROUP OF
TENANCY OCI_TENANCY TO read objectstorage-namespaces IN TENANCY"]' -description "The policies to allow DTS to process the export job"
{
"data": {
"compartment-id": "ocid1.tenancy.region1..exampleuniqueID",
"defined-tags": {},
"description": "The policies to allow DTS to process the export job",
"freeform-tags": {},
"id": "ocid1.policy.region1..uniqueID",
"inactive-status": null,
"lifecycle-state": "ACTIVE",
"name": "e2e-export-test-af3df5176d46_Policy",
"statements": [
"DEFINE TENANCY OCI_TENANCY AS ocid1.tenancy.oc1..exampleuniqueID",
"DEFINE GROUP OCI_EXPORT_GROUP AS
ocid1.group.region1..exampleuniqueID",

Oracle Cloud Infrastructure User Guide

1099


**Requesting the Export Appliance**

This section describes how to request an export appliance from Oracle.

*To request an export appliance using the Console*

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Exports**.
2. Select the **Compartment** from the list.

   The export jobs in that compartment are displayed.
3. Click the export job link for which you want to request the export appliance.

   The Details page for that export job appears.
4. Click **Request Export Appliance**.

   The Request Export Appliance dialog appears prompting you to review the manifest file before continuing with the export appliance request.

   Review the manifest file to ensure all your export job information, such as the bucket and contact information is correct. If anything is not correct, cancel the application request and correct the export job information before trying again to request an export application.
5. Click **Request**.

   The Details page is updated to indicate **Appliance Requested**. The state of your export job is updated to **Pending Approval** in the list of export jobs.

*To request an export appliance using the CLI*

```
oci dts export request-appliance --job-id <job_id>
```

For example:

```json
oci dts export request-appliance --job-id ocid1.datatransferapplianceentitlement.oc1..exampleuniqueID
{
  "data": {
    "appliance-decryption-passphrase": null,
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "appliance-serial-number": null,
    "bucket-access-policies": [
      "DEFINE TENANCY OCI_TENANCY AS ocid1.tenancy.oc1..exampleuniqueID",
      "DEFINE GROUP OCI_EXPORT_GROUP AS ocid1.group.region1..exampleuniqueID",
      "ADMIT GROUP OCI_EXPORT_GROUP OF TENANCY OCI_TENANCY TO read objects IN TENANCY where target.bucket.name='MyExportBucket'",
      "ADMIT GROUP OCI_EXPORT_GROUP OF TENANCY OCI_TENANCY TO read objectstorage-namespaces IN TENANCY"
    ],
    "bucket-name": "MyExportBucket",
    "compartment-id": "ocid1.compartment.region1..exampleuniqueID",
    "creation-time": "2020-07-09T18:36:59+00:00",
    "customer-shipping-address": {
      "address1": "123 Main St.",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "DTS",
      "care-of": "John Doe",

"range-end": "oci_data_export_export-job-50",
"range-start": "oci_data_export_export-job-37",
"receiving-security-tie": null,
"sending-security-tie": null,
"total-size-in-bytes": "85585303"
},
"etag": "1"
}

Tracking the Export Appliance Delivery

To track the export appliance delivery status using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports
2. Select the Compartment from the list.
   The export jobs in that compartment are displayed.
3. Click the export job for which you want to display the details.
   As an alternative, you can click the Actions icon ( ) associated with your export job, and then click View Details.

The status of the requested export appliance is listed under Appliance Information.

To track the export appliance delivery status using the CLI

oci dts export show --job-id <job_id> <options>

<options> are:

- --from-json: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The --generate-full-command-json-input option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options” link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.
For example:

```bash
oci dts export show --job-id
ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID
```

```json
{
  "data": {
    "appliance-decryption-passphrase": "********",
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "appliance-serial-number": null,
    "bucket-access-policies": [
      "POLICIES CREATION IN PROGRESS"
    ],
    "bucket-name": "MyExportJobs",
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2020-06-18T17:24:13+00:00",
    "customer-shipping-address": {
      "address1": "123 Main St.",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",
      "city-or-locality": "Anytown",
      "country": "US",
      "email": "jdoe@mycompany.com",
      "phone-number": "4085551212",
      "state-or-region": "CA",
      "zipcode": "12345"
    },
    "defined-tags": {},
    "display-name": "MyExportJob1",
    "first-object": null,
    "freeform-tags": {},
    "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
    "last-object": null,
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": "PENDING_MANIFEST_GENERATION",
    "manifest-file": null,
    "manifest-md5": null,
    "next-object": null,
    "number-of-objects": null,
    "prefix": null,
    "range-end": null,
    "range-start": null,
    "receiving-security-tie": null,
    "sending-security-tie": null,
    "total-size-in-bytes": null
  },
  "etag": "1--gzip"
}
```

The status of the requested export appliance is listed in the appliance attributes in the returned information.

**Notifying the Data Administrator**

When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Oracle Cloud Infrastructure CLI configuration files
- Export job ID
What's Next

You can follow the progress of the export job and view the metrics associated with the copying of files from Oracle Cloud Infrastructure to your appliance. See Monitoring the Export Job Status and Data Transfer Metrics on page 1103.

Monitoring the Export Job Status and Data Transfer Metrics

This topic describes the monitoring tasks you can perform after your appliance request has been approved and the export job begins. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1085.

Note:

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Once Oracle approves the appliance request and the export job begins, follow progress of the export job status.

To monitor the status of your export job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the Compartment from the list.
   - The export jobs in that compartment are displayed.
3. Click the export job for which you want to display the details.
   - As an alternative, you can click the Actions icon ( ⚙️ ) associated with your export job, and then click View Details.
4. Look at the State and Details fields. See Export Appliance State Values on page 1103 for a list of the states and their details.

To monitor the status of your export job using the CLI

At the command prompt on the host, run dts appliance show to monitor the export appliance status.

oci dts export show --job-id <job_id>

See Export Appliance State Values on page 1103 for a list of the states and their details.

Export Appliance State Values

Here are the export job and appliance state values, including their details:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating</td>
<td>The job is in the initialization phase. Additional steps are required from the user before it becomes Active.</td>
<td>Pending Manifest Generation</td>
<td>Generate an export manifest for the bucket from where data is being exported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pending Submission</td>
<td>The export job is in a pending state until you request an appliance for the export job.</td>
</tr>
<tr>
<td>State</td>
<td>Description</td>
<td>Details</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
<td>--------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>The job is awaiting approval from Oracle before an appliance can be assigned for this export job.</td>
<td>Appliance Provisioning</td>
<td>An appliance is being provisioned for the export job.</td>
</tr>
<tr>
<td>In Progress</td>
<td>The export job is approved and is actively being worked on.</td>
<td>Downloading</td>
<td>Data download to the appliance is in progress.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Oracle Shipped</td>
<td>Oracle has shipped the appliance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Customer Received</td>
<td>The appliance has been delivered to the customer site.</td>
</tr>
<tr>
<td></td>

<td>Customer Processing</td>
<td>The appliance is being processed at the customer site.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Customer Shipped</td>
<td>The appliance has been shipped to Oracle from the customer site.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Oracle Received</td>
<td>Oracle has received back the appliance after export.</td>
</tr>
<tr>
<td>Succeeded</td>
<td>The export is complete.</td>
<td>Closed</td>
<td>The export job is closed.</td>
</tr>
<tr>
<td>Failed</td>
<td>The export job failed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cancelled</td>
<td>The export job was canceled before an appliance was requested for export.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Deleted</td>
<td>The export job was canceled.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Viewing Data Transfer Metrics**

Once the data transfer begins, you can view the metrics associated with the export job in the Transfer Appliance Details page in chart or table format.

**Tip:**

Set up your notifications to alert you when the data transfer from Oracle Cloud Infrastructure to the appliance is occurring. When the state changes to **In Progress Downloading**, you can start viewing data transfer metrics.

Select **Metrics** under **Resources** to display each of these measures:

- **Export Files Downloaded** - Total number of files downloaded to the appliance for export.
- **Export Bytes Downloaded** - Total number of bytes downloaded to the appliance for export.
- **Export Files Remaining** - Total number of files left to be downloaded for export.
- **Export Bytes Remaining** - Total number of bytes left to be downloaded for export.
- **Export Files in Error** - Total number of files in error for export.
- **Export Download Verification Progress** - Progress of verification of files that have already been downloaded for export.

Select the **Start Time** and **End Time** for these measures. You can either set them manually by entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. You can also select from a list of standard times (last hour, last 6 hours, and so forth) from the **Quick Selects** list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.
Choose additional actions from the **Options** list, including viewing the query in the **Metrics Explorer**, capturing the URL for the measure, and switching between chart and table view.

Click **Reset Charts** to delete any existing information in the charts and begin recording new metrics.

See **Monitoring Overview** on page 2660 for general information on monitoring your Oracle Cloud Infrastructure services.

**What's Next**

You are now ready to configure the export appliance after you receive it from Oracle. See **Configuring the Export Appliance** on page 1105.

### Configuring the Export Appliance

This topic describes the tasks associated with configuring the export appliance after you receive it from Oracle. The Infrastructure Engineer role typically performs these tasks. See **Roles and Responsibilities** on page 1085.

#### Unpacking and Connecting the Appliance to the Network

When the shipping vendor delivers your export appliance, Oracle updates the status as **Delivered** and provides the date and time the appliance was received in the **Appliance Information** section.

Your export appliance arrives in a transit case with a telescoping handle and wheels. The case amenities allow for easy movement to the location where you intend to place the appliance to upload your data.

**Important:**

**Retain all packaging materials!** When shipping the export appliance back to Oracle, you must package the appliance in the same manner and packaging in which the appliance was received.

Here are the tasks involved in unpacking and getting your export appliance ready to configure.

1. Inspect the tamper-evident security tie on the transit case.
   
   If the appliance was tampered with during transit, the tamper-evident security tie serves to alert you.

   **Caution:**
   
   If the security tie is damaged or is missing, do not plug the appliance into your network! Immediately file a Service Request (SR).

2. Remove and compare the number on the security tie with the number logged by Oracle.
3. Open the transit case and ensure that the case contains the following items:
   
   - Appliance unit and power cable (two types of power cables provided: C14 and C13 to 14)
   - USB to DB-9 serial cable
   - Return shipping instructions (retain these instructions)
   - Return shipping label, label sleeve, tie-on tag, and zip tie
   - Return shipment tamper-evident security tie (use this tie to ensure secure transit case back to Oracle)
4. Compare the number on the return shipment security tie with the number logged by Oracle.
5. Remove the export appliance from the case and place the appliance on a solid surface or in a rack.

**Caution:**

We recommend assistance lifting the export appliance out of the transit case and placing the appliance in a rack or on a desk top. The total shipping weight is about 64 lbs (29.0299 kg) and appliance weight is 38 lbs (17.2365 kg).

6. Connect the appliance to your local network using one of the following:
   - 10GBase-T: Standard RJ-45
   - SFP+: The transceiver must be compatible with Intel X520 NICs.

7. Attach one of the provided power cords to the appliance and plug the other end into a grounded power source.

8. Turn on the appliance by flipping the power switch on the back of the appliance.

---

**To see the security tie number logged by Oracle using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Find the export job and export appliance associated with the removed security tie.
3. Click the Actions icon ( ), and then click View Details.
4. Look at the contents of the Send Security Tie ID field in the Appliance Information section and compare that number with the number on the physical tag.

**To see the security tie number logged by Oracle using the CLI**

At the command prompt on the Control Host, run `oci dts appliance show` to delete an export appliance.

```
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```

**Caution:**

If the number on the physical security tie does not match the number logged by Oracle, do not plug the appliance into your network! Immediately file a Service Request (SR).

**Note:**

Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

---

**To see the security tie number logged by Oracle using the Console**

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Find the export job and export appliance associated with the return shipment security tie.
3. Click the Actions icon ( ), and then click View Details.
4. Look at the contents of the Return Security Tie ID field in the Appliance Information section and compare that number with the number on the physical tag.

**To see the security tie number logged by Oracle using the CLI**

```
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```
Connecting the Appliance to the Terminal Emulation Host

Connect the appliance to your designated Terminal Emulation Host computer using the provided USB to DB-9 serial cable.

Note:
You might need to download the driver for this cable on your Terminal Emulation Host: https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support

Setting Up Terminal Emulation

Set up terminal emulation so you can communicate with the appliance device through the appliance's serial console. This communication requires installing serial console terminal emulator software. We recommend using the following:

- PuTTY for Windows
- ZOC for OS X
- PuTTY or Minicom for Linux

Configure the following terminal emulator software settings:

- Baud Rate: 115200
- Emulation: VT102
- Handshaking: Disabled/off
- RTS/DTS: Disabled/off

Note:
PuTTY does not allow you to configure all of these settings individually. However, you can configure the PuTTY default settings by selecting the Serial connection type and specifying ”115200” for the Serial Line baud speed. This is sufficient to use PuTTY as a terminal emulator for the appliance.

Configuring the Export Appliance Networking

When the appliance boots up, an appliance serial console configuration menu is displayed on the Terminal Emulation Host to which the appliance is connected.

Oracle Cloud Data Transfer Appliance
- For use with minimum dts version: dts-0.4.140
- See "Help" for determining your dts version

1) Configure Networking
2) Show Networking
3) Reset Authentication
4) Show Authentication
5) Show Status
6) Collect Appliance Diagnostic Information
7) Generate support bundle
8) Shutdown Appliance
9) Reboot Appliance
10) Help

Caution:
If the number on the return security tie does not match the number logged by Oracle, file a Service Request (SR). These security tie numbers must match or Oracle cannot upload data from your returned export appliance.
The appliance supports a single active network interface on any of the 10-Gbps network ports. If only one interface is cabled and active, that interface is chosen automatically. If multiple interfaces are active, you are given the choice to select the interface to use.

**To configure your export appliance networking**

1. From the Terminal Emulation Host, select **Configure Networking** from the appliance serial console menu.
2. Provide the required networking information when prompted:
   - **IP Address**: IP address of the export appliance.
   - **Subnet Mask Length**: The count of leading 1 bit in the subnet mask. For example, if the subnet mask is 255.255.255.0 then the length is 24.
   - **Default Gateway**: Default gateway for network communications.

For example:

```
Configure Networking:
^C to cancel

Configuring IP address, subnet mask length, gateway
Example:
IP Address : 10.0.0.2
Subnet Mask Length : 24
Gateway : 10.0.0.1
Address: 10.0.0.1
Subnet Mask Length: 24
Gateway: 10.0.0.1

Configuring IP address 10.0.0.1 netmask 255.255.255.0 default gateway 10.0.0.1
Enabling enp0s3
Now trying to restart the network

Network configuration is complete
New authentication material created.
Client access token                   : 4iH1gw1okPJO
Press ENTER to return...
```

When you configure a network interface, the appliance software generates a new client access token and appliance X.509/SSL certificate. The access token is used to authorize your Control Host to communicate with the Data Transfer Appliance's Management Service. The x.509/SSL certificate is used to encrypt communications with the Data Transfer Appliance's Management Service over the network. Provide the access token and SSL certificate fingerprint values displayed here when you use the CLI commands to `initialize authentication on your host machine`.

You can change the selected interface, network information, and reset the authentication material at any time by selecting **Configure Networking** again from the appliance serial console menu.
Notify the Data Administrator

After completing the tasks in this topic, send the following appliance information IP address of the export appliance to the Data Administrator:

- Appliance IP address
- Access token
- SSL certificate fingerprint

What's Next

You are now ready to copy your data from the export appliance to your data center. See Copying Data from the Export Appliance on page 1109.

Copying Data from the Export Appliance

This topic describes the tasks associated with copying data from the export appliance to your data center's Data Host using the Control Host. The Data Administrator role typically performs these tasks. See Roles and Responsibilities on page 1085.

Note:

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Information Prerequisites

Before performing any export appliance copying tasks, you must obtain the following information:

- Appliance IP address - typically is provided by the Infrastructure Engineer.
- IAM login information, Data Transfer Utility configuration files, export job ID, and job label - typically is provided by the Project Sponsor.

Setting Up an HTTP Proxy Environment

You might need to set up an HTTP proxy environment on the Control Host to allow access to the public internet. This proxy environment allows the Oracle Cloud Infrastructure CLI to communicate with the Data Transfer Appliance Management Service and the export appliance over a local network connection. If your environment requires internet-aware applications to use network proxies, configure the Control Host to use your environment's network proxies by setting the standard Linux environment variables on your Control Host.

Assume that your organization has a corporate internet proxy at http://www-proxy.myorg.com and that the proxy is an HTTP address at port 80. You would set the following environment variable:

```
export HTTPS_PROXY=http://www-proxy.myorg.com:80
```

If you configured a proxy on the Control Host and the export appliance is directly connected to that host, the Control Host tries unsuccessfully to communicate with the export appliance using a proxy. Set a `no_proxy` environment variable for the appliance. For example, if the appliance is on a local network at 10.0.0.1, you would set the following environment variable:

```
export NO_PROXY=10.0.0.1
```

Setting Firewall Access

If you have a restrictive firewall in the environment where you are using the Oracle Cloud Infrastructure CLI, you may need to open your firewall configuration to the following IP address ranges: 140.91.0.0/16.
Configuring the Export Appliance

After you have physically set up the export appliance and connected it to your network, you can configure it using the CLI to allow the copying of the data it contains to your data center.

**Note:**
You can only use the CLI command to configure the appliance.

To configure the export appliance using the CLI:

```bash
oci dts export configure-physical-appliance --job-id <job-id> --appliance-cert-fingerprint <fingerprint> --appliance-ip <appliance_ip> --rw <rw> --world <world><options>
```

- `<fingerprint>` is the export appliance X.509/SSL certificate fingerprint.
- `<appliance_ip>` is the IP address of the export appliance.
- `<rw>` indicates whether the exported data has read/write permissions. Specify `true` or `false`.
- `<world>` indicates whether the exported data is accessible by all. Specify `true` or `false`.
- `<options>` are:
  - `--appliance-port`: The port number used by the export appliance.
  - `--appliance-profile`: User-defined name or description of the transfer appliance. This is useful if you have multiple transfer appliances.
  - `--access-token`: The access token to authenticate with the export appliance.
  - `--appliance-port`: The port number used by the export appliance.
  - `--subnet-mask-length`: The subnet mask length for the IP address.

### Setting Your Data Host as an NFS Client

**Note:**
Only Linux machines can be used as Data Hosts.

Set up your Data Host as an NFS client:

- For Debian or Ubuntu, install the `nfs-common` package. For example:
  ```bash
  sudo apt-get install nfs-common
  ```
- For Oracle Linux or Red Hat Linux, install the `nfs-utils` package. For example:
  ```bash
  sudo yum install nfs-utils
  ```

### Mounting the NFS Share

To mount the NFS share:

At the command prompt on the Data Host, create the mountpoint directory:

```bash
mkdir -p /mnt/<mountpoint>
```

For example:

```bash
mkdir -p /mnt/nfs-ds-1
```

Next, use the `mount` command to mount the NFS share.

```bash
mount -t nfs <appliance_ip>:/data/<dataset_name>/<mountpoint>
```
Data Transfer

For example:

```
mount -t nfs 10.0.0.1:/data/nfs-ds-1 /mnt/nfs-ds-1
```

**Note:**
The appliance IP address in this example (10.0.0.1) may be different that the one you use for your appliance.

After the NFS share is mounted, you can write data to the share.

Copying Files to the Data Host

Copy your file from the appliance to your NFS-mounted Data Host using normal file system tools.

Viewing Data Export Metrics

You can view the metrics associated with an export job in the Transfer Appliance Details page in chart or table format. Select Metrics under Resources to display each of these measures:

- **Export Files Downloaded** - Total number of files downloaded to the appliance for export.
- **Export Bytes Downloaded** - Total number of bytes downloaded to the appliance for export.
- **Export Files Remaining** - Total number of files left to be downloaded for export.
- **Export Bytes Remaining** - Total number of bytes left to be downloaded for export.
- **Export Files in Error** - Total number of files in error for export.
- **Export Download Verification Progress** - Progress of verification of files that have already been downloaded for export.

Select the **Start Time** and **End Time** for these measures, either by manually entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. As an alternative to selecting a start and end time, you can also select from a list of standard times (last hour, last 6 hours, and so forth) from the **Quick Selects** list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.

**Tip:**
Mean is the most useful statistic for data export.

Choose additional actions from the **Options** list, including viewing the query in the **Metrics Explorer**, capturing the URL for the measure, and switching between chart and table view.

Click **Reset Charts** to delete any existing information in the charts and begin recording new metrics.

See **Monitoring Overview** on page 2660 for general information on monitoring your Oracle Cloud Infrastructure services.

Erasing Files from the Export Appliance

Use standard system tools to remove your data from the export appliance after you have copied your files.

Notifying Export Appliance Return

When the erasure of the client data from the export appliance is complete, notify the Infrastructure Engineer that the appliance is ready to be returned to Oracle.

What's Next

You are now ready to ship the export appliance back to Oracle. See **Returning the Export Appliance to Oracle** on page 1112.
Returning the Export Appliance to Oracle

This topic describes the tasks associated with shipping the export appliance back to Oracle after you have copied your data to your data center. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1085.

**Note:**
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

**Shutting down the Export Appliance**

Shut down the export appliance before packing up and shipping it back to Oracle.

*To shut down the export appliance*

Using the terminal emulator on the host machine, select **Shutdown** from the appliance serial console.

**Packing and Shipping the Export Appliance to Oracle**

Return the export appliance to Oracle within 30 days. If you need the appliance beyond the standard 30-day window, you can file a Service Request (SR) to ask for an extension of up to 60 days.

**Important:**
Review and follow the instructions that were provided in the transit case with the appliance.

*To pack and ship the export appliance*

1. Unplug the power cord from the power source and detach the other end of the cord from the export appliance.
2. Disconnect the appliance from your network.
3. Remove the return shipment tamper-evident security tie from the transit case.
4. Place the appliance, power cord, and serial cable in the transit case.

**Caution:**
We recommend assistance lifting and placing the appliance back into the transit case. The total shipping weight is about 64 lbs (29.0299 kg) and appliance weight is 38 lbs (17.2365 kg).

5. Close and secure the transit case with the return tamper-evident security tie.
6. Loop the top of the plastic tie-on tag with return shipping label through the handle of the transit case. Remove the protective tape from the back of the tie-on tag, exposing the adhesive area on which to secure the tag onto itself. Use the provided zip tie to secure the tie-on tag to the handle.
7. Return the transit case to FedEx by doing one of the following:
   - Drop off the packed, sealed, and labeled transit case to an FedEx Authorized ShipCenter location or a nearby FedEx Office location. Obtain a receipt from the vendor to certify transfer of custody.
   - Schedule a pickup with FedEx at your location. Ensure that the transit case is packed, sealed, and labeled before FedEx arrives for pickup.

The shipping vendor notifies Oracle when the appliance is returned to Oracle.

**Tracking the Export Appliance Return**

Use your shipping carrier's tracking feature to following the progress of your export appliance after you return it to Oracle.
Data Export Reference

This topic provides complete task details that are not otherwise fully documented in other topics. Use this topic as a reference to learn and use commands associated with components included in the data export procedure.

Export Jobs

Export Jobs are what determine how and when data is copied from Oracle Cloud Infrastructure to the export appliance. Perform the following export job tasks using the Console or the CLI:

Creating Export Jobs

To create an export job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the Compartment you are to use for data exports from the list.
   A list of export jobs that have already been created is displayed.
3. Click Create Export Job.
   The Create Export Job dialog appears.
4. Enter a Job Name. Avoid entering confidential information. Then, select the Upload Bucket from the list.
5. (Optional) Complete the following fields:
   - Prefix: List of objects with names matching this prefix would be part of this export job.
   - Range Start: Object names returned by a list query must be greater or equal to this parameter.
   - Range End: Object names returned by a list query must be strictly less than this parameter.
6. Complete the following fields:
   - Company Name
   - Recipient Name
   - Recipient Email
   - Address 1
   - Address 2
   - City/Locality
   - State/Province/Region
   - Zip/Postal Code
   - Country
7. (Optional) Add any tagging information, including the tag namespace, key, and value in the associated fields.
8. Click Create Transfer Job.

To create an export job using the CLI

oci dts export create --compartment-id <compartment_id> --bucket-name <bucket_name> --display-name <display_name> --addressee <addressee> --care-of <care_of> --address1 <address1> --city-or-locality <city_or_locality> --state-province-region <state_province_region> --country <country> --zip-postal-code <zip_postal_code> --phone-number <phone_number> --email <email> <options>

<display_name> is the name of the export job as it appears. Avoid entering confidential information.
<addressee> is the company or person to receiving the appliance.
<care_of> is the contact associated with the addressee.
<address> is the required address of the addressee.
<city_or_locality> is city or locality of the addressee.
<state_province_region> is the state, province, or region of the addressee.
**Data Transfer**

- `<country>` is the country of the addressee.
- `<zip_postal_code>` is the zip or postal code of the addressee.
- `<phone_number>` is the phone number of the addressee or contact.
- `<email>` is the email address of the addressee or contact.

**<options>** are:

- **--setup-notifications**: Sets up the required export notifications as part of the export job creation process.
- **--prefix**: List of objects with names matching this prefix would be part of this export job.
- **--range-start**: Object names returned by a list query must be greater or equal to this parameter.
- **--range-end**: Object names returned by a list query must be strictly less than this parameter.
- **--freeform-tags**: Free-form tags for this resource. Each tag is a simple key-value pair with no predefined name, type, or namespace. Example: `{"Department": "Finance"}` This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The `--generate-param-json-input` option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
- **--defined-tags**: Defined tags for this resource. Each key is predefined and scoped to a namespace. For more information, see [Resource Tags]. Example: `{"Operations": {"CostCenter":"42"}}` This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The `--generate-param-json-input` option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
- **--wait-for-state**: This operation creates, modifies or deletes a resource that has a defined lifecycle state: CREATING, ACTIVE, IN PROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED. Specify this option to perform the action and then wait until the resource reaches a given lifecycle state. Multiple states can be specified, returning on the first state. For example, `--wait-for-state SUCCEEDED --wait-for-state FAILED` would return on whichever lifecycle state is reached first. If timeout is reached, a return code of 2 is returned. For any other error, a return code of 1 is returned.
- **--max-wait-seconds**: The maximum time in seconds to wait for the resource to reach the lifecycle state defined by the `--wait-for-state` attribute. Default is 1200.
- **--wait-interval-seconds**: The check interval in seconds to determine whether the resource to see if it has reached the lifecycle state defined by the `--wait-for-state`. Default is 30.
- **--address2**: Optional address line 2.
- **--address3**: Optional address line 3.
- **--address4**: Optional address line 4.
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path/to/file syntax. The `--generate-full-command-json-input` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id -> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusings.htm#AdvancedJSONOptions.

For example:

```bash
oci dts export create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket-name MyBucket1 --display-name MyExportJob1 --addressee "MyCompany Corp" --care-of "John Doe" --address1 "123 Main St." --city-or-locality Anytown --state-province-region CA --country USA --zip-postal-code 12345 --phone-number "4085551212" --email jdoe@mycompany.com
```
"data": {
    "appliance-decryption-passphrase": "********",
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "appliance-serial-number": null,
    "bucket-access-policies": ["POLICIES CREATION IN PROGRESS"],
    "bucket-name": "MyExportJobs",
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2020-06-18T17:24:13+00:00",
    "customer-shipping-address": {
        "address1": "123 Main St.",
        "address2": null,
        "address3": null,
        "address4": null,
        "addressee": "MyCompany Corp",
        "care-of": "John Doe",
        "city-or-locality": "Anytown",
        "country": "USA",
        "email": "jdoe@mycompany.com",
        "phone-number": "4085554321",
        "state-or-region": "CA",
        "zipcode": "12345"
    },
    "defined-tags": {},
    "display-name": "MyExportJob1",
    "first-object": null,
    "freeform-tags": {},
    "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
    "last-object": null,
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": "PENDING_MANIFEST_GENERATION",
    "manifest-file": null,
    "manifest-md5": null,
    "next-object": null,
    "number-of-objects": null,
    "prefix": null,

    "range-start": null,
    "receiving-security-tie": null,
    "sending-security-tie": null,
    "total-size-in-bytes": null
},
"etag": "4--gzip"
}

Notifications

If you do not include the --setup-notification option when you run the command, the following is returned:

It is a pre-requisite to setup notifications for export. Do you want to setup notifications? [y/N]:

If you do not have the necessary permissions to set up the notifications for export, or if you have previously done this step, then select N. Otherwise, select y. See Setting Up Notifications on page 1093 for more information.

Listing Export Jobs

To display a list of export jobs using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the **Compartment** from the list.

The export jobs in that compartment are displayed.

To display a list of export jobs using the CLI

```
oci dts export list --compartment-id <compartment_id> <options>
```

<**options**> are:

- **--lifecycle-state**: Filter the returned export jobs by the specified lifecycle state (specify one only): CREATING, ACTIVE, INPROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED.
- **--display-name**: Filter the returned exports jobs by the specified display name.
- **--limit**: The maximum number of results per page, or items to return. For important details about how pagination works, see [List Pagination]. Example: `50`
- **--page**: The value of the `opc- next-page` response header from the previous "List" call. For important details about how pagination works, see [List Pagination].
- **--all**: Returns all pages of results. If you provide this option, then you cannot provide the **--limit** option.
- **--page-size**: Specify the number of export jobs returned per call. Only valid when used with **--all** or **--limit**, and ignored otherwise.
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The **--generate-full-command-json-input** option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our “using CLI with advanced JSON options” link: [https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions].

For example:

```
oci dts export list --compartment-id ocid.compartment.oc1..exampleuniqueID
{
  "data": [
  {
    "bucket-name": "MyExportJobs",
    "creation-time": "2020-06-18T17:24:13+00:00",
    "defined-tags": {},
    "display-name": "MyExportJob1",
    "freeform-tags": {},
    "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": "PENDING_MANIFEST_GENERATION"
  }
  {
    "bucket-name": "MyTestExportJobs",
    "creation-time": "2020-06-18T18:07:59+00:00",
    "defined-tags": {},
    "display-name": "MyTestExportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID",
    "lifecycle-state": "CREATING",
    "lifecycle-state-details": "PENDING_MANIFEST_GENERATION"
  }
  ]
}
```

**Displaying Export Job Details**
Data Transfer

**Displaying Export Job Details**

To show the details of an export job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Exports**.
2. Select the **Compartment** from the list.
   
   The export jobs in that compartment are displayed.
3. Find the export job for which you want to display the details.
4. Click the **Actions** icon (⋮), and then click **View Details**.

To show the details of an export job using the CLI

```
oci dts export show --job-id <job_id> <options>
```

<options> are:

- `--from-json`: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The `--generate-full-command-json-input` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: [https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions](https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions).

For example:

```
oci dts export show --job-id ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID

{
  "data": {
    "appliance-decryption-passphrase": "********",
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "appliance-serial-number": null,
    "bucket-access-policies": [
      "POLICIES CREATION IN PROGRESS"
    ],
    "bucket-name": "MyExportJobs",
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2020-06-18T17:24:13+00:00",
    "customer-shipping-address": {
      "address1": "123 Main St.",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",

Oracle Cloud Infrastructure User Guide 1117
Editing Export Jobs

To edit an export job using the Console

1. Open the navigation menu. Under Core Infrastructure, go to Object Storage and click Data Transfer - Exports.
2. Select the Compartment from the list.
   The export jobs in that compartment are displayed.
3. Click the link under Transfer Jobs for the export job whose name you want to edit.
   The Details page for that export job appears.

   Alternatively, you can click the Actions icon ( ), and then click View Details.
4. Click Edit in the Details page.
   The Edit Export Job dialog appears.
5. Edit any of the attributes displayed, including the job name, bucket, and address.
   Avoid entering confidential information.
6. Click Save Changes.
   You are returned to the Details page for that export job.

To edit an export job using the CLI

oci dts export update --job-id <job_id> <options>

<options> are:

• --bucket-name: Name of the bucket associated with the data export. Avoid entering confidential information.
• --prefix: List of objects with names matching this prefix would be part of this export job.
• --range-start: Object names returned by a list query must be greater or equal to this parameter.
• --range-end: Object names returned by a list query must be strictly less than this parameter.
• --display-name: Name of the export job as it appears.
• --lifecycle-state: CREATING, ACTIVE, INPROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED.
• --lifecycle-state-details: A property that can contain details on the lifecycle.
• --manifest-file: Manifest file associated with this export job.
• --manifest-md5: md5 digest of the manifest file.
• --number-of-objects: Total number of objects that are exported in this job.
• --total-size-in-bytes: Total size of objects in bytes that are exported in this job.
Data Transfer

- **--first-object**: First object in the list of objects that are exported in this job.
- **--last-object**: Last object in the list of objects that are exported in this job.
- **--next-object**: First object from which the next potential export job could start.
- **--freeform-tags**: Free-form tags for this resource. Each tag is a simple key-value pair with no predefined name, type, or namespace. Example: `{"Department": "Finance"}`. This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The --generate-param-json-input option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
- **--defined-tags**: Defined tags for this resource. Each key is predefined and scoped to a namespace. For more information, see [Resource Tags]. Example: `{"Operations": {"CostCenter": "42"}}`. This is a complex type whose value must be valid JSON. The value can be provided as a string on the command line or passed in as a file using the file://path/to/file syntax. The --generate-param-json-input option can be used to generate an example of the JSON which must be provided. We recommend storing this example in a file, modifying it as needed and then passing it back in via the file:// syntax.
- **--if-match**: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object's tag matches the tag specified in the request.
- **--force**: Perform task without prompting for confirmation.
- **--wait-for-state**: This operation creates, modifies or deletes a resource that has a defined lifecycle state: CREATING, ACTIVE, IN PROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED. Specify this option to perform the action and then wait until the resource reaches a given lifecycle state. Multiple states can be specified, returning on the first state. For example, --wait-for-state SUCCEEDED --wait-for-state FAILED would return on whichever lifecycle state is reached first. If timeout is reached, a return code of 2 is returned. For any other error, a return code of 1 is returned.
- **--max-wait-seconds**: The maximum time in seconds to wait for the resource to reach the lifecycle state defined by the --wait-for-state attribute. Default is 1200.
- **--wait-interval-seconds**: The check interval in seconds to determine whether the resource to see if it has reached the lifecycle state defined by the --wait-for-state. Default is 30.
- **--address**: Company or person to receiving the appliance.
- **--care-of**: Contact associated with the addressee.
- **--address1**: Required address of the addressee (line 1).
- **--address2**: Optional address of the addressee (line 2).
- **--address3**: Optional address of the addressee (line 3).
- **--address4**: Optional address of the addressee (line 4).
- **--city-or-locality**: City or locality of the addressee.
- **--state-province-region**: State, province, or region of the addressee.
- **--country**: Country of the addressee.
- **--zip-postal-code**: Zip or postal code of the addressee.
- **--phone-number**: Phone number of the addressee or contact.
- **--email**: Email address of the addressee or contact.
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The --generate-full-command-json-input option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.
For example:

```bash
oci dts export update --job-id ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID --care-of "Robert Roe" --phone-number 4085554321 --email rroe@mycompany.com
```

Running the command displays the following message:

```
WARNING: Updates to customer-shipping-address and freeform-tags and defined-tags will replace any existing values. Are you sure you want to continue? [y/N]:
```

Confirm you want to continue. The information returned contains the update items you specified:

```json
"bucket-name": "MyExportJobs",
"compartment-id": "ocid.compartment.oc1..exampleuniqueID",
"creation-time": "2020-06-18T17:24:13+00:00",
"customer-shipping-address": {
  "address1": "123 Main St.",
  "address2": null,
  "address3": null,
  "address4": null,
  "addressee": "MyCompany",
  "care-of": "Robert Roe",
  "city-or-locality": "Anytown",
  "country": "US",
  "email": "rroe@mycompany.com",
  "phone-number": "4085554321",
  "state-or-region": "CA",
  "zipcode": "12345"
}
```

**Moving Export Jobs Between Compartments**

To move an export job to a different compartment using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Exports**.
2. Select the **Compartment** from the list.
   The export jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the export job that you want to move.
   The Details page for that export job appears.

   Alternatively, you can click the **Actions** icon ( ⚙ ), and then click **Move Resource**.
4. Click **Move Resource** in the Details page.
   The Move Resource to a Different Compartment dialog appears.
5. Choose the compartment you want to which you want to move the export job from the list.
6. Click **Move Resource**.
   You are returned to the Details page for that export job.

To move an export job to a different compartment using the CLI

```bash
oci dts export change-compartment --job-id <job_id> compartment-id <compartment_id> <options>
```

<compartment_id> is the compartment to which the data export job is being moved.
<options> are:
• **--if-match**: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object’s tag matches the tag specified in the request.

• **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The **--generate-full-command-json-input** option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our “using CLI with advanced JSON options’ link: [https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions](https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions).

For example:

```
oci dts export change-compartment --jpb-id
ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID --compartment-id
ocid.compartment.oc1..exampleuniqueID
```

To confirm the transfer, display the list of transfer jobs in the new compartment. See [Listing Export Jobs](#) on page 1115 for more information.

**Deleting Export Jobs**

To delete an export job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer - Exports**.
2. Select the **Compartment** from the list.
   
   The export jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the export job whose name you want to delete.
   
   The Details page for that export job appears.
   
   Alternatively, you can click the **Actions** icon (⋮), and then click **Delete**.
4. Click **Delete** in the Details page.
   
   The Delete Export Job dialog appears to confirm the deletion.
5. Click **Delete**.
   
   The export job is deleted and you are returned to the export jobs page.

To delete an export job using the CLI

```
oci dts export delete --job-id <job_id> <options>
```

<options> are:

• **--if-match**: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object’s tag matches the tag specified in the request.

• **--force**: Perform task without prompting for confirmation.

• **--wait-for-state**: This operation creates, modifies or deletes a resource that has a defined lifecycle state: CREATING, ACTIVE, IN PROGRESS, SUCCEEDED, FAILED, CANCELLED, or DELETED. Specify this option to perform the action and then wait until the resource reaches a given lifecycle state. Multiple states can be specified, returning on the first state. For example, **--wait-for-state SUCCEEDED --wait-for-state FAILED** would return on whichever lifecycle state is reached first. If timeout is reached, a return code of 2 is returned. For any other error, a return code of 1 is returned.

• **--max-wait-seconds**: The maximum time in seconds to wait for the resource to reach the lifecycle state defined by the **--wait-for-state** attribute. Default is 1200.

• **--wait-interval-seconds**: The check interval in seconds to determine whether the resource to see if it has reached the lifecycle state defined by the **--wait-for-state**. Default is 30.
Data Transfer

- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The --generate-full-command-json-input option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

For example:

```bash
oci dts export delete --job-id ocid1.datatransferapplianceexportjob.oc1..exampleuniqueID
```

Confirm the deletion when prompted. The export job is deleted with no further action or return. To confirm the deletion, display the list of export jobs in the compartment. See Displaying Export Job Details on page 1117 for more information.

### Troubleshooting

This topic describes various troubleshooting issues related to the Data Transfer Service.

#### General

Troubleshooting entries in this section can apply to all data transfer methods.

**Installing a Specific CLI Version**

You may need to change the version of the Oracle Cloud Infrastructure command line interface (CLI) to address issues with a particular feature. Installation of a CLI version other than the one currently installed requires the following steps in order:

1. Go to the following site: https://github.com/oracle/oci-cli/releases.
2. Scroll down to the version you need and download it to your local machine.

**Uninstalling the Existing version of the CLI Version**

If you manually installed the CLI using `pip`, run the following command:

```
pip uninstall oci-cli
```

If you manually installed the CLI in a virtualenv, run the following command:

```
<virtualenv_path>/bin/pip uninstall oci-cli
```

**Installing the Downloaded CLI Version**

See Manual Installation on page 4197 for installation instructions for your downloaded CLI version.

**Appliance-Based Data Transfers**

These troubleshooting entries are associated with appliance-based import and export jobs.

**Troubleshooting the Appliance**

You can generate performance information for troubleshooting issues with the appliance through the terminal emulator on the host machine. Select Collect Appliance Diagnostic Information from the serial console.
configuration menu. The diagnostic tool generates system, network, storage, and performance data while the transfer job is running. It then forwards the data to the appliance serial console. Here you can scroll through the terminal to view it.

You can also use the log capture feature of the serial port emulator to capture the output. Serial port emulators often support the ability to copy the session to a file. Refer to the documentation of your serial port emulation package for instructions. Copying to a log file is useful if you need assistance from Oracle or if your emulation session does not allow you to scroll back and see all the output.

For each operation, the display shows exactly what command was executed and all the options.

Here is an example of the diagnostic output:

```
- systemctl -l --type service --state=active
```

UNIT LOAD ACTIVE SUB DESCRIPTION
audid.service loaded active running Security Auditing Service
blk-availability.service loaded active exited Availability of block devices
chronyd.service loaded active running NTP client/server
console-diags@39-3147-1001.service loaded active running Diagnostic Collection Server for the XA (PID 3147/UID 1001)
crond.service loaded active running Command Scheduler
data-transfer-appliance.service loaded active running Data Transfer Appliance
data-transfer-console.service loaded active running Data Transfer Serial Console

Any problem with the diagnostic data collection results in the console output being written to the log file of the service. Failure of the commands is indicative of a serious problem, perhaps requiring the return of the appliance. Here is an example of the log:

```
Mar 6 17:55:33 localhost console-diags: {"Module": "main", "Type": "Info", "Message": "Received message {"cmd": "collect"}"}
Mar 6 17:55:33 localhost console-diags: {"Module": "main", "Type": "Info", "Message": "Setting up output file. First to remove all /tmp/xa-diags-results"}
```

**Initializing Appliance Fails Because of IP Address Issues**

Initializing the Appliance can fail because of using the incorrect IP address. The IP address for `initialize-auth` can differ from the IP address obtained when running ping or ssl connect. If you experience an initialization failure, ensure that you are using the correct IP address for your Appliance and try initializing again.

**Initialize Authentication Fails with "connection refused" or "connection timed out"**

If you try to configure networking using the appliance serial console but fail with a "connection refused" or "connection timed out" message, follow these troubleshooting steps.

Run the following command at the command prompt on the host:

```
ping <appliance_ip>
```

If a failure occurs, run the following command to verify appliance IP and the path to appliance.

```
ping -I <local_interface> <appliance_ip>
```

To determine expected interface, run `ip route` or an equivalent command. Verify that routing table is sane. Try running `traceroute` if you’re not sure to see the network path to the appliance IP.
Run the following command:

```
curl -k https://<appliance_ip>
```

You should receive the response "Not found." This failure can indicate the IP address may be wrong. For example, nothing is listening on port 443. If you receive a failure message, run the following command:

```
openssl s_client -showcerts -connect <appliance_ip>:443
```

You should see a certificate issued for "Oracle Cloud Infrastructure" / "Data Transfer Appliance."

This command is similar to `curl` but does not use HTTPS and so proxies do not affect it. If this command works, and `curl` fails, then verify there are no proxy environmental variables.

**Dataset Sealing Process Fails**

The dataset sealing process can fail sometimes because there are special files in the dataset:

```
dts nfs-dataset seal-status --name nfs-ds-1
```

Seal Status:
- success : false
- failureReason :
Number of special files : 5
- startTime : 2019/03/26 11:52:37 PDT
- endTime : 2019/03/26 11:52:39 PDT
- numFilesToProcess : 0
- numFilesProcessed : 0
- bytesToProcess : 0.00 KB
- bytesProcessed : 0.00 KB

At the command prompt on the host, reactivate the NFS dataset.

```
ocli dts nfs-dataset activate --name <dataset_name>
```

Then run `find` to get the full list of all special files and the specific type of each one.

```
find <mountpoint> ! -type f ! -type d | xargs file
```

For example:

```
$ find /mnt/nfs-ds-1 ! -type f ! -type d | xargs file
/mnt/nfs-ds-1/myfile1: symbolic link to `/home/user1/myfile1'
/mnt/nfs-ds-1/myfile2: symbolic link to `/home/user1/myfile2'
```

Next, review the list and remove all special files from the NFS mount point.

```
find <mountpoint> ! -type f ! -type d | xargs rm
```

Deactivate the NFS dataset.

```
ocli dts nfs-dataset deactivate --name <dataset_name>
```

Finally, reseal the dataset.

```
ocli dts nfs-dataset seal --name <dataset_name> [--wait]
```

Monitor the seal progress. Wait for it to complete successfully and continue with the subsequent steps.
Special Characters in Names Cause Data Sealing Failures

Data sealing fails if the names of the files being transferred contain characters that are not UTF-8, contain a newline, or include a return. The error returned is similar to the following:

failureReason": "nNumber of file paths with invalid chars: 1

If this error occurs, activate the data set, mount it, and run the following find command on the filesystem:

```
find . -print0 | perl -n0e 'chomp; print $_, "\n" if /[[:^ascii:][:cntrl:]]/'
```

Rename or delete those files that appear in the returned list.

Disk-Based Data Transfers

These troubleshooting entries are associated with disk-based import jobs.

Data Transfer Utility Fails because of Lack of Exclusive Access to Disk

The Data Transfer Utility requires exclusive access to the disk. If you have any drivers that already claim exclusive access to the disk, then the Data Transfer Utility fails. For example, if you employ a devicemapper multipath driver over all your disk devices, you must first remove the disk used for the data transfer from the list of devices managed by the multipath driver.

Be sure that access to the disk is not done through any devicemapper or volume manager. During the data transfer, the expectation is that the file system is created on a "raw" device. Any layering or mapping through intermediate drivers or abstraction layers makes it impossible for the disk to be uploaded at the transfer site. The source of these failures can include drivers like multipath, md, striping, logical volume managers, and potentially others as well.

You can confirm that the Data Transfer Utility has exclusive access by attempting to manually format the disk being used for your data transfer. The Data Transfer Utility uses the `cryptsetup` utility to create an encrypted device.

You can run `cryptsetup` from the command line (root privileges required):

```
cryptsetup luksFormat -c aes-xts-plain64 -s 512 -h sha512 --iter-time 2000 --use-random /dev/<sdXX>
```

<sdXX> is the name of the disk being used for the data transfer.

When prompted, respond that you do want to encrypt the device. You are required to provide a passphrase. Any passphrase is acceptable as the `cryptsetup` utility can run on a disk repeatedly without any problems.

If the command succeeds, then you know that the Data Transfer Utility can gain exclusive ownership of the disk to do the necessary for the data transfer.

Data Transfer Utility Fails with "Processing exception..." While Communicating to Oracle Cloud Infrastructure

Check if your environment has proxies to the internet. If so, update them to the latest version and set "https_proxy." If you are using the appliance, set "no_proxy" environmental variables. See Installing the Data Transfer Utility on page 974 for more information on proxies.

Data Transfer Utility Fails with "invalid configuration file"

If you attempt to run Data Transfer commands and receive the error message "invalid configuration file," verify that the following files are present on your host and are correctly set up:

- ~/.oci/config
- ~/.oci/config_upload_user

Both files must have "[DEFAULT] " as the first line. Use of the "~" character in a path is not valid in the file's contents.
Creating Transfer Disk Fails Because of Serial Number Error

Creating a transfer disk using the Data Transfer can fail because of a serial number error:

dts disk create --job-id ocid1.datatransferjob.ocl..exampleuniqueID --block-device /dev/sdb
ERROR : Unable to determine serial number for device /dev/sdb

This error may result from a garbled serial number resulting from the `hdparm -I` command. For example:

```
/bin/sh -c "hdparm -I /dev/sdb"
/dev/sdb:
SG_IO: bad/missing sense data, sb[]: 70 00 05 00 00 00 00 0a 00 00 00 00 24
00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
ATA device, with non-removable media
Standards:
Likely used: 1
Configuration:
Logical max current
heads 0 0
sectors/track 0 0
-
Logical/Physical Sector size: 512 bytes
device size with M = 1024*1024: 0 MBytes
device size with M = 1000*1000: 0 MBytes
cache/buffer size = unknown
Capabilities:
IORDY not likely
Cannot perform double-word IO
R/W multiple sector transfer: not supported
DMA: not supported
PIO: pio0
```

If you see this type of error, use the following workaround:

1. Run the following command at the prompt:

```
lsblk --nodeps -no serial /dev/<device> <serial_number>
```

2. Create an `hdparm` script in your Home directory using the following command:

```
vi $HOME/hdparm
#!/usr/bin/bash
while getopts ":Iht" opt;do
case ${opt} in
h) # process option h
;;
t)
;;
I)
    echo "Serial Number: <serial_number>"
;;
esac
done
```

Use the same serial number in your script that was returned when you ran the `lsblk` command in the previous step.

3. Make the script you just created executable.
4. Change your path using the following command:

```bash
export PATH=/<home_dir_path>:PATH
```

5. Retry creating the transfer disk.

**Help Sheets**

Oracle provides a number of help sheets to print and carry with you as you perform your data transfer tasks.

**Disk Import**

- Disk Import Job Checklist
- Prepare for Disk Import Jobs
- Disk Import Procedures

**Appliance Import**

- Appliance Import Job Checklist
- Prepare for Appliance Import Job
- Appliance Import Procedures

**Help Sheet - Disk Import Job Checklist**

Use this checklist for preparing to use the transfer disk for use in an import job. Check each item in order to ensure you are fully prepared for the data transfer.

- USB 2.0/3.0 external hard disk drive.
- Someone tasked to create labels for the FedEx, UPS, or DHL carriers.
- Linux machine running Oracle Linux 6 or greater, Ubuntu 14.04 or greater, or SUSE 11 or greater.
- Users interacting with the Linux machine must have *root* access.
- Physical access to the Linux machine to connect the hard disk drive.
- Linux operating system can create an EXT file system.
- Java 1.8 or Java 1.11 installed on Linux machine.
- Hdfparm 9.0 or later installed on Linux machine.
- Cryptsetup 1.2.0. or greater installed on Linux machine.
- Open firewall for Linux machine to OCI Data Transfer Service on the IP address ranges: 140.91.0.0/16.
- Open firewall to OCI Object Storage IP address ranges: 134.70.0.0/17.
- Download and install the Data Transfer Utility.
- Install OCI Command Line Interface.
- Generate public/ private keys for users who will copy data on the Linux machine (run `oci setup keys` command)
- Administrative user on tenancy who can create users, groups, compartments, and add policies

**Help Sheet - Prepare for Disk Import Jobs**

Use this help sheet to preparing and running your disk import job.
Preparing

1. Ensure you have the following set up in your environment:
   - USB 2.0/3.0 external hard disk drive (disk) to be used as your import disk.
   - Computer running one of the following Linux operating systems:
     - Oracle Linux 6 or greater
     - Ubuntu 14.04 or greater
     - SUSE 11 or greater

   All Linux operating systems must have the ability to create an EXT file system. Make sure the system has the following installed:
     - Java 1.8 or Java 1.11
     - hdparm 9.0 or later
     - Cryptsetup 1.2.0 or greater

2. Download and install the Data Transfer Utility on the Linux machine where the data will be copied from and the disk will be mounted. You should have root access to this machine.

   Installation instructions are located at: https://docs.cloud.oracle.com/iaas/Content/DataTransfer/Tasks/disk_preparing.htm

3. Install OCI Command Line Interface on the Linux machine where the data will be copied from and the disk will be mounted. You should have root access to this Linux machine.

   Installation instructions are located at: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliinstall.htm

4. On the machine where data will be copied from generate public/private keys for the user(s) who will do the data copy, run the following command:

   `oci setup keys`

   See https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm for more information on keys.

5. Login to OCI with an Administrative user for the tenancy.

6. Create the user policies. Ensure that the policies include the following:

   `Allow group <group_name> to {DTA_ENTITLEMENT_CREATE} in tenancy`

   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingpolicies.htm for more information on policies

7. Create a compartment where the transfer job and landing bucket will reside.

   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingcompartments.htm for more information on compartments.

8. Create the necessary user accounts for those individuals who will copy data to the disk. Include the public key that was previously generated.

   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingusers.htm for more information on users.

   See https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm for more information on public keys.

9. Create a group for the user who will copy data to the disk. Include the following policies in the group:

   ```
   Allow group <group_name> to manage data-transfer-jobs in compartment <compartment_name>
   Allow group <group_name> to manage buckets in compartment <compartment_name>
   ```
Allow group <group_name> to manage objects in compartment <compartment_name>

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managinggroups.htm for more information on groups.

If you want to include notifications for the group, includes these additional policies:

- Allow group <group name> to manage ons-topics in tenancy
- Allow group <group name> to manage ons-subscriptions in tenancy
- Allow group <group name> to manage cloudevents-rules in tenancy
- Allow group <group name> to inspect compartments in tenancy

See https://docs.cloud.oracle.com/iaas/Content/Notification/Concepts/notificationoverview.htm for more information on notifications.

See https://docs.cloud.oracle.com/iaas/Content/Events/Concepts/eventsoverview.htm for more information on events.

10. Create an upload user for Oracle personnel to upload data into the bucket.

   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingusers.htm for more information on users.

11. Create a group for the upload user, and include the public key that was previously generated.

   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managinggroups.htm for more information on groups.

   See https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm for more information on public keys.

12. Add the following policies for the upload user group:

- Allow group <group_name> to manage buckets
  in compartment <compartment_name> where all
  
  - request.permission='BUCKET_READ', target.bucket.name='<bucket_name>'

- Allow group <group_name> to manage objects
  in compartment <compartment_name> where all
  
  - target.bucket.name='<bucket_name>', any
    
    - request.permission='OBJECT_CREATE',
    - request.permission='OBJECT_OVERWRITE',
    - request.permission='OBJECT_INSPECT'}

The permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingpolicies.htm for more information on policies.

13. Open firewall to OCI Data Transfer Service on the IP address ranges:

   140.91.0.0/16

14. Open firewall to OCI Object Storage IP address ranges:

   134.70.0.0/17

Creating the Transfer Job

Run these command line items on the host where you plan on mounting USB HDD and copying data and/or the host that you will use to manage the data transfer job:

1. As root, create the configuration files:

   ```
   sudo bash
   mkdir /root/.oci
   cd /root/.oci
   ```
vi config
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>

vi config_upload_user
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
endpoint=https://objectstorage.<region information>.com

2. Get the tenancy namespace:
oci os ns get

3. Create a bucket in the compartment created for the transfer job
oci os bucket create --namespace <object_storage_namespace> --name <bucket name> --compartment-id <compartment_id>

4. Verify the data transfer upload user credentials:
dts job verify-upload-user-credentials --bucket <bucket_name>

5. Create the transfer job:
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>

The job OCID is displayed in the Data Transfer Utility return after you create the job. Send this job OCID to the person who will copy data to the disk.

6. (Optional) Add notifications:
oci dts job setup-notifications --job-id <job_id>

7. Create a virtual representation of the physical shipping package for the disk called a transfer package:
dts package create --job-id <job_id>

8. Get the package label:
dts job show --job-id <job_id>

The package label is included in the Data Transfer Utility return. Send it to the person who will copy data to the disk.
9. Get the shipping address for the disk:

   dts package show --job-id <job_id> --package-label <package_label>

Shipping information is included in the Data Transfer Utility return. Send it to the person who will create the shipping labels.

10. Create a FedEx, UPS, or DHL shipping label for the disk using the address from above to ship the disk to Oracle. Send the carrier-provided tracking to the person who will copy data to the disk.

11. Create a return label for the disk and send it electronically or in person to the person who will ship the disk. Send the tracking number for the return label to the person who will copy data to the disk.

Help Sheet - Disk Import Procedures

Before Starting

Before starting, ensure the following:

- You have the following information available:
  - The disk transfer job OCID
  - The package label
  - The shipping vendor and tracking ID
  - The return shipping vendor and tracking ID
- You have root access to the Linux machine where the data will be copied
- The configuration files and Data Transfer Utility are already installed on the Linux machine where the data will be copied.

Attach and Create the Transfer Disk

To attach and create the transfer disk:

1. Physically attach the import disk to the Linux host where data will be copied.

   As part of this process, do the following:
   a. Run `lsblk` and verify you can see the device, take note of the device path as it will be needed in future steps
   b. Run `hdparm -I <device>` and verify the disk provides a valid response, particularly a readable serial number.

      The disk should have not have any partitions or filesystems. If it does, run:

       `wipefs -a /dev/<path>`

2. Use the Data Transfer Utility to create the transfer disk, it will also generate and display an encryption passphrase, create a unique mount point, and mount the disk:

   dts disk create --job-id <job_id> --block-device <block_device>

   The encryption passphrase will be displayed to output. Store it in a secure place as it will not be displayed or accessible again.

   Record the disk label from the output. You will need it later in the procedure.

   Verify there is a new mount point called `/mnt/orcdts_<disk_label>`
3. Copy files to the data transfer disk using the mount point from the previous step. We recommend the `tar` is recommended but you can use other types of copy methods such as `cp` or `rsync`.

Here are two examples:

```
• tar -cvzf /mnt/<disk_label>/filesystem.tgz filesystem/
• tar -cvzf /mnt/<disk_label>/filesystem.tgz filesystem/ | xargs -I '{}' sh -c "test -f '{}' \&\& md5sum '{}'" | tee tarzip_md5
```

You can only copy regular files to disks. Special files (links, sockets, pipes, and so forth) cannot be copied directly. To transfer special files, create a tar archive of the files and copy the tar archive to the disk.

Do not disconnect the disk until you copy all files from the Data Host and generate the manifest file. If you accidentally disconnect the disk before copying all files, you must unlock the disk using the encryption passphrase.

4. Generate a manifest file after all data has been copied to the disk:

```
dts disk manifest --job-id <job_id> --disk-label <disk_label>
```

The manifest file will be on the transfer disk.

5. Lock the transfer disk:

```
dts disk lock --job-id <job_id> --disk-label <disk_label> --block-device <block_device>
```

6. Attach the transfer disk to the transfer package:

```
dts disk attach --job-id <job_id> --package-label <package_label> --disk-label <disk_label>
```

7. Update the transfer package with the tracking information:

```
dts package ship --job-id <job_id> --package-label <package_label> --package-vendor <vendor_name> --tracking-number <tracking_number> --return-tracking-number <return_tracking_number>
```

8. Physically disconnect the disk from the Linux host.

9. Have the disk packaged, insert the printed return label, attach the shipping label to the outside of the package.

10. Pass the disk to the vendor to ship to Oracle

11. Monitor the status of the transfer package:

```
dts package show --job-id <job_id> --package-label <package_label>
```

12. Review the upload status after Oracle receives the disk and uploads your files.

13. Close the transfer job after the job is complete and the import disk is returned to you:

```
dts job close --job-id <job_id>
```

**Help Sheet - Appliance Import Job Checklist**

Use this checklist for preparing to use the Data Transfer Appliance (import appliance) for use in an import job. Check each item in order to ensure you are fully prepared for the data transfer.

- **Administrative user to the tenancy who can create users, groups, compartments, add policies, and request import appliance entitlement.**
- **Access to the main buyer or administrator who is VP-level or higher who can sign the terms and conditions document.**
Data Transfer

- Linux machine running Oracle Linux 6.10/7.3-7.5/8.0, Ubuntu 16.04/18.04, or CentOS 6.9/6.10/7.0.
- Root access for the prepare and copy on the Linux machine.
- Someone who has physical access to where the import appliance will be installed.
- Meet all appliance specifications and physical environment requirements.
- Terminal emulation host that can connect to the import appliance using USB or DB-9 serial cable.
- Terminal emulation host with one of the following installed: PuTTY for Windows, ZOC for OS X, PuTTY or Minicom for Linux.
- Network connection to the import appliance consisting of either a 10GBase-T: Standard RJ-45 or SFP+ with transceiver compatible with Intel X520NICS.
- IP address for the import appliance ________.
- Subnet mask length for the import appliance subnet ________.
- Default gateway for the import appliance network ________.
- NFS communication between the import appliance subnet and servers from where data will be copied
- HTTP Proxy information if your corporation uses an internet proxy ________.
- Open firewall for Linux machine for preparation and copying to OCI Data Transfer Service on the IP address ranges: 140.91.0.0/16.
- Open firewall for Linux machine for preparation and copying to OCI Object Storage IP address ranges: 134.70.0.0/17.
- Installation of OCI Command Line Interface.
- Generate public/private keys for users who will copy data on the Linux machine (run `oci setup keys` command).

Help Sheet - Prepare for Appliance Import Jobs

Use this help sheet to prepare and use your Data Transfer Appliance

Preparing

1. Install the OCI Command Line Interface on the Linux machine where the data will be copied from and the Data Transfer Appliance will be mounted. You should have root access to the Linux machine.
   
   Installation instructions are located at: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliinstall.htm
   
   On the machine where data will be copied from generate public/private keys for the user(s) who will do the data copy, run the following command:

   ```
   oci setup keys
   ```
   
   See https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm for more information on keys.
   
2. Login to OCI with an Administrative user for the tenancy.

3. Create the user policies. Ensure that the policies include the following:

   ```
   Allow group <group_name> to (DTA_ENTITLEMENT_CREATE) in tenancy
   ```
   
   See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingpolicies.htm for more information on policies.
4. Create a compartment where the transfer job and landing bucket will reside. This compartment must be in a region that supports usage of the Data Transfer Appliance.

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingcompartments.htm for more information on compartments.

5. Create the necessary user accounts for those individuals who will copy data to the appliance. Include the public key that was previously generated.

6. Create a group for the user who will copy data to the appliance. Include the following policies in the group:

```
Allow group <group_name> to manage data-transfer-jobs in compartment <compartment_name>
Allow group <group_name> to manage buckets in compartment <compartment_name>
Allow group <group_name> to manage objects in compartment <compartment_name>
```

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managinggroups.htm for more information on groups.

If you want to include notifications for the group, includes these additional policies:

```
Allow group <group_name> to manage ons-topics in tenancy
Allow group <group_name> to manage ons-subscriptions in tenancy
Allow group <group_name> to manage cloudevents-rules in tenancy
Allow group <group_name> to inspect compartments in tenancy
```

See https://docs.cloud.oracle.com/iaas/Content/Notification/Concepts/notificationoverview.htm for more information on notifications.

See https://docs.cloud.oracle.com/iaas/Content/Events/Concepts/eventsoverview.htm for more information on events.

7. Create an upload user for Oracle personnel to upload data into the bucket.

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingusers.htm for more information on users.

8. Create a group for the upload user, and include the public key that was previously generated.

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managinggroups.htm for more information on groups.

9. Add the following policies for the upload user group:

```
Allow group <group_name> to manage buckets
in compartment <compartment_name> where all
{ request.permission='BUCKET_READ', target.bucket.name='<bucket_name>' }
Allow group <group_name> to manage objects
in compartment <compartment_name> where all
{ target.bucket.name='<bucket_name>', any
{ request.permission='OBJECT_CREATE',
request.permission='OBJECT_OVERWRITE',
request.permission='OBJECT_INSPECT' }}
```

The permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

See https://docs.cloud.oracle.com/iaas/Content/Identity/Tasks/managingpolicies.htm for more information on policies.

10. Open firewall to OCI Data Transfer Service on the IP address ranges:

140.91.0.0/16

11. Open firewall to OCI Object Storage IP address ranges:

134.70.0.0/17
Creating the Transfer Job

Run these command line items on the host where you plan on mounting USB HDD and copying data and/or the host that you will use to manage the data transfer job:

1. As root, create the configuration files:

   ```bash
   sudo bash
   mkdir /root/.oci
   cd /root/.oci
   vi config
   [DEFAULT]
   user=<The OCID for the data transfer administrator>
   fingerprint=<The fingerprint of the above user's public key>
   key_file=<The _absolute_ path to the above user's private key file on the host machine>
   tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
   region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
   vi config_upload_user
   [DEFAULT]
   user=<The OCID for the data transfer upload user>
   fingerprint=<The fingerprint of the above user's public key>
   key_file=<The _absolute_ path to the above user's private key file on the host machine>
   tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
   region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
   endpoint=https://objectstorage.<region information>.com
   ```

2. Get the tenancy namespace:

   ```bash
   oci os ns get
   ```

3. Create a bucket in the compartment created for the transfer job:

   ```bash
   oci os bucket create -namespace <object_storage_namespace> --name <bucket_name> --compartment-id <compartment_id>
   ```

4. Verify the data transfer upload user credentials:

   ```bash
   dts job verify-upload-user-credentials --bucket <bucket_name>
   ```

5. Create the transfer job:

   ```bash
   oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
   ```

   The job OCID is displayed in the CLI return after you create the job. Send this job OCID to the person who will copy data to the disk.

6. (Optional) Add notifications:

   ```bash
   oci dts job setup-notifications --job-id <job_id>
   ```

7. Request the appliance:

   ```bash
   oci dts appliance request --job-id <job_id> --addressee <addressee> --care-of <care_of> --address1 <address_line1> --
Help Sheet - Appliance Import Procedures

Follow the tasks in this help sheet after you login to the host where you will be mounting the Data Transfer Appliance (import appliance) and copying data. You need to run all Command Line Interface (CLI) tasks as sudo.

• Make sure you have the IP address for the import appliance.
• Make sure you have the access token for the import appliance.
• Have the transfer job OCID.
• Have the appliance label information.
• Make sure there is no firewall and communication is open between the import appliance the host where it will be mounted.
• Open firewall to OCI Data Transfer Service on the IP address ranges: 140.91.0.0/16.
• Open firewall to OCI Object Storage IP address ranges: 134.70.0.0/17.
• Set the environment variable If HTTP proxy environment is needed to allow access to the internet. The proxy environment allows Oracle Cloud Infrastructure CLI to communicate with the Data Transfer Appliance Management Service and the import appliance over a local network connection.

    export HTTPS_PROXY=http://www-proxy.myorg.com:80

• Go to root as sudo and install NFS utilities if they are not already installed (first command for RHEL, OEL and second command for Debian, Ubuntu):

    sudo yum install nfs-utils
    sudo apt-get install nfs-common

• Continue as root.
• Initialize the appliance. Have the import appliance access token ready.

    oci dts physical-appliance initialize-authentication --job-id <job_id> --appliance-cert-fingerprint <fingerprint> --appliance-ip <appliance_ip> --appliance-label <appliance_label>

When prompted, supply the access token, and answer y to permit overwriting of data.

• Configure the import appliance encryption:

    oci dts physical-appliance configure-encryption --job-id <job_id> --appliance-label <appliance_label>

Note the appliance label in the output (the label will begin with "XA"). You will need to this label value for other commands involving the appliance.

To include job notifications when requesting an import appliance, include the --setup-notifications option:

    oci dts appliance request --job-id <job_id> --addressee <addressee> --address1 <address_line1> --city-or-locality <city_or_locality> --state-or-region <state_or_region> --country <country> --zip-postal-code <zip_postal_code> ...
    --setup-notifications

If you have already made your appliance request without including notifications, but subsequently want to include them, run the following:

    oci dts appliance setup-notifications --appliance-label <appliance_label>
- Unlock the import appliance:

```
oci dts physical-appliance unlock --job-id <job_id> --appliance-label <appliance_label>
```

- Create an NFS dataset:

```
oci dts nfs-dataset create --name <dataset_name>
```

- Export the dataset:

```
oci dts nfs-dataset set-export --name <dataset_name> --rw true --world true
```

- Activate the dataset:

```
oci dts nfs-dataset activate --name <dataset_name>
```

- Check the dataset is exported:

```
showmount -e <appliance_IP>
```

- Mount the dataset:

```
mkdir -p /mnt/<mountpoint_name>
oci dts nfs-dataset activate --name <dataset_name>
```

- Copy files to the DTA. The `tar` method is recommended but other types of copies such as `cp` or `rsync` can also be used.

Here are two examples:

- `tar -cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/`

- `tar cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/ | xargs -I '{}' sh -c "test -f '{}' && md5sum '{}"" | tee tarzip_md5`

- Deactivate the dataset:

```
oci dts nfs-dataset deactivate --name <dataset_name>
```

- Seal the dataset. Note this can be a long running process.

```
oci dts nfs-dataset seal --name <dataset_name> [--wait]
```

- Monitor the sealing process:

```
oci dts nfs-dataset seal-status --name <dataset_name>
```

- Download the dataset seal manifest:

```
oci dts nfs-dataset get-seal-manifest --name <dataset_name> --output-file <file_path>
```

- Finalize the import appliance:

```
oci dts physical-appliance finalize --job-id <job_id> --appliance-label <appliance_label>
```

- Shut down the import appliance by selecting option #8 on the terminal emulation host.
- Have the import appliance packed and shipped to Oracle.
• Monitor the status of the data upload from the DTA to your object storage bucket in OCI:

```bash
oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>
```

• Once the data upload is finished, check the object storage bucket from the Console and get the upload file location

• Download the upload file and review them to understand what was transferred:

```bash
oci os object get --namespace <object_storage_namespace> --bucket-name <bucket_name> --name <object_name> --file <file_location>
```

• Close the import job:

```bash
oci dts job close --job-id <job_id>
```

• Delete the import appliance associated with the import job:

```bash
oci dts appliance delete --job-id <job_id> --appliance-label <appliance_label>
```

• Delete the transfer job:

```bash
oci dts job delete --job-id <job_id>
```
This chapter explains how to launch a DB System and manage databases on DB Systems.

**Overview of the Database Service**

The Database service offers autonomous and co-managed Oracle Database cloud solutions. Autonomous databases are preconfigured, fully-managed environments that are suitable for either transaction processing or for data warehouse workloads. Co-managed solutions are bare metal, virtual machine, and Exadata DB systems that you can customize with the resources and settings that meet your needs.

You can quickly provision an autonomous database or co-managed DB system. You have full access to the features and operations available with the database, but Oracle owns and manages the infrastructure.

You can also extend co-managed database services into your data center by using Exadata Cloud@Customer, which applies the combined power of Exadata and Oracle Cloud Infrastructure while enabling you to meet your organization's data-residency requirements.

For details about each offering, start with the following overview topics:

**Autonomous Databases**

The Database service offers Oracle's Autonomous Database with transaction processing and data warehouse workload types.

**Co-managed Systems**

- Bare Metal and Virtual Machine DB Systems on page 1352
- Exadata Cloud Service on page 1221
- Exadata Cloud@Customer

**Note:**

For information about MySQL Database, see MySQL Database.

**License Types and Bring Your Own License (BYOL) Availability**

**Database Service License Options**

Oracle Cloud Infrastructure supports a licensing model with two license types. With License included, the cost of the cloud service includes a license for the Database service. With Bring Your Own License (BYOL), Oracle Database customers can use existing licenses with Oracle Cloud Infrastructure. Note that Oracle Database customers remain responsible for complying with license restrictions applicable to their BYOL licenses, as defined in their program order for those licenses.

You do not need separate on-premises licenses and cloud licenses. BYOL databases support all advanced Database service manageability functionality, including backing up and restoring a DB system, patching, and Oracle Data Guard.
You can choose BYOL when you launch a cloud-hosted Oracle Cloud Infrastructure database or DB system. Choosing BYOL impacts how the usage data for the instance is metered and subsequent billing. You can also switch license types after provisioning.

Note that on some provisioning dialogs in the Console, the BYOL option is labeled **My Organization Already Owns Oracle Database Software Licenses**.

For additional information about license pricing and features, see Oracle Cloud Database Services. For guidelines on using Oracle Database licenses, see Database Licensing.

**Switching Database Service License Types**

You can switch license type after provisioning your resource. For information about switching the license type, see the following:

- To change the license type of an Autonomous Database on page 1172
- To change the license type of an Exadata Cloud Service cloud VM cluster or DB system on page 1261
- To change the license type of a bare metal or virtual machine DB system on page 1387

**Always Free Database Resources**

The Database service is one of the Oracle Cloud Infrastructure services that provides you with Always Free resources as a part of Oracle's Free Tier. For an introduction to the Free Tier, see Oracle Cloud Infrastructure Free Tier on page 140. For details about the Always Free Autonomous Database, see Always Free Availability on page 1149 in the Autonomous Database overview topic. To provision an Always Free Autonomous Database, see To create an Always Free Autonomous Database on page 1159.

**Moving Database Resources to a Different Compartment**

You can move DB systems, Autonomous Database resources, and Exadata Cloud@Customer resources from one compartment to another. When you move a Database resource to a new compartment, its dependent resources move with it. After you move the resource to the new compartment, inherent policies apply immediately and affect access to that resource and its dependent resources through the Console.

**Important:**

- To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service on page 2240.
- If your database resource is in a security zone compartment, the destination compartment must also be in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

**Dependent Resource Details**

Details about dependent resources are as follows:

- **Bare metal, virtual machine, and Exadata DB systems**: Dependent resources that move with these DB systems include Database Homes and databases, as well as the metadata for automatic backups. To verify the compartment of a dependent resource, check the compartment of the DB system.
- **Autonomous Database**: Autonomous Database dependent resources are limited to its automatic backups. Autonomous Exadata Infrastructure instances and Autonomous Container Databases have no dependent resources that move with them. Associated (non-dependent) resources remain in their current compartments.
- **Exadata Cloud@Customer**: Resources that can be moved are Exadata Infrastructure, VM clusters, and backup destinations. VM cluster networks are dependent resources of Exadata Infrastructure instances, so they move with
them. VM clusters have the following dependent resources: Database Homes, and databases and their automatic backups. Backup destinations have no dependent resources.

For more information about moving resources to other compartments, see To move a resource to a different compartment on page 2444.

**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

For information about available Database service metrics and how to view them, see Database Metrics on page 1578.

**Creating Automation with Events**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 1784.

See Database on page 1843 for details about Database resources that emit events.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 4225.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For more information on tenancies and compartments, see Key Concepts and Terminology in the Oracle Cloud Infrastructure Getting Started Guide. For general information about using the API, see REST APIs on page 4368. For information on deprecated Database Service APIs, see Deprecated Database Service APIs on page 1672.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to write policies that provide stricter access to database resources, see Details for the Database Service on page 2240.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2135. For specific details about writing policies for each of the different services, see Policy Reference on page 2167.
If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize Oracle Cloud Infrastructure Database users, see Common Policies.

For in-depth information on granting users permissions for the Database service, see Details for the Database Service in the IAM policy reference.

Security Zone Integration

A security zone is associated with a compartments and a set of policies called a security zone recipe. When you create and update resources in a security zone, Oracle Cloud Infrastructure validates these operations against the list of policies defined in the security zone recipe. If any security zone policy is violated, then the operation is denied.

The Database service allows you to create and update your databases and associated resources in security zones. For a general overview of the security zones, see the Security Zone documentation. For an overview of the Database service's integration with the security zone feature, see Security Zone Integration on page 1574.

Limits on the Database Service

See Service Limits on page 215 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Note:

Service limits and compartment quotas do not apply to Exadata Cloud@Customer.

Many Database API operations are subject to throttling.

Work Requests Integration

The Database service is integrated with the Oracle Cloud Infrastructure Work Requests API. Work requests allow you to monitor long-running operations such as the provisioning of DB systems. A work request is an activity log that enables you to track each step in the operation's progress. Each work request has an OCID that allows you to interact with it programmatically and use it for automation.

For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests on page 258 and the Work Requests API. See Database Service Work Requests Reference on page 1143 for a listing of Database service operations that create work requests.

Database Service Work Requests Reference

This topic lists the Database service operations generate work requests. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests on page 258 and the Work Requests API.

Autonomous Database on Shared Exadata Infrastructure

Lifecycle operations:

- Create
- Delete
- Start
- Restart
- Stop
- Restore

Database management operations:

- Scale
• Rename
• Reset password
• Update license type
• Update workload type
• Update open mode / permission level (*read-only/read-write, and admin only/all users*)
• Upgrade version
• Update tags
• Change compartment
• Rotate instance wallet
• Rotate regional wallet

*Network access operations:*
• Update network ACL (*public endpoint only*)
• Update network security group (NSG) (*private endpoint only*)
• Update private endpoint

*Backup operations:*
• Create backup
• Delete backup

*Refreshable clone operations:*
• Manual refresh
• Disconnect refreshable clone
• Update refreshable lag time

*Autonomous Data Guard operations:*
• Enable Data Guard
• Disable Data Guard
• Failover
• Switchover

*Associated services operations:*
• Register with Data Safe
• Deregister with Data Safe
• Enable Operations Insights
• Disable Operations Insights

**Autonomous Database on Dedicated Exadata Infrastructure**

*Database lifecycle operations:*
• Create
• Update
• Delete
• Start
• Restart
• Stop
• Restore

*Backup operations:*
• Create backup
• Delete backup

*Container database operations:*
- Create
- Delete
- Update
- Restart
- Rotate container database encryption key
- Rotate database encryption key

*Infrastructure resource operations:*
- Create
- Terminate
- Update

*Autonomous Data Guard operations:*
- Setup Data Guard
- Failover Autonomous Container Database
- Switchover Autonomous Container Database
- Reinstate Autonomous Container Database

*Associated services operations:*
- Register with Data Safe
- Deregister with Data Safe

**Exadata Cloud Service, Virtual Machine DB Systems, and Bare Metal DB Systems**

**DB systems (Exadata, bare metal, and virtual machine)**

*Lifecycle operations:*
- Create
- Create from backup
- Update
- Terminate

*DB system management operations:*
- Change compartment
- Scale storage
- Scale CPU
- Add SSH key
- Update license type
- Configure IORM
- Update shape
- Apply FIPS security

*Maintenance operations:*
- Precheck system for patching
- Patch system
- Upgrade database
- Install DB system component
- Switch to the new exadata API and user experience

**Note:**

Virtual machine DB systems have a single database that is created and terminated as part of the creation or termination of the parent DB system.
**Cloud Exadata infrastructure operations (new resource model)**
- Create
- Update
- Scale (*flexible shape systems only*)
- Delete
- Change compartment

**Exadata Cloud VM cluster operations**

*Lifecycle operations:*
- Create
- Delete

*Management operations:*
- Change compartment
- Scale CPU
- Add SSH key
- Update license type
- Scale compute (*flexible shape systems only*)
- Scale storage (*flexible shape systems only*)

*Maintenance operations:*
- Precheck for grid infrastructure (GI) patch
- Apply GI patch
- Precheck for grid infrastructure (GI) upgrade
- Upgrade grid infrastructure (GI)
- Upgrade database
- Precheck for OS update
- Apply OS update

**Database Homes: Exadata, Virtual Machine, and Bare Metal Cloud Service Instances**

*Lifecycle operations:*
- Create
- Delete

*Maintenance operations:*
- Patch
- One-off Patch

**Database Nodes: Exadata, Virtual Machine, and Bare Metal Cloud Service Instances**

- Start
- Stop
- Reboot

**Virtual Machines: Exadata Cloud Service (New Infrastructure Resource Model only)**

- Start
- Stop
- Reboot
- Precheck customer-managed (Vault service) database key
Migrate customer-managed (Vault service) database key
Rotates customer-managed (Vault service) database key

**Databases: Exadata, Virtual Machine, and Bare Metal Cloud Service Instances**

*Lifecycle operations:*
- Create
- Update
- Restore
- Delete

*Maintenance operations:*
- Upgrade database
- Rollback database upgrade

*Note:*
Virtual machine DB systems have a single database that is created and terminated as part of the creation or termination of the parent DB system

**Database Backups: Exadata, Virtual Machine, and Bare Metal Cloud Service Instances**

Create
Delete

**Data Guard: Exadata, Virtual Machine, and Bare Metal Cloud Service Instances**

Create Data Guard
Delete Data Guard
Switch over Data Guard
Fail over Data Guard
Reinstate Data Guard

**Exadata Cloud Service Instances (New Infrastructure Resource Model)**

**Cloud Exadata infrastructure operations**

*Lifecycle operations:*
- Create
- Update
- Delete

*Management operations:*
- Scale (flexible shape systems only)
- Change compartment

**Cloud VM cluster operations**

*Lifecycle operations:*
- Create
- Delete

*Management operations:*
- Change compartment
• Scale CPU
• Add SSH key
• Update license type
• Scale compute \textit{(flexible shape systems only)}
• Scale storage \textit{(flexible shape systems only)}

\textit{Maintenance operations:}
• Precheck for grid infrastructure (GI) patch
• Apply grid infrastructure (GI) Patch
• Precheck for grid infrastructure (GI) upgrade
• Upgrade grid infrastructure (GI)
• Precheck for OS update
• Apply OS update

\textbf{Exadata Cloud@Customer Systems}

\textit{Exadata Cloud@Customer infrastructure operations:}
• Create
• Update
• Activate
• Delete

\textit{Exadata Cloud@Customer VM cluster operations:}
• Create
• Update
• Delete
• Change compartment

\textit{Exadata Cloud@Customer Autonomous VM cluster operations:}
• Create
• Update
• Delete
• Change compartment

\textit{Exadata Cloud@Customer VM cluster network operations:}
• Create
• Update
• Validate
• Delete

\textit{Additional maintenance and management operations:}
• Update VM cluster licence type
• Patch VM cluster
• Patch VM cluster database
• Update VM cluster OCPU count
• Update SSH key
• Update VM cluster memory
• Update VM cluster Exadata storage
• Update VM cluster local storage
• Update Exadata database backup configuration
Databases Software Images

- Creating a Database Software Image
- Deleting a Database Software Image
- Moving a Database Software Image to a new compartment

Getting Oracle Support Help for Your Database Resources

You can open a My Oracle Support ticket for individual Database resources while viewing them in the Oracle Cloud Infrastructure Console. For more information, see Getting Help and Contacting Support on page 125.

Overview of Autonomous Databases

Oracle Cloud Infrastructure's Autonomous Database is a fully-managed, preconfigured database environment with three workload types available, Autonomous Transaction Processing, Autonomous Data Warehouse and Autonomous JSON Database. You do not need to configure or manage any hardware or install any software. After provisioning, you can scale the number of CPU cores or the storage capacity of the database at any time without impacting availability or performance. Autonomous Database handles creating the database, as well as the following maintenance tasks:

- Backing up the database
- Patching the database
- Upgrading the database
- Tuning the database

Always Free Availability

Autonomous Database can be used without charge as part of Oracle Cloud Infrastructure's suite of Always Free resources. Users of both paid and free Oracle Cloud Infrastructure accounts have access to two Always Free instances of Autonomous Database. Always Free Autonomous Databases have a fixed 8 GB of memory, 20 GB of storage, 1 OCPU, and can be configured for either Autonomous Transaction Processing or Autonomous Data Warehouse workloads.

Always Free databases have only single available version. You can see the version that is being used for your database in the details screen. After a newer Oracle Database version is available in Oracle Cloud Infrastructure, your database will be automatically upgraded during one of your database's upcoming maintenance windows.

To learn about Free Tier Databases, see Oracle Cloud Infrastructure Free Tier on page 140. To learn about the details of the Always Free Autonomous Database, see Overview of the Always Free Autonomous Database on page 1220. To provision an Always Free Autonomous Database, see Creating an Autonomous Database on Shared Exadata Infrastructure on page 1157.

For information on regional availability of Always Free Autonomous Database, see the "Always Free Cloud Services" section of Data Regions for Platform and Infrastructure Services.

Available Workload Types

Autonomous Database offers the following workload types:

- **Autonomous Data Warehouse**: Built for decision support and data warehouse workloads. Offers fast queries over large volumes of data.
  
  For a complete product overview of Autonomous Data Warehouse, see Autonomous Data Warehouse. For Autonomous Data Warehouse tutorials, see Quick Start tutorials.

  
  Autonomous JSON Database is Oracle Autonomous Transaction Processing, but specialized for developing NoSQL-style applications that use JavaScript Object Notation (JSON) documents. You can upgrade an
Autonomous JSON Database service to an Autonomous Transaction Processing service if you need the additional functionality of Autonomous Transaction Processing. Currently available on shared Exadata infrastructure.

For a complete product overview of Autonomous JSON Database, see Using Oracle Autonomous JSON Database. Also available in the Oracle Help Center are Autonomous JSON Database tutorials and the JSON Developer's Guide.

- **Autonomous Transaction Processing**: Built for transactional workloads. Offers high concurrency for short-running queries and transactions.

  For a complete product overview of Autonomous Transaction Processing, see Autonomous Transaction Processing. For Autonomous Transaction Processing tutorials, see Quick Start tutorials.

- **Oracle APEX Application Development (APEX Service)**: Optimized for application developers, who want a transaction processing database for application development using Oracle APEX, that enables creation and deployment of low-code applications, including databases. See Oracle APEX Application Development Documentation for more information about the APEX service and Oracle APEX Application Development Specific Limitations for a list of use restrictions.

  **Note:**
  You can use the APEX service with each of the other workload types.

**Infrastructure Options**

Autonomous Databases have the following Exadata infrastructure options:

- **Dedicated Exadata Infrastructure**: With this option, you have exclusive use of the Exadata hardware. Dedicated Exadata infrastructure offers multitenant database architecture, allowing you to create and manage multiple Autonomous Databases within a single database system. Both workload types (transaction processing and warehouse) can be provisioned on dedicated Exadata infrastructure. You have the following hardware configuration options:
  - **System Models**: X7 and X8
  - **Configurations**: quarter rack, half rack, and full rack

  See Overview of Autonomous Database on Dedicated Exadata Infrastructure on page 1193 for more information about dedicated Exadata infrastructure architecture, features, and hardware specifications.

- **Shared Exadata Infrastructure**: With this option, you provision and manage only the Autonomous Database, while Oracle deploys and manages the Exadata infrastructure. Both workload types (transaction processing and warehouse) can be provisioned with shared Exadata infrastructure.

**Oracle Data Guard for Autonomous Databases with Shared Exadata Infrastructure**

Autonomous Database uses a feature called Autonomous Data Guard to enable a standby (peer) database to provide data protection and disaster recovery for Autonomous Databases using shared Exadata infrastructure. For more information, see Using a Standby Database with Autonomous Database.

**Per-Second Billing Billing for Autonomous Database Resources**

**Shared Exadata Infrastructure**

Autonomous Database on Shared Exadata infrastructure uses per-second billing. This means that OCPU and storage usage is billed by the second. OCPU resources have a minimum usage period of 1 minute.

**Dedicated Exadata Infrastructure**

For each Autonomous Exadata Infrastructure instance you provision, you are billed for the infrastructure for a minimum of 48 hours, and then by the second after that. Each OCPU you add to the system is billed by the second, with a minimum usage period of 1 minute.
Private Endpoint for Autonomous Databases with Shared Exadata Infrastructure

When you provision an Autonomous Database with Shared Exadata infrastructure, you can configure the network access so that the database uses a private endpoint within one of your tenancy's virtual cloud networks (VCNs). When you use a private endpoint, your database is only accessible via the IP address of the associated private endpoint. For more information, see Autonomous Database with Private Endpoint on page 1163.

CPU Scaling

You can manually scale the database's base number of CPU cores up or down at any time. Note the following:

- CPU scaling does not require any downtime.
- CPU utilization information is available for all Autonomous Databases on the database details page in the Metrics section. CPU utilization is reported as a percentage of available CPUs, aggregated across all consumer groups.

For databases using Shared Exadata infrastructure, you can also view hourly snapshots of the database's CPU usage (actual number of cores allocated) over the most recent 8 days. This information is available in the Service Console, in the Overview page graph "Number of OCPUs Allocated". For more information, see To view OCPU allocation hourly snapshot data for an Autonomous Database on page 1171.

Autonomous Database's auto scaling feature allows your database to use up to three times the current base number of CPU cores at any time. As demand increases, auto scaling automatically increases the number of cores in use. Likewise, as demand drops, auto scaling automatically decreases the number of cores in use. Scaling takes place without any lag time, and you are only billed for your actual average CPU core usage per hour. Note the following points regarding the auto scaling feature:

- Auto scaling is enabled by default and can be enabled or disabled at any time.
- The auto scaling status for a database (enabled or disabled) is displayed on the database details page.
- The base number of OCPU cores allocated to a database is guaranteed. For databases on dedicated Exadata infrastructure, the maximum number of cores available to a database depends on the total number of cores available in the Exadata infrastructure instance, and is further limited by the number of free cores that aren't being used by other auto scaling databases to meet high-load demands. Available OCPU cores are enabled on a "first come, first served basis" for autoscaling databases sharing an Autonomous Exadata Infrastructure instance.

The following table illustrates OCPU core availability for a single database on an X8 quarter rack dedicated Exadata infrastructure instance. As you increase the database's base core count from 1 to 40 cores, the maximum core count scales until it reaches the hardware limit of 100 OCPUs. The final column, which shows the remaining available OCPUs that can be allocated to additional databases, assumes that no other databases exist on the quarter rack instance.

Example: OCPU auto scaling for a single database on an X8 quarter rack as base OCPU is increased

<table>
<thead>
<tr>
<th>Base OCPU core count</th>
<th>Maximum OCPU core count</th>
<th>OCPU cores remaining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>99</td>
</tr>
<tr>
<td>8</td>
<td>24</td>
<td>92</td>
</tr>
<tr>
<td>32</td>
<td>96</td>
<td>68</td>
</tr>
<tr>
<td>40</td>
<td>100</td>
<td>60</td>
</tr>
</tbody>
</table>

The following table illustrates OCPU core availability for four databases on an X8 half rack dedicated Exadata infrastructure instance. The hardware limit is 200 OCPUs. The Base OCPU count for each database is guaranteed to be available to the database at all times. In the example, the three database with auto scaling enabled are in contention for the 60 available cores that are not allocated to any database as base cores. Databases Sales and Development each auto scaled to take a combined 140 OCPU, and database Chicago (with auto scaling disabled) is using its 10 base OCPU. That leaves only 50 OCPU remaining in the half rack hardware instance, and the base OCPU of database HR is 50. Therefore, database HR cannot auto scale up until cores are released by the other auto scaling databases.

Example: OCPU auto scaling for four databases on an X8 half rack
Storage Scaling

Autonomous Database allows you to scale the storage capacity of the database at any time without impacting availability or performance.

Performance Monitoring using Oracle Performance Hub

You can monitor and analyze the performance of an Autonomous Database in the Oracle Cloud Infrastructure Console using the Performance Hub ASH Analytics, SQL Monitoring, Workload, Blocking Sessions, and ADDM features.

- The Blocking Sessions feature provides information about blocking and waiting sessions for a selected Autonomous Database, includes procedures to display detailed information about the sessions, and explains how to kill sessions as needed.
- The ADDM feature displays findings and recommendations for performance problems.

Detailed information about these features and how to use them is located in Using Performance Hub to Analyze Database Performance on page 1597.

Operations Insights

Operations Insights is a cloud-native service that enables users to make informed, data-driven, Oracle Autonomous database resource and performance management decisions. See To enable or disable Operations Insights on an Autonomous Database on page 1174 for information about managing Operations Insights.

Oracle Database Preview Version Availability

Oracle Cloud Infrastructure periodically offers Autonomous Database preview versions of Oracle Database for testing purposes. You can provision an Autonomous Database using preview version software to test applications before the general availability of the software in Autonomous Database. Oracle will notify Autonomous Database customers when preview versions are available. Preview version software is available for a limited time. Databases provisioned with preview version software will display the end date of the preview period at the top of the database details page in the Console. If you are using the Console, you can also see the end date of the preview period in the Create Database provisioning dialog before the database is created.

Preview version software should not be used for production databases or for databases that need to persist beyond the limited preview period. Note that preview databases and their associated resources (including backups) are terminated automatically at the conclusion of the preview period. Oracle will notify customers prior to the conclusion of the preview period regarding the end date of the preview.

Any existing Autonomous Database (including those provisioned with preview version software) can be cloned using a preview version of Autonomous Database. However, preview version databases cannot be cloned using the regular (general-availability) Autonomous Database software.

See Creating an Autonomous Database on Shared Exadata Infrastructure on page 1157 for details on provisioning a preview version of Autonomous Database.
Oracle Database Versions for Autonomous Database with Shared Exadata Infrastructure

Depending on the region where you provision or clone your database, Autonomous Database supports one or more Oracle Database versions.

When multiple database versions are available, you choose an Oracle Database version when you provision or clone a database.

Note:
Always Free Autonomous Databases can be provisioned with either version 19c or version 21c, depending on the region. Most regions offer both versions. Note that Always Free Autonomous Databases can only be provisioned in the home region of your tenancy or account. See Overview of the Always Free Autonomous Database on page 1220 for more information.

Upgrading a Database

Autonomous Database instances currently use Oracle Database 19c. There is no database software upgrade currently available.

Regional Availability

Autonomous Database is currently available in all regions of the commercial realm. Autonomous Database is currently not available in regions within the Government Cloud realm.

Security Considerations

Safeguard Your Data with Data Safe on Autonomous Database

Oracle Data Safe is a fully-integrated, regional Cloud service providing features that help you protect sensitive and regulated data in your Autonomous Transaction Processing database. See the Data Safe documentation for more information.

Private Access Using a Service Gateway

Autonomous Database is one of the Oracle Cloud Infrastructure services that can be privately accessed through a service gateway within a VCN. This means you do not need a public IP or NAT to access your Autonomous Database instance from any of the cloud services within the Oracle Services Network. For example, if you have a Compute instance that uses a VCN with a service gateway, you can route traffic between your Compute instance and an Autonomous Database in the same region without the traffic going over the internet. For information on setting up a VCN service gateway and configuring it to access all supported Oracle Service Network services (which include Autonomous Database), see Access to Oracle Services: Service Gateway on page 3256.

Access Control Lists (ACLs) for Databases on Shared Exadata Infrastructure

For Autonomous Databases on shared Exadata infrastructure, an access control list (ACL) provides additional protection for your database by allowing only specified IP addresses and VCNs in the list to connect to the database. Specified IP addresses can include private IP addresses from your on-premises network that connect to your database using transit routing and allow traffic to move directly from your on-premises network to your Autonomous Database without going over the internet. See Transit Routing: Private Access to Oracle Services on page 2803 for more information on this method of access.

You can add the following to your ACL:

- Public IP addresses (individually, or in CIDR blocks)
- An entire VCN (specified by OCID)
- Private IP addresses within a specified VCN (individually, or in CIDR blocks)
- Private IP addresses within an on-premises network that have access using a transit routing
You can create an ACL during database provisioning, or at any time thereafter. You can also edit an ACL at any time. Removing all entries from the list makes the database accessible to all clients with the applicable credentials. See To manage the access control list of an Autonomous Database on shared Exadata infrastructure on page 1176 to learn how to create, update, or delete an ACL.

**Important:**

If you want to only allow connections coming through a service gateway you need to use the IP address of the service gateway in your ACL definition. To do this you need to add an ACL rule using the CIDR source type and the value 240.0.0.0/4. Note that this is not recommended. Instead, you can specify individual VCNs in your ACL definition for the VCNs you want to allow access from. See Access to Oracle Services: Service Gateway on page 3256 for more information.

Note the following about using an ACL with your Autonomous Database:

- When you restore a database the existing ACLs are not overwritten by the restore.
- The network ACL applies to the database connections and Oracle Machine Learning notebooks. If an ACL is defined and you try to login to Oracle Machine Learning from a client whose IP is not specified on the ACL you will see a "login rejected based on access control list set by the administrator" error.
- Oracle Application Express (APEX), RESTful services, and Oracle Database Actions are subject to ACLs. You can create rules specifying Virtual Cloud Networks, Virtual Cloud Network OCIDs, IP addresses, or CIDR blocks to control access to these tools.
- The Autonomous Database Service console is not subject to ACL rules.
- If you have a private subnet in your VCN that is configured to access the public internet through an NAT gateway, you need to enter the public IP address of the NAT gateway in your ACL definition. Clients in the private subnet do not have public IP addresses. See NAT Gateway on page 3247 for more information.

**Network Security Groups for Databases Resources That Use Private Endpoints**

Network security groups (NSGs) are an optional Networking security feature available for dedicated Exadata infrastructure and databases on shared Exadata infrastructure that use private endpoints. NSGs act as a virtual firewall for your Autonomous Database resources. An NSG consists of a set of ingress and egress security rules that apply only to a set of VNICs of your choice within a single VCN. For more information, see the following topics:

- Network Security Groups on page 2841
- NSG security rule guidelines for private endpoint on page 1163
- To edit the network security groups (NSGs) for your Autonomous Exadata Infrastructure resource on page 1204
- To update the network configuration of an Autonomous Database on shared Exadata infrastructure that uses a private endpoint on page 1177

**Automatic Maintenance**

For Autonomous Databases on shared Exadata infrastructure, Oracle manages the automatic maintenance. You can view the next scheduled maintenance in the Console on the details page for your Autonomous Database. For Autonomous Databases on dedicated Exadata infrastructure, see Overview of Dedicated Exadata Infrastructure Maintenance on page 1196.

**Development and Administration Tools**

Oracle's Database Actions, Application Express (APEX), and Machine Learning applications are available for Autonomous Databases. For information on how to use these applications and access them from the Console, see Autonomous Database Tools on page 1216.

**Compartment Quotas for Autonomous Databases**

You can use compartment quotas to control how Autonomous Database OCPU and storage resources are allocated to Oracle Cloud Infrastructure compartments. You can use compartment quota policy statements to control
OCPU and storage resources by both workload type and Exadata infrastructure type. For example, you can allocate 10 Autonomous Transaction Processing OCPUs on shared Exadata infrastructure to a specific compartment. This would not affect the number of OCPUs available to Autonomous Data Warehouse databases, or databases using dedicated Exadata infrastructure. For more information on using compartment quotas, see Compartment Quotas on page 243 and Database Quotas on page 252.

Using the Oracle Cloud Infrastructure Console to Manage Autonomous Databases

For information on provisioning, managing, and backing up an Autonomous Database in the Oracle Cloud Infrastructure Console, see the following topics:

- Creating an Autonomous Database on Shared Exadata Infrastructure on page 1157
- Managing an Autonomous Database on page 1169
- Connecting to an Autonomous Database on page 1181
- Backing Up an Autonomous Database Manually on page 1184
- Restoring an Autonomous Database on page 1187

Additional Autonomous Database Product Information

Autonomous Database on Shared Exadata Infrastructure

For in-depth documentation on using and managing your Autonomous Transaction Processing database on shared Exadata infrastructure, see the following topics:

- Getting Started with Autonomous Database
- Connecting to Autonomous Database
- Loading Data with Autonomous Database
- Querying External Data with Autonomous Database
- Creating Dashboards, Reports, and Notebooks with Autonomous Database
- Managing Users on Autonomous Database
- Managing and Monitoring Performance of Autonomous Database

For information on using a database client to manage your database, see Connect Autonomous Database Using a Client Application.

Autonomous Database Tutorials

Autonomous Database Quickstart

Learn about Autonomous Database on Shared Infrastructure and learn how to create an Autonomous Database in just a few clicks. Then load data into your database, query it, and visualize it.

Autonomous Database Quickstart Workshop

- Provision Autonomous Database
- Load Data
- Query and Visualize Data
- Wallets
- Manage and Monitor
- Scale

Analyzing Your Data with Autonomous Database

Connect using secure wallets and monitor your Autonomous Database instances. Use Oracle Analytics Desktop to visualize data in Autonomous Database. Use Oracle Machine Learning Notebooks to try your hand at predictive analytics.

Analyzing your data with Autonomous Database Workshop

- Provision Autonomous Database
- Load Data
• Query and Visualize Data
• Wallets
• Manage and Monitor
• Scale
• Machine Learning Notebooks
• Build a Machine Learning Algorithm

**Autonomous Database on Dedicated Exadata Infrastructure**

For in-depth documentation on using and managing your Autonomous Database on dedicated Exadata infrastructure, see the following topics:

- Getting Started with Autonomous Database
- Connecting to Autonomous Database
- Loading Data into Autonomous Database
- Managing Dedicated Autonomous Databases
- Managing Database Users
- Managing and Monitoring Performance
- Backing Up and Restoring Autonomous Database
- Cloud Object Storage URI Formats
- Using Oracle Database Features in Dedicated Autonomous Database Deployments

For information on how application developers connect their applications to Autonomous Databases, see Developer’s Guide to Oracle Autonomous Database on Dedicated Exadata Infrastructure.

See Fleet Administrator’s Guide to Oracle Autonomous Database on Dedicated Exadata Infrastructure for information on administering multiple sets of Autonomous Database resources provisioned on dedicated Exadata Infrastructure.

For known issues, see Known Issues for Oracle Autonomous Database on Dedicated Exadata Infrastructure.

**Autonomous JSON Database**

Autonomous JSON Database is available on shared Exadata infrastructure. For in-depth documentation on using and managing your Autonomous JSON Database, see the following topics:

- Get Started Using Autonomous JSON Database
- Use SQL Developer Web with JSON Collections
- Develop RESTful Services
- Build an Application
- Load JSON Documents
- Code for High Performance

See JSON Developer's Guide for information on using Autonomous JSON Database as a part of application development.

**Oracle APEX Application Development**

Oracle APEX Application Development is available on Autonomous Database for shared Exadata infrastructure. For in-depth documentation on using and managing your Oracle APEX Application Development instance, see the following topics:

- What's Included in Oracle APEX Application Development
- Sign Up for Oracle APEX Application Development
- Access APEX Service
- Manage APEX Service
- Learn About Oracle Application Express
Creating an Autonomous Database on Shared Exadata Infrastructure

This topic describes how to provision a new Autonomous Database on Shared Exadata infrastructure using the Oracle Cloud Infrastructure Console or the API. Autonomous Databases can be provisioned on Dedicated Exadata infrastructure or Shared Exadata infrastructure. Your database can be optimized for either data warehouse, JSON, transaction processing, or APEX service workloads.

To provision an Always Free Autonomous Database, see To create an Always Free Autonomous Database on page 1159. For more information on the Free Tier, see Oracle Cloud Infrastructure Free Tier on page 140.

For Oracle By Example tutorials on provisioning Autonomous Databases, see Provisioning Autonomous Transaction Processing and Provisioning Autonomous Data Warehouse Cloud.

Prerequisites

- To create an Autonomous Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

  Tip:

  See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax.

- For information on additional prerequisites for provisioning an Autonomous Transaction Processing database, see What Do You Need? Likewise, for information on additional prerequisites for provisioning an Autonomous Data Warehouse, see What Do You Need?

- To create an Autonomous Transaction Processing database on Dedicated Exadata infrastructure, you must first provision the infrastructure and at least one Autonomous Container Database. For more information, see Creating an Autonomous Exadata Infrastructure Resource on page 1198 and Creating an Autonomous Container Database on page 1205.

Using the Oracle Cloud Infrastructure Console

To create an Autonomous Database on shared Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Provide the following information for the Autonomous Database:

   - **Compartment:** Select the compartment of the Autonomous Database.
   - **Display name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique. Avoid entering confidential information.
   - **Database name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters.

Note:

You cannot use the same database name concurrently for an Autonomous Data Warehouse, an Autonomous JSON, or an Autonomous Transaction Processing database for databases using shared Exadata infrastructure.
Names associated with databases terminated within the last 60 days cannot be used when creating a database.

3. Choose a workload type. See About Autonomous Data Warehouse, About Autonomous JSON Database, About Autonomous Transaction Processing, and About Oracle Application Express for information about each workload type.

4. Choose the **Shared Infrastructure** deployment type.

   **Note:**
   
   If you choose JSON or APEX as your workload type, then Shared Infrastructure is the only available deployment type.

5. Configure the database:

   - **Always Free**: Use this selector to show only Always Free configuration options if you are provisioning an Always Free Autonomous Database. See Overview of the Always Free Autonomous Database on page 1220 for more information.

     **Note:**
     
     This option is not available for either JSON or APEX workload types.

   - **Choose database version**: Select a database version from the available versions.

   - **OCPU count**: Specify the number of cores for your Autonomous Database. The actual number of available cores is subject to your tenancy's service limits.

     Deselect **Auto scaling** to disable auto scaling. By default auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. See CPU Scaling for more information.

   - **Storage (TB)**: Specify the storage you wish to make available to your Autonomous Database, in terabytes.

   - **Enable preview version**: *(This option only displays during periods when a preview version of Autonomous Database is available)* Select this option to provision the database with an Autonomous Database preview version. Preview versions of Autonomous Database are made available for limited periods for testing purposes. Do not select this option if you are provisioning a database for production purposes or if you will need the database to persist beyond the limited availability period of the preview version.

6. **Create administrator credentials**: Set the password for the Autonomous Database ADMIN user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using a SQL client tool.

   **Password criteria:**
   
   - Contains from 12 to 30 characters and includes at least one uppercase letter, one lowercase letter, and one numeric character.
   - Does not contain the string "admin", regardless of case
   - Is not one of the last four passwords used for the ADMIN user
   - Does not contain the double quotation mark ("")
   - Cannot be the same password that was set less than 24 hours ago

7. Choose the type of network access.

   - **Allow secure access from anywhere**: This option provides access using a public endpoint that you secure with an access control list (ACL). Use this option if you need to access your database from the internet or your on-premises network. See Adding an Access Control List (ACL) to an Autonomous Database with a Public Endpoint on page 1161 for more information.

   - **Virtual cloud network**: This option creates a private endpoint for your database within a specified VCN. See Configuring a Virtual Cloud Network (VCN) for Private Endpoint Access to Your Autonomous Database on page 1162 for more information.
Choose a license type. Your choice affects metering for billing. You have the following options:

- **Bring Your Own License (BYOL):** Bring my existing database software licenses to the database cloud service.
- **License Included:** Subscribe to new database software licenses and the Database cloud service.

**Note:**
If you choose either JSON or APEX as your workload type, then License Included is the only available license type.

Clicking **Show Advanced Options** allows you to configure the following:

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

**Click Create Autonomous Database.**

**WHAT NEXT?**

- Connect to the database
- Create database users - Data Warehouse | Transaction Processing
- Load data into the database - Data Warehouse | JSON | Transaction Processing
- Connect applications that use the database - Data Warehouse | JSON | Transaction Processing
- Create APEX applications that use the database - Data Warehouse | Transaction Processing
- Register the database with Data Safe
- Set up Object Storage for manual backups

**To create an Always Free Autonomous Database**

**Note:**
An Always Free Autonomous Database cannot be created in a security zone compartment. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse or Autonomous Transaction Processing.

**Note:**
The JSON workload type is not available for Always Free Autonomous Database. You can use the Autonomous Transaction Processing workload type to work with JSON objects. Always Free Autonomous Transaction Processing databases can be converted to paid Autonomous JSON Databases.

2. Provide the following information for the Autonomous Database:

- **Compartment:** Select the compartment of the Autonomous Database.
- **Display name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique. Avoid entering confidential information.
- **Database name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters.

**Note:**
You cannot use the same database name concurrently for both an Autonomous Data Warehouse and an Autonomous Transaction Processing database for databases using shared Exadata infrastructure.
3. Choose a workload type. See About Autonomous Data Warehouse, About Autonomous JSON Database, About Autonomous Transaction Processing, and About Oracle Application Express for information about each workload type.

**Note:**
The Oracle Application Express workload type is not available with Always Free Autonomous Databases

4. Choose the **Shared Infrastructure** deployment type.

5. Configure the database:

- **Always Free:** Move this selector to the right so that the provisioning workflow shows only the Always Free configuration options. Note that the **Core CPU count** and **Storage** configuration fields are disabled when provisioning an Always Free Autonomous Database. Your database will have 1 OCPU, 8 GB of memory, and 20 GB of storage.
- **Choose database version:** Select a database version from the available versions.

**Note:**
You can select only the current database version or a newer one. You cannot downgrade to an older database version.

6. **Create administrator credentials:** Set the password for the Autonomous Database ADMIN user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using a SQL client tool.

Password criteria:

- Contains from 12 to 30 characters and includes at least one uppercase letter, one lowercase letter, and one numeric character.
- Does not contain the string "admin", regardless of case
- Is not one of the last four passwords used for the ADMIN user
- Does not contain the double quotation mark ("")
- Cannot be the same password that was set less than 24 hours ago

7. Network access for Always Free Autonomous Database is **Allow secure access from anywhere**. This option provides access using a public endpoint that you secure with an access control list (ACL). Use this option if you need to access your database from the internet or your on-premises network. See Adding an Access Control List (ACL) to an Autonomous Database with a Public Endpoint on page 1161 for more information on creating an ACL.

8. Clicking **Show Advanced Options** allows you to configure the following:

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

9. Click **Create Autonomous Database**.

**Note:**
The following naming restrictions apply to Autonomous Transaction Processing and Autonomous Data Warehouse databases using Shared Exadata Infrastructure:

- Names associated with databases terminated within the last 60 days cannot be used when creating a new database.
- A database name cannot be used concurrently for two Autonomous Databases, regardless of workload type.

**WHAT NEXT?**
- Create database users - Data Warehouse | Transaction Processing
• Load data into the database - Data Warehouse | Transaction Processing
• Connect applications that use the database - Data Warehouse | Transaction Processing
• Create APEX applications that use the database - Data Warehouse | Transaction Processing
• Connect to the database

Using the API

Use the CreateAutonomousDatabase API operation to create Autonomous Databases of either the Autonomous Data Warehouse (DW), Autonomous JSON Database (AJD), or Autonomous Transaction Processing (OLTP) workload types.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

For More Information

• Oracle APEX Application Development Videos (video tutorials)

Adding an Access Control List (ACL) to an Autonomous Database with a Public Endpoint

This topic describes how to add an access control list (ACL) when provisioning an Autonomous Database on shared Exadata infrastructure that uses the Allow secure access from anywhere networking option. See Choose the type of network access in the To create an Autonomous Database on shared Exadata infrastructure on page 1157 topic to return to the provisioning instructions.

The network access rules you create for an access control list (ACL) provide protection for your Autonomous Database by allowing only the public and VCN IP addresses in the list to connect to the database. Click Configure Access Control Rules in the Create Autonomous Database dialog to create an ACL for your database.

You can specify the following types of addresses in your list by using the IP notation type drop-down selector:

• IP Address allows you to specify one or more individual public IP address. Use commas to separate your addresses in the input field.
• CIDR Block allows you to specify one or more ranges of public IP addresses using CIDR notation. Use commas to separate your CIDR block entries in the input field.
• Virtual Cloud Network allows you to specify an existing VCN. The drop-down listing in the input field allows you to choose from the VCNs in your current compartment for which you have access permissions. Click the Change Compartment link to display the VCNs of a different compartment.
• Virtual Cloud Network (OCID) allows you input the OCID of a VCN in a text box. You can use this input method if the VCN you are specifying is in a compartment which you do not have permission to access.
Caution:

If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

If you add a Virtual Cloud Network to your ACL, you can limit further by specifying allowed VCN IP addresses or CIDR ranges. Enter those addresses or CIDR blocks in the IP Addresses or CIDRs field that is displayed below your Virtual Cloud Network choice. Use commas to separate your VCN addresses and CIDR blocks in the input field.

You can specify the following types of IP addresses at the VCN level:

- Private IP addresses within your Oracle Cloud Infrastructure VCN
- Private IP addresses within an on-premises network that have access to your Autonomous Database using a transit routing and a private connection via FastConnect or VPN Connect.

Click + Another Entry to add additional access rules to your list.

Return to the Create Autonomous Database dialog instructions

Configuring a Virtual Cloud Network (VCN) for Private Endpoint Access to Your Autonomous Database

This topic describes how to configure a virtual cloud network (VCN) when provisioning an Autonomous Database on shared Exadata infrastructure that uses the Virtual cloud network networking option to provide private endpoint access. See Choose the type of network access in the To create an Autonomous Database on shared Exadata infrastructure on page 1157 topic to return to the provisioning instructions.

Note:

- See Networking Prerequisites Needed for Private Endpoint on page 1163 for information on creating the Networking resources needed for this configuration.
- If you are creating an Autonomous Database in a security zone compartment, your private endpoint networking configuration must use a subnet that is also in a security zone compartment. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

Select Virtual cloud network in the Create Autonomous Database dialog to configure private access, then specify the following information:

- **Virtual cloud network**: The VCN in which to launch the Autonomous Database. Click Change Compartment to select a VCN in a different compartment. **Important**: You cannot change the specified VCN after provisioning, except by switching to the Allow secure access from anywhere option, then switching back to the Virtual cloud network option and creating a new private endpoint network configuration.

- **Subnet**: The subnet to which the Autonomous Database should attach. Click change compartment to select a subnet in a different compartment. **Important**: You cannot change the specified subnet after provisioning, except by switching to the Allow secure access from anywhere option, then switching back to the Virtual cloud network option and creating a new private endpoint network configuration.

- **Hostname prefix**: Optional. This specifies a host name prefix for the Autonomous Database and associates a DNS name with the database instance, in the following form:

  hostname_prefix.adb.region.oraclecloud.com

  The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). You can use up to 63 alphanumeric characters for your hostname prefix.

  If you choose not to specify a hostname prefix, Oracle creates a unique DNS name for your database.

- **Network security groups**: You must specify at least one network security group (NSG) for your Autonomous Database. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to
your database. A maximum of five NSGs can be specified. See NSG security rule guidelines for private endpoint on page 1163 for details on configuring an NSG for your Autonomous Database.

For more information on creating and working with NSGs, see Network Security Groups on page 2841.

Note that if you choose a subnet with a security list, the security rules for the database will be a union of the rules in the security list and the NSGs.

**Tip:**

When connecting to your database from an on-premises network, Oracle recommends using a FastConnect connection. If you are using an IPSec VPN connection, see the configuration tips in the Hanging Connection on page 3327 topic in the Networking service documentation to avoid connection problems.

*Return to the Create Autonomous Database dialog instructions*

**Autonomous Database with Private Endpoint**

**Note:**

This topic applies only to Autonomous Databases with shared Exadata infrastructure.

*Private endpoint* refers to a network setup for your Autonomous Database with shared Exadata infrastructure where all network traffic moves through a private endpoint within a VCN in your tenancy. If your organization has strict security mandates that do not allow you to have a public endpoint for your database, this provides you with the necessary private endpoint. Additionally, this configuration uses no public subnets and allows you to keep all traffic to and from your Autonomous Database off of the public internet.

**Overview of Private Endpoint**

Enabling a private endpoint for an Autonomous Database ensures that the only access path to the database is via a VCN inside your Oracle Cloud Infrastructure tenancy. This network configuration completely blocks access to the database from public endpoints. A private endpoint offers the following advantages over other methods of private network access:

- Does not require you to set up transit routing in you VCN and use a service gateway to connect.
- Can satisfy security requirements that forbid the use of a public endpoint.

The private endpoint option is available for both new and existing Autonomous Databases on shared Exadata infrastructure. See To create an Autonomous Database on shared Exadata infrastructure on page 1157 for instructions on creating a new Autonomous Database with a private endpoint. See To change the network access of an Autonomous Database on shared Exadata infrastructure from private endpoint to public endpoint for information on switching network access configuration of an existing database.

**Networking Prerequisites Needed for Private Endpoint**

To provision an Autonomous Database with a private endpoint, you must have the following resources already created:

- A VCN within the region that will contain your Autonomous Database with shared Exadata infrastructure. Cannot be changed after provisioning.
- A private subnet within your VCN configured with default DHCP options. Cannot be changed after provisioning.
- At least 1 network security group (NSG) within your VCN for the Autonomous Database. Can be changed or edited after provisioning.

NSGs create a virtual firewall for your Autonomous Database using security rules. You can specify up to five NSGs to control access to your Autonomous Database.

*NSG security rule guidelines for private endpoint*

Your security rules for the NSG of your Autonomous Database need to be configured as follows:
• The private endpoint feature supports both stateful and stateless security rules within NSGs.
• Your rule covering ingress traffic must specify the **IP Protocol** "TCP", and your **Destination Port Range** must be 1522.
• To use Oracle Application Express, Oracle SQL Developer Web, and Oracle REST Data Services, add port 443 to the NSG rule.

To connect another resource located inside Oracle Cloud Infrastructure (for example, a Compute instance) to your Autonomous Database, the second resource needs a security rule that allows all egress traffic to the NSG of the Autonomous Database. This means you specify the NSG of the Autonomous Database as the **Destination** for this security rule. The second resource’s security rule can be part of an NSG or a security list.

See [Network Security Groups](#) on page 2841 and [To create an NSG](#) on page 2847 for more information on working with NSGs.

**Connecting to an Autonomous Database with a Private Endpoint**

You can connect to an Autonomous Database that uses a private endpoint from within Oracle Cloud Infrastructure resources, or from your data center. See [To find the Fully Qualified Domain Name (FQDN) and IP address of your private endpoint](#) for information on locating the IP address and URL of your endpoint.

**Example 1: Connecting from Within Oracle Cloud Infrastructure**

You can connect from a resource (like a Compute instance) within the same VCN as the private endpoint. Note that you can also connect from a resource located in a different VCN from the private endpoint by using local or remote VCN peering.

![Diagram of connecting to an Autonomous Database with a private endpoint](image)

Example network layout for connecting to an Autonomous Database with a private endpoint from within Oracle Cloud Infrastructure

You set up:

• A **VCN and a private subnet**
• An NSG for the Autonomous Database that includes either stateful or stateless security rules, as described in Networking Prerequisites Needed for Private Endpoint

Example stateful security rule for the Autonomous Database NSG. Note that stateless rules are also supported.

• An NSG security rule for the resource that will be allowed access to the Autonomous Database. This stateful egress security rule allows all egress traffic to the NSG of the Autonomous Database.

Example stateful egress security rule for the NSG of the resource connecting to the Autonomous Database

Example 2: Connecting from an On-Premise Data Center

Example network layout for connecting to an Autonomous Database with a private endpoint from an on-premises network

You set up:

• A VCN and a private subnet
• An NSG for the Autonomous Database that includes one or more security rules as described in see Networking Prerequisites Needed for Private Endpoint allowing traffic to a CIDR within your on-premises network

Example stateful security rule for the Autonomous Database NSG
• A Oracle Cloud Infrastructure FastConnect dedicated private connection or a VPN Connect IPSec VPN connection
• A dynamic routing gateway (DRG)
• A route table

Tip:
When connecting from an on-premises network, Oracle recommends using a FastConnect connection. If you are using an IPSec VPN connection, see the configuration tips in the Hanging Connection on page 3327 topic in the Networking service documentation to avoid connection problems.

To find the Fully Qualified Domain Name (FQDN) and IP address of your private endpoint

Your database's private endpoint IP address is displayed on the Autonomous Database Details page in the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click the display name of the database you want to connect to.
4. On the Autonomous Database Details page, in the Network section, the Private Endpoint IP Private Endpoint URL fields display the IP address and URL of the endpoint.

To resolve the Autonomous Database private endpoint in your on-premise host's /etc/hosts file

To resolve the Autonomous Database private endpoint, a Fully Qualified Domain Name (FQDN) requires that you add an entry in your on-premise client's hosts /etc/hosts file. For example:

# example /etc/hosts entry
10.0.2.7 example.adb.us-phoenix-1.oraclecloud.com

To use Oracle Application Express, Oracle SQL Developer Web, and Oracle REST Data Services, add another entry with the same IP. For example:

# example /etc/hosts entry
10.0.2.7 example.adb.ca-toronto-1.oraclecloudapps.com

You find the private endpoint IP and the FQDN as follows:
• The Private IP is shown on the Oracle Cloud Infrastructure Console Autonomous Database details page for the instance.
• The FQDN is shown in the tnsnames.ora file in the Autonomous Database client credential wallet.

Alternatively you can set up a hybrid DNS in Oracle Cloud Infrastructure for DNS name resolution.

Additional Information
See To create an Autonomous Database on shared Exadata infrastructure on page 1157 for instructions on provisioning an Autonomous Database that uses a private endpoint.
See To update the network configuration of an Autonomous Database on shared Exadata infrastructure that uses a private endpoint on page 1177 for information on editing networking settings related to a private endpoint.

See Private Access on page 3253 in the Networking service documentation for an overview of the options for enabling private access to services within Oracle Cloud Infrastructure.

See Hanging Connection on page 3327 in the Networking service documentation for troubleshooting IPSec VPN connection issues that can occur when connecting from your on-premises network.

Creating an Autonomous Database on Dedicated Exadata Infrastructure

This topic describes how to provision a new Autonomous Database on dedicated Exadata infrastructure using the Oracle Cloud Infrastructure Console or the API. Autonomous Databases can be provisioned on either dedicated Exadata infrastructure or shared Exadata infrastructure. Your database can be optimized for either transaction processing or data warehouse workloads, and you can create a standby database to facilitate disaster recovery by enabling Autonomous Data Guard.

For Oracle By Example tutorials on provisioning Autonomous Databases, see Provisioning Autonomous Transaction Processing and Provisioning Autonomous Data Warehouse Cloud.

Prerequisites

• To create an Autonomous Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Tip:

See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax.

• For information on additional prerequisites for provisioning an Autonomous Transaction Processing database, see What Do You Need? Likewise, for information on additional prerequisites for provisioning an Autonomous Data Warehouse, see What Do You Need?

• To create an Autonomous Transaction Processing database on Dedicated Exadata infrastructure, you must first provision the infrastructure and at least one Autonomous Container Database. For more information, see Creating an Autonomous Exadata Infrastructure Resource on page 1198 and Creating an Autonomous Container Database on page 1205.

Using the Oracle Cloud Infrastructure Console

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Provide the following information for the Autonomous Database:

   • Compartment: Select the compartment of the Autonomous Database.
   • Display name: A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique. Avoid entering confidential information.
   • Database name: The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters.

3. Choose a workload type. See About Autonomous Data Warehouse and About Autonomous Transaction Processing for information about each workload type.

4. Click the Dedicated Infrastructure deployment type.
5. In the **Choose Autonomous Container Database** section, select an Autonomous Container Database from the **Autonomous Container Database in compartment** drop-down.

You can change the compartment from which to choose an Autonomous Container Database by clicking the **CHANGE COMPARTMENT** link.

You can provision a standby Autonomous Container Database to provide data protection, high availability, and to facilitate disaster recovery for the primary database.

**a.** Select **Autonomous Data Guard-enabled Autonomous Container Databases** to list Autonomous Container Databases that have Oracle Data Guard enabled.

**b.** Select an Autonomous Container Database from the **Autonomous Container Database in compartment** drop-down.

**Note:**

The standby Autonomous Container Database inherits the resource configuration (OCPUs count and amount of storage) from the primary database.

- See **Creating an Autonomous Container Database** on page 1205 for information about provisioning a container database.
- See **Database System Resource types** on page 1193 in the Dedicated Deployment overview for information about the container database resource type.
- See **Managing a Standby Autonomous Container Database** on page 1214 for more information about Oracle Data Guard.

6. Configure the database:

- **OCPUs count:** Specify the number of cores for your Autonomous Database. The actual number of available cores is subject to your tenancy’s service limits.

  Deselect **Auto scaling** to disable auto scaling. By default auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. See **CPU Scaling** for more information.

- **Storage (TB):** Specify the storage you wish to make available to your Autonomous Database, in terabytes.

7. **Create administrator credentials:** Set the password for the Autonomous Database ADMIN user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using a SQL client tool.

Password criteria:

- Contains from 12 to 30 characters and includes at least one uppercase letter, one lowercase letter, and one numeric character.
- Does not contain the string "admin", regardless of case
- Is not one of the last four passwords used for the ADMIN user
- Does not contain the double quotation mark ("),
- Cannot be the same password that was set less than 24 hours ago

**Note:**

If you enable Autonomous Data Guard, then the standby Autonomous Database that gets provisioned has the same ADMIN user password as the primary database.
8. Click **Show Advanced Options** to configure the following:

   - **Encryption Key**: Whichever encryption key-management choice you made, either Oracle managed or your own encryption key, when you created the Autonomous Container Database, is displayed. The Autonomous Database you are creating inherits key management from the Autonomous Container Database.

     See [Managing Keys](#) on page 3962 for more information about encryption keys.

   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

9. Click **Create Autonomous Database**.

### Using the API

Use the `CreateAutonomousDatabase` API operation to create Autonomous Databases of either the Autonomous Data Warehouse (DW), Autonomous JSON Database (AJD), or Autonomous Transaction Processing (OLTP) workload types.

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

- [Autonomous Data Warehouse: Videos](#) (video tutorials)

### Managing an Autonomous Database

**Autonomous Database**

This topic describes the database management tasks for Autonomous Databases that you complete using the Oracle Cloud Infrastructure Console or the API. These tasks apply to Autonomous Databases of either the Data Warehouse, JSON Database, or Transaction Processing workload types. You can filter Autonomous Databases by workload type on the [Autonomous Databases](#) page of the Oracle Cloud Infrastructure Console.

**Note:**

Some database management tasks not described here are performed using the [Autonomous Transaction Processing service console](#) or the [Autonomous Data Warehouse service console](#).

**Prerequisites**

To perform the management tasks in this topic, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See [Authentication and Authorization](#) for more information on user authorizations for the Oracle Cloud Infrastructure Database.
Using the Console

_Lifecycle Management Operations_

To check the lifecycle state of your Autonomous Database

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. In the Information tab, note the value displayed for **Lifecycle State**. For some lifecycle states, an information icon (ⓘ) is displayed to provide additional details regarding the lifecycle state or ongoing operations such as backups, restores, or terminations. The database has one of the following lifecycle states:

   - Available
   - Available needs attention
   - Backup in progress
   - Provisioning
   - Restore in progress
   - Scaling in progress
   - Starting
   - Stopping
   - Stopped
   - Terminating
   - Terminated
   - Unavailable

To stop or start an Autonomous Database

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Stop** (or **Start**). When you stop your Autonomous Database, billing stops for CPU usage. Billing for storage continues when the database is stopped.
5. Confirm that you want to stop or start your Autonomous Database in the confirmation dialog.

**Note:**

Stopping your database has the following consequences:

- On-going transactions are rolled back.
- CPU billing is halted
- You will not be able to connect to your database using database clients or tools.

To restart an Autonomous Database

**Tip:**

Restarting a database is equivalent to manually stopping and then starting the database. Using restart allows you to minimize downtime and requires only a single action.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Restart**.
5. Confirm that you want to restart your Autonomous Database in the confirmation dialog. The system stops and then immediately starts your database.

To terminate an Autonomous Database

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terminating an Autonomous Database permanently deletes it. The database data, including automatic backups, will be lost when the system is terminated. Manual backups remain in Object Storage and are not automatically deleted when you terminate an Autonomous Database. Oracle recommends that you create a manual backup prior to terminating.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Terminate**.
5. Confirm that you want to terminate your Autonomous Database in the confirmation dialog.

To scale the CPU core count or storage of an Autonomous Database

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Click **Scale Up/Down**.
5. Enter a new value for **CPU Core Count** or **Storage** from 1 to 128. The number you enter represents the total value for your database's CPU core count or storage.

   The number of available cores is subject to your tenancy's service limits. An Autonomous Database database can have a maximum of 128 cores and 128 TB of storage. Scaling the CPU core count affects your CPU billing.
6. Click **Update**.

To enable or disable auto scaling for an Autonomous Database

Note the following points regarding the auto scaling feature:

- With auto scaling enabled, the database can use up to three times more CPU and IO resources than specified by the number of OCPUs currently shown in the **Scale Up/Down** dialog. See **CPU Scaling** for more information.
- If auto scaling is disabled while more CPU cores are in use than the database's currently assigned number of cores, then Autonomous Database scales the number of CPU cores in use down to the assigned number.
- Enabling auto scaling does not change the concurrency and parallelism settings for the predefined services. See **Managing Concurrency and Priorities on Autonomous Data Warehouse** and **Managing Priorities on Autonomous Transaction Processing** for more information.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Click **Scale Up/Down**.
5. Check **Auto Scaling** to enable the auto scaling feature, or uncheck **Auto Scaling** to disable the feature.
6. Click **Update**.

To view OCPU allocation hourly snapshot data for an Autonomous Database
1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. In the list of Autonomous Databases, click the display name of the database for which you want to view CPU usage data.

4. Click the Service Console button. The Service Console opens in a new tab or window.

5. In the Overview screen, the Number of OCPUs allocated graph shows hourly snapshot data of OCPU allocation over the last eight days. Place your cursor over the graph and move it to the left or right to see data for a specific day and hour.

Database Management Tasks

To set the Admin password

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. In the list of Autonomous Databases, click the display name of the database you want to administer.

4. Go to More Actions, and then click Admin Password. The Admin Password dialog opens.

5. Enter a password for the Autonomous Database. The password must meet the following criteria:
   - Contains from 12 to 30 characters
   - Contains at least one lowercase letter
   - Contains at least one uppercase letter
   - Contains at least one number
   - Does not contain the double quotation mark ("")
   - Does not contain the string "admin", regardless of case
   - Is not one of the last four passwords used for the database
   - Is not a password you previously set within the last 24 hours

6. Enter the password again in the Confirm Password field.

7. Click Update.

To access the Autonomous Database service console for databases on shared Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. In the list of Autonomous Databases, click the display name of the database you want to administer.

4. Click Service Console.

For information on using the Autonomous Transaction Processing service console features, see Managing and Monitoring Performance of Autonomous Transaction Processing. For information on using the Autonomous Data Warehouse service console features, see Managing and Monitoring Performance of Autonomous Data Warehouse Cloud.

To change the license type of an Autonomous Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. In the list of Autonomous Databases, click the display name of the database you want to administer.

4. Go to More Actions, and then click Update License Type.

   The dialog displays the options with your current license type selected.

5. Select the new license type.

6. Click Update.

See Known Issue.
To rename an Autonomous Database on shared Exadata infrastructure

**Note:**
Renaming a database changes the contents of the database wallet and requires that you download a new wallet.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Select the compartment, from the **Compartment** drop-down, that contains the database you want to rename.
3. From the list of Autonomous Databases contained in the compartment, click the display name of the database you want to rename to display the Autonomous Database Details page for that database.
4. Click **More Actions** to display a list of actions.
5. Click **Rename Database** to display the **Rename Database** dialog.
6. Enter a database name that contains only letters and numbers, begins with a letter, and does not exceed 14 characters.
7. Enter the current database name to confirm the name change.
8. Click **Rename Database**.

To change the workload type of an Autonomous Database

You can change the workload type of an Autonomous Database from **JSON** or **APEX** to Transaction Processing if you require additional capabilities offered by Autonomous Transaction Processing.

**Note:**
This change results in billing changes and cannot be reversed.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Click **Autonomous Database** to display a list of Autonomous Databases of all workload types.
3. If you are not in the correct compartment, then select the compartment from the **Compartment** drop-down that contains the database for which you want to change the workload type.
4. Click the display name of the Autonomous Database of either **JSON** or **APEX** workload type for which you want to change the workload type to display the Autonomous Database Details page for that database.
5. Click **More Actions** to display a list of operations. Click **Change Workload Type** to display the **Change Workload Type to Transaction Processing** confirmation dialog.
6. Click **Convert**.

To change the access mode of an Autonomous Database

You can select an operation mode for an Autonomous Database. The default mode is read/write but you can select read-only to limit users to querying the database, only. In addition, for either of these modes you can restrict access to only allow a user with administrator privileges to access the database.

**Note:**
Changing access modes and permission level do not apply to an Autonomous JSON Database.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your compartment from the **Compartment** drop-down.
3. In the list of Autonomous Databases, click the name of the database for which you want to change the access mode to display the details page for that database.

**Note:**
The database you choose must be in the Available state to successfully change the access mode.
4. On the **Autonomous Database Information** tab, click the **Edit** link in the **Mode** field.
5. In the Edit Database Mode dialog, choose either **Read/Write** or **Read-only**, depending on the access mode you want. By default, an Autonomous Database is provisioned in read/write mode.

   You can also restrict access to the ADMIN user or users with administrator privileges by checking **Allow administrator access only**. You can apply this restriction whether the database is in read/write or read-only mode.

6. Click **Confirm** to apply the change.

   **Note:**
   - Changing the permission level requires that users and applications reestablish connections to the database.
   - When the database is in read-only mode:
     - You cannot change the ADMIN user password.
     - You cannot upgrade the database.

To enable or disable Operations Insights on an Autonomous Database

Operations Insights is an Oracle Cloud Infrastructure service that provides analytics that you can use to monitor an Autonomous Database on either dedicated or shared Exadata infrastructure.

   **Note:**
   Enabling Operations Insights for the first time takes a few minutes to complete. Subsequent enabling operations take less time.

To enable Operations Insights:

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse** or **Autonomous Transaction Processing**.
2. If necessary, choose the compartment from the **Compartment** drop-down that contains the Autonomous Database you want to register with Operations Insights.
3. From the list of Autonomous Databases, click the display name of the database to display the details page for that database.
4. In the **Operations Insights** section, click **Enable** or **Disable** to display a confirmation dialog.
   - Once enabled, click the **View** link in the **Operations Insights** section to display the various metrics.
5. Click **Confirm**.

**Networking Management Tasks**

To change the network access type of an Autonomous Database on shared Exadata infrastructure from public endpoint to private endpoint

   Autonomous Databases on shared Exadata infrastructure can use either of the following network access options:
   - **Virtual cloud network**: This option uses a private endpoint within a VCN in your tenancy. The private endpoint connects to the private endpoint in either an Autonomous Database with private endpoint using dedicated Exadata infrastructure or an Autonomous Database with a private endpoint in the Shared Exadata infrastructure.
   - **Allow secure access from everywhere**: This option uses a public endpoint provided by Oracle.

   This topic describes how to switch a database's network access to the **Virtual cloud network** option. See **Autonomous Database with Private Endpoint** on page 1163 more information on this option, including the prerequisites needed to switch.

   **Note:**
   - Your Oracle Database version must be 19c or higher to perform an in-place switch the network access type after provisioning.
To change the network access configuration from a private to a public endpoint, the Autonomous Database must have the **Available** lifecycle state.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Update Network Access**.
5. In the **Update Network Access** dialog, select **Virtual cloud network**.

   **Note:**
   
   If Data Safe is enabled,
   
   a. Ensure that you have created a private endpoint in the selected VCN for Autonomous Database with a private endpoint
   
   b. Ensure that you have configured the security rules to allow traffic from Data Safe to Autonomous Database. For more information, see the Data Safe documentation.

6. Specify the following information:
   
   a. **Virtual cloud network**: The VCN in which to launch the Autonomous Database. Click **Change Compartment** to select a VCN in a different compartment.
   
   b. **Subnet**: The subnet to which the Autonomous Database should attach. Click **change compartment** to select a subnet in a different compartment. Oracle recommends that you specify a private subnet.
   
   c. **Hostname prefix**: **Optional.** This specifies a host name prefix for the Autonomous Database and associates a DNS name with the database instance, in the following form:

   
   
   hostname_prefix.**adb.*region.**oraclecloud.com

   
   The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). You can use up to 63 alphanumeric characters for your hostname prefix.

   If you choose not to specify a hostname prefix, Oracle creates a unique DNS name for your database.

   d. **Network security groups**: You must specify at least one network security group (NSG) for your Autonomous Database. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your database. A maximum of five NSGs can be specified.

   For more information on creating and working with NSGs, see **Network Security Groups** on page 2841.

   Note that if you choose a subnet with a **security list**, the security rules for the database will be a union of the rules in the security list and the NSGs.

7. Click **Update**.

8. In the **Confirm** dialog, type the Autonomous Database name to confirm the change.

   Click **Update**.

**Notes:**

a. After updating the network access type all database users must obtain a new wallet and use the new wallet to access the database. See **About Downloading Client Credentials (Wallets)** for more information.

b. If you had access control list (ACL) rules defined for the public endpoint, the rules do not apply for the private endpoint.

To change the network access of an Autonomous Database on shared Exadata infrastructure from private endpoint to public endpoint

Autonomous Databases on shared Exadata infrastructure can use either of the following network access options:

a. **Virtual cloud network**: This option uses a private endpoint within a VCN in your tenancy.
• **Allow secure access from everywhere**: This option uses a public endpoint provided by Oracle.

This topic describes how to switch a database's network access to the **Allow secure access from everywhere** option.

**Note:**
- Your Oracle Database version must be 19c or higher to perform an in-place switch the network access type after provisioning.
- To change the network access configuration from a private to a public endpoint, the Autonomous Database must have the *Available* lifecycle state.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Update Network Access**.
5. In the **Update Network Access** dialog, select **Allow secure access from everywhere**.
6. Click **Update**.
7. In the **Confirm** dialog, type the Autonomous Database name to confirm the change.
8. Click **Update**.

Notes:
- After updating the network access type all database users must obtain a new wallet and use the new wallet to access the database. See **About Downloading Client Credentials (Wallets)** for more information.
- After the update completes, you can define access control rules for the public endpoint by specifying ACLs. See **To manage the access control list of an Autonomous Database on shared Exadata infrastructure** for more information. See **Access Control Lists (ACLs) for Databases on Shared Exadata Infrastructure** on page 1153 for details and restrictions regarding ACLs.

To manage the access control list of an Autonomous Database on shared Exadata infrastructure

This task applies to Autonomous Databases using the **Allow secure access from everywhere** network access option. This option uses a public endpoint provided by Oracle.

An access control list (ACL) provides additional protection for your Autonomous Database by allowing only the IP addresses in the list to connect to the database. An ACL must contain at least one entry representing an IP address or a range of addresses. To create or edit an ACL for an existing database that uses shared Exadata infrastructure, do the following:

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Under **Network** in the database details, find the **Access Control List** field and click **add** (if no ACL currently exists) or **edit** (to update an existing ACL).
5. In the **Access Control List** dialog, add or modify entries, as applicable.

**Note:**
If you are editing an ACL, the ACL's existing entries display in the **Access Control List** dialog. Do not overwrite the existing values unless you intend...
You can specify the following types of addresses in your list by using the IP notation type drop-down selector:

- **IP Address** allows you to specify one or more individual public IP address. Use commas to separate your addresses in the input field.
- **CIDR Block** allows you to specify one or more ranges of public IP addresses using CIDR notation. Use commas to separate your CIDR block entries in the input field.
- **Virtual Cloud Network** allows you to specify an existing VCN. The drop-down listing in the input field allows you to choose from the VCNs in your current compartment for which you have access permissions. Click the **Change Compartment** link to display the VCNs of a different compartment.
- **Virtual Cloud Network (OCID)** allows you input the OCID of a VCN in a text box. You can use this input method if the VCN you are specifying is in a compartment which you do not have permission to access.

**Caution:**
If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

If you add a Virtual Cloud Network to your ACL, you can limit further by specifying allowed VCN IP addresses or CIDR ranges. Enter those addresses or CIDR blocks in the **IP Addresses or CIDRs** field that is displayed below your Virtual Cloud Network choice. Use commas to separate your VCN addresses and CIDR blocks in the input field. You can specify the following types of IP addresses at the VCN level:

- Private IP addresses within your Oracle Cloud Infrastructure VCN
- Private IP addresses within an on-premises network that have access to your Autonomous Database using a transit routing and a private connection via FastConnect or VPN Connect.

Click **+ Another Entry** to add additional access rules to your list.

**Important:**
If you are using a service gateway, ensure that the CIDR range 240.0.0.0/4 is included in the list to allow clients accessing the database through the service gateway to connect to it.

To remove the ACL, simply delete all entries in the list. This action allows all clients to connect to the database.

6. **Click Update.**

If the Lifecycle State is **Available** when you click **Update**, the Lifecycle State changes to **Updating** until the ACL update is complete. The database is still up and accessible, there is no downtime. When the update is complete the Lifecycle State returns to **Available** and the network ACL rules from the access control list are in effect.

For more information about access control lists, see **Security Considerations** on page 1153.

To update the network configuration of an Autonomous Database on shared Exadata infrastructure that uses a private endpoint

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer. The **Autonomous Database Details** page displays.
4. In the **Autonomous Database Information** tab, the **Network** section displays the names of your database's virtual cloud network (VCN), subnet, and network security groups (NSGs). The following networking configuration changes are possible:

   • Clicking the names of your VCN and subnet will take you to the resource details pages of those resources. While you can edit the configurations of those resources, you cannot assign a different VCN or subnet to your Autonomous Database.

   • You can add or remove NSGs by clicking the **edit** link by the listed NSGs in the Network section on the **Autonomous Database Details** page. Note that your specified NSGs must contain stateless security rules.

   • You can edit the security rules of any of your Autonomous Database's NSGs by clicking the name of the NSG. Clicking the name takes you to the **Network Security Group Details** page of the NSG.

**Management Tasks for the Oracle Cloud Infrastructure Platform**

To view a work request for your Autonomous Database

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. In the **Resources** section, click **Work Requests**. The status of all work requests appears on the page.
5. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the **More information** section.

For associated resources, you can click the the Actions icon (three dots) next to a resource to copy the resource's OCID.

For more information, see **Work Requests** on page 258.

To move an Autonomous Database to another compartment

**Note:**

- To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see **Details for the Database Service** on page 2240.

- **Security zone considerations:**
  - If your Autonomous Database is in a security zone, the destination compartment must also be in a security zone.
  - If your Autonomous Database uses a public endpoint, you cannot move it to a security zone compartment unless you first switch the networking configuration to use a private endpoint.
  - If your Autonomous Database is not in a security zone and has Data Guard standby database, you cannot move the database into a security zone compartment while the standby remains in a compartment that is not in a security zone.

See the **Security Zone Policies** topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to move.
4. Go to **More Actions**, and then click **Move Resource**.
5. Select the new compartment.
6. Click **Move Resource**.

For information about dependent resources for Database resources, see *Moving Database Resources to a Different Compartment* on page 1141.

To manage tags for your Autonomous Database

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to administer.
4. Go to **More Actions**, and then click **Apply Tag(s)** to add new tags. Or click the **Tags** tab to view or edit the existing tags.

For more information, see *Resource Tags* on page 211.

To upgrade an Always Free Autonomous Database to a paid instance

If you are using a paid account, you can upgrade an Always Free/Autonomous Database to a paid instance. Paid instances include the ability to scale the OCPU count and storage.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click the display name of the database you want to upgrade.
4. Go to **More Actions**, and then click **Upgrade Instance to Paid**.
5. In the **Confirm Upgrade** dialog, confirm that you want to upgrade the instance by clicking the **Upgrade Instance to Paid** button.

The lifecycle state of the Autonomous Database will change to **Updating** while your upgrade is in progress. You database remains online and accessible while the upgrade is in progress. After your instance is upgraded to paid, you will be able to provision a new Always Free/Autonomous Database in place of your upgraded instance.

*Security Management Tasks*

For information on network security management tasks, see *Networking Management Tasks* on page 1174.

To register or deregister an Autonomous Database with Data Safe

To use Oracle Data Safe with an Autonomous Database, you register your database with Data Safe. To discontinue using Data Safe, you deregister the database. For information about using Data Safe, see the Data Safe documentation.

*Prerequisites for Autonomous Databases with private endpoints*

- Data Safe must be enabled in the region containing the Autonomous Database. For information about creating and using Data Safe instances, see the Data Safe documentation.
- Ensure that the Data Safe instance has a private endpoint. Instructions for creating a Data Safe private endpoint are located in the Register DB Systems that have Private IP Addresses topic in this manual.
- Enable communication from the Data Safe private endpoint to your database. To do this, update the security list or network security group (NSG) rules in the database's VCN to allow the Data Safe private endpoint to access the database. See the Access and Security section in this manual for information about network security groups, security rules, and security lists. See To update the network configuration of an Autonomous Database on shared Exadata infrastructure that uses a private endpoint on page 1177 for information on updating NSG rules for Autonomous Databases running on shared Exadata infrastructure. See and To edit the network security groups (NSGs) for your Autonomous Exadata Infrastructure resource on page 1204 for information on updating NSG rules for Autonomous Databases running on dedicated Exadata infrastructure.
Registering and deregistering an Autonomous Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. In the list of Autonomous Databases, click the display name of the database you want to manage.

4. In the Details page, under Data Safe, click register or deregister depending on the status of the database.
   - If the database uses dedicated Exadata infrastructure, enter the ADMIN password and click Confirm to start the registration or deregistration process. The ADMIN password is needed to unlock Data Safe so that it can monitor the database.
   - If the database uses Shared Exadata infrastructure, click Confirm to start the registration or deregistration process.

If the registration fails and the database is using a private endpoint, ensure that the prerequisites listed in this topic for allowing network access have been met.

5. You can optionally use either or both of the following to monitor the registration and deregistration process:
   - Use the work request created by the system to monitor the progress of the registration or deregistration.
   - Click View Console to display the Data Safe user interface for the registered database.

Registering and deregistering an Autonomous Database when Database Vault is enabled

When Database Vault is enabled on the database you are registering or deregistering, complete the following additional steps to register or deregister the database. These are needed to accommodate the additional database security provided by Database Vault.

- The Database Vault account manager must first grant specific access rights to the ADMIN database user before they can register or deregister an Autonomous Database. Otherwise, an "insufficient privileges" error is displayed.
- After the database has been registered or deregistered, the Database Vault account manager can remove the access rights to limit access during normal operations.
- After the database registration is complete, the Database Vault owner must grant specific access rights to the DS $ADMIN database user to enable normal operations. See the Data Safe documentation to learn about the access rights needed.

For more information on using Database Vault with an Autonomous Database, see the following user guides:

- Using Oracle Autonomous Transaction Processing on Shared Exadata Infrastructure
- Using Oracle Autonomous Transaction Processing on Dedicated Exadata Infrastructure
- Using Oracle Autonomous Data Warehouse on Shared Exadata Infrastructure
- Using Oracle Autonomous Data Warehouse on Dedicated Exadata Infrastructure
To rotate the encryption key for an Autonomous Database

Rotating the encryption key creates a new version of the vault key that replaces the current version of the vault key.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your compartment from the Compartment drop-down.

3. Click the display name of the Autonomous Database for which you want to rotate the encryption key to display the details page for that database.

   **Note:**
   The Autonomous Database you choose must be on dedicated Exadata infrastructure and in an Available state.

4. Click the More Actions drop-down.

5. Click Rotate Encryption Key to display a confirmation dialog.

6. Click Rotate Key.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage Autonomous Databases:

- ListAutonomousDatabases
- GetAutonomousDatabase
- UpdateAutonomousDatabase
- ChangeAutonomousDatabaseCompartment
- StartAutonomousDatabase
- RestartAutonomousDatabase
- StopAutonomousDatabase
- DeleteAutonomousDatabase

**For More Information**

- Using Oracle Autonomous Database on Shared Exadata Infrastructure ([full product documentation](#))
- Using Oracle Autonomous Database on Dedicated Exadata Infrastructure ([full product documentation](#))

**Connecting to an Autonomous Database**

This topic describes the following actions related to connecting client applications to an Autonomous Database:

- Obtaining the credentials and information (wallet) you need to create a connection (applies to both shared Exadata infrastructure and dedicated Exadata infrastructure)
- Rotating the keys and credentials (wallet) needed for a connection (applies to shared Exadata infrastructure only)
- Obtaining access URLs for Oracle Application Express (APEX) and Oracle Database Actions

   **Tip:**
   For more information on connecting a client to an Autonomous Database on dedicated Exadata infrastructure, see Connecting to Autonomous Database.

**About Connecting to Autonomous Databases**

Applications and tools connect to Autonomous Databases by using Oracle Net Services (also known as SQL*Net). SQL*Net supports a variety of connection types to Autonomous Databases, including Oracle Call Interface (OCI), ODBC drivers, JDBC OC, and JDBC Thin Driver.

To support connections of any type, you must download the client security credentials and network configuration settings required to access your database. You must also supply the applicable TNS names or connection strings for a connection, depending on the client application or tool, type of connection, and service level. You can view or copy
the TNS names and connection strings in the **DB Connection** dialog for your Autonomous Database. For detailed information about the TNS names, see **Predefined Database Service Names for Autonomous Transaction Processing** and **Predefined Database Service Names for Autonomous Data Warehouse**.

**Connecting to an Autonomous Database**

You can connect to an Autonomous Database that uses shared Exadata infrastructure from a VCN with either a public or private endpoint.

To connect to Autonomous Databases that use a **public endpoint** from a VCN, the VCN must be configured with one of the following gateways:

- **internet gateway**: For access from a public subnet in the VCN
- **service gateway**: For access from a private subnet in the VCN

Make sure to configure the subnet's **route table** with a rule that sends the desired traffic to the specific gateway. Also configure the subnet's **security lists** to allow the desired traffic.

You can also connect to your database from private IP addresses in your on-premises network by using transit routing with an Oracle Cloud Infrastructure VCN. This allows traffic to move directly from your on-premises network to your Autonomous Database without going over the internet. See **Transit Routing: Private Access to Oracle Services** on page 2803 for more information on this method of access.

To connect to Autonomous Databases that use a **private endpoint** from a VCN, you must configure a security rule within one of the database's **network security groups** (NSGs) to allow access to the Autonomous Database endpoint. For more information on private endpoint network configuration, see **Networking Prerequisites Needed for Private Endpoint**.

**About Downloading Client Credentials**

The client credentials .zip that you download contains the following files:

- **cwallet.sso** - Oracle auto-login wallet
- **ewallet.p12** - PKCS #12 wallet file associated with the auto-login wallet
- **sqlnet.ora** - SQL*Net profile configuration file that includes the wallet location and TNSNAMES naming method
- **tnsnames.ora** - SQL*Net configuration file that contains network service names mapped to connect descriptors for the local naming method
- **Java Key Store (JKS)** files - Key store files for use with JDBC Thin Connections

**Important:**

Wallet files, along with the database user ID and password, provide access to data in your Autonomous Database. Store wallet files in a secure location. Share wallet files only with authorized users. If wallet files are transmitted in a way that might be accessed by unauthorized users (for example, over public email), transmit the wallet password separately and securely.

For Autonomous Databases on **shared Exadata infrastructure**, you have the choice of downloading an **instance wallet** file or a **regional wallet** file. The instance wallet contains only credentials and keys for a single Autonomous Database. The regional wallet contains credentials and keys for all Autonomous Databases in a specified region. For security purposes, Oracle recommends that regional wallets be used only by database administrators, and that instance wallets be supplied to other users whenever possible.

For Autonomous Databases on **dedicated Exadata infrastructure**, the wallet file contains only credentials and keys for a single Autonomous Database.

**About Rotating Your Autonomous Database Wallet**

For Autonomous Databases on **shared Exadata infrastructure**, you can rotate an instance or regional wallet for security purposes. When your wallet rotation is complete, you will have a new set of certificate keys and credentials, and the old wallet's keys and credentials will be invalid. Rotating an instance wallet does not invalidate the regional wallet that covers the same database instance. Rotating a regional wallet affects all databases in the specified region. User session termination begins after wallet rotation completes, however this process does not happen immediately.
**Important:**

If you are rotating a wallet to address a security breach and need to reestablish all database connections immediately using the keys and credentials of your newly rotated wallet, stop and restart the database instance.

**Before You Begin**

The Autonomous Database is preconfigured to support Oracle Net Services (a TNS listener is installed and configured to use secure TCPS and client credentials.) The client computer must be prepared to use Oracle Net Services to connect to the Autonomous Database. Preparing your client includes downloading the client credentials. See the following links for steps you might have to perform before you access the client credentials and connection information for your Autonomous Database:

*Shared Exadata Infrastructure*

- Preparing for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections

* Dedicated Exadata infrastructure

- Preparing for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections
- Preparing for JDBC Thin Connections

**Using the Oracle Cloud Infrastructure Console**

To download a wallet for an Autonomous Database on shared Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Click DB Connection.
5. In the Download Client Credentials (Wallet) section, select the Wallet Type. You can choose to download an instance wallet or a regional wallet.
6. To obtain the client credentials, click Download Wallet.
   - You will be prompted to provide a password to encrypt the keys inside the wallet. The password must be at least 8 characters long and must include at least 1 letter and either 1 numeric character or 1 special character.
   - Save the client credentials zip file to a secure location. See About Downloading Client Credentials on page 1182 for information about the files included in the download.
7. Take note of or copy the TNS names or connection strings you need for your connection. See About Connecting to Autonomous Databases on page 1181 for information about making connections.

To download a wallet for an Autonomous Database on dedicated Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Click DB Connection.
5. Select the DB Connection option.
6. Click the DB Connection tab.
7. To obtain the client credentials, click Download.
   - You will be prompted to provide a password to encrypt the keys inside the wallet. The password must be at least 8 characters long and must include at least 1 letter and either 1 numeric character or 1 special character.
   - Save the client credentials zip file to a secure location. See About Downloading Client Credentials on page 1182 for information about the files included in the download.
8. Take note of or copy the TNS names or connection strings you need for your connection. See About Connecting to Autonomous Databases on page 1181 for information about making connections.

WHAT NEXT?

Connect to the database - Data Warehouse | Transaction Processing

To rotate the wallet of an Autonomous Database on shared Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Click DB Connection.
5. In the Download Client Credentials (Wallet) section, select the Wallet Type. You can choose to rotate an instance wallet or a regional wallet.
6. Click Rotate Wallet. A confirmation dialog will prompt you to enter the database name to confirm the rotation.
7. Enter the name of the database, then click Rotate Wallet.

The rotation takes a few minutes to complete.

To obtain access URLs for Oracle Application Express (APEX) and Oracle SQL Developer Web for an Autonomous Database on dedicated Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Select the Application Connection option.
5. Application URLs are displayed in plain text in the Application URL field. Copy the URL string using the Copy link.
6. Paste the URL into a browser running on a Compute instance that is inside of the VCN of the Autonomous Database. Alternately, you can use the URL with a compute instance that has a direct connection to the VCN of the Autonomous Database.

Using the API

Use the GenerateAutonomousDatabaseWallet API operation to download the client credentials for your Autonomous Database.

Use the UpdateAutonomousDatabaseWalletDetails API operation to rotate the wallet for your Autonomous Database.

Use the AutonomousDatabase API operation to get the access URLs for Application Express (APEX) and SQL Developer Web.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Backing Up an Autonomous Database Manually

This topic describes how to create manual backups of Autonomous Databases. You can use the Oracle Cloud Infrastructure Console or the API to perform these tasks.

Oracle Cloud Infrastructure automatically backs up your Autonomous Databases and retains these backups for 60 days. Automatic backups are weekly full backups and daily incremental backups. You can also create manual backups to supplement your automatic backups. Manual backups are stored in an Object Storage bucket that you create, and are retained for 60 days.
Prerequisites

- To create or manage Autonomous Database backups, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service. See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax.
- To create a manual backup for an Autonomous Database, you must first configure an Object Storage bucket to serve as a destination for your manual backups. See Setting Up a Bucket to Store Manual Backups for instructions.

Using the Console

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, find the database that you want to back up.
4. Click the name of the Autonomous Database to display the Autonomous Database details.
5. In the database details page, click Create Manual Backup.

   The create Manual Backup dialog box is displayed.

   a. If you have properly configured your database for manual backups, continue to step 6.
   b. If the database is not properly configured for manual backups, a message box informs you that you must first configure the database before you can create a manual backup. See Setting Up a Bucket to Store Manual Backups for instructions.
   c. Click Close, configure your database according to the instructions, and click Create Manual Backup again.
6. In the Create Manual Backup dialog box, enter a name for your backup. Avoid entering confidential information.
7. In the Create Manual Backup dialog box, click Create.

   Your backup may take several hours to complete, depending on the size of your database.

8. Optionally, you can check the state of your backup in the list of backups on the database details page. For some states, an information icon (i) is displayed to provide additional details regarding the state or ongoing operations like deletions. The backup has one of the following states:

   - Creating
   - Active
   - Deleting
   - Deleted
   - Failed

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage Autonomous Database backups:
Setting Up a Bucket to Store Manual Backups

You must create an Oracle Cloud Infrastructure Object Storage bucket to hold your Autonomous Database manual backups and configure your database to connect to it. This is a one-time operation.

To set up an object store and user credentials for your manual backups

Some of the steps in this procedure require you to connect to the database by using an Oracle Database client such as SQL Developer. See Connecting with Oracle SQL Developer (18.2 or later) for information and instructions on connecting to an Autonomous Transaction Processing database. See Connecting with Oracle SQL Developer (18.2 or later) for information and instructions on connecting to an Autonomous Data Warehouse database.

1. If you have not already done so, generate an auth token for the Oracle Cloud Infrastructure Object Storage user to access the bucket you create in the next step. See To create an auth token on page 2463 to learn how to do this. (You will need this auth token for the database credential you create in step 4.)

2. In the Oracle Cloud Infrastructure Console, create a bucket in your designated Object Storage Swift compartment to hold the backups.

For example, if your backup bucket is named "backup_database1", the URL would be:

```
Note:
When you create your bucket:
• Pick Standard as the storage tier. Manual backups are only supported with buckets created in the standard storage tier.
• Ensure that you use the database name, and not the display name, as the bucket name.
```

3. Using an Oracle Database client, log in to the database as the administrator set the database DEFAULT_BACKUP_BUCKET property to the URL of your Object Storage bucket. The format of the tenancy URL is https://swiftobjectstorage.region.oraclecloud.com/v1/object_storage_namespace/bucket_name.

   For example:

   ```
   ALTER DATABASE PROPERTY SET default_backup_bucket='https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/ansh8lvrlulzpz/backup_database1';
   ```

   In the example, the Object Storage namespace is ansh8lvrlulzpz.

   Tip:
   • To determine the Object Storage namespace string to use, click View Bucket in the actions (three dots) menu of the bucket you created in the previous step.
   • Do not include the bucket name in the URL.
   • Ensure that you follow the format indicated. Do not use a pre-authenticated request URL.

4. With the tenancy user and the auth token referenced in step 1, create the credential for your Oracle Cloud Infrastructure Object Storage account. Use DBMS_CLOUD.CREATE_CREDENTIAL to create the credential.

   For example:

   ```
   BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL(
   credential_name => 'DEF_CRED_NAME',
   username => 'db1_user@oracle.com',
   ```
password => '<auth_token>'
);
END;
/

For more information on creating this credential, see CREATE_CREDENTIAL Procedure.

5. Set the database property `default_credential` to the credential you created in the previous step.

For example:

```sql
ALTER DATABASE PROPERTY SET DEFAULT_CREDENTIAL = 'ADMIN.DEF_CRED_NAME';
```

To list the current value for the default bucket, run the following command:

```sql
SELECT PROPERTY_VALUE from database_properties WHERE PROPERTY_NAME='DEFAULT_BUCKET';
```

After completing these steps you can take manual backups any time you want.

**Manual Backup Notes**

Database configuration notes:

- If you previously configured manual backups using the `DEFAULT_BUCKET` property, you do not need to make any changes to perform manual backups with your existing configuration. In this case, the `DEFAULT_BUCKET` property is set to the value of Oracle Cloud Infrastructure Object Storage tenancy URL and the required bucket name is in the format of `backup_databasename`, where databasename is lowercase. However, Oracle recommends that you configure Autonomous Database for manual backups using the `DEFAULT_BACKUP_BUCKET` database property.
- If you previously configured Autonomous Database to use manual backups using the `DEFAULT_BUCKET` property and created backups, then after configuring the `DEFAULT_BACKUP_BUCKET` property to use a new manual backup bucket, the old manual backups in the old bucket are not available for restore. If you want to use the old backups then you must change the value of the `DEFAULT_BACKUP_BUCKET` property to specify the URL of the old manual backup bucket.
- If you previously configured Autonomous Database to use manual backups and you rename your Autonomous Database, then your backups will continue to work without changes.

Manual backup notes:

- Each manual backup creates a full backup on your Oracle Cloud Infrastructure Object Storage bucket and the backup can only be used by the Autonomous Database instance when you initiate a point-in-time-recovery.
- The retention period for manual backups is the same as for automatic backups, which is 60 days.
- While backing up a database, the database is fully functional. However, during the backup the lifecycle management operations, such as stopping the database, are not allowed.

**Restoring an Autonomous Database**

Autonomous Database

This topic describes how to restore an Autonomous Database from a backup. You can use the Oracle Cloud Infrastructure Console or the API to perform this task.

You can use any existing manual or automatic backup to restore your database, or you can restore and recover your database to any point in time in the 60-day retention period of your automatic backups. For point-in-time restores, you specify a timestamp, and your Autonomous Database decides which backup to use for the fastest restore.

**Note:**

Restoring Autonomous Database puts the database in the unavailable state during the restore operation. You cannot connect to a database in that state.
Prerequisites

To restore Autonomous Databases, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service. See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax.

Using the Oracle Cloud Infrastructure Console

To restore an Autonomous Database from a backup

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, find the database that you wish to restore.
4. Click the name of the Autonomous Database to display the database details.
5. Click the Restore button to open the restore dialog.
6. Click Select Backup.
7. Specify the date range for a list of backups to display.
8. Select the backup.
9. Click Restore.

To restore an Autonomous Database using point-in-time restore

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, find the database that you wish to restore.
4. Click the name of the Autonomous Database to display the database details.
5. Click the Restore button to open the restore dialog.
6. Click Specify Timestamp.
7. Enter a timestamp. Your Autonomous Database decides which backup to use for faster recovery. The timestamp input allows you to specify precision to the seconds level (YYYY-MM-DD HH:MM:SS GMT).
8. Click Restore.

Using the API

Use the RestoreAutonomousDatabase API operation to restore your Autonomous Database from a backup.

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Cloning an Autonomous Database

This topic describes how to clone an existing Autonomous Database using the Oracle Cloud Infrastructure Console or the API. You can use the cloning feature to create a point-in-time copy of your Autonomous Database for purposes such as testing, development, or analytics. To clone only the database schema of your source database, choose the metadata clone option.

Note:

- You can clone any existing Autonomous Database (including those provisioned with preview version software) using a preview version of Autonomous Database. However, preview-version databases cannot be
cloned using the regular (general-availability) Autonomous Database software.

- You cannot clone an Autonomous Database from one Autonomous Container Database to another Autonomous Container Database if one of the Autonomous Container Databases has different encryption management configured. Encryption management must be the same for both Autonomous Container Databases, either Oracle-managed or customer-managed.

### Clone Types

The clone feature offers the following types of Autonomous Database clones:

- **Full clone**: This option creates a database that includes the metadata and data from the source database.
- **Metadata clone**: This option creates a database that includes only the metadata from the source database.
- **Refreshable clone**: This option creates a clone that can be easily updated with changes from the source database. For information about creating and using refreshable clones, see Using Refreshable Clones with Autonomous Database.

### Clone Sources

You can use a running database to create a clone. For databases running on shared Exadata infrastructure, you can also use a backup as the source of your clone. When using a backup, you can select a listed backup to clone from, or create a point-in-time clone. Point-in-time clones contain all data up to a specified timestamp. The specified timestamp must be in the past.

**Note:**

When you create a clone from a backup, you must select a backup that is at least two hours old.

### Prerequisites

To clone an Autonomous Database, you must have the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

**Note:**

You can’t clone a database in a security zone to create a database that isn't in a security zone. This is true whether the source is a running database or a database backup. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

### Password Requirement for New Databases on Dedicated Exadata Infrastructure

When cloning a database on dedicated Exadata infrastructure, the password you set for the target database cannot be one of the three most recently used passwords of the source database.

### Using the Oracle Cloud Infrastructure Console

**Note:**

See Create a Refreshable Clone for an Autonomous Database Instance for instructions for creating a refreshable clone.

To clone an Autonomous Database to shared Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. If you are not already in the correct compartment, then choose one from the Compartment drop-down in the List Scope section that contains the database you want to clone.
3. In the list of Autonomous Databases, click the display name of the database you want to clone.

4. Go to More Actions, and then click Create Clone.

In the Create Autonomous Database Clone dialog, enter the following:

**Clone Type**
Select the type of clone you want to create. Choose either Full Clone or Metadata Clone.

**Clone Source**
The clone source selection allows you to specify whether the clone is created from a running database or from a database backup. Select one of the following options:

- **Clone from running database**: Creates a clone of a running database as it exists at the current moment.
- **Clone from a backup**: Creates a clone from a database backup. If you choose this option, select one of the following options:
  - **Specify a timestamp**: Creates a point-in-time clone.
  - **Select from a list of backups**: Creates a clone using all data from the specified backup. To limit your list of backups to a specific date range, enter the starting date in the From field and the ending date in the To field.

**Note:** You must select a backup that is at least 2 hours old, or the clone operation will fail.

**Database Information**

- **Compartment**: Your current compartment is the default selection.
- **Display Name**: A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
- **Database Name**: The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.
- **Choose database version**: Select a database version from the available versions.
- **CPU Core Count**: You can enable up to 128 cores for your Autonomous Database. The actual number of available cores is subject to your tenancy's service limits.

**Auto Scaling**: allows Autonomous Databases to automatically increase the number of CPU cores by up to three times the assigned CPU core count value, depending on demand for processing. The auto scaling feature reduces the number of CPU cores when additional cores are not needed. For databases with up to 42 assigned cores, you can increase the maximum number of cores available through auto scaling by increasing the CPU core count value.

**Note:**
The maximum number of cores that are available to any Autonomous Database database not using dedicated Exadata infrastructure is 128, regardless of whether auto scaling is enabled or not. This means that a database with a CPU core count of 64 could auto scale up to two times the assigned number of cores (2 x 64 = 128). A database with 42 cores (or fewer) could auto scale up to three times the assigned number (3 x 42 = 126). For billing purposes, the database service determines the average number of CPUs used per hour.

- **Storage**: Specify the storage you wish to make available to your Autonomous Database database, in terabytes. You can make up to 128 TB available. For full clones, the size of the source database determines the minimum amount of storage you can make available.
- **Enable Preview Version**: (This option only displays during periods when a preview version of Autonomous Database is available) Select this option to provision the database with an Autonomous Database preview version. Preview versions of Autonomous Database are made available for limited periods for testing.
purposes. Do not select this option if you are provisioning a database for production purposes or if you will need the database to persist beyond the limited availability period of the preview version.

**Administrator Credential**

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using an SQL client tool.

- Password cannot be one of the three most recently used passwords of the source database
- Contains from 12 to 30 characters
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark ("")
- Does not contain the string "admin", regardless of casing

**License Type**

The type of license you want to use for the Autonomous Transaction Processing database. Your choice affects metering for billing. You have the following options:

- **My Organization Already Owns Oracle Database Software Licenses**: This choice is used for the Bring Your Own License (BYOL) license type. If you choose this option, make sure you have proper entitlements to use for new service instances that you create.
- **Subscribe to New Database Software Licenses and the Database Cloud Service**: This is used for the License Included license type. With this choice, the cost of the cloud service includes a license for the Database service.

5. Click **Create Autonomous Database Clone**.

The Console displays the details page for the new clone of your database and the service begins provisioning the Autonomous Database. Note the following:

- The new clone displays the **Provisioning** lifecycle state until the provisioning process completes.
- The source database remains in the **Available** lifecycle state.
- Backups associated with the source database are not cloned for either the full clone or the metadata clone option.
- Oracle recommends that you evaluate the security requirements for the new database and implement them, as applicable. See Security Considerations on page 1153 for details.

**WHAT NEXT?**

- Modify the access control list
- Manage database users - Data Warehouse | Transaction Processing
- Load data into the database - Data Warehouse | Transaction Processing
- Connect applications that use the database - Data Warehouse | Transaction Processing
- Create APEX applications that use the database - Data Warehouse | Transaction Processing
- Register the database with Data Safe
- Set up Object Storage for manual backups
- Connect to the database

To clone an Autonomous Database to dedicated Exadata infrastructure

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. If you are not already in the correct compartment, then choose one from the **Compartment** drop-down in the **List Scope** section that contains the database you want to clone.
3. In the list of Autonomous Databases, click the display name of the database you want to clone.
4. Click **More Actions** to display a list of actions.
5. Click **Create Clone** to display the Create Autonomous Database Clone page.

In the **Clone Type** section, select the **type of clone** you want to create. Choose either **Full Clone** or **Metadata Clone**.

**Provide basic information for the Autonomous Database**

- **Create in Compartment**: Your current compartment is the default selection but you can select a different compartment in which to create the clone from the drop-down list.
- The name of the source database displays in the read-only **Source database name** field.
- **Display Name**: Enter a description or other information to identify the database clone. You can change the display name any time and it does not have to be unique. Avoid entering confidential information.
- **Database Name**: Enter a database name for the clone that contains only letters and numbers, begins with a letter, and does not exceed 14 characters. Avoid entering confidential information.
- **Autonomous Container Database in compartment**: You can choose to create the database clone in the same compartment and container database as the source database, or you can choose a different compartment by clicking **Change compartment**, and a different container database by choosing one from the drop-down list.

**Configure the database**

- **OCPU Count**: You can enable up to 92 cores for your cloned Autonomous Database.
- **Storage**: Specify the amount of storage, in terabytes, that you want to make available to your cloned Autonomous Database database, up to 128 TB. For full clones, the size of the source database determines the minimum amount of storage you can make available.

**Create administrator credentials**

Set the password for the Autonomous Database administrator user by entering a password that meets the following criteria.

- Password cannot be one of the three most recently used passwords of the source database
- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark ("")
- Does not contain the string "admin", regardless of casing

Use this password when accessing the service console and when using a SQL client tool.

6. Click **Create Autonomous Database Clone**.

The Console displays the details page for the new clone of your database and the service begins provisioning the Autonomous Database. Note the following:

- The new clone displays the **Provisioning** lifecycle state until the provisioning process completes.
- The source database remains in the **Available** lifecycle state.
- Backups associated with the source database are not cloned for either the full-clone or the metadata-clone option.
- Oracle recommends that you evaluate the security requirements for the new database and implement them, as applicable. See **Network Security Groups for Databases Resources That Use Private Endpoints** on page 1154 for details.

**WHAT NEXT?**

- Manage database users - Data Warehouse | Transaction Processing
- Load data into the database - Data Warehouse | Transaction Processing
- Create applications that use the database - Data Warehouse | Transaction Processing
- Connect to the database - Data Warehouse | Transaction Processing

**Using the API**

Use the **CreateAutonomousDatabase** API operation to clone an Autonomous Database.
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

**For More Information**

For information about optimizer statistics, resource management rules and performance data for a cloned database, see Using Oracle Autonomous Database on Shared Exadata Infrastructure, which has full product documentation for Autonomous Database.

**Maintenance Updates for Autonomous Databases with Shared Exadata Infrastructure**

Autonomous Databases perform maintenance updates and database patching for you. Your database remains available throughout the maintenance process. This topic describes Autonomous Database maintenance for shared Exadata infrastructure.

For information on maintenance for dedicated Exadata infrastructure, see Overview of Dedicated Exadata Infrastructure Maintenance on page 1196.

**Maintenance Duration**

For Autonomous Databases with shared Exadata infrastructure, Oracle performs regular maintenance updates that generally take no more than two hours.

**Checking the Scheduling of Maintenance Updates**

To see when your next scheduled maintenance update is, navigate to the Autonomous Database details page in the Console for the database you are interested in. The Next Maintenance metadata field displays the beginning and ending times of the next database maintenance. You can also use the GetAutonomousDatabase API operation to determine the time of your next maintenance update.

**Overview of Autonomous Database on Dedicated Exadata Infrastructure**

This topic describes the database system architecture, features, user roles and hardware shapes for Autonomous Database on dedicated Exadata infrastructure. For a general overview of Autonomous Databases that covers the basics common to both infrastructure options, see Overview of Autonomous Databases on page 1149.

**Database System Architecture Overview**

Autonomous Databases on dedicated Exadata infrastructure have a three-level database architecture model that makes use of Oracle multitenant database architecture.

**Database System Resource types**

Each level of the architecture model corresponds to one of the following resources types:

- An **Autonomous Exadata Infrastructure** resource. This is a hardware rack which includes compute nodes and storage servers, tied together by a high-speed, low-latency InfiniBand network and intelligent Exadata software. On dedicated Exadata infrastructure, you have exclusive use of the Exadata infrastructure and hardware on which your Autonomous Transaction Processing databases run.

For a list of the hardware and Oracle Cloud resource characteristics of Autonomous Exadata Infrastructure resources, see Characteristics of Autonomous Exadata Infrastructure Resources.
• An **Autonomous Container Database**, which provides a container for multiple user databases. This resource is sometimes referred to as a CDB, and is functionally equivalent to the multitenant container databases found in Oracle 12c and higher databases.

Multitenant architecture offers many advantages over non-CDB architecture. For example, it does the following:

• Allows you to easily manage multiple individual user databases
• Makes more efficient use of database hardware, as individual databases may use only a fraction of the server hardware capacity
• Allows for easier and more rapid movement of data and code
• Allows for easier testing, as development databases can be housed within the same container as production databases
• Allows for the separation of duties between database administrators, who manage only the individual Autonomous Database instances to which they are granted privileges, and fleet managers, who manage infrastructure resources and container databases.

• An **Autonomous Database**. You can create multiple Autonomous Databases within the same container database. This level of the database architecture is analogous to the pluggable databases (PDBs) found in non-Autonomous Exadata systems. Your Autonomous Database can be configured for either transaction processing or data warehouse workloads.

**Database System Resource Deployment Order**

You must create the dedicated Exadata infrastructure resources in the following order:

1. **Autonomous Exadata Infrastructure.** See [Creating an Autonomous Exadata Infrastructure Resource](#) on page 1198 for more information.

2. **Autonomous Container Database.** See [Creating an Autonomous Container Database](#) on page 1205 for more information.

3. **Autonomous Database.** See [Creating an Autonomous Database on Dedicated Exadata Infrastructure](#) on page 1167 for more information.

**Related Database System Resources**

Related resources and prerequisites include:

• A **Virtual Cloud Network (VCN)** and a **Subnet**, which you create using Oracle Cloud Infrastructure's Networking service. You must have at least one VCN and one subnet available to provision an Autonomous Database with dedicated Exadata infrastructure.

For more information, see the following topics:

• [Network Isolation](#) (from Fleet Administrator’s Guide to Oracle Autonomous Transaction Processing on Dedicated Exadata Infrastructure)

• [Networking Overview](#) on page 2748

• [To create a VCN](#) on page 2825

• [To create a subnet](#) on page 2825

• **Autonomous Backups**, created for you automatically by the Autonomous Database service. By default, backups are stored for 60 days. Using the Console, you can choose to change the retention period to 7, 15, or 30 days.

• **Manual Backups**. Optionally, you can create on-demand manual backups. Manual backups are subject to the retention policy you have in place for the Autonomous Container Database.

**User Roles**

Your organization may choose to split the administration of the Autonomous Database on dedicated Exadata infrastructure into the following roles:

• **Fleet Administrator**. Fleet administrators create, monitor and manage Autonomous Exadata Infrastructure and Autonomous Container Database resources. A fleet administrator must have permissions for using the networking
resources required by the dedicated Exadata infrastructure, and permissions to manage the infrastructure and container database resources.

See Fleet Administrator’s Guide to Oracle Autonomous Transaction Processing on Dedicated Exadata Infrastructure for a complete overview of the fleet administrator role.

- **Database Administrator.** Database administrators create, monitor and manage Autonomous Databases. They also create and manage users within the database. Database administrators must have permissions for using container databases, for managing Autonomous Transaction Processing databases and backups, and for using the related networking resources. For manual backups, they must have permissions to use the designated Object Storage bucket. At the time of provisioning an Autonomous Database, the administrator provides user credentials for the automatically created ADMIN account, which provides administrative rights to the new database.

See Using Oracle Autonomous Transaction Processing on Dedicated Exadata Infrastructure for a complete overview of the database administrator role.

- **Database User.** Database users are the developers who write applications that connect to and use an Autonomous Database to store and access the data. Database users do not need Oracle Cloud Infrastructure accounts. They gain network connectivity to and connection authorization information for the database from the database administrator.

### CPU Provisioning, CPU Scaling, and Storage Scaling

You can scale the CPU count and the storage capacity of the database at any time without impacting availability or performance. Autonomous Database on dedicated Exadata infrastructure does not currently support over-provisioning, the ability for multiple Autonomous Databases to share a single CPU core. Therefore, an Autonomous Exadata Infrastructure resource can currently support, across all its Autonomous Container Databases, up to as many Autonomous Databases as it has CPU cores. This maximum number will increase when Oracle Autonomous Database supports over-provisioning.

### Available Exadata Infrastructure Hardware Shapes

Oracle Cloud Infrastructure currently offers Autonomous Database with the following dedicated Exadata infrastructure system models and configurations:

- **System Models:** X7 and X8
- **Configurations:** quarter rack, half rack, and full rack

The subsections that follow provide the details for each shape's configuration.

**Exadata X8 Shapes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Quarter Rack</th>
<th>Half Rack</th>
<th>Full Rack</th>

**Using the Oracle Cloud Infrastructure Console to Manage Dedicated Exadata Infrastructure**

For information on provisioning, managing, and backing up dedicated Exadata infrastructure resources in the Oracle Cloud Infrastructure Console, see the following topics:

**For Database Fleet Administrators**
- Creating an Autonomous Exadata Infrastructure Resource on page 1198
- Creating an Autonomous Container Database on page 1205
- Managing an Autonomous Exadata Infrastructure Resource on page 1201
- Managing an Autonomous Container Database on page 1208
- Fleet Administrator’s Guide to Oracle Autonomous Database on Dedicated Exadata Infrastructure (complete fleet administrator guide)

**For Database Administrators**
- Creating an Autonomous Database on Dedicated Exadata Infrastructure on page 1167
- Managing an Autonomous Database on page 1169
- Connecting to an Autonomous Database on page 1181
- Backing Up an Autonomous Database Manually on page 1184
- Restoring an Autonomous Database on page 1187
- Using Oracle Autonomous Database on Dedicated Exadata Infrastructure (complete database administrator guide)

**Additional Information**

For known issues, see Known Issues for Oracle Autonomous Database on Dedicated Exadata Infrastructure.

**Overview of Dedicated Exadata Infrastructure Maintenance**

Autonomous Database systems on dedicated Exadata infrastructure have separate regularly scheduled maintenance runs for both Autonomous Exadata Infrastructure resources and Autonomous Container Databases. You can choose to set the scheduling for your maintenance runs, or let the system schedule maintenance. You can view the maintenance history for infrastructure instances and container databases in the Oracle Cloud Infrastructure Console. Additionally, one-off patching is available for certain resources on dedicated Exadata infrastructure when you file a service request for an eligible resource with My Oracle Support.
Autonomous Exadata Infrastructure Maintenance

Exadata infrastructure maintenance takes place at least once each quarter and is mandatory. You can schedule a maintenance window to control the time, day of the week, and week of the month for Exadata infrastructure maintenance. Exadata infrastructure maintenance patches the Exadata infrastructure (including patching of the Exadata grid infrastructure code and operating systems updates), and do not include database patching. Oracle notifies you about upcoming Exadata infrastructure maintenance in the weeks before quarterly Exadata infrastructure patching occurs. You can also view scheduled maintenance runs in the Oracle Cloud Infrastructure console. The following tasks explain how to view scheduled and past maintenance updates, and how to edit the maintenance schedule for an Exadata infrastructure instance:

- To configure the automatic maintenance schedule for an Autonomous Exadata Infrastructure resource on page 1201
- To view the next scheduled maintenance for an Autonomous Exadata Infrastructure resource on page 1202
- To view the maintenance history of an Autonomous Exadata Infrastructure resource on page 1202

You can use the GetMaintenanceRun, ListMaintenanceRun, and UpdateAutonomousExadataInfrastructure API operations to view details about scheduled and past maintenance updates, and to update the maintenance schedule of your infrastructure instance.

Autonomous Container Database Maintenance

Container database maintenance updates include Oracle Database software patches and take place at least once each quarter. You can configure a maintenance window to control the time, day of the week, and week of the month that your maintenance update run will begin. Otherwise, Oracle will schedule container database maintenance runs for you so that they are coordinated with the maintenance runs of the associated Exadata infrastructure.

- Tip:
  Container database maintenance runs must be scheduled to take place after quarterly Exadata infrastructure maintenance runs occur.

If a scheduled container database maintenance run cannot take place (because of changes made to infrastructure maintenance scheduling or other reasons), Oracle will automatically reschedule the container database maintenance for the following quarter. You can change your container database maintenance window or reschedule a single container database maintenance run to ensure that your container database maintenance runs follow infrastructure maintenance within the same quarter.

Autonomous Database offers two container database maintenance choices:

- Release Update (RU): Autonomous Database installs only the most current release update.
- Release Update Revision (RUR): Autonomous Database installs the release update plus additional fixes.

The following tasks explain how to view and edit maintenance updates information for Autonomous Container Databases:

- To configure the automatic maintenance schedule for an Autonomous Container Database on page 1209
- To view the maintenance history of an Autonomous Container Database on page 1210
- To reschedule or skip scheduled maintenance for an Autonomous Container Database on page 1210
- To configure the type of maintenance patching for an Autonomous Container Database on page 1209

Use the UpdateAutonomousContainerDatabase API operation to change the patching type for an Autonomous Container Database. Use the ListMaintenanceRun API operation to see past maintenance update information. Use the UpdateMaintenanceRun API operations to skip a container database maintenance update. You can skip maintenance runs for up to 2 consecutive quarters if needed.
Notifications for Maintenance of Autonomous Exadata Infrastructure and Autonomous Container Database Resources

Autonomous Database emits events for Autonomous Exadata Infrastructure and Autonomous Container Database maintenance runs. Using the Notifications service (which consumes events), you can create and subscribe to a Notifications topic, allowing you to receive notifications about your maintenance runs by email, PagerDuty alert, Slack, or https.

You can set up notifications based on the following events:

- A new maintenance run is scheduled
- A maintenance reminder email is sent
- A maintenance run begins
- A maintenance run ends.

See Getting Started with Events on page 1786 to learn about creating and subscribing to an Events topic. See Services that Produce Events for a full list of Database service events. See Managing Topics and Subscriptions on page 3356 to learn how to create and subscribe to a Notifications topic.

Managing One-off Patches as Part of Dedicated Exadata Infrastructure Maintenance

Oracle generates one-off patches when a user files a service request with My Oracle Support. If appropriate to resolve the service request, and Oracle and the user agree that a one-off patch is the best solution, then the service team generates a one-off patch and makes it available to the user that filed the service request. One-off patches are separate from scheduled maintenance patches.

If you enable Oracle Cloud Notifications and Oracle Cloud Events with a subscription to receive notifications regarding new updates, then when one-off patches become available, Oracle sends a notification that contains the OCID of the product to be patched. Otherwise, you can find the update in the My Oracle Support portal for the service request that you filed.

You can edit the scheduled start time or choose to install the one-off patch, immediately. By default, Oracle schedules a one-off patch to be applied within 72 hours of the patch becoming available and, if no action to change the schedule occurs, then the patch is automatically applied.

1. Copy the OCID from the notification and paste it into the Search field on the Oracle Cloud Infrastructure Console to navigate to the correct product.
2. On the product details page, in the Maintenance section, click the View link in the Next Maintenance field to display the Maintenance page for the product that you want to patch.
3. One-off patches are displayed in the Unplanned maintenance section and are denoted as one-off patches in the Type field. If the scheduled start time for the patch interferes with enterprise operations or is otherwise inconvenient, then click Edit to change the scheduled time to install the patch. Click Patch Now to immediately install the one-off patch.
4. Click Run Maintenance to start the patching operation.

Creating an Autonomous Exadata Infrastructure Resource

This topic describes how to provision an Autonomous Exadata Infrastructure resource for Autonomous Databases using the Oracle Cloud Infrastructure Console or the API. For an overview of dedicated Exadata infrastructure, see Overview of Autonomous Database on Dedicated Exadata Infrastructure on page 1193.

The infrastructure resource includes the physical Exadata hardware and intelligent Exadata software. Once you have provisioned an infrastructure instance, you can provision one or more Autonomous Container Databases to run on your infrastructure. To provision an Autonomous Database, you must have both an infrastructure resource and at least one container database available.

Note:

This topic is not applicable to Autonomous Databases on shared Exadata infrastructure.
Prerequisites

• To create an Autonomous Exadata Infrastructure resource, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

| Tip: |
| See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax. |

• You will also need a Virtual Cloud Network and a Subnet, which you create using Oracle Cloud Infrastructure's Networking service. For information on creating and managing these resources, see VCNs and Subnets on page 2821.

• If you are creating an Autonomous Exadata Infrastructure resource in a security zone compartment, your networking configuration must use a subnet that is also in a security zone compartment. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

Using the Oracle Cloud Infrastructure Console

To create an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Click Autonomous Exadata Infrastructure.
4. Click Create Autonomous Exadata Infrastructure.
5. In the Create Autonomous Exadata Infrastructure dialog, enter the following general information:
   • Compartment: Specify the compartment in which the Autonomous Exadata Infrastructure will be created.
   • Display Name: A user-friendly description or other information that helps you easily identify the infrastructure resource. The display name does not have to be unique. Avoid entering confidential information.
   • Availability Domain: Select an availability domain for the Autonomous Exadata Infrastructure.
   • System Model: Select a system model, either the X7 or X8. See Available Exadata Infrastructure Hardware Shapes on page 1195 for detailed information on available system models.
   • System Configuration: Select Quarter Rack, Half Rack, or Full Rack. Total available OCPUs and storage are displayed on the system configuration buttons. Total available OCPU and storage values are determined by the specified system model.
6. Enter the following network information:
   • Virtual cloud network compartment: The compartment containing the VCN you wish to use for the Autonomous Exadata Infrastructure. The default value is the user's current compartment. Click change compartment to select a VCN in a different compartment.
   • Virtual cloud network: The VCN in which to launch the Autonomous Exadata Infrastructure.
   • Subnet compartment: The compartment containing the subnet you wish to use for the Autonomous Exadata Infrastructure. The default value is the user's current compartment. Click change compartment to select a subnet in a different compartment.
   • Subnet: The subnet to which the Autonomous Exadata Infrastructure should attach.
   • Use network security groups to control traffic: Optional. You can specify up to five network security groups (NSGs) for your Autonomous Exadata Infrastructure resource by selecting this option. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your infrastructure resource. A maximum of five NSGs can be specified. To add an NSG, select the compartment containing the...
NSG using the **Network security group compartment** selector, then select the NSG itself using the **Network security group** selector.

For more information on creating and working with NSGs, see Network Security Groups on page 2841.

Note that if you choose a subnet with a security list, the security rules for the infrastructure resource will be a union of the rules in the security list and the NSGs.

7. Optionally, you can specify the date and start time for the Autonomous Exadata Infrastructure quarterly maintenance:

   a. Click **Modify Schedule**.
   b. In the Automatic Maintenance Schedule dialog, select **Specify a Schedule**.
   c. In the **Maintenance months** selector, specify at least one month for each quarter during which infrastructure maintenance will take place.
   d. For **Week of the Month**, select a week during the month that the maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. For example, to allow maintenance during the 2nd week of the month (from the 8th day to the 14th day of the month), use the value 2. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
   e. For **Day of the Week**, select the day of the week that the maintenance will take place.
   f. For **Start Hour**, select one of the six start time windows available. The maintenance will begin during the 4 hour time window that you specify and may continue beyond the end of the period chosen. The start time window is specified in universal coordinated time (UTC).
   g. Click **Update Maintenance Schedule**.

   **Tip:**

   Oracle recommends that you define the acceptable maintenance times for your Autonomous Exadata Infrastructure resources and Autonomous Container Databases. Doing so will prevent maintenance runs from occurring at times that would be disruptive to regular database operations.

8. Choose the license type you wish to use. Your choice affects metering for billing. You have the following options:
   - **Bring your own license**: If you choose this option, make sure you have proper entitlements to use for new service instances that you create.
   - **License included**: With this choice, the cost of the cloud service includes a license for the Database service.

9. The following **Advanced Options** are available:

   **Tags** - If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

10. Click **Create Autonomous Exadata Infrastructure**.

**WHAT NEXT?**

After creating an Autonomous Exadata Infrastructure resource, you can create one or more Autonomous Container Databases on your infrastructure. You must have provisioned both an infrastructure resource and at least one container database before you can create your first Autonomous Database in Oracle Cloud Infrastructure.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the LaunchAutonomousExadataInfrastructure API operation to create an Autonomous Exadata Infrastructure resource.
Managing an Autonomous Exadata Infrastructure Resource

This topic describes the Autonomous Exadata Infrastructure management tasks for Autonomous Databases that you complete using the Oracle Cloud Infrastructure Console or the API. Autonomous Databases use Autonomous Exadata Infrastructure resources on dedicated Exadata infrastructure. See Overview of Autonomous Database on Dedicated Exadata Infrastructure on page 1193 for more information.

**Note:**

This topic is not applicable to Autonomous Databases on shared Exadata infrastructure.

Using the Oracle Cloud Infrastructure Console

You can perform the following management operations on Autonomous Exadata Infrastructure resources in Oracle Cloud Infrastructure:

- Configuring the automatic maintenance schedule
- Rescheduling maintenance
- Viewing the next scheduled maintenance date and maintenance history
- Immediately patching an Autonomous Exadata Infrastructure
- Copying the Autonomous Exadata Infrastructure endpoint
- Terminating the Autonomous Exadata Infrastructure resource

**Tip:**

Oracle recommends that you define the acceptable maintenance times for your Autonomous Exadata Infrastructure resources and Autonomous Container Databases. Doing so will prevent maintenance runs from occurring at times that would be disruptive to regular database operations.

*To configure the automatic maintenance schedule for an Autonomous Exadata Infrastructure resource*

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure details page, under Maintenance, click the edit link in the Maintenance Schedule field.
6. In the Automatic Maintenance Schedule dialog, select Specify a schedule.
7. Under Maintenance months, specify at least one month for each maintenance quarter during which you want Autonomous Exadata Infrastructure maintenance to occur.

**Note:**

Maintenance quarters begin in February, May, August, and November, with the first maintenance quarter of the year beginning in February.

8. Under Week of the month, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
9. Under Day of the week, specify the day of the week on which the maintenance will occur.
10. Under Start hour, specify the hour during which the maintenance run will begin.
11. Click Update Maintenance Schedule.
To view the next scheduled maintenance for an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure details page, under Maintenance, click the view link in the Next Maintenance field.
6. On the Maintenance page, scheduled maintenance events are listed under the Regular Autonomous Exadata Infrastructure maintenance heading.

To reschedule maintenance of Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your compartment from the Compartment drop-down.
3. In the Dedicated Infrastructure section, click Autonomous Exadata Infrastructure.
4. In the list of Autonomous Exadata Infrastructures, click the display name of the Exadata infrastructure for which you want to reschedule maintenance.
5. On the Autonomous Exadata Infrastructure Details page, in the Maintenance section, click the View link in the Next Maintenance field.
6. The Maintenance page displays any Exadata infrastructure maintenance events planned for the next 15 days in the list of maintenance events.
7. To reschedule maintenance, click the Edit link in the Scheduled Start Time field to display the Edit Maintenance Start Time dialog.
8. Click the calendar icon and choose a date and time on which to run maintenance.
9. Click Save Changes.

To view the maintenance history of an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure details page, under Maintenance, click the view link in the Next Maintenance field.
6. On the Maintenance page, under Autonomous Database Maintenance, click History. In the list of past maintenance events, you can click on an individual event title to read the details of the maintenance that took place. Maintenance event details include the following:
   • The category of maintenance (quarterly software maintenance, hardware maintenance, or a critical patch)
   • Whether the maintenance was scheduled or unplanned
   • The OCID of the maintenance event. (Go to More Actions, then choose Copy OCID.)
   • The start time and date of the maintenance

To immediately patch an Autonomous Exadata Infrastructure

After you schedule maintenance for your Autonomous Exadata Infrastructures, you can patch the component, immediately, at any time before scheduled maintenance occurs. If you choose to patch your Autonomous Exadata Infrastructure, immediately, while another component is in the process of maintenance, then this maintenance operation gets queued and will begin, in turn.

1. Open the navigation menu. Under Database, click Autonomous Transaction Processing or Autonomous Data Warehouse.
2. Choose your compartment from the **Compartment** drop-down list.

3. In the **Dedicated Infrastructure** section, click **Autonomous Exadata Infrastructure** to display a list of Autonomous Exadata Infrastructures for your selected compartment.

4. Click the display name of the Autonomous Exadata Infrastructure that you want to patch.

5. On the Autonomous Exadata Infrastructure Details page, in the **Maintenance** section, click the **View** link in the **Next Maintenance** field to display the Maintenance page for the Autonomous Exadata Infrastructure that you want to patch.

6. In the **Autonomous Exadata Infrastructure** section, click the **Patch Now** link in the **Scheduled Start Time** field to display the **Run Maintenance** dialog.

7. Click **Run Maintenance** to start the patching operation.

---

**To view or copy the Autonomous Exadata Infrastructure endpoint**

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.

2. Choose your **Compartment**.

3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.

4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.

5. On the Autonomous Exadata Infrastructure Information tab, click **Show** or **Copy** in the **DB Infrastructure Endpoint Name field**.

---

**To manage security certificates in an Autonomous Exadata Infrastructure**

To maintain security compliance within an Autonomous Exadata Infrastructure, you must periodically rotate the security certificates for Oracle REST Data Services (ORDS) and Secure Sockets Layer (SSL).

**Note:**

Rotating the ORDS and SSL security certificates is not currently supported for Autonomous Exadata Infrastructure with Autonomous Data Guard enabled.

To rotate security certificates:

1. Open the navigation menu and click **Oracle Database**.

2. Click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.

3. Choose your compartment from the **Compartment** drop-down list.

4. In the **Dedicated Infrastructure** section, click **Autonomous Exadata Infrastructure** to display a list of Autonomous Exadata Infrastructures for your selected compartment.

5. Click the display name of the Autonomous Exadata Infrastructure for which you want to rotate security certificates.

6. Click **Manage Certificates** to display the **Manage Certificates** dialog.

7. Click either **Rotate ORDS Certificate** or **Rotate SSL Certificate**, depending on which operation you want to perform.

   If you are rotating the Oracle REST Data Services certificate, then click **Apply**.

   If you are rotating the SSL certificate, then you must enter the name of the Autonomous Exadata Infrastructure in which you are working to confirm the operation. Click **Apply**.

**Note:**

After you rotate an SSL certificate, you must download wallets for all of the Autonomous Databases in the Autonomous Exadata Infrastructure in which you are working.
To edit the network security groups (NSGs) for your Autonomous Exadata Infrastructure resource

Your Autonomous Exadata Infrastructure instance can use up to five network security groups (NSGs). Note that if you choose a subnet with a security list, the security rules for the infrastructure instance will be a union of the rules in the security list and the NSGs. For more information, see Network Security Groups on page 2841.

1. Open the navigation menu. Under Oracle Database, click Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. In the Network details, click the Edit link to the right of the Network Security Groups field.

To change an assigned NSG, click the drop-down menu displaying the NSG name, then select a different NSG.

To remove an NSG from your DB system, click the X icon to the right of the displayed NSG name.

7. Click Save.

To move an Autonomous Exadata Infrastructure resource to another compartment

Note:

- To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service on page 2240.
- If your Autonomous Exadata Infrastructure is in a security zone compartment, the destination compartment must also be in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you wish to move.
5. Click Move Resource.
6. Select the new compartment.
7. Click Move Resource.

For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment on page 1141.

To terminate an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. Go to More Actions, and then click Terminate.
6. Confirm that you wish to terminate your Autonomous Exadata Infrastructure in the confirmation dialog.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the UpdateAutonomousExadataInfrastructure API operation to configure the automatic maintenance schedule for your infrastructure resource.

Use the GetMaintenanceRun API to view the details of a maintenance run that is scheduled, in progress, or that has ended.

Use the ListMaintenanceRun API to get a list of maintenance runs in a specified compartment.

Use the ChangeAutonomousExadataInfrastructureCompartment API operation to move an Autonomous Exadata Infrastructure resource to another compartment.

Use the TerminateAutonomousExadataInfrastructure API operation to delete an Autonomous Exadata Infrastructure resource.

For More Information

Create and Manage Autonomous Exadata Infrastructure Resources (Fleet Administrator’s Guide to Oracle Autonomous Transaction Processing on Dedicated Exadata Infrastructure)

Creating an Autonomous Container Database

This topic describes how to provision a new Autonomous Container Database using the Oracle Cloud Infrastructure Console or the API. Container databases are only necessary for Autonomous Databases on dedicated Exadata infrastructure. For a brief overview, see Overview of Autonomous Database on Dedicated Exadata Infrastructure on page 1193.

Note:

This topic is not applicable to Autonomous Databases on shared Exadata infrastructure.

Prerequisites

• To create an Autonomous Container Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Tip:

See Let database and fleet admins manage Autonomous Databases on page 2151 for sample Autonomous Database policies. See Details for the Database Service on page 2240 for detailed information on policy syntax.

• To create an Autonomous Container Database, you must have an available Autonomous Exadata Infrastructure resource. For information on creating an infrastructure instance, see Creating an Autonomous Exadata Infrastructure Resource on page 1198.

• If you want to create your Autonomous Container Database in a security zone, the Autonomous Exadata Infrastructure that runs the container database must be in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

Using the Oracle Cloud Infrastructure Console

To create an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse or Autonomous Transaction Processing.

2. Under Dedicated Infrastructure, click Autonomous Container Database.
3. Click **Create Autonomous Container Database**.

4. In the **Create Autonomous Container Database** dialog, enter the following database information:
   - **Select a compartment**: Specify the compartment in which you want to create the container database, if different from the default.
   - **Display name**: Enter a description or other information that helps you identify the resource. The display name does not have to be unique. Avoid entering confidential information.
   - **Autonomous Exadata Infrastructure in compartment**: From the drop-down, choose an Autonomous Exadata Infrastructure for your container database. See Creating an Autonomous Exadata Infrastructure Resource on page 1198 for more information.
     
     You can change the compartment containing the Autonomous Exadata Infrastructure you want to use for your container database by clicking the **Change Compartment** link.

5. You can enable Autonomous Data Guard on your primary Autonomous Container Database to create a standby Autonomous Container Database.
   a. Select **Enable Autonomous Data Guard** to provision a peer Autonomous Container Database as a standby database.
   b. Select a compartment in which you want to provision a peer Autonomous Container Database from the **Select peer Autonomous Container Database compartment** drop-down.
   c. You can enter a display name in the **Peer Autonomous Container Database display name** field or accept the default display name. Avoid entering confidential information.
   d. Select a region in which you want to locate the peer Autonomous Container Database from the **Region** drop-down.
   e. Select an Autonomous Exadata Infrastructure to apply to the peer Autonomous Container Database.

   **Note:**
   You must provision the standby Autonomous Container Database with a different Autonomous Exadata Infrastructure from that of the primary database.

   You can change the compartment containing the Autonomous Exadata Infrastructure you want to use for your peer Autonomous Container Database by clicking the **Change Compartment** link.

   f. Select a protection mode for the peer Autonomous Container Database from the **Protection mode** drop-down:
      - **Maximum Availability**: Provides the highest level of data protection that is possible without compromising the availability of a primary database.
      - **Maximum Performance**: Provides the highest level of data protection that is possible without affecting the performance of a primary database. This is the default protection mode.

      See Oracle Data Guard Concepts and Administration for more information about protection modes.

   After you complete this task, the database you initially created is labeled in the Oracle Cloud Infrastructure console database list view as "Primary" and the peer database is labeled as "Standby".

6. Optionally, you can change the default scheduling and maintenance patching type for your Autonomous Container Database maintenance. The patch type choices are Release Update (RU) and Release Update Revision (RUR). The Release Update setting installs only the most current release update, while the Release Update Revision installs the release update plus additional fixes. For information about Release Updates (RUs) and Release Update Revisions (RURs), see Release Update Introduction and FAQ (Doc ID 2285040.1) in the My Oracle Support online help portal *(MOS login required)*.

   **Note:**
   - The patch type you choose for the primary Autonomous Container Database is also applied to the standby database.
   - Scheduled maintenance for a standby Autonomous Container Database must be between one and seven days before scheduled maintenance for a primary Autonomous Container Database.
7. Click **Show Advanced Options** to display the following:

- **Management**: Optionally, you can specify the backup retention policy, which controls the length of time you retain backups in the Autonomous Container Database. The choices are 7 days, 15 days, 30 days, and 60 days. The default setting is 60 days.

  \[
  \text{Note:} \\
  \text{The backup retention policy you specify also applies to the standby Autonomous Container Database.}
  \]

- **Encryption Key**: You can choose encryption based on either Oracle-managed encryption keys or encryption keys that you manage.

  If you choose encryption based on encryption keys that you manage, then you must have access to a valid encryption key.

  \[
  \text{Note:} \\
  \text{Customer-managed encryption keys are not applicable to Autonomous Data Guard-enabled Autonomous Container Databases.}
  \]

  - Select a vault that contains the encryption key you want to use. You can change the compartment containing the vault you want to use by clicking the **Change Compartment** link.
  - Select an encryption key. You can change the compartment containing the encryption key you want to use by clicking the **Change Compartment** link.

  \[
  \text{Note:} \\
  \begin{align*}
  &\text{You cannot change the vault or vault key once the Autonomous Container Database is provisioned.} \\
  &\text{Oracle supports using 256-bit and hardware security module (HSM) encryption keys for Autonomous Container Database encryption.}
  \end{align*}
  \]

  See **Managing Keys** on page 3962 for more information about encryption keys

- **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

8. Click **Create Autonomous Container Database**.

**WHAT NEXT?**

After creating an Autonomous Container Database, you can create one or more Autonomous Databases within the container database.

**To configure the Autonomous Container Database maintenance type and scheduling**

1. Click **Configure Maintenance**. In the **Edit Automatic Maintenance** dialog that opens, you can configure both the maintenance schedule and the patch type.

2. For **Maintenance Type**, select either **Release Update (RU)** or **Release Update Revision (RUR)**. Learn more.

3. To configure the maintenance schedule, select **Specify a schedule** in the **Configure the automatic maintenance schedule** section. Choose your preferred month, week, weekday, and start time for container database maintenance. Autonomous Container Database maintenance should be scheduled so that it follows after the maintenance scheduled for the associated Autonomous Exadata Infrastructure. To see the scheduling of the associated Autonomous Exadata Infrastructure, you can click **Show Autonomous Exadata Infrastructure maintenance schedule**. If you have not specified an infrastructure maintenance schedule (and Oracle is
scheduling infrastructure maintenance), your infrastructure maintenance will be scheduled to precede your container database maintenance.

- Under **Maintenance months**, specify at least one month for each quarter during which Autonomous Exadata Infrastructure maintenance will take place.
- Under **Week of the month**, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
- Under **Day of the week**, specify the day of the week on which the maintenance will occur.
- Under **Start hour**, specify the hour during which the maintenance run will begin.

4. Click **Save Changes**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the CreateAutonomousContainerDatabase API operation to create an Autonomous container database.

**Managing an Autonomous Container Database**

This topic describes the database management tasks for Autonomous Container Databases that you complete using the Oracle Cloud Infrastructure Console or the API. Container databases are used by Autonomous Databases on dedicated Exadata infrastructure. See Overview of Autonomous Database on Dedicated Exadata Infrastructure on page 1193 for more information.

**Note:**

This topic is not applicable to Autonomous Databases on shared Exadata infrastructure.

The following management operations can be performed on Autonomous Container Databases in Oracle Cloud Infrastructure:

- Edit the backup retention policy. By default, database backups are retained for 60 days. You have the option of retaining backups for 7, 15, 30, or 60 days. The current backup retention policy for an Autonomous Container Database is displayed on the Autonomous Container Database details page.
- Configure the type of database maintenance. You can choose to use Release Update (RU) or Release Update Revision (RUR) updates for your Autonomous Container Database maintenance. Release Update (RU): Autonomous Database installs only the most current release update. Release Update Revision (RUR): Autonomous Database installs the release update plus additional fixes.
  For information about Release Updates (RUs) and Release Update Revisions (RURs), see Release Update Introduction and FAQ (Doc ID 2285040.1) in the My Oracle Support online help portal (MOS login required).
- Configure the scheduling for your Autonomous Container Database.
- View the Autonomous Container Database next scheduled maintenance and maintenance history.
- Immediately patch an Autonomous Container Database.
- Skip a scheduled maintenance run. For container databases, you can skip maintenance runs for up to two consecutive quarters, if necessary.
- Edit the maintenance patch version of your Autonomous Container Database.
- Perform a rolling restart of databases within an Autonomous Container Database. You can perform a “rolling restart” on all the Autonomous Databases in an Autonomous Container Database to ensure that the current memory allocation is optimized. During a rolling restart, each node of an Autonomous Database is restarted separately while the remaining nodes continue to be available. No interruption of service occurs during a rolling restart. You cannot perform a container database restart if a backup is in progress.
- Rotate encryption keys for an Autonomous Container Database.
- Terminate an Autonomous Container Database. Note that you must terminate all Autonomous Databases within a container database before you can terminate the container database itself.
Using the Oracle Cloud Infrastructure Console

To set the backup retention policy for an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Under Autonomous Database, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under Backup, click the Edit link in the Backup Retention Field.
6. Specify a backup retention period from the list of choices.
7. Click Save Changes.

To configure the automatic maintenance schedule for an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Under Autonomous Database, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under Maintenance, click the edit link in the Maintenance Details field. In the Edit Automatic Maintenance dialog that opens, you can configure both the maintenance schedule and the patch type.
6. Optionally, you can change the maintenance patch type. To edit this setting, select either Release Update (RU) or Release Update Revision (RUR). Learn more.
7. To configure the maintenance schedule, select Specify a schedule in the Configure the automatic maintenance schedule section. Choose your preferred month, week, weekday, and start time for container database maintenance. Autonomous Container Database maintenance should be scheduled so that it follows after the maintenance scheduled for the associated Autonomous Exadata Infrastructure. To see the scheduling of the associated Autonomous Exadata Infrastructure, you can click Show Autonomous Exadata Infrastructure maintenance schedule. If you have not specified an infrastructure maintenance schedule (and Oracle is scheduling infrastructure maintenance), your infrastructure maintenance scheduling will be automatically modified so that it precedes your container database maintenance during each quarter.
   - Under Maintenance months, specify at least one month for each maintenance quarter during which you want Autonomous Exadata Infrastructure maintenance to occur.
   - Under Week of the month, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
   - Under Day of the week, specify the day of the week on which the maintenance will occur.
   - Under Start hour, specify the hour during which the maintenance run will begin.
8. Click Save Changes.

To configure the type of maintenance patching for an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Under Autonomous Database, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.

5. On the Autonomous Container Database details page, under Maintenance, click the Edit link in the Maintenance Details field.

6. In the Automatic Maintenance Schedule dialog, under Maintenance Type, select either Release Update (RU) or Release Update Revision (RUR).
   • Release Update (RU): Autonomous Database installs only the most current release update.
   • Release Update Revision (RUR): Autonomous Database installs the release update plus additional fixes.

7. Optionally, you can configure the automatic maintenance schedule as described in To configure the automatic maintenance schedule for an Autonomous Container Database on page 1209.

8. Click Save Changes.

To view the next scheduled maintenance run of an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Under Autonomous Database, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under Maintenance, click the View link in the Next Maintenance field.
6. On the Maintenance page, under Autonomous Database Maintenance, click Maintenance. In the list of maintenance events, you can the details of scheduled maintenance runs. Maintenance event details include the following:
   • The status of the scheduled maintenance run
   • The type of maintenance run (quarterly software maintenance or a critical patch)
   • The OCID of the maintenance event.
   • The start time and date of the maintenance

To view the maintenance history of an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. Under Autonomous Database, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
   a. On the Autonomous Container Database details page, under Maintenance, click the View link in the Next Maintenance field.
5. On the Maintenance page, under Autonomous Database Maintenance, click Maintenance History. In the list of past maintenance events, you can click on an individual event title to read the details of the maintenance that took place. Maintenance event details include the following:
   • The category of maintenance (quarterly software maintenance or a critical patch)
   • Whether the maintenance was scheduled or unplanned
   • The OCID of the maintenance event.
   • The start time and date of the maintenance

To reschedule or skip scheduled maintenance for an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the Autonomous Database section, click Autonomous Container Database.
4. In the list of Autonomous Container Databases, click the display name of the container database that you want to manage.
5. On the Autonomous Container Database details page, in the Maintenance section, click the View link in the Next Maintenance field.
6. On the Maintenance page, any container database maintenance events planned for the next 15 days will appear in the list of maintenance events.

To skip scheduled maintenance for a container database, click Skip.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot skip scheduled maintenance more than twice, consecutively.</td>
</tr>
</tbody>
</table>

To reschedule maintenance, click Edit and enter a start time for the update in the Edit Maintenance dialog. Make sure that your specified container database maintenance window is later in the quarter than your scheduled Exadata infrastructure maintenance.

To immediately patch an Autonomous Container Database

After you schedule maintenance for your Autonomous Container Databases, you can patch the component, immediately, at any time before scheduled maintenance occurs. If you choose to patch a Autonomous Container Database, immediately, while another component is in the process of maintenance, then this maintenance operation gets queued and will begin, in turn.

1. Open the navigation menu. Click Oracle Database, click Autonomous Transaction Processing or Autonomous Data Warehouse.
2. Choose your compartment from the Compartment drop-down.
3. In the Dedicated Infrastructure section, click Autonomous Container Database to display a list of Autonomous Container Databases for your selected compartment.
4. Click the display name of the Autonomous Container Database that you want to patch.
5. On the Autonomous Container Database Details page, in the Maintenance section, click the View link in the Next Maintenance field to display the Maintenance page for the Autonomous Container Database that you want to patch.
6. In the Autonomous Container Database section, click the Patch Now link in the Scheduled Start Time field to display the Run Maintenance dialog.
7. Click Run Maintenance to start the patching operation.

To edit the maintenance patch version of an Autonomous Container Database

You can select from a list of available patches of either maintenance type (release update or release update revision) to apply to your Autonomous Container Database during scheduled maintenance.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your compartment from the Compartment drop-down.
3. In the Autonomous Database section, click either Autonomous Container Database or Autonomous Exadata Infrastructure.
4. In the list of Autonomous Container Databases, click the display name of the container database that you want to manage. Alternatively, if you clicked Autonomous Exadata Infrastructure in the previous step, then click the name of the Exadata infrastructure that contains the Autonomous Container Database that you want to edit.
5. On the Autonomous Container Database details page or the Autonomous Exadata Infrastructure Details page, in the Maintenance section, click the View link in the Next Maintenance field.
6. On the Maintenance page, click the Edit link in the Version field to display the Edit Maintenance dialog.
7. Select the database version with which you want to patch your Autonomous Container Database.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• You must select a version that is later than the current version of the Autonomous Container Database.</td>
</tr>
</tbody>
</table>
• The list of available versions may contain both release update (RU) and release update revision (RUR) maintenance types. Your configured maintenance policy does not change if you choose a maintenance type other than that for which your Autonomous Container Database maintenance schedule is configured.

8. Click Save Changes.

To perform a rolling restart of databases within an Autonomous Container Database

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. Under Autonomous Database, click Autonomous Container Database.

4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.

5. On the Autonomous Container Database details page, click Restart.

6. In the confirmation dialog, type the name of the Autonomous Container Database.

7. Click Restart.

To move an Autonomous Container Database to another compartment

Note:

• To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service on page 2240.

• If your Autonomous Container Database is in a security zone, the destination compartment must also be in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your Compartment.

3. Under Autonomous Database, click Autonomous Container Database.

4. In the list of Autonomous Container Databases, click on the display name of the container database you wish to move.

5. Click Move Resource.

6. Select the new compartment.

7. Click Move Resource.

For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment on page 1141.

To rotate the encryption key for an Autonomous Container Database

Rotating the encryption key creates a new version of the vault key that replaces the current version of the vault key.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.

2. Choose your compartment from the Compartment drop-down.

3. In the Dedicated Infrastructure section, click Autonomous Container Database to display a list of Autonomous Container Databases for your selected compartment.

4. Click the display name of the database for which you want to rotate the encryption key to display the details page for that database.

5. Click Rotate Encryption Key to display a confirmation dialog.
6. Click **Rotate Key**.

**To rotate the encryption key for an Autonomous Database**

Rotating the encryption key creates a new version of the vault key that replaces the current version of the vault key.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your compartment from the **Compartment** drop-down.
3. Click the display name of the Autonomous Database for which you want to rotate the encryption key to display the details page for that database.

   **Note:**

   The Autonomous Database you choose must be on dedicated Exadata infrastructure and in an **Available** state.

4. Click the **More Actions** drop-down.
5. Click **Rotate Encryption Key** to display a confirmation dialog.
6. Click **Rotate Key**.

**To terminate an Autonomous Container Database**

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. In the **List Scope** section, if not already selected, then select the compartment that contains the Autonomous Container Database you want to terminate from the **Compartment** drop-down.
3. In the **Dedicated Infrastructure** section, click **Autonomous Container Database** to display a list of Autonomous Container Databases contained in the compartment.
4. Click the display name of the Autonomous Container Database that you want to terminate to display the details page for that database.
   
   If you want to terminate a standby Autonomous Container Database, then click the display name of the database you want to terminate that is labeled "Standby" to display the details page for that database.
5. Click **Terminate** to display a confirmation dialog.
6. You must enter the display name of the Autonomous Container Database to confirm that you want to terminate the database.

   **Note:**

   Terminating a standby Autonomous Container Database disables Autonomous Data Guard and affects high availability and disaster recovery for any associated peer Autonomous Container Databases.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **UpdateAutonomousContainerDatabase** API operation to perform the following management actions:

- Set the backup retention period for an Autonomous Container Database.
• Set the maintenance patching type of an Autonomous Container Database.

Use the UpdateMaintenanceRun API operation to skip a container database maintenance run.

Use the ListMaintenanceRun API to get a list of maintenance runs in a specified compartment. Can be used to see maintenance history and scheduled maintenance runs.

Use the RestartAutonomousContainerDatabase API operation to perform a rolling restart on a container database.

Use the ChangeAutonomousContainerDatabaseCompartment API operation to move a container database to another compartment.

Use the TerminateAutonomousContainerDatabase API operation to terminate a container database.

Managing a Standby Autonomous Container Database

Enabling Autonomous Data Guard on an Autonomous Container Database creates a standby (peer) Autonomous Container Database that provides data protection, high availability, and facilitates disaster recovery for the primary database.

Once the standby database is provisioned, you can perform various management tasks related to the standby database, including:

• Manually switching over a primary database to a standby database
• Manually failing over a primary database to a standby database
• Reinstating a primary database to standby role after failover
• Terminating a standby database

See

• Creating an Autonomous Container Database on page 1205 for information about enabling Autonomous Data Guard
• To terminate an Autonomous Container Database

Autonomous Data Guard-enabled databases are identified in the Oracle Cloud Infrastructure console as "Primary" and "Standby" depending on the role assigned to a given database, and the status of Autonomous Data Guard is displayed in the Autonomous Data Guard column.

When you view the details page of a particular Autonomous Container Database, the Autonomous Data Guard section displays the status of Autonomous Data Guard and the state of the peer database associated with the database you are viewing. Additionally, in the Resources section of the details page, you can click Autonomous Data Guard to view Autonomous Data Guard configuration details and information, such as transport lag and apply lag, for peer Autonomous Container Databases.

Using the Oracle Cloud Infrastructure Console

Use the Oracle Cloud Infrastructure console to perform the following Autonomous Data Guard management tasks.

To switch over a primary database to a standby database

When you switch a primary Autonomous Container Database over to a standby Autonomous Container Database, you change the roles of the respective databases.

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. If you are not already in the compartment that contains the Autonomous Container Database you want to switch over, then choose the appropriate compartment from the Compartment drop-down in the List Scope section.
3. In the Dedicated Infrastructure section, click Autonomous Container Database to display a list of Autonomous Container Databases for the compartment. Peer databases are labeled as "Primary" and "Standby" in the list.
4. Click the display name of the Autonomous Container Database you want to switch to display the details page for that database.
5. In the **Resources** section click **Autonomous Data Guard Associations** to display a list of peer databases for the Autonomous Container Database you are managing.

The state of each of the databases must be **Available** to perform a switchover.

6. Click the ellipse in the **Created** column and click **Switchover**.

The states of the peer databases become **Role Change in Progress...** until the switchover action is complete.

At the conclusion of the operation, the respective roles of the two Autonomous Container databases change. The primary database assumes the standby role and the standby database assumes the primary role.

*To fail over a primary database to a standby database*

In the event that a primary Autonomous Container Database becomes unavailable, you can fail over the primary database to the standby Autonomous Container Database.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.

2. If you are not already in the compartment that contains the Autonomous Container Database you want to switch over, then choose the appropriate compartment from the **Compartment** drop-down in the **List Scope** section.

3. In the **Dedicated Infrastructure** section, click **Autonomous Container Database** to display a list of Autonomous Container Databases for the compartment. Peer databases are labeled as "Primary" and "Standby" in the list.

4. Click the display name of the standby Autonomous Container Database associated with the primary Autonomous Container Database that you want to fail over to display the details page for that database.

5. In the **Resources** section click **Autonomous Data Guard Associations** to display a list of peer databases for the primary database you are managing.

6. For the primary Autonomous Container Database you are failing over, click the ellipse in the **Created** column and click **Failover**.

7. Confirm that you want to perform the failover operation.

**Caution:**

Fail over to a standby Autonomous Container Database only in the event of a catastrophic failure of the primary database, when there is no possibility of recovery. Failover can result in data loss, depending on the protection mode in effect at the time the primary database fails.

The states of the peer databases become **Role Change in Progress...** until the failover action is complete.

At the conclusion of the operation, the respective roles of the two Autonomous Container databases change. The primary database is labeled as "Disabled Standby" and the standby database assumes the primary role.

*To reinstate a primary database to its former standby role*

After a failover has occurred and the failed primary Autonomous Container Database assumes a disabled, standby role, you can reinstate the failed database to an enabled, standby role.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse, Autonomous JSON Database**, or **Autonomous Transaction Processing**.

2. If you are not already in the compartment that contains the Autonomous Container Database you want to switch over, then choose the appropriate compartment from the **Compartment** drop-down in the **List Scope** section.

3. In the **Dedicated Infrastructure** section, click **Autonomous Container Database** to display a list of Autonomous Container Databases for the compartment. The primary database that you failed over is labeled as "Disabled Standby" in the list.

4. Click the display name of the disabled standby Autonomous Container Database that you want to reinstate.

5. In the **Resources** section click **Autonomous Data Guard Associations** to display a list of peer databases for the primary database you are managing.
6. For the Autonomous Container Database you are reinstating, click the ellipsis in the **Created** column and click **Reinstate**.

   The states of the peer databases become **Role Change in Progress**... until the reinstate action is complete.

At the conclusion of the operation, the role of the original primary database changes from disabled standby to standby. You can now perform a switchover operation to revert the respective databases to their original roles.

See **To manually switch over a primary database to a standby database**

**Autonomous Database Tools**

**Autonomous Database Development and Administration Tools**

This topic describes the Oracle Database tools available for Autonomous Database using the Console and how to access them using the Console. The following tools can be accessed directly from the Oracle Cloud Infrastructure Console:

- **Oracle Database Actions** on page 1216
- **Oracle Application Express** on page 1217
- **Oracle Machine Learning User Administration** on page 1217 (available on shared Exadata infrastructure only)

**Tip:**

Autonomous Database supports a range of other Oracle and third-party tools and applications. See **Autonomous Data Warehouse Tools and Application Test Matrix** to learn about other tools you can use with your Autonomous Database.

For Autonomous Databases on shared Exadata infrastructure, additional tools can be accessed through the **Service Console**.

**Oracle Database Actions**

Database Actions is a web-based interface that uses Oracle REST Data Services to provide development, data tools, administration and monitoring features for Oracle Autonomous Database. Database is available for databases with both the dedicated Exadata infrastructure and shared Exadata infrastructure deployment options.

The main features of are:

**Development**

- **SQL**: Enter and execute SQL and PL/SQL commands, and create database objects.
- **Data Modeler**: Create diagrams from existing database schemas, generate DDL statements, and create reports.
- **APEX**: Link to the Oracle Application Express sign-in page. Application Express is a rapid web application development platform for the Oracle database.
- **REST**: Develop RESTful web services and ensure secure access.
- **JSON**: Manage and query JSON collections. JSON is available only if you are signed in as a database user with the SODA_APP role.

**Data Tools**

- **Data Load**: Load or access data from local files or remote databases.
- **Catalog**: Understand data dependencies and the impact of changes.
- **Data Insights**: Discover anomalies, outliers, and hidden patterns in your data.
- **Business Models**: Create business models for performance and analysis.
- **Data Transforms**: Design your data flows and workflows graphically. Data Transforms is available only to an Oracle Data Integrator on Oracle Cloud Marketplace user that has connectivity enabled from Database Actions in the Oracle Data Integrator user interface.

Administration

- **Database Users**: Perform user management tasks such as create, edit, and REST enable users. Database Users is available only if you are signed in as a database user with administrator rights.

Monitoring

- Monitor database activity and performance using various tools. Monitoring is available only on dedicated Exadata infrastructure and only if you are signed in as a database user with administrator rights.

Complete product information can be found in About Database Actions.

Oracle Application Express

Oracle Application Express (APEX) is a low-code development platform that enables you to build scalable, secure enterprise applications with world-class features that can be deployed anywhere. APEX provides you with an easy-to-use browser-based environment to load data, manage database objects, develop REST interfaces, and rapidly build applications for both desktop and mobile devices.

Oracle Application Express is available for databases with both the dedicated Exadata infrastructure and shared Exadata infrastructure deployment options.

See Oracle Application Express

For complete information, see the APEX topics in the Autonomous Transaction Processing and the Autonomous Data Warehouse user guides. Use the following links:

- Using Oracle Autonomous Transaction Processing
- Using Oracle Autonomous Data Warehouse

Oracle Machine Learning User Administration

Oracle Machine Learning is a collaborative web-based interface that provides a development environment to create data mining notebooks where you can perform data analytics, data discovery and data visualizations. Using the Oracle Cloud Infrastructure Console, you can quickly get to the Oracle Machine Learning User Administration interface to create and manage users.

Machine Learning is currently available for databases with shared Exadata infrastructure only.

Using the Oracle Cloud Infrastructure Console

For Autonomous Databases on Shared Exadata Infrastructure

To access Oracle Database Actions

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you want to work with.
4. Click the Tools tab on the Autonomous Database Details page.
5. Click Open Database Actions

To access Oracle Application Express from an Autonomous Database

To access the Oracle Application Express (Oracle APEX) development environment from an Autonomous Database with the APEX workload type:

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Click Autonomous Database to display a list of Autonomous Databases of all workload types.
3. If you are not in the correct compartment, then select the compartment from the Compartment drop-down that contains the database for which you want to change the workload type.
4. Click the display name of the Autonomous Database of APEX workload type from which you want to access Oracle Application Express to display the Autonomous Database Details page for that database.
5. Click the **Tools** tab to display administration and developer tools available for the database.

6. Click **Open APEX** to access the Oracle APEX sign-in page.

   Additionally, you can access Oracle APEX from the APEX Instance details page, as follows:
   
   a. On the Autonomous Database Details page click the instance name in the **APEX Instance** section.
   
   b. Click **Launch APEX**.

7. Sign into Oracle APEX using the ADMIN password for the Autonomous Database.

**WHAT NEXT?**

- Create an APEX Workspace - Data Warehouse | Transaction Processing
- Access APEX App Builder - Data Warehouse | Transaction Processing
- Use web services with APEX - Data Warehouse | Transaction Processing

**To switch between database details and Oracle APEX instance details**

When you create an Autonomous Database of the APEX workload type, you create a database instance that is optimized for working with Oracle Application Express (Oracle APEX). Oracle APEX-related activities are displayed on a details page separate from that of the database.

To view the Oracle APEX instance details page:

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Click **Autonomous Database** to display a list of Autonomous Databases of all workload types.
3. If you are not in the correct compartment, then select the compartment from the **Compartment** drop-down that contains the database for which you want to view the details.
4. Click the display name of the Autonomous Database of APEX workload type to display the Autonomous Database Details page for that database.
5. In the **APEX Instance** section, click the instance name link to display the APEX Instance Details page.

You can switch back to the database details page by clicking the database name in the **APEX Instance Information** tab.

**To access Oracle Machine Learning's User Administration Interface**

To use Oracle Machine Learning with your Autonomous Database, you must first create a user account within the application. The following steps explain how to navigate to the User Administration interface for Machine Learning from the Autonomous Database details page within the Console.

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you want to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open Oracle ML User Administration**

**For Autonomous Databases on Dedicated Exadata Infrastructure**

The Console provides access URLs for Application Express (APEX) and SQL Developer Web that you can use to connect to these applications. The URLs only work from browsers within the same VCN as the Autonomous Database being accessed by the applications. Therefore, to use these URLs, you will need to open a browser running on a computer that meets one of the following conditions:

- The computer is a Compute instance is provisioned in the VCN of the Autonomous Database.
- The computer has a direct connection to the VCN of the Autonomous Database

To access APEX or SQL Developer Web, paste the appropriate access URL into the browser's address field, and then provide the Autonomous Database username and password when prompted. For more information on APEX, see the APEX documentation. For more information on SQL Developer Web, see Oracle SQL Developer Web.
The following tasks explain how to obtain an access URLs for APEX and SQL Developer Web.

To obtain the access URL for Oracle Database Actions for an Autonomous Database on dedicated Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you want to work with.
4. Click the Tools tab on the Autonomous Database Details page.
5. Click Open Database Actions

To obtain the access URLs for Oracle Application Express (APEX) for an Autonomous Database on dedicated Exadata infrastructure

1. Open the navigation menu. Under Oracle Database, click Autonomous Data Warehouse, Autonomous JSON Database, or Autonomous Transaction Processing.
2. Choose your Compartment.
3. In the list of Autonomous Databases, click on the display name of the database you want to work with.
4. Click the Tools tab on the Autonomous Database Details page.
5. Click Open APEX

Using Your Autonomous Database

The topics listed in this section provide detailed information and instructions on how to use your Autonomous Database database on shared Exadata infrastructure and dedicated Exadata infrastructure.

<table>

Overview of the Always Free Autonomous Database

Oracle Cloud Infrastructure's Always Free Autonomous Database is part of Oracle Cloud Infrastructure's Free Tier of services. You can provision up to two Always Free Autonomous Databases in the home region of your tenancy. These databases are provided free of charge, and they are available to users of both free and paid accounts. You can use these Autonomous Databases for small-scale applications, for development, or testing purposes, or for learning about and exploring Oracle Cloud Infrastructure.

Always Free Autonomous Database versions

Always Free Autonomous Databases support only a single Oracle Database version.

- You can see only the installed Always Free database version on the details page.
- If your Always Free database is not the latest version, Oracle automatically migrates it to the latest version at a preselected date about which you will be notified several weeks in advance. You can also update the database by selecting the version on the database details page. See To create an Always Free Autonomous Database on page 1159 for more information.

Note:

- You can provision Autonomous Databases only in your Home Region.
- Not all regions support the same database version. The supported version may be 19c-only or 21c-only, depending on the region.
- You cannot create an Always Free Autonomous Database in any Home Region where Always Free Autonomous Databases are not supported. To learn which regions support them, see Data Regions for Platform and Infrastructure Services.

Always Free Autonomous Database Specifications

- **Processor:** 1 Oracle CPU processor (cannot be scaled)
- **Memory:** 8 GB RAM
- **Database Storage:** 20 GB storage (cannot be scaled)
- **Workload Type:** Your choice of either the transaction processing or data warehouse workload type
  - The **Autonomous Transaction Processing** workload type configures the database for a transactional workload, with a bias towards high volumes of random data access.
    - For a complete product overview of Autonomous Transaction Processing, see Autonomous Transaction Processing. For Autonomous Transaction Processing tutorials, see Quick Start tutorials.
  - The **Autonomous Data Warehouse** workload type configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
    - For a complete product overview of Autonomous Data Warehouse, see Autonomous Data Warehouse. For Autonomous Data Warehouse tutorials, see Quick Start tutorials.
- **Database Version:** Oracle Database 19c or Oracle Database 21c.
- **Infrastructure Type:** Shared Exadata infrastructure
- **Maximum Simultaneous Database Sessions:** 20

Lifecycle for Always Free Autonomous Databases

After provisioning, you can continue using your Always Free Autonomous Database for as long as you want at no charge. You can terminate the database at any time.

Lifecycle Management for Inactive Always Free Autonomous Databases

If your Always Free Autonomous Database has no activity for a period of 7 consecutive days, the Database service will stop the database automatically. If this happens, restart the database and continue using it. If your Always Free Autonomous Database remains in a stopped state for 3 consecutive months, the database will be reclaimed (automatically terminated) by the Database service.
Using Events and Notifications to Stay Informed About Inactive Always Free Autonomous Databases

You can use Oracle Cloud Infrastructure's Events service to send structured JSON messages about your Always Free Autonomous Database lifecycle events to applications used for automation. For example, you can create automatic email, Slack, PagerDuty, or HTTPS notifications (using the Notifications service) to be alerted if a database is going to be stopped or terminated in the next 48 hours. You can also set up notifications to be alerted when a database is automatically stopped or and terminated.

See the following topics for more information:

- Getting Started with Events on page 1786 for details on working with Events messages.
- Autonomous Database Event Types for details on the currently available Always Free Autonomous Database lifecycle events messages.
- How Notifications Works for an overview of setting up automated notifications based on the JSON messages emitted by the Events service.

Exadata Cloud Service

Exadata Cloud Service allows you to leverage the power of Exadata in the cloud. You can provision flexible X8M systems that allow you to add database compute servers and storage servers to your system as your needs grow. X8M systems offer RDMA over Converged Ethernet (RoCE) networking for high bandwidth and low latency, persistent memory (PMEM) modules, and intelligent Exadata software. X8M systems can be provisioned using an shape equivalent to a quarter rack X8 system, and then database and storage servers can be added at any time after provisioning. For more information on X8M systems, see Overview of X8M Scalable Exadata Infrastructure on page 1227.

X8 and X7 systems are also available in fixed-shapes (quarter, half, and full rack systems). These systems use InfiniBand networking, and do not have the ability to scale database and storage servers. You can also provision an Exadata base system, which has a smaller capacity than a quarter rack system.

For all Exadata Cloud Service instances, you can configure automatic backups, optimize for different workloads, and scale the OCPU and storage allocations as needed.

Note:

Exadata Cloud Service instances launched on or after March 14, 2019 run Oracle Linux 7. Previously launched systems are running Oracle Linux 6. See OS Updates on page 1274 for important information about updating existing Exadata DB system operating systems.

Supported Database Edition and Versions

Exadata Cloud Service instances require Enterprise Edition - Extreme Performance. This edition provides all the features of Oracle Database Enterprise Edition, plus all the database enterprise management packs and all the Enterprise Edition options, such as Oracle Database In-Memory and Oracle Real Application Clusters (RAC).

Exadata Cloud Service instances support the following software releases:

- Oracle Database 19c (19.0)
- Oracle Database 18c (18.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)
- Oracle Database 11g Release 2 (11.2)

Note:

- If you plan to run Oracle Database 19c on a cloud VM cluster or DB system in the Exadata Cloud Service, you must specify version 19c when you create the resource. Earlier database versions are supported on a 19c cloud VM cluster or DB system, and can be created at anytime.
Cloud VM clusters and DB systems created with earlier Oracle Database versions will not automatically support Oracle Database 19c.

- For information on upgrading an existing 18c or earlier database to Oracle Database 19c, see Upgrading Exadata Databases on page 1301.

Subscription Types

The only subscription type available for Exadata Cloud Service instances is the Monthly Flex purchase model under Universal Credit Pricing. See the Universal Credit Pricing FAQ for more information.

Metering Frequency and Per-Second Billing

For each Exadata Cloud Service instance you provision, you are billed for the infrastructure for a minimum of 48 hours, and then by the second after that. Each OCPU you add to the system is billed by the second, with a minimum usage period of 1 minute. For X8M systems, if you terminate the cloud VM cluster and do not terminate the cloud Exadata infrastructure resource, billing will continue for the infrastructure resource.

Scaling Options

Three kinds of scaling operations are supported for an Exadata Cloud Service:

- For all Exadata Cloud Service instances, you can scale the compute node processing power within the provisioned system, adding or subtracting CPU cores as needed.
- For X8M systems, the flexible shape allows you to add additional database and storage servers to the cloud Exadata infrastructure resource as you need them.
- For X6, X7 and X8 Exadata DB systems, you can scale by moving the system to a different shape configuration, for example, from a quarter rack to a half rack.

For more information on each type of scaling, see Scaling an Exadata Cloud Service Instance on page 1229.

Scaling CPU Cores Within an Exadata Cloud Service Instance

If an Exadata Cloud Service instance requires more compute node processing power, you can scale up the number of enabled CPU cores symmetrically across all the nodes in the system as follows:

**X8M flexible infrastructure systems:** You can scale CPU cores in multiples of the number of database servers currently provisioned for the cloud VM cluster. For example, if you have 6 database servers provisioned, you can add CPU cores in multiples of 6. At the time of provisioning, X8M systems have 2 database servers. For more information on adding compute and storage resources to an X8M system, see Scaling Exadata X8M Compute and Storage on page 1230.

**Non-X8M fixed-shape systems:** For a base system or an X7 or X8 quarter rack, you can scale in multiples of 2 across the 2 database compute nodes. For an X7 or X8 half rack, you can scale in multiples of 4 across the 4 database compute nodes. For an X7 or X8 full rack, you can scale in multiples of 8 across the 8 database compute nodes.

For a non-metered service instances, you can temporarily modify the compute node processing power (bursting) or add compute node processing power on a more permanent basis. For a metered service instance, you can simply modify the number of enabled CPU cores.

You can provision an Exadata Cloud Service instance with zero CPU cores, or scale the service instance down to zero cores after you provision it. With zero cores, you are billed only for the infrastructure until you scale up the system. For detailed information about pricing, see Exadata Cloud Service Pricing.

Tip:

OCPUs scaling activities are done online with no downtime.

For information on CPU cores per configuration, see Exadata Shape Configurations on page 1223. To learn how to scale a system, see To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system on page 1258.
Scaling X6, X7 and X8 Exadata DB System Configurations

Scaling an Exadata X6, X7, or X8 Exadata Cloud Service instance by moving to a shape with more capacity enables you to meet the needs of your growing workload. This is useful when a database deployment requires:

- Processing power that is beyond the capacity of the current system configuration.
- Storage capacity that is beyond the capacity of the current system configuration.
- A performance boost that can be delivered by increasing the number of available compute nodes.
- A performance boost that can be delivered by increasing the number of available Exadata Storage Servers.

You can move your workloads to a larger fixed shape (X7 and X8 hardware shapes), or move to the flexible X8M shape that allows for easy expansion of compute and storage resources as your workloads grow.

To assist with moving your database deployments between Exadata Cloud Service instances, you can restore a backup to a different service instance that has more capacity, or create a Data Guard association for your database in a service instance with more capacity, and then perform a switchover so that your new standby database assumes the primary role. To start the process, contact Oracle and request a service limit increase so that you can provision the larger service instance needed by your database.

Exadata Shape Configurations

Each Exadata Cloud Service instance consists of compute nodes and storage servers. The compute nodes are each configured with a Virtual Machine (VM). You have root privilege for the compute node VMs, so you can load and run additional software on them. However, you do not have administrative access to the Exadata infrastructure components, including the physical compute node hardware, network switches, power distribution units (PDUs), integrated lights-out management (ILOM) interfaces, or the Exadata Storage Servers, which are all administered by Oracle.

For X8M systems, the Exadata hardware is administered through two resource types, the cloud Exadata infrastructure resource and the cloud VM cluster. See The New Exadata Cloud Service Resource Model on page 1228 for more details.

For X6, X7, and X8 systems, the Exadata hardware is administered through the DB system resource.

For all hardware models, you have full administrative privileges for your databases, and you can connect to your databases by using Oracle Net Services from outside the Oracle Cloud Infrastructure. You are responsible for database administration tasks such as creating tablespaces and managing database users. You can also customize the default automated maintenance set up, and you control the recovery process in the event of a database failure.

For full details on the available shape configurations, see Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base on page 1351

Customer-Managed Keys in Exadata Cloud Service

Customer-managed keys for Exadata Cloud Service is a feature of Oracle Cloud Infrastructure Vault service that enables you to encrypt your data using encryption keys that you control. The Vault service provides you with centralized key management capabilities that are highly available and durable. This key-management solution also offers secure key storage using isolated partitions (and a lower-cost shared partition option) in FIPS 140-2 Level 3-certified hardware security modules, and integration with select Oracle Cloud Infrastructure services. Use customer-managed keys when you need security governance, regulatory compliance, and homogenous encryption of data, while centrally managing, storing, and monitoring the life cycle of the keys you use to protect your data.

You can:

- Enable customer-managed keys when you create databases in Exadata Cloud Service
- Switch from Oracle-managed keys to customer-managed keys on databases that are not enabled with Oracle Data Guard
- Rotate your keys to maintain security compliance

Related Topics

### Storage Configuration

When you launch an Exadata Cloud Service instance, the storage space inside the Exadata storage servers is configured for use by Oracle Automatic Storage Management (ASM). By default, the following ASM disk groups are created:

- The DATA disk group is intended for the storage of Oracle Database data files.
- The RECO disk group is primarily used for storing the Fast Recovery Area (FRA), which is an area of storage where Oracle Database can create and manage various files related to backup and recovery, such as RMAN backups and archived redo log files.
- The `/acfs` file systems contain system files that support various operations. You should not store custom files, Oracle Database data files, or backups inside the ACFS disk groups. Custom ACFS mounts can be created using the DATA ASM disk group for files that are not service-related.

The disk group names contain a short identifier string that is associated with your Exadata Database machine environment. For example, the identifier could be C2, in which case the DATA disk group would be named DATAC2, the RECO disk group would be named RECOC2, and so on.

In addition, you can create a SPARSE disk group. A SPARSE disk group is required to support Exadata snapshots. Exadata snapshots enable space-efficient clones of Oracle databases that can be created and destroyed very quickly and easily. Snapshot clones are often used for development, testing, or other purposes that require a transient database.

Note that you cannot change the disk group layout after service creation.

### Impact of Configuration Settings on Storage

If you choose to perform database backups to the Exadata storage, or to create a sparse disk group, or to do both, your choices profoundly affect how storage space in the Exadata storage servers is allocated to the ASM and sparse disk groups.

The table that follows shows the approximate percentages of storage allocated for DATA, RECO, and SPARSE disk groups for each possible configuration.

<table>
<thead>
<tr>
<th>Configuration Settings</th>

Moving Databases to Oracle Cloud Exadata Systems Using Zero Downtime Migration

Oracle now offers the **Zero Downtime Migration** service, a quick and easy way to move on-premises Oracle Databases and Oracle Cloud Infrastructure Classic databases to Oracle Cloud Infrastructure. You can migrate databases to the following types of Oracle Cloud Infrastructure systems: Exadata, Exadata Cloud@Customer, bare metal, and virtual machine.

Zero Downtime Migration leverages Oracle Active Data Guard to create a standby instance of your database in an Oracle Cloud Infrastructure system. You switch over only when you are ready, and your source database remains available as a standby. Use the Zero Downtime Migration service to migrate databases individually or at the fleet level. See **Move to Oracle Cloud Using Zero Downtime Migration** for more information.

Exadata Shape Configurations

This topic describes the available Exadata Cloud Service instance shapes in Oracle Cloud Infrastructure.

See the following sections for shape specifications:

- Exadata X8M on page 1225
- Exadata Base System on page 1226
- Exadata X8 Shapes on page 1226
- Exadata X7 Shapes on page 1227
- Exadata X6 Shapes on page 1227

**Exadata X8M**

After provisioning, the X8M shape is expandable, unlike X6, X7, and X8 shapes. The values in the table that follows represent the specifications for an X8M cloud service instance that has not been expanded. The initial configuration of 2 database servers and 3 storage servers is similar to the quarter rack shape offered for X6, X7 and X8 infrastructure resources.

**X8M Capacity at Provisioning**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shape Name</td>
<td>Exadata X8M-2</td>
</tr>
<tr>
<td>Number of Compute Nodes</td>
<td>2 (value can increased after provisioning)</td>
</tr>
<tr>
<td>Total Minimum Number of Enabled CPU Cores</td>
<td>0</td>
</tr>
<tr>
<td>Total Maximum Number of Enabled CPU Cores</td>
<td>100 (for 2 initial database servers)</td>
</tr>
<tr>
<td>Total RAM Capacity</td>
<td>2780 GB (initial value)</td>
</tr>
<tr>
<td>Number of Exadata Storage Servers</td>
<td>3 (value can increased after provisioning)</td>
</tr>
<tr>
<td>Total Raw Flash Storage Capacity</td>
<td>76.8 TB (for 3 initial storage servers)</td>
</tr>
<tr>
<td>Total Usable Storage Capacity</td>
<td>149 TB (for 3 initial storage servers)</td>
</tr>
</tbody>
</table>

**X8M Expansion Server Capacity**

When you add additional database or storage servers to an X8M system, the expansion servers have the following capacity.
Database

Database Servers

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum OCPUs</td>
<td>50 OCPUs</td>
</tr>
<tr>
<td>Total memory available</td>
<td>1,390 GB</td>
</tr>
</tbody>
</table>

Storage Servers

<table>
<thead>
<tr>
<th>Property</th>

<td>168 TB</td>
<td>336 TB</td>
</tr>
</tbody>
</table>

Exadata X6 shapes provide 200 GB of user disk space for database homes.

**Overview of X8M Scalable Exadata Infrastructure**

Oracle Cloud Infrastructure scalable Exadata X8M system model allows you to add additional database and storage servers after provisioning and create a system that matches your capacity needs.
**The New Exadata Cloud Service Resource Model**

Exadata Cloud Service instances can now be provisioned with a new infrastructure resource model that replaces the *DB system* resource. In the new model, the DB system is split into two resources, the *cloud Exadata infrastructure* resource, and the *cloud VM cluster* resource.

The X8M system model is only compatible with the new resource model. For provisioning new X7 and X8 systems, Oracle recommends using the new resource model so that your instance will not have to be switched to the new resource model later.

Oracle will continue to support the Exadata DB system resource for an interim period (for both Exadata instance creation and management) before the DB system resource is deprecated in the Exadata Cloud Service. Existing Exadata DB systems can be easily switched to the new resource model with no downtime. For instructions on switching, see *To switch an Exadata DB system to the new Exadata resource model* on page 1229.

**The Cloud Exadata Infrastructure Resource**

The infrastructure resource is the top-level (parent) resource. At the infrastructure level, you control the number of database and storage servers. You also control Exadata system maintenance scheduling at the Exadata infrastructure level. This resource is created using the *CreateCloudExadataInfrastructure* API.

See *To add compute and storage resources to a flexible cloud Exadata infrastructure resource* on page 1230 for information on scaling the X8M cloud Exadata infrastructure resource. Note that after adding storage or database servers to the infrastructure resource, you must then add them to the system's VM cluster to utilize the new capacity.

**The Cloud VM Cluster Resource**

The VM cluster is a child resource of the infrastructure resource, providing a link between your Exadata cloud infrastructure resource and Oracle Database. Networking, OCPU count, IORM, and Oracle Grid Infrastructure are configured and managed at the VM cluster level. This resource is created using the *CreateCloudVmCluster* API.

See *To add database server or storage server capacity to a cloud VM cluster* on page 1230 for information on adding available storage or database servers to the VM cluster. Note that you must add servers to the infrastructure resource before you can add capacity to the VM cluster.

Exadata Cloud Service instances currently support creating a single cloud VM cluster.

**Additional Exadata Cloud Service Instance Resources**

The new Exadata resource model retains the rest of the resource types found in DB systems: Oracle Databases, database backups, Data Guard Associations, Work Requests, Oracle Database Homes, and database server nodes (also called "virtual machines").

**Note:**

The database server file system for database server nodes (also known as "virtual machines") has changed with the X8M generation of hardware. See *The X8M Virtual Machine File System Structure* on page 1352 for details on the X8M database server node file system.

**Switching an Exadata DB System to the New Resource Model and APIs**

If you have existing Exadata DB systems in Oracle Cloud Infrastructure, you can switch them to the new resource model and APIs. This does not change to the underlying hardware or shape family of your Exadata Cloud Service instance. The existing DB system APIs will be deprecated for Exadata by Oracle Cloud Infrastructure for all users following written notification and a transition period allowing you to switch to the new API and Console interfaces. Note that this change will not affect bare metal and virtual machine DB systems.

Switching to the new resource model does not impact the DB system's existing Exadata databases or client connections. If you have created automation that uses the existing DB system API, your applications may need to be updated to use the new API.
Important! Support for the Exadata DB system APIs will end on May 15, 2021. Oracle recommends that you migrate your Exadata Cloud Service instances to the new resource model APIs as soon as possible. Converting to the new resource model does not involve any system downtime.

After converting your DB system, you will have two new resources in place of the DB system resource: a cloud Exadata infrastructure resource, and a cloud VM cluster resource.

What to Expect After Switching

- Your new cloud Exadata infrastructure resource and cloud VM cluster are created in the same compartment as the DB system they replace
- Your new cloud Exadata infrastructure resource and cloud VM cluster use the same networking configuration as the DB system they replace
- After the switch, you cannot perform operations on the old Exadata DB system resource
- Switching is permanent, and the change cannot be undone
- X6, X7, X8 and Exadata base systems retain their fixed shapes after the switch, and cannot be expanded

To switch an Exadata DB system to the new Exadata resource model

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. In the list of DB systems, find the Exadata DB system you want to switch to the new resource model, and click its highlighted name to view the system details.
4. Click More Actions, then Switch to New API.
5. In the displayed confirmation page, read the What to expect after switching section. When you are ready to switch to the new resource model and APIs, click Start.

Caution:

Switching an Exadata DB system to the new resource model and APIs cannot be reversed. If you have automation for your system that utilizes the DB system APIs, you may need to update your applications prior to switching.

Scaling an Exadata Cloud Service Instance

This topic describes the scaling options available for Exadata Cloud Service instances.

Scaling CPU Cores Within an Exadata Cloud Service Instance

If an Exadata Cloud Service instance requires more compute node processing power, you can scale up the number of enabled CPU cores symmetrically across all the nodes in the system as follows:

X8M flexible infrastructure systems: You can scale CPU cores in multiples of the number of database servers currently provisioned for the cloud VM cluster. For example, if you have 6 database servers provisioned, you can add CPU cores in multiples of 6. At the time of provisioning, X8M systems have 2 database servers. For more information on adding compute and storage resources to an X8M system, see Scaling Exadata X8M Compute and Storage on page 1230.

Non-X8M fixed-shape systems: For a base system or an X7 or X8 quarter rack, you can scale in multiples of 2 across the 2 database compute nodes. For an X7 or X8 half rack, you can scale in multiples of 4 across the 4 database compute nodes. For an X7 or X8 full rack, you can scale in multiples of 8 across the 8 database compute nodes.

For a non-metered service instances, you can temporarily modify the compute node processing power (bursting) or add compute node processing power on a more permanent basis. For a metered service instance, you can simply modify the number of enabled CPU cores.

You can provision an Exadata Cloud Service instance with zero CPU cores, or scale the service instance down to zero cores after you provision it. With zero cores, you are billed only for the infrastructure until you scale up the system. For detailed information about pricing, see Exadata Cloud Service Pricing.
Tip:
OCPUs scaling activities are done online with no downtime.

For information on CPU cores per configuration, see Exadata Shape Configurations on page 1223. To learn how to scale a system, see To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system on page 1258.

Scaling Exadata X8M Compute and Storage

The flexible X8M system model is designed to be easily scaled in place, with no need to migrate the database using a backup or Data Guard. You can scale an X8M service instance in the Console on the cloud Exadata infrastructure details page. After adding additional database or storage servers to your cloud Exadata infrastructure resource, you must add the increased capacity to the associated cloud VM cluster to utilize the newly-provisioned CPU or storage resources. After adding additional database servers to a VM cluster, you can then allocate the new CPU cores as described in To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system on page 1258. After adding additional storage servers to your VM cluster, you do not need to take any further action to utilize the new storage.

Note:
- The Exadata X8M shape does not support removing storage or database servers from an existing X8M instance.
- For OCI Exadata Cloud Service databases configured with either Oracle Data Guard or customer-managed keys (encryption keys stored and managed using the OCI, Vault service), the database cannot currently utilize additional compute nodes added to the Exadata infrastructure.
- For OCI Exadata Cloud Service VM clusters that use node subsetting (meaning the clusters are configured to use only a subset of all nodes available in the dedicated Exadata infrastructure instance), you cannot currently add additional compute nodes to the VM cluster.

See Overview of X8M Scalable Exadata Infrastructure on page 1227 for more information on X8M systems.

To add compute and storage resources to a flexible cloud Exadata infrastructure resource

This task describes how to use the Oracle Cloud Infrastructure Console to scale a flexible cloud Exadata infrastructure resource. Currently, only Exadata X8M systems in Oracle Cloud Infrastructure have the ability to add database (compute) and storage servers to an existing service instance.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Under Exadata at Oracle Cloud, click Exadata Infrastructure.
3. In the list of cloud Exadata infrastructure resources, click the name of the resource you want to scale.
4. Click Scale Infrastructure.
5. Adding database servers: To add compute servers to the infrastructure resource, select the Database Servers radio button, then enter the number of servers you want to add in the Database servers field.

Adding storage servers: To add storage servers to the infrastructure resource, select the Storage Servers radio button, then enter the number of servers you want to add in the Storage servers field.
6. Click Scale.

Tip:
After scaling your infrastructure, you must add the new capacity to the cloud VM cluster before you can use the additional CPU and storage resources in the Exadata Cloud Service instance.

To add database server or storage server capacity to a cloud VM cluster

If you have scaled a flexible cloud Exadata infrastructure resource by adding additional database (compute) or storage servers to the service instance, you must add the additional capacity to the cloud VM cluster to utilize the additional resources. This topic describes how to use the Oracle Cloud Infrastructure (OCI) Console to add the new capacity to your cloud VM cluster.
Database

Note:

• For OCI Exadata Cloud Service databases configured with either Oracle Data Guard or customer-managed keys (encryption keys stored and managed using the OCI, Vault service), the database cannot currently utilize additional compute nodes added to the Exadata infrastructure.
• For OCI Exadata Cloud Service VM clusters that use node subsetting (meaning the clusters are configured to use only a subset of all nodes available in the dedicated Exadata infrastructure instance), you cannot currently add additional compute nodes to the VM cluster.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Under Exadata at Oracle Cloud, click Exadata VM Clusters.
3. In the list of cloud VM clusters, click the name of the cluster to which you want to add capacity.
4. On the VM Cluster Details page, click Scale VM Cluster.
5. If you have additional capacity available as a result of scaling the cloud Exadata infrastructure resource, a banner at the top of the Scale VM Cluster panel provides a message telling you the type and amount of additional capacity available to the VM cluster. Check the Add Capacity box.
6. Select either the Add Database Server or the Add Storage radio button, depending on which type of capacity you want to add to the cloud VM cluster.
7. Click Update. The cloud VM cluster goes into the Updating state. When the capacity has been successfully added, the cluster returns to the Available state.

Tip:

If you have added additional database servers to the cluster, you can allocate the new CPU cores once the cluster is in the Available state by clicking the Scale VM Cluster button again. See To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system on page 1258 for more information on adding CPU cores to your cloud VM cluster.

Scaling X6, X7 and X8 Exadata DB System Configurations

Scaling an Exadata X6, X7, or X8 Exadata Cloud Service instance by moving to a shape with more capacity enables you meet the needs of your growing workload. This is useful when a database deployment requires:

• Processing power that is beyond the capacity of the current system configuration.
• Storage capacity that is beyond the capacity of the current system configuration.
• A performance boost that can be delivered by increasing the number of available compute nodes.
• A performance boost that can be delivered by increasing the number of available Exadata Storage Servers.

You can move you workloads to a larger fixed shape (X7 and X8 hardware shapes), or move to the flexible X8M shape that allows for easy expansion of compute and storage resources as your workloads grow.

To assist with moving your database deployments between Exadata Cloud Service instances, you can restore a backup to a different service instance that has more capacity, or create a Data Guard association for your database in a service instance with more capacity, and then perform a switchover so that your new standby database assumes the primary role. To start the process, contact Oracle and request a service limit increase so that you can provision the larger service instance needed by your database.

Best Practices for Exadata Cloud Service Instances

Oracle recommends that you follow these best practice guidelines to ensure the manageability of your Exadata Cloud Service instance:

• Wherever possible, use the Oracle-supplied cloud interfaces such as the Oracle Cloud Infrastructure Console, API, or CLI, or cloud-specific tools such as dbaascli and dbaasapi to perform lifecycle management and administrative operations on your Exadata Cloud Service instance. For example, use the exadbcpatchmulti command to apply Oracle Database patches instead of manually running opatch. In addition, if an operation
can be performed by using the Console as well as a command line utility, Oracle recommends that you use the Console. For example, use the Console instead of using `dbaasapi` to create databases.

- Do not change the compute node OS users or manually manipulate SSH key settings associated with your Exadata DB system.
- Apply only patches that are available through the Database service. Do not apply patches from any other source unless you are directed to do so by Oracle Support.
- Apply the quarterly patches regularly, every quarter if possible.
- Do not change the ports for Oracle Net Listener.

**Network Setup for Exadata Cloud Service Instances**

Before you set up an Exadata Cloud Service instance, you must set up a virtual cloud network (VCN) and other networking service components. This topic describes the recommended configuration for the VCN and several related requirements for the Exadata Cloud Service instance.

**VCN and Subnets**

To launch an Exadata Cloud Service instance, you must have:

- A VCN in the region where you want the Exadata Cloud Service instance
- At least two subnets in the VCN. The two subnets are:
  - Client subnet
  - Backup subnet

**Note:**

For Exadata Cloud Service instances using the new Exadata resource model, networking is configured on the cloud VM cluster resource. For instances using DB system resource model, networking is configured on the DB system resource.

In general, Oracle recommends using regional subnets, which span all availability domains in the region. If you instead use AD-specific subnets, both the client and backup subnets must be in the same availability domain. The important thing to know for your Exadata Cloud Service instance is that the resources you create in the two subnets must be in the same availability domain. For more information, see Overview of VCNs and Subnets on page 2822.

You will create custom route tables for each subnet. You will also create security rules to control traffic to and from the client network and backup network of the Exadata compute notes (for cloud VM clusters, nodes are called virtual machines). More information follows about those items.

**Option 1: Public Client Subnet with Internet Gateway**

This option can be useful when doing a proof-of-concept or development work. You can use this setup in production if you want to use an internet gateway with the VCN, or if you have services that run only on a public network and need access to the database. See the following diagram and description.
You set up:

- **Subnets**:
  - *Public* client subnet (*public* means that the resources in the subnet can have public IP addresses at your discretion).
  - *Private* backup subnet (*private* means that the resources in the subnet cannot have public IP addresses and therefore cannot receive incoming connections from the internet).

- **Gateways for the VCN**:
  - Internet gateway (for use by the client subnet).
  - Service gateway (for use by the backup subnet). Also see Option 1: Service Gateway Access Only to Object Storage on page 1237.

- **Route tables**:
  - Custom route table for the public client subnet, with a route for 0.0.0.0/0, and target = the internet gateway.
  - Separate custom route table for the private backup subnet, with a route rule for the service CIDR label called *OCI <region> Object Storage*, and target = the service gateway. Also see Option 1: Service Gateway Access Only to Object Storage on page 1237.
  - Security rules to enable the desired traffic to and from the Exadata virtual machines compute nodes. See Security Rules for the Exadata Cloud Service instance on page 1239.
  - Static route on the Exadata Cloud Service instance's compute nodes (to enable access to Object Storage by way of the backup subnet).

**Important:**

See this known issue for information about configuring route rules with *service gateway* as the target on route tables associated with public subnets.
Option 2: Private Subnets

Oracle recommends this option for a production system. Both subnets are private and cannot be reached from the internet. See the following diagram and description.

You set up:

- **Subnets:**
  - *Private* client subnet.
  - *Private* backup subnet.

- **Gateways for the VCN:**
  - Dynamic routing gateway (DRG), with a FastConnect or IPSec VPN to your on-premises network (for use by the client subnet).
  - Service gateway (for use by the backup subnet to reach Object Storage, and for use by the client subnet to reach the Oracle YUM repository for OS updates). Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos on page 1238.
  - NAT gateway (for use by the client subnet to reach public endpoints not supported by the service gateway).

- **Route tables:**
  - Custom route table for the private client subnet, with two rules:
    - A rule for the on-premises network's CIDR, and target = DRG.
    - A rule for the service CIDR label called *All <region> Services in Oracle Services Network*, and target = the service gateway. The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. The rule enables the client subnet to reach the regional Oracle YUM repository for OS updates. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos on page 1238.
    - A rule for 0.0.0.0/0, and target = NAT gateway.
  - Separate custom route table for the private backup subnet, with one rule:
    - The same rule as for the client subnet: for the service CIDR label called *All <region> Services in Oracle Services Network*, and target = the service gateway. This rule enables the backup subnet to reach the regional Object Storage for backups.
  - Security rules to enable the desired traffic to and from the Exadata nodes. See Security Rules for the Exadata Cloud Service instance on page 1239.
• **Static route** on the compute nodes (for VM clusters, the virtual machines) to enable access to Object Storage by way of the backup subnet.

**Requirements for IP Address Space**

If you're setting up Exadata Cloud Service instances (and thus VCNs) in more than one region, make sure the IP address space of the VCNs does not overlap. This is important if you want to set up disaster recovery with Oracle Data Guard.

The two subnets you create for the Exadata Cloud Service instance must not overlap with 192.168.128.0/20.

The following table lists the minimum required subnet sizes, depending on the Exadata rack size. For the client subnet, each node requires two IP addresses, and in addition, three addresses are reserved for Single Client Access Names (SCANs). For the backup subnet, each node requires one address.

<table>
<thead>
<tr>
<th>Rack Size</th>
<th>Client Subnet: # Required IP Addresses</th>
<th>Client Subnet: Minimum Size</th>
<th>Backup Subnet: # Required IP Addresses</th>
<th>Backup Subnet: Minimum Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base System or Quarter Rack</td>
<td>(2 addresses * 2 nodes) + 3 for SCANs + 3 reserved in subnet = 10</td>
<td>/28 (16 IP addresses)</td>
<td>(1 address * 2 nodes) + 3 reserved in subnet = 5</td>
<td>/29 (8 IP addresses)</td>
</tr>
<tr>
<td>Half Rack</td>
<td>(2 * 4 nodes) + 3 + 3 = 14</td>
<td>/28 (16 IP addresses)</td>
<td>(1 * 4 nodes) + 3 = 7</td>
<td>/29 (8 IP addresses)</td>
</tr>
<tr>
<td>Full Rack</td>
<td>(2* 8 nodes) + 3 + 3 = 22</td>
<td>/27 (32 IP addresses)</td>
<td>(1 * 8 nodes) + 3 = 11</td>
<td>/28 (16 IP addresses)</td>
</tr>
</tbody>
</table>

**Tip:**

The Networking service reserves three IP addresses in each subnet.

Allocating a larger space for the subnet than the minimum required (for example, at least /25 instead of /28) can reduce the relative impact of those reserved addresses on the subnet's available space.

**VCN Creation Wizard: Not for Production**

The Networking section of the Console includes a handy wizard that creates a VCN along with related resources. It can be useful if you just want to try launching an instance. However, the wizard automatically creates a public subnet and an internet gateway. You may not want this for your production network, so Oracle recommends you create the VCN and other resources individually yourself instead of using the wizard.

**DNS: Short Names for the VCN, Subnets, and Exadata Cloud Service instance**

For the nodes to communicate, the VCN must use the Internet and VCN Resolver. It enables hostname assignment to the nodes, and DNS resolution of those hostnames by resources in the VCN. It enables round robin resolution of the database's SCANs. It also enables resolution of important service endpoints required for backing up databases, patching, and updating the cloud tooling on an Exadata Cloud Service instance. The Internet and VCN Resolver is the VCN's default choice for DNS in the VCN. For more information, see DNS in Your Virtual Cloud Network on page 2910 and also DHCP Options on page 2917.

When you create the VCN, subnets, and Exadata, you must carefully set the following identifiers, which are related to DNS in the VCN:

- VCN domain label
- Subnet domain label
- Hostname prefix for the Exadata Cloud Service instance's cloud VM cluster or DB system resource

These values make up the node's fully qualified domain name (FQDN):
<hostname_prefix>-<subnet_domain_label>.<vcn_domain_label>.oraclevcn.com

For example:

exacs-abcdel.clientpvtad1.acmevcniad.oraclevcn.com

In this example, you assign exacs as the hostname prefix when you create the cloud VM cluster or DB system. The Database service automatically appends a hyphen and a five-letter string with the node number at the end. For example:

- Node 1: exacs-abcdel.clientpvtad1.acmevcniad.oraclevcn.com
- Node 2: exacs-abcdel2.clientpvtad1.acmevcniad.oraclevcn.com
- Node 3: exacs-abcdel3.clientpvtad1.acmevcniad.oraclevcn.com
- And so on

Requirements for the hostname prefix:

- Recommended maximum: 12 characters. For more information, see the example under the following section, "Requirements for the VCN and subnet domain labels".
- Cannot be the string localhost

Requirements for the VCN and subnet domain labels:

- Recommended maximum: 14 characters each. The actual underlying requirement is a total of 28 characters across both domain labels (excluding the period between the labels). For example, both of these are acceptable: subnetad1.verylongvcnphx or verylongsubnetad1.vcnphx. For simplicity, the recommendation is 14 characters each.
- No hyphens or underscores.
- Recommended: include the region name in the VCN's domain label, and include the availability domain name in the subnet's domain label.
- In general, the FQDN has a maximum total limit of 63 characters. Here is a safe general rule:

```
<12_chars_max>-<subnet_domain_label>.<vcn_domain_label>.oraclevcn.com
```

The preceding maximums are not enforced when you create the VCN and subnets. However, if the labels exceed the maximum, the Exadata deployment fails.

**DNS: Between On-Premises Network and VCN**

To enable the use of hostnames when on-premises hosts and VCN resources communicate with each other, you have two options:

- Set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see Hybrid DNS Configuration.
- Manage hostname resolution yourself manually.

**Node Access to Object Storage: Static Route**

To be able to back up databases, and patch and update cloud tools on an Exadata Cloud Service instance, you must configure access to Oracle Cloud Infrastructure Object Storage. Regardless of how you configure the VCN with that access (for example, with a service gateway), you may also need to configure a static route to Object Storage on each of the compute nodes in the cluster. This is only required if you are not using automatic backups. If you are using customized backups using the backup APIs, then you must route traffic destined for Object Storage through the backup interface (BONDETH1). This is not necessary if you are using the automatic backups created with the Console, APIs, or CLIs.

**Important:**

You must configure a static route for Object Storage access on each compute node in an Exadata Cloud Service instance if you are not creating automatic backups with the Console, APIs, or CLIs. Otherwise, attempts to back up databases, and patch or update tools on the system, can fail.
Object Storage IP allocations

Oracle Cloud Infrastructure Object Storage uses the CIDR block IP range 134.70.0.0/17 for all regions. This range was introduced in April and May of 2018.

As of June 1, 2018, Object Storage no longer supports the following discontinued IP ranges. Oracle recommends that you remove these older IP addresses from your access-control lists, firewall rules, and other rules after you have adopted the new IP ranges.

The discontinued IP ranges are:

- Germany Central (Frankfurt): 130.61.0.0/16
- UK South (London): 132.145.0.0/16
- US East (Ashburn): 129.213.0.0/16
- US West (Phoenix): 129.146.0.0/16

To configure a static route for Object Storage access

1. SSH to a compute node in the Exadata Cloud Service instance.

   ```
   ssh -i <private_key_path> opc@<node_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile.

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Identify the gateway configured for the BONDETH1 interface.

   ```
   [root@dbsys ~]# grep GATEWAY /etc/sysconfig/network-scripts/ifcfg-bondeth1 | awk -F=" " '{print $2}'
   ```

   ```
   10.0.4.1
   ```

4. Add the following static rule for BONDETH1 to the /etc/sysconfig/network-scripts/route-bondeth1 file:

   ```
   10.0.X.0/XX dev bondeth1 table 211
   default via <gateway> dev bondeth1 table 211
   134.70.0.0/17 via <gateway_from_previous_step> dev bondeth1
   ```

5. Restart the interface.

   ```
   [root@dbsys ~]# ifdown bondeth1; ifup bondeth1;
   ```

   The file changes from the previous step take effect immediately after the ifdown and ifup commands run.

6. Repeat the preceding steps on each compute node in the Exadata Cloud Service instance.

Service Gateway for the VCN

Your VCN needs access to both Object Storage for backups and Oracle YUM repos for OS updates.

Depending on whether you use option 1 or option 2 described previously, you use the service gateway in different ways. See the next two sections.

Option 1: Service Gateway Access Only to Object Storage

You configure the backup subnet to use the service gateway for access only to Object Storage. As a reminder, here's the diagram for option 1:
In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called `OCI <region> Object Storage`.
- In the task for updating routing, add a route rule to the `backup` subnet's custom route table. For the destination service, use `OCI <region> Object Storage` and target = the service gateway.
- In the task for updating security rules in the subnet, perform the task on the `backup` network's network security group (NSG) or custom security list. Set up a security rule with the destination service set to `OCI <region> Object Storage`. See Rule Required Specifically for the Backup Network on page 1242.

**Option 2: Service Gateway Access to Both Object Storage and YUM Repos**

You configure both the `client subnet` and `backup subnet` to use the `service gateway` for access to the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos.

**Important:**

See this known issue for information about accessing Oracle YUM services through the service gateway.

As a reminder, here's the diagram for option 2:
In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called **All <region> Services in Oracle Services Network**.
- In the task for updating routing in each subnet, add a rule to each subnet's custom route table. For the destination service, use **All <region> Services in Oracle Services Network** and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the backup network's network security group (NSG) or custom security list. Set up a security rule with the destination service set to **OCI <region> Object Storage**. See Rule Required Specifically for the Backup Network on page 1242. Note that the client subnet already has a broad egress rule that covers access to the YUM repos.

Here are a few additional details about using the service gateway for option 2:

- Both the client subnet and backup subnet use the service gateway, but to access different services. You cannot enable both the **OCI <region> Object Storage** service CIDR label and the **All <region> Services in Oracle Services Network** for the service gateway. To cover the needs of both subnets, you must enable **All <region> Services in Oracle Services Network** for the service gateway. The VCN can have only a single service gateway.
- Any route rule that targets a given service gateway must use an enabled service CIDR label and not a CIDR block as the destination for the rule. That means for option 2, the route tables for both subnets must use **All <region> Services in Oracle Services Network** for their service gateway rules.
- Unlike route rules, security rules can use either any service CIDR label (whether the VCN has a service gateway or not) or a CIDR block as the source or destination CIDR for the rule. Therefore, although the backup subnet has a route rule that uses **All <region> Services in Oracle Services Network**, the subnet can have a security rule that uses **OCI <region> Object Storage**. See Rule Required Specifically for the Backup Network on page 1242.

**Security Rules for the Exadata Cloud Service instance**

This section lists the security rules to use with your Exadata Cloud Service instance. Security rules control the types of traffic allowed for the client network and backup network of the Exadata's compute nodes. The rules are divided into three sections.

There are different ways to implement these rules. For more information, see Ways to Implement the Security Rules on page 1242.

**Rules Required for Both the Client Network and Backup Network**

This section has several general rules that enable essential connectivity for hosts in the VCN.
If you use security lists to implement your security rules, be aware that the rules that follow are included by default in the default security list. Update or replace the list to meet your particular security needs. The two ICMP rules (general ingress rules 2 and 3) are required for proper functioning of network traffic within the Oracle Cloud Infrastructure environment. Adjust the general ingress rule 1 (the SSH rule) and the general egress rule 1 to allow traffic only to and from hosts that require communication with resources in your VCN.

**General ingress rule 1: Allows SSH traffic from anywhere**

- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: 0.0.0.0/0
- **IP Protocol**: SSH
- **Source Port Range**: All
- **Destination Port Range**: 22

**General ingress rule 2: Allows Path MTU Discovery fragmentation messages**

This rule enables hosts in the VCN to receive Path MTU Discovery fragmentation messages. Without access to these messages, hosts in the VCN can have problems communicating with hosts outside the VCN.

- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: 0.0.0.0/0
- **IP Protocol**: ICMP
- **Type**: 3
- **Code**: 4

**General ingress rule 3: Allows connectivity error messages within the VCN**

This rule enables the hosts in the VCN to receive connectivity error messages from each other.

- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: Your VCN's CIDR
- **IP Protocol**: ICMP
- **Type**: 3
- **Code**: All

**General egress rule 1: Allows all egress traffic**

- **Stateless**: No (all rules must be stateful)
- **Destination Type**: CIDR
- **Destination CIDR**: 0.0.0.0/0
- **IP Protocol**: All

**Rules Required Specifically for the Client Network**

The following security rules are important for the client network.

**Important:**

- Client ingress rules 1 and 2 only cover connections initiated from within the client subnet. If you have a client that resides outside the VCN, Oracle recommends setting up two additional similar rules that instead have the **Source CIDR** set to the public IP address of the client.
- Client ingress rules 3 and 4 and client egress rules 1 and 2 allow TCP and ICMP traffic inside the client network and enable the nodes to...
communicate with each other. If TCP connectivity fails across the nodes,
the Exadata cloud VM cluster or DB system resource fails to provision.

Client ingress rule 1: Allows ONS and FAN traffic from within the client subnet

The first rule is recommended and enables the Oracle Notification Services (ONS) to communicate about Fast Application Notification (FAN) events.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 6200
- **Description:** An optional description of the rule.

Client ingress rule 2: Allows SQL*NET traffic from within the client subnet

This rule is for SQL*NET traffic and is required in these cases:

- If you need to enable client connections to the database
- If you plan to use Oracle Data Guard

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 1521
- **Description:** An optional description of the rule.

Client egress rule 1: Allows all TCP traffic inside the client subnet

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 22
- **Description:** An optional description of the rule.

Client egress rule 2: Allows all egress traffic (allows connections to the Oracle YUM repos)

Client egress rule 3 is important because it allows connections to the Oracle YUM repos. It is redundant with the general egress rule in Security Rules for the Exadata Cloud Service instance on page 1239 (and in the default security list). It is optional but recommended in case the general egress rule (or default security list) is inadvertently changed.

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All
- **Description:** An optional description of the rule.
Database

Rule Required Specifically for the Backup Network

The following security rule is important for the backup network because it enables the DB system to communicate with Object Storage through the service gateway (and optionally with the Oracle YUM repos if the client network doesn't have access to them). It is redundant with the general egress rule in Security Rules for the Exadata Cloud Service instance on page 1239 (and in the default security list). It is optional but recommended in case the general egress rule (or default security list) is inadvertently changed.

Backup egress rule: Allows access to Object Storage

- **Stateless**: No (all rules must be stateful)
- **Destination Type**: Service
- **Destination Service**:
  - The service CIDR label called OCI `<region>` Object Storage
  - If the client network does not have access to the Oracle YUM repos, use the service CIDR label called All `<region>` Services in Oracle Services Network
- **IP Protocol**: TCP
- **Source Port Range**: All
- **Destination Port Range**: 443 (HTTPS)
- **Description**: An optional description of the rule.

Ways to Implement the Security Rules

The Networking service offers two ways to implement security rules within your VCN:

- **Network security groups**
- **Security lists**

For a comparison of the two methods, see Comparison of Security Lists and Network Security Groups on page 2833.

*If you use network security groups*

If you choose to use network security groups (NSGs), here is the recommended process:

1. Create an NSG for the client network. Add the following security rules to that NSG:
   - The rules listed in Rules Required for Both the Client Network and Backup Network on page 1239
   - The rules listed in Rules Required Specifically for the Client Network
2. Create a separate NSG for the backup network. Add the following security rules to that NSG:
   - The rules listed in Rules Required for Both the Client Network and Backup Network on page 1239
   - The rules listed in Rule Required Specifically for the Backup Network on page 1242
3. When the database administrator creates the Exadata Cloud Service instance, they must choose several networking components (for example, which VCN and subnets to use):
   - When they choose the client subnet, they can also choose which NSG or NSGs to use. Make sure they choose the client network's NSG.
   - When they choose the backup subnet, they can also choose which NSG or NSGs to use. Make sure they choose the backup network's NSG.

You could instead create a separate NSG for the general rules. Then when the database administrator chooses which NSGs to use for the client network, make sure they choose both the general NSG and the client network NSG. Similarly for the backup network, they choose both the general NSG and the backup network NSG.

*If you use security lists*

If you choose to use security lists, here is the recommended process:
1. Configure the client subnet to use the required security rules:
   a. Create a custom security list for the client subnet and add the rules listed in Rules Required Specifically for the Client Network on page 1240.
   b. Associate the following two security lists with the client subnet:
      • VCN's default security list with all its default rules. This automatically comes with the VCN. By default it contains the rules in Rules Required for Both the Client Network and Backup Network on page 1239.
      • The new custom security list you created for the client subnet.
2. Configure the backup subnet to use the required security rules:
   a. Create a custom security list for the backup subnet and add the rules listed in Rule Required Specifically for the Backup Network on page 1242.
   b. Associate the following two security lists with the backup subnet:
      • VCN's default security list with all its default rules. This automatically comes with the VCN. By default it contains the rules in Rules Required for Both the Client Network and Backup Network on page 1239.
      • The new custom security list you created for the backup subnet.

Later when the database administrator creates the Exadata Cloud Service instance, they must choose several networking components. When they select the client subnet and backup subnet that you've already created and configured, the security rules are automatically enforced for the nodes created in those subnets.

Caution:
Do not remove the default egress rule from the default security list. If you do, make sure to instead include the following replacement egress rule in the client subnet's security list:
• Stateless: No (all rules must be stateful)
• Destination Type: CIDR
• Destination CIDR: 0.0.0.0/0
• IP Protocol: All

Creating an Exadata Cloud Service Instance

This topic explains how to create an Oracle Exadata Cloud Service instance. It also describes how to configure required access to the Oracle Cloud Infrastructure Object Storage service and set up DNS.

When you create an Exadata Cloud Service instance using the Console or the API, the system is provisioned to support Oracle databases. The service creates an initial database based on the options you provide and some default options described later in this topic.

Resources to Be Created

You will create different Exadata Cloud Service resources depending on which resource model you use to create your Exadata Cloud Service instance.

New Resource Model (Supported for All Exadata Shapes)

If you are using the new Exadata Cloud Service resource model, you will provision the following resources separately:

• Cloud Exadata infrastructure resource: The infrastructure resource is the top-level (parent) resource. At the infrastructure level, you control the number of database and storage servers. You also control Exadata system maintenance scheduling at the Exadata infrastructure level.
• Cloud VM cluster resource: The VM cluster is a child resource of the infrastructure resource, providing a link between your Exadata cloud infrastructure resource and Oracle Database. Networking, OCPU count, IORM, and Oracle Grid Infrastructure are configured and managed at the VM cluster level. To create a cloud VM cluster, you must have an existing cloud Exadata infrastructure resource to house the VM cluster.

Notes:
• Use the new resource model to provision both the flexible X8M shape and fixed-shape systems (X7/X7/Exadata Base System)
• Exadata Cloud Service instance currently support only one cloud VM cluster

| Tip: |
| Oracle recommends using the new resource model to provision Exadata Cloud Service instances, regardless of the hardware shape family you are choosing (X7, X8, or X8M). Doing so will allow you to use the new APIs for these resource types, and you will not have to convert your service instance resources (or any automation associated those resources) at a later time. |

Old Resource Model (X7, X8, and Exadata Base Shape Families Only)
You can use the older Exadata Cloud Service resource model if needed to provision X7 and X8 systems. The old resource model creates a single Exadata DB system resource. See To create an X7 or X8 Exadata DB system on page 1248 for more information.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

Prerequisites
• The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the system via SSH. A sample public key, abbreviated for readability, is shown below.

```
ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA....lo/gKMLVM2xzclxJr/Hc26biw3TXWGEakrK1OQ== rsa-key-20160304
```

For more information, see Managing Key Pairs on Linux Instances on page 693.
• A correctly configured virtual cloud network (VCN) to launch the system in. Its related networking resources (gateways, route tables, security lists, DNS, and so on) must also be configured as necessary for the system. For more information, see Network Setup for Exadata Cloud Service Instances on page 1232.

Default Options for the Initial Database
To simplify launching an Exadata Cloud Service instance in the Console and when using the API, the following default options are used for the initial database:

• Console Enabled: False
• Create Container Database: False for version 11.2.0.4 databases. Otherwise, true.
• Create Instance Only (for standby and migration): False
• Database Home ID: Creates a database home
• Database Language: AMERICAN
• Database Sizing Template: odb2
• Database Storage: Automatic Storage Management (ASM)
• Database Territory: AMERICA
• Database Unique Name: The user-specified database name and a system-generated suffix, for example, dbtst_phx1cs.
• PDB Admin Name: pdbuser (Not applicable for version 11.2.0.4 databases.)
Using the Console

To create a cloud Exadata infrastructure resource

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Under Exadata at Oracle Cloud, click Exadata Infrastructure.
3. Click Create Exadata Infrastructure.
5. Display name: Enter a display name for the Exadata infrastructure. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the cloud Exadata infrastructure resource. Avoid entering confidential information.
7. Select the Exadata system model: Select either a fixed-shape system (quarter, half, or full rack X7-2 or X8-2 shapes), or a scalable system (X8M-2).
   - X8M-2: If you select the flexible X8M-2 system model, your initial Exadata Cloud Service instance will have 2 database servers and 3 storage servers (the equivalents of an X8 quarter rack shape). After provisioning, you can scale the service instance as needed by adding additional storage servers, compute servers, or both.
   - X7 and X8: If you select an X7 or X8 system, you are given the choice of provisioning a quarter, half, or full rack. See Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base on page 1351 for hardware and capacity details.
   - Exadata Base: The Exadata base shape comes in a single configuration, and provides an economical alternative to provisioning a quarter rack system. See Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base on page 1351
8. Configure automatic maintenance: Click this button to specify a schedule for the quarterly automatic infrastructure maintenance. In the Automatic Infrastructure Maintenance Schedule dialog that opens, do the following:
   a. Click the Specify a schedule radio button to choose your preferred month, week, weekday, and start time for infrastructure maintenance.
   b. Under Maintenance months, specify at least one month for each quarter during which Exadata infrastructure maintenance will take place. You can select more than one month per quarter. If you specify a long lead time for advanced notification (for example, 4 weeks), then you may want to specify two or three months per quarter during which maintenance runs can occur. This will ensure that your maintenance updates are applied in a timely manner after accounting for your required lead time. Lead time is discussed in the following steps.
   c. Under Week of the month, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of seven days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
   d. Optional. Under Day of the week, specify the day of the week on which the maintenance will occur. If you do not specify a day of the week, then Oracle will run the maintenance update on a weekend day to minimize disruption.
   e. Optional. Under Start hour, specify the hour during which the maintenance run will begin. If you do not specify a start hour, then Oracle will choose the least disruptive time to run the maintenance update.
   f. Under Lead Time, specify the number of weeks ahead of the maintenance event you would like to receive a notification message. Your lead time ensures that a newly released maintenance update is scheduled to account for your required period of advanced notification.
   g. Click Update Maintenance Schedule.
9. Click Show Advanced Options to specify advanced options for the initial database.
   In the Tags tab, you can add tags to the database. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
10. Click Create Exadata Infrastructure. The cloud Exadata infrastructure appears in the Exadata Infrastructure list with a status of Provisioning. The infrastructure's icon changes from yellow to green (or red to indicate errors).

WHAT NEXT?
After the cloud Exadata infrastructure resource is successfully provisioned and in the Available status, you can create a cloud VM cluster on your infrastructure. You must provision both an infrastructure resource and a VM cluster before you can create your first database in the new Exadata Cloud Service instance.

To create a cloud VM cluster resource

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To create a cloud VM cluster in an Exadata Cloud Service instance, you must have first created a cloud Exadata infrastructure resource. Exadata Cloud Service instances currently support creating a single cloud VM cluster.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Under Exadata at Oracle Cloud, click Exadata VM Clusters.
3. Click Create Exadata VM Cluster.

   The Create Exadata VM Cluster page is displayed. Provide the required information to configure the VM cluster.

4. Compartment: Select a compartment for the VM cluster resource.
5. Display name: Enter a user-friendly display name for the VM cluster. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system. Avoid entering confidential information.
6. Select Exadata infrastructure: Select the infrastructure resource that will contain the VM cluster. Currently, cloud Exadata infrastructure resources support only one VM cluster, so you must choose an infrastructure resource that does not have an existing VM cluster. Click Change Compartment and pick a different compartment from the one you are working in to view infrastructure resources in other compartments.
7. Configure the VM cluster: Specify the number of OCPU cores you want to allocate to each of the VM cluster's virtual machine compute nodes. The read-only Requested OCPU count for the Exadata VM cluster field displays the total number of OCPU cores you are allocating.
8. Configure Exadata storage: Specify the following:
   - Allocate storage for Exadata sparse snapshots: Select this configuration option if you intend to use snapshot functionality within your VM cluster. If you select this option, the SPARSE disk group is created, which enables you to use VM cluster snapshot functionality for PDB sparse cloning. If you do not select this option, the SPARSE disk group is not created and snapshot functionality will not be available on any database deployments that are created in the environment.
   - Allocate storage for local backups: Select this option if you intend to perform database backups to the local Exadata storage within your Exadata Cloud Service instance. If you select this option, more space is allocated to the RECO disk group, which is used to store backups on Exadata storage. If you do not select this option, more space is allocated to the DATA disk group, which enables you to store more information in your databases.
9. Add SSH key: Add the public key portion of each key pair you want to use for SSH access to the DB system.
   - Upload SSH key files: Select this radio button to browse or drag and drop .pub files.
   - Paste SSH keys: Select this radio button to paste in individual public keys. To paste multiple keys, click + Another SSH Key, and supply a single key for each entry.
10. **Configure the network settings:** Specify the following:

- **Virtual cloud network:** The VCN in which you want to create the VM cluster. Click **Change Compartment** to select a VCN in a different compartment.

- **Client subnet:** The subnet to which the VM cluster should attach. Click **Change Compartment** to select a subnet in a different compartment.

  Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

- **Backup subnet:** The subnet to use for the backup network, which is typically used to transport backup information to and from Oracle Cloud Infrastructure Object Storage, and for Data Guard replication. Click **Change Compartment** to select a subnet in a different compartment, if applicable.

  Do not use a subnet that overlaps with 192.168.128.0/20. This restriction applies to both the client subnet and backup subnet.

  If you plan to back up databases to Object Storage, see the network prerequisites in Managing Exadata Database Backups on page 1320.

- **Network Security Groups:** Optionally, you can specify one or more network security groups (NSGs) for both the client and backup networks. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress **security rules** to your Exadata Cloud Service VM cluster. A maximum of five NSGs can be specified. For more information, see Network Security Groups on page 2841 and Network Setup for Exadata Cloud Service Instances on page 1232.

  Note that if you choose a subnet with a security list, the security rules for the VM cluster will be a union of the rules in the security list and the NSGs.

  **To use network security groups:**

  - Check the **Use network security groups to control traffic** check box. This box appears under both the selector for the client subnet and the backup subnet. You can apply NSGs to either the client or the backup network, or to both networks. Note that you must have a virtual cloud network selected to be able to assign NSGs to a network.

  - Specify the NSG to use with the network. You might need to use more than one NSG. If you're not sure, contact your network administrator.

  - To use additional NSGs with the network, click **+ Another Network Security Group**.

- **Hostname prefix:** Your choice of host name for the Exadata DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for an Exadata DB system is 12.

  **Important:**

  The host name must be unique within the subnet. If it is not unique, the VM cluster will fail to provision.

- **Host domain name:** The domain name for the VM cluster. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

  If you plan to store database backups in Object Storage, Oracle recommends that you use a VCN Resolver for DNS name resolution for the client subnet because it automatically resolves the Swift endpoints used for backups.

- **Host and domain URL:** This read-only field combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.
11. **Choose a license type:** The type of license you want to use for the VM cluster. Your choice affects metering for billing.

   - **License Included** means the cost of the cloud service includes a license for the Database service.
   - **Bring Your Own License (BYOL)** means you are an Oracle Database customer with an Unlimited License Agreement or Non-Unlimited License Agreement and want to use your license with Oracle Cloud Infrastructure. This removes the need for separate on-premises licenses and cloud licenses.

12. **Click Show Advanced Options** to specify advanced options for the VM cluster:

   - **Time zone:** The default time zone for the DB system is UTC, but you can specify a different time zone. The time zone options are those supported in both the Java.util.TimeZone class and the Oracle Linux operating system. For more information, see [DB System Time Zone](#) on page 1575.

     **Tip:**
     
     If you want to set a time zone other than UTC or the browser-detected time zone, and if you do not see the time zone you want, try selecting the **Select another time zone** option, then selecting “Miscellaneous” in the **Region or country** list and searching the additional **Time zone** selections.

   - **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see [Resource Tags](#) on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

13. **Click Create Exadata VM Cluster.**

**WHAT NEXT?**

After your VM cluster is successfully created and in the Available state, you can view the VM Cluster Details page by clicking the name of the VM cluster in the list of clusters. From the VM Cluster Details page, you can create your first database in the cluster by clicking **Create Database**. 

*To create an X7 or X8 Exadata DB system*

**Tip:**

Oracle recommends using the new [Exadata Cloud Service resource model](#) when provisioning a new service instance. The new resource model is compatible with all available Exadata shape families (X7, X8, and X8M).

The DB system resource described in this topic will be deprecated after a period where both resource models are supported. If you need to provision a service instance using the DB system resource model, you will be able to switch the instance to the new resource model. See [To switch an Exadata DB system to the new Exadata resource model](#) on page 1229 for more information. Customers with existing Exadata DB systems will be notified in advance regarding the deprecation of the DB system resource model.

1. Open the navigation menu. Under Oracle Database, click **Bare Metal, VM, and Exadata**.
2. Click **Create DB System**.
3. On the **Create DB System** page, provide the basic information for the DB system:

- **Select a compartment:** By default, the DB system launches in your current compartment and you can use the network resources in that compartment.

- **Name your DB system:** A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system. Avoid entering confidential information.

- **Select an availability domain:** The *availability domain* in which the DB system resides.

- **Select a shape type:** The shape type you select sets the default shape and filters the shape options in the next field.

When you select Exadata, you are asked if you would like to use the newer Exadata resource model that replaces the DB system resource with a cloud Exadata infrastructure resource and a cloud VM cluster. These resources are compatible with X7, X8, and X8M hardware generations. Click **Continue Creating DB System** if you do not want to use the new resource model.

- **Select a shape:** The shape determines the type of DB system and the resources allocated to the system. To specify a shape other than the default, click **Change Shape**, and select an available shape from the list. See Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base on page 1351 for available shapes in Oracle Cloud Infrastructure.

Note that the X8M shape is not available when using the DB system resource model.

- **Configure the DB system:** Specify the following:
  
  - **Total node count:** The number of nodes in the DB system. The number depends on the shape you select.
  
  - **Oracle Database software edition:** The database edition supported by the DB system. Exadata DB systems only support Enterprise Edition - Extreme Performance.
  
  - **CPU core count:** The number of CPU cores for the DB system. The text below the field indicates the acceptable values for that shape. The core count is evenly divided across the nodes.

You can increase the CPU cores to accommodate increased demand after you launch the DB system.

For an X8 or X7 Exadata DB system, or an Exadata base system, you can specify zero (0) CPU cores when you launch the system. This will provision the system and immediately stop it. See Scaling CPU Cores Within an Exadata Cloud Service Instance on page 1222 for information about CPU core scaling and the impact on billing. Oracle recommends that if you are not provisioning a stopped system (0 cores), that you specify at least 3 cores per node.

- **Configure storage:** Specify the following:

  - **Cluster Name:** *(Optional)* A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive. Avoid entering confidential information.

  - **Storage Allocation:** The configuration settings that determine the percentage of storage assigned to DATA, RECO, and optionally, SPARSE disk:

    - **Database Backups on Exadata Storage:** Select this option if you intend to perform database backups to the local Exadata storage within your Exadata DB system environment. If you select this option, more space is allocated to the RECO disk group, which is used to store backups on Exadata storage. If you do not select this option, more space is allocated to the DATA disk group, which enables you to store more information in your databases.

    - **Create Sparse Disk Group:** Select this configuration option if you intend to use snapshot functionality within your Exadata DB system environment. If you select this option, the SPARSE disk group is created, which enables you to use Exadata DB system snapshot functionality for PDB sparse cloning. If you do not select this option, the SPARSE disk group is not created and Exadata DB system snapshot functionality will not be available on any database deployments that are created in the environment.

    **Important:**

    Creating a sparse disk group impacts the storage available for the ASM disk groups (DATA and RECO) and you cannot change the storage allocation configuration after you provision your DB system.
For information about the percentage of storage that will be assigned to DATA, RECO, and SPARSE disk based on your configuration, see Storage Configuration on page 1224. Similar information will display under the options in the Console dialog.

- **Add public SSH keys**: The public key portion of each key pair you want to use for SSH access to the DB system. You can browse or drag and drop .pub files, or paste in individual public keys. To paste multiple keys, click + Another SSH Key, and supply a single key for each entry.

- **Choose a license type**: The type of license you want to use for the DB system. Your choice affects metering for billing.
  - **License Included** means the cost of the cloud service includes a license for the Database service.
  - **Bring Your Own License (BYOL)** means you are an Oracle Database customer with an Unlimited License Agreement or Non-Unlimited License Agreement and want to use your license with Oracle Cloud Infrastructure. This removes the need for separate on-premises licenses and cloud licenses.

4. Specify the network information:

- **Virtual cloud network**: The VCN in which to launch the DB system. Click Change Compartment to select a VCN in a different compartment.

- **Client subnet**: The subnet to which the Exadata DB system should attach. Click Change Compartment to select a subnet in a different compartment.

  Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

- **Backup subnet**: The subnet to use for the backup network, which is typically used to transport backup information to and from Oracle Cloud InfrastructureObject Storage, and for Data Guard replication. Click Change Compartment to select a subnet in a different compartment, if applicable.

  Do not use a subnet that overlaps with 192.168.128.0/20. This restriction applies to both the client subnet and backup subnet.

  If you plan to back up databases to Object Storage, see the network prerequisites in Managing Exadata Database Backups on page 1320.

- **Network Security Groups**: Optionally, you can specify one or more network security groups (NSGs) for both the client and backup networks. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your DB system. A maximum of five NSGs can be specified. For more information,
see Network Security Groups on page 2841 and Network Setup for Exadata Cloud Service Instances on page 1232.

Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs.

To use network security groups:

- Check the Use Network Security Groups to Control Client Traffic check box. Note that you must already selected a VCN to be able to assign NSGs to the client network.
- Specify the NSG to use with the client network. You might need to use more than one NSG. If you're not sure, contact your network administrator.
- To use additional NSGs with the client network, click + Another Network Security Group.
- Check the Use Network Security Groups to Control Backup Traffic check box.
- Specify the NSG to use with the backup network just as described previously for the client subnet.
- **Hostname prefix:** Your choice of host name for the Exadata DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for an Exadata DB system is 12.

![Important:]

The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

- **Host domain name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

If you plan to store database backups in Object Storage, Oracle recommends that you use a VCN Resolver for DNS name resolution for the client subnet because it automatically resolves the Swift endpoints used for backups.

- **Host and domain URL:** Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

5. Click Show Advanced Options to specify advanced options for the DB system:

- **Disk redundancy:** Exadata DB systems support only high redundancy (3-way mirroring).
- **Time zone:** The default time zone for the DB system is UTC, but you can specify a different time zone. The time zone options are those supported in both the Java.util.TimeZone class and the Oracle Linux operating system. For more information, see DB System Time Zone on page 1575.

![Tip:]

If you want to set a time zone other than UTC or the browser-detected time zone, and if you do not see the time zone you want, try selecting the Select another time zone option, then selecting "Miscellaneous" in the Region or country list and searching the additional Time zone selections.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

6. After you completed the network configuration and any advanced options, click Next.
7. Provide information for the initial database:

- **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.

- **Database version:** The version of the initial database created on the DB system when it is launched. After the DB system is active, you can create additional databases on it. You can mix database versions on the DB system.

  **Note:**
  
  If you plan to run Oracle Database 19c on your Exadata DB system, you must specify version 19c when you create the DB system. Earlier database versions are supported on a 19c Exadata DB system and can be created at anytime. Exadata DB systems created with earlier Oracle Database versions will not automatically support Oracle Database 19c. The DB system must be upgraded manually.

- **PDB name:** Not applicable to version 11.2.0.4. The name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).

- **Create administrator credentials:** A database administrator SYS user will be created with the password you supply.
  
  - **Username:** SYS
  
  - **Password:** Supply the password for this user. The password must meet the following criteria:
    
    A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
  
  - **Confirm password:** Re-enter the SYS password you specified.

- **Select workload type:** Choose the workload type that best suits your application:
  
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.

- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  
  - **Enable automatic backups:** Check the check box to enable automatic incremental backups for this database.
  
  - **Backup retention period:** (Optional) If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  
  - **Backup scheduling (UTC):** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default
Database window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Automatic Incremental Backups for more information.

- Click **Show Advanced Options** to specify advanced options for the initial database.

In the **Management** tab you can specify the following options:

- **Character set**: The character set for the database. The default is AL32UTF8.
- **National character set**: The national character set for the database. The default is AL16UTF16.

In the **Encryption** tab, **Use Oracle-managed keys** is the only selection and cannot be changed during this creation process. You can change encryption management to use encryption keys that you manage after the database is provisioned. See To administer Vault encryption keys on page 1311 for more information.

In the **Tags** tab, you can add tags to the database. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

8. Click **Create DB System**. The DB system appears in the list with a status of Provisioning. The DB system's icon changes from yellow to green (or red to indicate errors).

After the DB system's icon turns green in the list of DB systems and displays the Available status, you can click the highlighted DB system name to see details about the DB system. Note the IP addresses. You'll need the private or public IP address, depending on network configuration, to connect to the DB system.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create Exadata Cloud Service components.

**APIs for the New Exadata Cloud Service Resource Model**

The new Exadata resource model is compatible with all offered Exadata shape families (X7, X8, and X8M). See The New Exadata Cloud Service Resource Model on page 1228 for more information.

<table>
<thead>

Configuring a Static Route for Accessing the Object Store

All the traffic in an Exadata Cloud Service instance is, by default, routed through the data network. To route backup traffic to the backup interface (BONDETH1), you need to configure a static route on each of the compute nodes in the cluster. For instructions, see Node Access to Object Storage: Static Route on page 1236.

Setting Up DNS for an Exadata Cloud Service Instance

DNS lets you use host names instead of IP addresses to communicate with an Exadata Cloud Service instance. You can use the Internet and VCN Resolver (the DNS capability built into the VCN) as described in DNS in Your Virtual Cloud Network on page 2910. Oracle recommends using a VCN Resolver for DNS name resolution for the client subnet. It automatically resolves the Swift endpoints required for backing up databases, patching, and updating the cloud tooling on an Exadata instance.

Maintaining an Exadata Cloud Service Instance

User-Managed Maintenance Updates

Maintaining a secure Exadata Cloud Service instance in the best working order requires you to perform the following tasks regularly:

- Patching the Oracle Grid Infrastructure and Oracle Database software on the Exadata compute nodes. See Patching an Exadata Cloud Service Instance Manually on page 1289 and Oracle Clusterware Configuration and Administration for information and instructions.
- Updating the operating system and the tooling on the compute nodes. See Updating an Exadata Cloud Service Instance on page 1274 for information and instructions.

Oracle-Managed Infrastructure Maintenance Updates

In addition to the maintenance tasks you perform, Oracle manages the patching and updating of all other infrastructure components, including the physical compute nodes (Dom0), the Exadata storage servers, and the Exadata InfiniBand switches. This is referred to as DB system infrastructure maintenance.

Overview of the Infrastructure Patching Process

Infrastructure maintenance begins with patching of the Exadata compute nodes. Compute nodes are updated in a rolling fashion, with a single node being shut down, patched, and then brought back online while other nodes remain operational. This process continues until all nodes are patched. After compute node patching completes, Oracle patches the storage nodes. Storage server patching does not impact compute node availability.

Note that while databases are expected to be available during the patching process, Oracle does not verify that all database services and pluggable databases are available after a node is brought back online, as these can depend on the application service definition. Oracle recommends reviewing the documentation on workload management, application continuity, and client failover best practices to reduce the potential for an outage with your applications. By following the guidelines in the documentation, the impact of infrastructure patching will be only minor service degradation due to connection loss as compute nodes are sequentially patched.

Oracle recommends that you follow the Maximum Availability Architecture (MAA) best practices and use Oracle Data Guard to ensure the highest availability for your critical applications. For databases with Oracle Data Guard enabled, Oracle recommends that you separate the patching windows for the infrastructure instances running the
primary and standby databases, and perform a switchover prior to the maintenance operations for the infrastructure instance hosting the primary database, to avoid any impact to your primary database during infrastructure patching.

The approximate time for patching operations is as follows:

- Quarter rack: five hours
- Half rack: 10 hours
- Full rack: 20 hours

Typically, Exadata compute nodes require one and half hours each for patching, and storage servers require one hour each.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not perform major maintenance operations on your databases or applications during the patching window, as these operations could be impacted by the rolling patch operations.</td>
</tr>
</tbody>
</table>

**Scheduling Oracle-Managed Infrastructure Updates**

Exadata Cloud Service infrastructure updates are released on a quarterly basis. You can set a maintenance window to determine the time your quarterly infrastructure maintenance will begin. You can also view scheduled maintenance runs and the maintenance history of your Exadata Cloud Service instance in the Oracle Cloud Infrastructure Console on the Exadata Infrastructure Details or DB System Details page. For more information:

- To set the automatic maintenance schedule for Exadata Cloud Service infrastructure on page 1262
- To view or edit the time of the next scheduled maintenance for Exadata Cloud Service infrastructure on page 1263
- To view the maintenance history of an Exadata Cloud Service infrastructure resource on page 1263

In exceptional cases, Oracle can update your system apart from the regular quarterly updates to apply time-sensitive changes such as security updates. While you cannot opt out of these infrastructure updates, Oracle alerts you in advance through the Cloud Notification Portal to help you plan for them.

**Monitoring Patching Operations Using Lifecycle State Information**

The lifecycle state of your infrastructure resource (either the cloud Exadata infrastructure or the DB system resource) enables you to monitor when the patching of your infrastructure resource begins and ends. In the Oracle Cloud Infrastructure Console, you can see lifecycle state details messages on the Exadata Infrastructure Details or DB System Details page when a tool tip is displayed beside the **Status** field. You can also access these messages using the **ListCloudExadataInfrastructures** API (for cloud Exadata infrastructure resources) or the **ListDbSystems** API (for Exadata DB systems), and using tools based on the API, including SDKs and the **OCI CLI**.

During patching operations, you can expect the following:

- If you specify a maintenance window, then patching begins at your specified start time. The patching process starts with a series of prerequisite checks to ensure that your system can be successfully patched. These checks take approximately 30 minutes to complete. While the system is performing the checks, the infrastructure resource's lifecycle state remains "Available," and there is no lifecycle state message.

  For example, if you specify that patching should begin at 8:00 a.m., then Oracle begins patching operations at 8:00, but the infrastructure resource's lifecycle state does not change from "Available" to "Maintenance in Progress" until approximately 8:30 a.m.

- When Exadata compute node patching starts, the infrastructure resource's lifecycle state is "Maintenance in Progress", and the associated lifecycle state message is "The underlying infrastructure of this system (dbnodes) is being updated."

- When cell storage patching starts, the infrastructure resource's lifecycle state is "Maintenance in Progress", and the associated lifecycle state message is "The underlying infrastructure of this system (cell storage) is being updated and this will not impact Database availability."

- After cell patching is complete, the networking switches are patched one at a time, in a rolling fashion.

- When patching is complete, the infrastructure resource's lifecycle state is "Available", and the Console and API-based tools do not provide a lifecycle state message.
For More Information

For information about the update policy, and details such as the duration and impact on your system's availability and performance, see Oracle Database Cloud Exadata Service Supported Software Versions and Planning for Updates.

Managing an Exadata Cloud Service Instance

This topic describes management operations you can perform on an Exadata Cloud Service instance at the infrastructure level.

Note:

If your instance uses the older DB system resource model, all of the management operations discussed in this topic take place on the DB system resource.

If your instance uses the newer Exadata Cloud Service instance resource model, most of the management operations discussed in this topic take place on the cloud VM cluster resource. However, some operations, including those related to infrastructure maintenance, take place on the cloud Exadata infrastructure resource.

For all of the management tasks, this topic states which resource types the operation takes place on.

You can perform the management tasks discussed in this topic by using the Oracle Cloud Infrastructure Console or the API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

Using the Console

To check the status of a cloud Exadata infrastructure resource

Note:

This topic only applies to Exadata Cloud Service instances using the new Exadata Cloud Service instance resource model.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Click Exadata Infrastructure under Exadata at Oracle Cloud.
4. In the list of cloud Exadata infrastructure resources, click the name of the infrastructure you're interested in and check its icon. The icon text indicates the status of the system. The following lifecycle states apply to the cloud Exadata infrastructure resource:

- **Provisioning**: Resources are being reserved for the cloud Exadata infrastructure resource. Provisioning can take several minutes. The resource is not ready to use yet.
- **Available**: The cloud Exadata infrastructure was successfully provisioned. You can create a cloud VM cluster on the resource to complete the infrastructure provisioning.
- **Updating**: The cloud Exadata infrastructure is being updated. The resource goes into the updating state during management tasks. For example, when moving the resource to another compartment, or creating a cloud VM cluster on the resource.
- **Terminating**: The cloud Exadata infrastructure is being deleted by the terminate action in the Console or API.
- **Terminated**: The cloud Exadata infrastructure has been deleted and is no longer available.
- **Failed**: An error condition prevented the provisioning or continued operation of the cloud Exadata infrastructure.

**To check the status of a cloud VM cluster**

**Note:**
This topic only applies to Exadata Cloud Service instances using the new Exadata Cloud Service instance resource model.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Click Exadata VM Clusters under Exadata at Oracle Cloud.
4. In the list of cloud VM clusters, find the cluster you're interested in and check its icon. The icon text indicates the status of the system. The following lifecycle states apply to the cloud VM cluster:

- **Provisioning**: Resources are being reserved for the cloud Exadata infrastructure resource. Provisioning can take several minutes. The resource is not ready to use yet.
- **Available**: The cloud Exadata infrastructure was successfully provisioned. You can create a cloud VM cluster on the resource to complete the infrastructure provisioning.
- **Updating**: The cloud Exadata infrastructure is being updated. The resource goes into the updating state during management tasks. For example, when moving the resource to another compartment, or creating a cloud VM cluster on the resource.
- **Terminating**: The cloud Exadata infrastructure is being deleted by the terminate action in the Console or API.
- **Terminated**: The cloud Exadata infrastructure has been deleted and is no longer available.
- **Failed**: An error condition prevented the provisioning or continued operation of the cloud Exadata infrastructure.

To view the status of a virtual machine (database node) in the cloud VM cluster, under Resources, click Virtual Machines to see the list of virtual machines. In addition to the states listed for a cloud VM cluster, a virtual machine's status can be one of the following:

- **Starting**: The database node is being powered on by the start or reboot action in the Console or API.
- **Stopping**: The database node is being powered off by the stop or reboot action in the Console or API.
- **Stopped**: The database node was powered off by the stop action in the Console or API.

**To check the status of an Exadata DB system**

**Note:**
This topic only applies to Exadata Cloud Service instances using the DB system resource model.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.

A list of DB systems is displayed.
3. In the list of DB systems, find the system you're interested in and check its icon. The icon text indicates the status of the system. The following lifecycle states apply to the DB system resource:

- **Provisioning:** Resources are being reserved for the DB system, the system is booting, and the initial database is being created. Provisioning can take several minutes. The system is not ready to use yet.
- **Available:** The DB system was successfully provisioned. A few minutes after the system enters this state, you can SSH to it and begin using it.
- **Terminating:** The DB system is being deleted by the terminate action in the Console or API.
- **Terminated:** The DB system has been deleted and is no longer available.
- **Failed:** An error condition prevented the provisioning or continued operation of the DB system.

To view the status of a database node, under Resources, click **Nodes** to see the list of nodes. In addition to the states listed for a DB system, a node's status can be one of the following:

- **Starting:** The database node is being powered on by the start or reboot action in the Console or API.
- **Stopping:** The database node is being powered off by the stop or reboot action in the Console or API.
- **Stopped:** The database node was powered off by the stop action in the Console or API.

You can also check the status of DB systems and database nodes using the **ListDbSystems** or **ListDbNodes** API operations, which return the `lifecycleState` attribute.

**To start, stop, or reboot an Exadata Cloud Service cloud VM cluster or DB system**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system you want to start, stop, or reboot:

   - **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under **Bare Metal, VM, and Exadata**, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Under **Resources**, click **Virtual Machines** (for cloud VM clusters) or **Nodes** (for DB systems) to display the compute nodes of the cloud service instance. Click the Actions icon (three dots) for a node and then click one of the following actions:

   - **Start:** Restarts a stopped node. After the node is restarted, the **Stop** action is enabled.
   - **Stop:** Shuts down the node. After the node is powered off, the **Start** action is enabled.
   - **Reboot:** Shuts down the node, and then restarts it.

**Note:**

- For billing purposes, the **Stop** state has no effect on the resources you consume. Billing continues for virtual machines or nodes that you stop, and related resources continue to apply against any relevant quotas. You must **Terminate** a cloud VM cluster or DB system to remove its resources from billing and quotas.
- After you restart or reboot a node, the floating IP address might take several minutes to be updated and display in the Console.

**To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system**

**Note:**

For information on adding additional database (compute) and storage servers to **X8M cloud VM clusters**, see **To add compute and storage resources to a flexible cloud Exadata infrastructure resource** on page 1230 and **To add database server or storage server capacity to a cloud VM cluster** on page 1230. Adding additional database servers to your X8M cloud VM cluster will increase the number of CPU cores available for scaling.
If an Exadata Cloud Service instance requires more compute node processing power, you can scale up (increase) the number of enabled CPU cores (OCPUs) in the instance.

You can also scale a cloud VM cluster or DB system (except for X6 systems) down to zero (0) CPU cores to temporarily stop the system and be charged only for the hardware infrastructure. For more information about scaling down, see Scaling Options on page 1222. Oracle recommends that if you are not scaling down to a stopped system (0 cores), that you scale to at least 3 cores per node.

CPU cores must be scaled symmetrically across all nodes in the cloud VM cluster or DB system. Use multiples of two for a base system or quarter rack, multiples of four for a half rack, and multiples of eight for a full rack. The total number of CPU cores in a rack must not exceed the maximum limit for that shape.

| Tip: |
| OCPU scaling activities are done online with no downtime. |

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to scale:
   - **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Click Scale VM Cluster (for cloud VM clusters) or Scale CPU Cores (for DB systems) and then specify a new number of CPU cores. The text below the field indicates the acceptable values, based on the shape used when the DB system was launched.
5. Click Update.

| Note: |
| If you scale a cloud VM cluster or DB system (except for X6 systems) down to zero (0) CPU cores, the floating IP address of the nodes might take several minutes to be updated and display in the Console. |

**To move an Exadata Cloud Service infrastructure resource to another compartment**

| Note: |
| - To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service on page 2240.
  - If your Exadata Cloud Service instance is in a security zone, the destination compartment must also be in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources. |

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud Exadata infrastructure, cloud VM cluster or DB system you want to move:

**Cloud Exadata infrastructure (new resource model):** Under [Exadata at Oracle Cloud](https://oracle.com), click **Exadata Infrastructure**. In the list of infrastructure resources, find the infrastructure you want to access and click its highlighted name to view its details page.

**Cloud VM clusters (new resource model):** Under [Exadata at Oracle Cloud](https://oracle.com), click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

**DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Click **Move Resource**.

5. Select the new compartment.

6. Click **Move Resource**.

For information about dependent resources for Database resources, see [Moving Database Resources to a Different Compartment](https://oracle.com) on page 1141.

### To terminate Exadata Cloud Service infrastructure-level resources

This topic describes how to terminate a cloud Exadata infrastructure, cloud VM cluster, or DB system resource in an Exadata Cloud Service instance.

**Note:**

The database data is local to the cloud VM cluster or DB system hosting it and is lost when the system is terminated. Oracle recommends that you back up any data in the cloud VM cluster or DB system before terminating it.

Terminating an Exadata Cloud Service resource permanently deletes it and any databases running on it.

---

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.

3. Navigate to the cloud Exadata infrastructure, cloud VM cluster or DB system you want to move:

   **Cloud Exadata infrastructure (new resource model):** Under [Exadata at Oracle Cloud](https://oracle.com), click **Exadata Infrastructure**. In the list of infrastructure resources, find the infrastructure you want to access and click its highlighted name to view its details page.

   **Cloud VM clusters (new resource model):** Under [Exadata at Oracle Cloud](https://oracle.com), click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. For cloud VM clusters and DB systems, click **More Actions**, then **Terminate** on the resource details page. For cloud Exadata infrastructure resources, click **Terminate** on the resource details page.

   Confirm when prompted.

   The resource's icon indicates Terminating.

**Note:**

If you are terminating a cloud Exadata infrastructure resource that contains a cloud VM cluster, you must check the box labelled **Also delete the VM cluster associated with this infrastructure** to confirm that you intend to delete the VM cluster.

At this point, you cannot connect to the system and any open connections are terminated.
To edit the network security groups (NSGs) for your client or backup network

Your client and backup networks can each use up to five network security groups (NSGs). Note that if you choose a subnet with a security list, the security rules for the cloud VM cluster or DB system will be a union of the rules in the security list and the NSGs. For more information, see Network Security Groups on page 2841 and Network Setup for Exadata Cloud Service Instances on page 1232.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to manage:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. In the Network details, click the Edit link to the right of the Client Network Security Groups or Backup Network Security Groups field.
5. In the Edit Network Security Groups dialog, click + Another Network Security Group to add an NSG to the network.

   To change an assigned NSG, click the drop-down menu displaying the NSG name, then select a different NSG.

   To remove an NSG from the network, click the X icon to the right of the displayed NSG name.

6. Click Save.

To manage your BYOL database licenses

If you want to control the number of database licenses that you run at any given time, you can scale up or down the number of OCPUs on the instance. These additional licenses are metered separately.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to scale:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Click Scale VM Cluster (for cloud VM clusters) or Scale CPU Cores (for DB systems) and then specify a new number of CPU cores. The text below the field indicates the acceptable values, based on the shape used when the DB system was launched.

5. Click Update.

To change the license type of an Exadata Cloud Service cloud VM cluster or DB system

Note:

Updating the license type is not supported for systems running on the X6 shape. The feature is supported for X7 and higher shapes.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to manage:

   * **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   * **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. On the resource details page, click Update License Type.

   The dialog displays the options with your current license type selected.

5. Select the new license type.

6. Click Save.

To manage tags for your Exadata Cloud Service resources

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Choose your Compartment.

3. Find the cloud Exadata infrastructure, cloud VM cluster, DB system or database resource you're interested in, and click the name.

4. Click the Tags tab to view or edit the existing tags. Or click More Actions and then Apply Tags to add new ones.

   For more information, see Resource Tags on page 211.

To view a work request for your Exadata Cloud Service resources

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Choose your Compartment.

   A list of DB systems is displayed.

3. Find the cloud Exadata infrastructure, cloud VM cluster, DB system or database resource you're interested in, and click the name.

4. In the Resources section, click Work Requests. The status of all work requests appears on the page.

5. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the More information section.

   For associated resources, you can click the Actions icon (three dots) next to a resource to copy the resource's OCID.

   For more information, see Work Requests on page 258.

To set the automatic maintenance schedule for Exadata Cloud Service infrastructure

This task describes how to set the maintenance schedule for a cloud Exadata infrastructure or Exadata DB system resource. See Oracle-Managed Infrastructure Maintenance Updates on page 1254 for more information on this type of maintenance.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Navigate to the cloud Exadata infrastructure or DB system you want to access:

   * **Cloud Exadata infrastructure (new resource model):** Under Exadata at Oracle Cloud, click Exadata Infrastructure. In the list of infrastructure resources, find the infrastructure you want to access and click its highlighted name to view its details page.

   * **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

3. On the resource details page, under Maintenance or Infrastructure Maintenance, click the edit link in the Maintenance Schedule field.

4. In the Automatic Maintenance Schedule dialog, select Specify a schedule.

5. Under Maintenance months, specify at least one month for each quarter during which Exadata infrastructure maintenance will take place. You can select more than one month per quarter. If you specify a long lead time for advanced notification (for example, 4 weeks), then you may want to specify two or three months per quarter.
during which maintenance runs can occur. This will ensure that your maintenance updates are applied in a timely manner after accounting for your required lead time. Lead time is discussed in the following steps.

6. **Under Week of the month**, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of seven days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.

7. **Optional.** Under **Day of the week**, specify the day of the week on which the maintenance will occur. If you do not specify a day of the week, then Oracle will run the maintenance update on a weekend day to minimize disruption.

8. **Optional.** Under **Start hour**, specify the hour during which the maintenance run will begin. If you do not specify a start hour, then Oracle will choose the least disruptive time to run the maintenance update.

9. Under **Lead Time**, specify the number of weeks ahead of the maintenance event you would like to receive a notification message. Your lead time ensures that a newly released maintenance update is scheduled to account for your required period of advanced notification.

10. Click **Update Maintenance Schedule**.

To **view or edit the time of the next scheduled maintenance for Exadata Cloud Service infrastructure**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Navigate to the cloud Exadata infrastructure or DB system you want to access:

   * **Cloud Exadata infrastructure (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata Infrastructure**. In the list of infrastructure resources, find the infrastructure you want to access and click its highlighted name to view its details page.

   * **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

3. On the resource details page, under **Maintenance** or **Infrastructure Maintenance**, click the **view** link in the **Next Maintenance** field.

4. On the **Maintenance** page, scheduled maintenance events are listed.

5. **Optional.** To change the time of the next scheduled maintenance, click the Edit link in the **Scheduled Start Time** field.

6. In the **Edit Infrastructure Maintenance Scheduled Start Time** dialog, enter a date and time in the **Scheduled start time** field.

   The following restrictions apply:
   
   - Infrastructure maintenance cannot be rescheduled to occur more than six months after the announcement of the maintenance update's availability. If a new patch is announced prior to your rescheduled maintenance run, the newer patch will be applied on your specified date. You can reschedule your maintenance to take place earlier than it is currently scheduled.
   - Oracle reserves certain dates each quarter for internal maintenance operations, and you cannot schedule your maintenance on these dates. When using the Console, the selection of these dates is disabled.

7. Click **Update Scheduled Start Time**.

To **view the maintenance history of an Exadata Cloud Service infrastructure resource**

This task describes how to view the maintenance history for a cloud Exadata infrastructure or DB system resource. See **Oracle-Managed Infrastructure Maintenance Updates** on page 1254 for more information on this type of maintenance.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Navigate to the cloud Exadata infrastructure or DB system you want to access:

   * **Cloud Exadata infrastructure (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata Infrastructure**. In the list of infrastructure resources, find the infrastructure you want to access and click its highlighted name to view its details page.

   * **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
3. On the resource details page, under **Maintenance** or **Infrastructure Maintenance**, click the **view** link in the **Next Maintenance** field.

4. Click **Maintenance History** to see a list of past maintenance events including details on their completion state.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage Exadata Cloud Service instance components.

**Cloud Exadata infrastructure resource (new resource model):**

- ListCloudExadataInfrastructures
- GetCloudExadataInfrastructure
- ChangeCloudExadataInfrastructureCompartment
- UpdateCloudExadataInfrastructure
- DeleteCloudExadataInfrastructure

**Cloud VM cluster (new resource model)**

- ListCloudVmClusters
- GetCloudVmCluster
- ChangeCloudVmClusterCompartment
- UpdateCloudVmCluster
- GetCloudVmClusterIormConfig
- UpdateCloudVmClusterIormConfig

**Managing Exadata Cloud Service I/O Resource Management (IORM)**

This topic explains the I/O Resource Management (IORM) feature and how to enable it, modify the IORM settings, and disable it by using the Console or the API.

**About IORM**

The I/O Resource Management (IORM) feature allows you to manage how multiple databases share the I/O resources of an Oracle Exadata cloud VM cluster (for systems using the **new resource model**) or DB system.

On an Exadata VM cluster or DB system, all databases share dedicated storage servers which include flash storage. By default, the databases are given equal priority with respect to these resources. The Exadata storage management software uses a first come, first served approach for query processing. If a database executes a major query that overloads I/O resources, overall system performance can be slowed down.

IORM allows you to assign priorities to your databases to ensure critical queries are processed first when workloads exceed their resource allocations. You assign priorities by creating directives that specify the number of shares for each database. The number of shares corresponds to a percentage of resources given to that database when I/O resources are stressed.
Directives work together with an overall optimization objective you set for managing the resources. The following objectives are available:

- **Auto** - Recommended. IORM determines the optimization objective and continuously and dynamically determines the optimal settings, based on the workloads observed, and resource plans enabled.
- **Balanced** - For critical OLTP and DSS workloads. This setting balances low disk latency and high throughput. This setting limits disk utilization of large I/Os to a lesser extent than low latency to achieve a balance between good latency and good throughput.
- **High throughput** - For critical DSS workloads that require high throughput.
- **Low latency** - For critical OLTP workloads. This setting provides the lowest possible latency by significantly limiting disk utilization.

For more information about IORM, see Exadata System Software User's Guide.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

**Using the Console**

*To enable IORM on your Exadata cloud VM cluster*

**Note:**

This topic only applies to Exadata Cloud Service systems using the new infrastructure resource model. If you are enabling IORM for an Exadata DB system, see To enable IORM on your Exadata DB system on page 1266.

Enabling IORM includes specifying an optimization objective and configuring your resource plan directives.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Click Exadata VM Clusters under the Exadata at Oracle Cloud.
4. In the list of VM clusters, find the VM cluster for which you want to enable IORM, and click its highlighted name. The cluster's details are displayed, showing the IORM status as “Disabled.”
5. Click More Actions, then Enable IORM.
   
   It might take a minute for the Enable I/O Resource Management dialog to retrieve the VM cluster information.
6. Select the objective to apply to the resource plan:
   
   - **Auto** - (Recommended) Dynamically changes the objective based on the resource plan and observed workloads.
   - **Balanced** - Weighs high throughput and low latency evenly.
   - **High throughput** - Provides the best throughput for DSS workloads.
   - **Low latency** - Provides the best latency for critical OLTP workloads.
7. Configure the resource plan default directive by setting the number of shares. This number of shares is assigned to each database not associated with a specific directive.
8. In the Resource Plan Directives section, add a directive for each database you want to assign a greater or lesser number of shares than the default directive.

   To add a directive, click + Additional Directive, then specify the database and the number of shares for that database.
9. When you are done adding directives, click **Enable**.

While the IORM configuration settings are being applied, the VM cluster details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your VM cluster. After a successful update, the IORM status shows as "Enabled."

**To modify the IORM configuration on your cloud VM cluster**

**Note:**

This topic only applies to Exadata Cloud Service systems using the new infrastructure resource model. If you are updating an Exadata DB system, see To modify the IORM configuration on your Exadata DB system on page 1267.

Use this procedure to change your IORM settings or to disable IORM.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Click **Exadata VM Clusters** under **Exadata at Oracle Cloud**.
4. In the list of VM clusters, find the VM cluster for which you want to update IORM, and click its highlighted name. The cluster's details are displayed, showing the IORM status as "Enabled."
5. Click **More Actions**, then **Update IORM**.
6. In the Update I/O Resource Management dialog, take one of the following actions:
   - Change your settings - Specify a new objective and adjust your directives, as applicable, and then click **Update**.
   - Disable IORM - Click **Disable IORM**. Disabling IORM removes all your resource plan directives and restores a basic objective for I/O resource management.

While the new IORM configuration settings are being applied, the system details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your DB system. After a successful update, the IORM status shows as "Enabled" or "Disabled," depending on the action you took.

**To enable IORM on your Exadata DB system**

**Note:**

This topic only applies to Exadata Cloud Service instances using the DB system resource model.

Enabling IORM includes specifying an optimization objective and configuring your resource plan directives.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, find the Exadata DB system for which you want to enable IORM, and click its highlighted name.
   
   The system details are displayed, showing the IORM status as "Disabled."
4. Click **More Actions**, then **Enable IORM**.
   
   It might take a minute for the Enable I/O Resource Management dialog to retrieve the DB system information.
5. Select the objective to apply to the resource plan:
   - **Auto** - (Recommended) Dynamically changes the objective based on the resource plan and observed workloads.
   - **Balanced** - Weighs high throughput and low latency evenly.
   - **High throughput** - Provides the best throughput for DSS workloads.
   - **Low latency** - Provides the best latency for critical OLTP workloads.
6. Configure the resource plan default directive by setting the number of shares. This number of shares is assigned to each database not associated with a specific directive.
7. In the Resource Plan Directives section, add a directive for each database you want to assign a greater or lesser number of shares than the default directive.

To add a directive, click **Additional Directive**, then specify the database and the number of shares for that database.

8. When you are done adding directives, click **Enable**.

While the IORM configuration settings are being applied, the system details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your DB system. After a successful update, the IORM status shows as "Enabled."

**To modify the IORM configuration on your Exadata DB system**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>This topic only applies to Exadata Cloud Service instances using the DB system resource model.</td>

</tbody>
</table>

Use this procedure to change your IORM settings or to disable IORM.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, find the Exadata DB system for which you want to modify the IORM configuration, and click its highlighted name.

The system details are displayed, showing the IORM status as "Enabled."

4. Click **More Actions**, then **Update IORM**.
5. In the Update I/O Resource Management dialog, take one of the following actions:

   - Change your settings - Specify a new objective and adjust your directives, as applicable, and then click **Update**.
   - Disable IORM - Click **Disable IORM**. Disabling IORM removes all your resource plan directives and restores a basic objective for I/O resource management.

While the new IORM configuration settings are being applied, the system details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your DB system. After a successful update, the IORM status shows as "Enabled" or "Disabled," depending on the action you took.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage the I/O resources of an Exadata cloud VM cluster (see **The New Exadata Cloud Service Resource Model** on page 1228 for more information on this resource type).

- **ListCloudVmClusters**
- **GetCloudVmCluster**
- **GetCloudVmClusterIormConfig**
- **UpdateCloudVmClusterIormConfig**

Use these API operations to manage the I/O resources of an Exadata DB system.

- **UpdateExadataIormConfig**
Managing Exadata Resources with Oracle Enterprise Manager Cloud Control

This topic provides a short introduction to Oracle Enterprise Manager Cloud Control, a tool that can be used to manage and monitor Exadata Cloud and Exadata Cloud@Customer resources. For complete documentation and Oracle By Example tutorials, see Additional Information on page 1268 at the end of this topic.

Overview

Oracle Enterprise Manager Cloud Control provides a complete lifecycle management solution for Oracle Cloud Infrastructure's Exadata Cloud and Exadata Cloud@Customer services.

Enterprise Manager Cloud Control discovers Exadata Cloud and Exadata Cloud@Customer services as a single target and automatically identifies and organizes all dependent components. Using Enterprise Manager Cloud Control you can then:

- Monitor and manage all Exadata, Exadata Cloud and Exadata Cloud@Customer systems, along with any other targets, from a single interface
- Visualize storage and compute data
- View performance metrics of your Exadata components

Features

Enterprise Manager Target for Exadata Cloud

The target for Oracle Cloud Infrastructure Exadata resources (which covers both Exadata Cloud and Exadata Cloud@Customer) does the following:

- Automatically identifies and organizes related targets
- Provides a high-level integration point for Enterprise Manager framework features such as incident rules, groups, notifications, and monitoring templates

Improved Performance Monitoring

Enterprise Manager Cloud Control enhances performance monitoring in the following ways:

- Adds Exadata Storage Server and Exadata Storage Grid targets
- Offers visualization of storage and compute performance for your Exadata Cloud and Exadata Cloud@Customer resources
- Enables use of the same Maximum Availability Architecture (MAA) key performance indicators (KPI) developed for Oracle Exadata Database Machine

Scripted CLI-based Discovery

Enterprise Manager Cloud Control uses scripts to discover Oracle Cloud Infrastructure Exadata resources. Scripts comb the existing hosts, clusters, ASM, databases and related targets, as well as adding the storage server targets

"Single Pane of Glass" View of On-Premises and Oracle Cloud Infrastructure Exadata Resources

Enterprise Manager Cloud Control's use of a single Exadata target type provides a consistent Enterprise Manager experience across on-premises, Exadata Cloud, and Exadata Cloud@Customer resources. The common Exadata target menu allows you to easily navigate to, monitor and manage all of your Exadata systems.

Visualization

Enterprise Manager Cloud Control allows you to visualize the database and related targets associated with each Exadata Cloud and Exadata Cloud@Customer system.

Additional Information

For more information on Oracle Enterprise Manager Cloud Control, see the following documentation resources:

- Oracle Enterprise Manager Cloud Control for Oracle Exadata Cloud
Connecting to an Exadata Cloud Service Instance

This topic explains how to connect to an Exadata Cloud Service instance using SSH or SQL Developer. How you connect depends on how your cloud network is set up. You can find information on various networking scenarios in Networking Overview on page 2748, but for specific recommendations on how you should connect to a database in the cloud, contact your network security administrator.

Prerequisites

For SSH access to a compute node in an Exadata Cloud Service instance, you'll need the following:

• The full path to the file that contains the private key associated with the public key used when the system was launched.
• The public or private IP address of the Exadata Cloud Service instance.

Use the private IP address to connect to the system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console as follows:

• Cloud VM clusters (new resource model): On the Exadata VM Cluster Details page, click Virtual Machines in the Resources list.
• DB systems: On the DB System Details page, click Nodes in the Resources list.

The values are displayed in the Public IP Address and Private Address & DNS Name columns of the table displaying the Virtual Machines or Nodes of the Exadata Cloud Service instance.

Connecting to a Compute Node with SSH

You can connect to the compute nodes in an Exadata DB System by using a Secure Shell (SSH) connection. Most UNIX-style systems (including Linux, Solaris, BSD, and OS X) include an SSH client by default. For Windows, you can download a free SSH client called PuTTY from http://www.putty.org.

To connect from a UNIX-style system

Use the following SSH command to access a compute node:

```
$ ssh -i <private key> opc@<DB System IP address>
```

<private key> is the full path and name of the file that contains the private key associated with the Exadata DB System you want to access.

Use the private or public IP address depending on your network configuration. For more information, see Prerequisites on page 1391.

To connect from a Windows system

1. Open putty.exe.
2. In the Category pane, select Session and enter the following fields:
   • Host Name (or IP address): opc@<ip_address>
     Use the compute node's private or public IP address depending on your network configuration. For more information, see Prerequisites on page 1391.
   • Connection type: SSH
   • Port: 22
3. In the Category pane, expand Connection, expand SSH, and then click Auth, and browse to select your private key.
4. Optionally, return to the Session category screen and save this session information for reuse later.
5. Click Open to start the session.
To access a database after you connect to the compute node

1. Log in as opc and then sudo to the oracle user.

```
login as: opc
[opc@<host_name> ~]$ sudo su - oracle
```

2. Source the database's .env file to set the environment.

```
[oracle@<host_name>]# . <database_name>.env
```

In the following example, the host name is "ed1db01" and the database name is "cdb01".

```
[oracle@ed1db01]# . cdb01.env
ORACLE_SID = [root] ? +ASM1
The Oracle base has been set to /u01/app/grid
```

Connecting to a Database with SQL Developer

You can connect to a database with SQL Developer by using one of the following methods:

- Create a temporary SSH tunnel from your computer to the database. This method provides access only for the duration of the tunnel. (When you are done using the database, be sure to close the SSH tunnel by exiting the SSH session.)

- Open port 1521 for the Oracle default listener by updating the security list used for the cloud VM cluster or DB system resource in the Exadata Cloud Service instance. This method provides more durable access to the database. For more information, see Updating the Security List on page 1305.

After you’ve created an SSH tunnel or opened port 1521 as described above, you can connect to a Exadata Cloud Service instance using SCAN IP addresses or public IP addresses, depending on how your network is set up and where you are connecting from. You can find the IP addresses in the Console, in the Database details page.

To connect using SCAN IP addresses

You can connect to the database using the SCAN IP addresses if your client is on-premises and you are connecting using a FastConnect or VPN connection. You have the following options:

- Use the private SCAN IP addresses, as shown in the following tnsnames.ora example:

  ```
  testdb=
  (DESCRIPTION =
   (ADDRESS_LIST=
    (ADDRESS = (PROTOCOL = TCP)(HOST = <scanIP1>)(PORT = 1521))
    (ADDRESS = (PROTOCOL = TCP)(HOST = <scanIP2>)(PORT = 1521)))
   (CONNECT_DATA =
    (SERVER = DEDICATED)
    (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
   )
  )
  ```

- Define an external SCAN name in your on-premises DNS server. Your application can resolve this external SCAN name to the DB System's private SCAN IP addresses, and then the application can use a connection string that includes the external SCAN name. In the following tnsnames.ora example, extscanname.example.com is defined in the on-premises DNS server.

  ```
  testdb =
  (DESCRIPTION =
   (ADDRESS = (PROTOCOL = TCP)(HOST = <extscanname.example.com>)(PORT = 1521))
  )
  ```
To connect using public IP addresses

You can use the node's public IP address to connect to the database if the client and database are in different VCNs, or if the database is on a VCN that has an internet gateway. However, there are important implications to consider:

- When the client uses the public IP address, the client bypasses the SCAN listener and reaches the node listener, so server side load balancing is not available.
- When the client uses the public IP address, it cannot take advantage of the VIP failover feature. If a node becomes unavailable, new connection attempts to the node will hang until a TCP/IP timeout occurs. You can set client side sqlnet parameters to limit the TCP/IP timeout.

The following tnsnames.ora example shows a connection string that includes the CONNECT_TIMEOUT parameter to avoid TCP/IP timeouts.

```sql
TEST=
  (DESCRIPTION =
    (CONNECT_TIMEOUT=60)
    (ADDRESS_LIST=
      (ADDRESS = (PROTOCOL = TCP)(HOST = <publicIP1>)(PORT = 1521))
      (ADDRESS = (PROTOCOL = TCP)(HOST = <publicIP2>)(PORT = 1521))
    )
  (CONNECT_DATA =
    (SERVER = DEDICATED)
    (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
  )
)
```

Managing Exadata Cloud Service Software Images Using the Dbaascli Utility

You can create custom database software images for your Exadata Cloud Service instances using the Console or API. These images are stored in Object Storage, and can be used to provision a Database Home in your Exadata instance. See Oracle Database Software Images on page 1567 more information.

You can control the version of Oracle binaries that is installed when you provision a new database on an Exadata Cloud Service instance by maintaining the software images on the system. Oracle provides a library of cloud software images that you can view and download onto your instance by using the dbaascli utility.

When you create a new database with a new Oracle Home (Database Home) directory location, the Oracle Database binaries are sourced from a software image that is stored on your Exadata Cloud Service instance. Over time, the software images on your instance become outdated if they are not maintained. Using an outdated software image makes it necessary for you to apply patches to newly installed binaries to bring them up to date. Oracle recommends that you maintain your instance with up-to-date software images to avoid this extra patching step which can be time-consuming and error prone.

Viewing Information About Available Software Images

You can view information about Oracle Database software images that are available to download to your Exadata Cloud Service instance by using the cswlib list subcommand of the dbaascli utility.
To view information about available software images

1. Connect to a compute node as the opc user.
   For detailed instructions, see Connecting to a Compute Node with SSH on page 1269.
2. Start a root-user command shell:
   
   $ sudo -s
   #
3. Execute the dbaascli command with the cswlib list subcommand:
   
   # dbaascli cswlib list

   The command displays a list of available software images, including version and bundle patch information that you can use to download the software image.
4. Exit the root-user command shell:
   
   # exit
   $

Downloading Software Images

You can download available software images onto your Exadata Cloud Service instance by using the cswlib download subcommand of the dbaascli utility.

To downloaded a software image

1. Connect to a compute node as the opc user.
   For detailed instructions, see Connecting to a Compute Node with SSH on page 1269.
2. Start a root-user command shell:
   
   $ sudo -s
   #
3. Execute the dbaascli command with the cswlib download subcommand:
   
   # dbaascli cswlib download [--version <software_version>] [--bp <software_bundle_patch>]

   The command displays a list of software images that are downloaded to your Exadata Cloud Service environment, including version and bundle patch information.

   The optional parameters are:
   
   • **version**: specifies an Oracle Database software version. For example, 19000, 18000, or 12201.
   • **bp**: identifies a bundle patch release. For example, APR2021, JAN2021, or OCT2020.

   If you do not include the optional parameters, the dbaascli cswlib download command downloads the latest available software image for all available Oracle Database software versions.
4. Exit the root-user command shell:
   
   # exit
   $

Updating an Exadata Cloud Service VM Cluster Operating System

Exadata VM Cluster Image Updates is a feature that enables ExaCS customers to update the OS image on their Exadata VM Cluster nodes in an automated manner from their OCI console and APIs.
**Introduction**

Exadata VM Cluster Image Updates allows you to update the OS image on your Exadata VM Cluster nodes in an automated manner from the OCI console and APIs. This automated feature greatly simplifies and speeds up the process, makes it less error prone, and eliminates the need to use Patch Manager.

When you apply a patch, the system runs a precheck operation to ensure your VM cluster, Exadata DB system, or Database Home meets the requirements for that patch. If the precheck is not successful, the patch is not applied, and the system displays a message that the patch cannot be applied because the precheck failed. A separate precheck operation that you can run in advance of the planned update is also available.

**Supported versions**

The following versions and limitations are supported:

- Only Exadata image major versions 19 and above are supported.
- You cannot move to a new major version. For example, if the ExaCS VM Cluster is on major version 20 then you can apply only image updates for version 20.
- Only the latest generation of Exadata VM Cluster images are shown on the console and can be applied.

**Updating the operating system**

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. In the list of DB systems, click the name of the Exadata DB system that you want to patch to display the DB system details.
4. In the Version section, to the right of the Updates Available label, click View Updates to display the Updates/patches page.
5. Review the list of available patches for the DB system.
6. To the right of the Created field, click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - **Run Precheck.** Precheck checks the prerequisites to ensure that the patch can be successfully applied. Oracle highly recommends that you run the precheck operation before you apply a patch. The reason is that things can change in a database any time, and the precheck you run just before running a patch may find errors that the previous precheck did not find.
   - **Apply Exadata Image Update.** This link displays the Apply Exadata Image Update dialog box that you use to apply the patch. The dialog box shows the name of the database system you are patching, the current version of the database, and the new version of the database after the patch is applied. To start the process, click Apply Exadata Image Update.
   - **Copy OCID.** This copies the Oracle Cloud ID. This can be used when troubleshooting a patch or to give to Support when contacting them.

**Note:**

If the precheck fails, the system displays a message in the Apply OS Image Update dialog box that the last precheck has failed. Oracle recommends that you run the precheck again.

**Note:**

While the patch is running:

- Run Precheck and Apply OS Image Update are not available. When the patch has completed, these actions are available again.
- If the Exadata infrastructure containing this VM cluster is scheduled for maintenance that conflicts with the timing of the patch, the patch fails and the system displays a message explaining why. After the infrastructure maintenance is complete, run the patch again.

7. Confirm when prompted.
8. The patch list displays the status of the operation in the Version section of the database details page. Click **View Updates** to view more details about an individual patch status and to display any updates that are available to run. If no new updates are available, the system displays a message that says **No Updates Available**.

**Patching and Precheck states, and DB system status**

The following table shows the various states of precheck and patch operations and the status of the DB system during each operation.

<table>
<thead>
<tr>
<th>Operation</th>
<th>DB System Status</th>
<th>Patch State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Available</td>
<td>Available</td>
<td>The update is available to patch a database or database home.</td>
</tr>
<tr>
<td>Precheck</td>
<td>Available</td>
<td>Checking</td>
<td>The precheck is in progress</td>
</tr>
<tr>
<td>Precheck (failed)</td>
<td>Available</td>
<td>Available (Information icon)</td>
<td>The precheck failed but the patch is still available. The reason for the failure is included in the image update history.</td>
</tr>
<tr>
<td>Patching</td>
<td>Updating</td>
<td>Applying Update</td>
<td>The update is in progress. While a patch is being applied, the status of the patch displays as Applying Update and the DB system's status displays as Updating. Life cycle operations on the DB system and its resources might be temporarily unavailable. An entry is made in the update history log.</td>
</tr>
<tr>
<td>Patching (failed)</td>
<td>Available</td>
<td>Available (Information icon)</td>
<td>The update failed. The update information is available in the update history log. The system displays a message asking you to do a rollback before attempting another update.</td>
</tr>
<tr>
<td>Patching (success)</td>
<td>DB System up to date</td>
<td>Applied</td>
<td>The update is successful. The patch name is removed from the update list and an entry is made in the update history log.</td>
</tr>
</tbody>
</table>

**Updating an Exadata Cloud Service Instance**

This topic covers how to update the operating system and the tooling on the compute server nodes (for cloud VM clusters, these are called virtual machines) of an Exadata Cloud Service instance. Review all of the information carefully before you begin the updates.

**OS Updates**

You update the operating systems of Exadata compute nodes by using the `patchmgr` tool. This utility manages the entire update of one or more compute nodes remotely, including running pre-reboot, reboot, and post-reboot steps. You can run the utility from either an Exadata compute node or a non-Exadata server running Oracle Linux. The server on which you run the utility is known as the "driving system." You cannot use the driving system to update itself. Therefore, if the driving system is one of the Exadata compute nodes on a system you are updating, you must run a separate operation on a different driving system to update that server.

The following two scenarios describe typical ways of performing the updates:

**Scenario 1: Non-Exadata Driving System**

The simplest way to run the update the Exadata system is to use a separate Oracle Linux server to update all Exadata compute nodes in the system.

**Scenario 2: Exadata Node Driving System**

You can use one Exadata compute node to drive the updates for the rest of the compute nodes in the system, and then use one of the updated nodes to drive the update on the original Exadata driver node.

For example: You are updating a half rack Exadata system, which has four compute nodes - node1, node2, node3, and node4. First, use node1 to drive the updates of node2, node3, and node4. Then, use node2 to drive the update of node1.

The driving system requires root user **SSH** access to each compute node the utility will update.
Preparing for the OS Updates

**Caution:**

Do not install NetworkManager on the Exadata Cloud Service instance. Installing this package and rebooting the system results in severe loss of access to the system.

- Before you begin your updates, review *Exadata Cloud Service Software Versions* (Doc ID 2333222.1) to determine the latest software version and target version to use.
- Some steps in the update process require you to specify a YUM repository. The YUM repository URL is:

Region identifiers are text strings used to identify Oracle Cloud Infrastructure regions (for example, us-phoenix-1). You can find a complete list of region identifiers in Regions.

You can run the following `curl` command to determine the latest version of the YUM repository for your Exadata Cloud Service instance region:

```
```

This example returns the most current version of the YUM repository for the US West (Phoenix) region:

```
<a href="18.1.4.0.0/">18.1.4.0.0/</a> 01-Mar-2018 03:36 -
```

- To apply OS updates, the system's VCN must be configured to allow access to the YUM repository. For more information, see Option 2: Service Gateway Access to Both Object Storage and YUM Repos on page 1238.

To update the OS on all compute nodes of an Exadata Cloud Service instance

This example procedure assumes the following:

- The system has two compute nodes, node1 and node2.
- The target version is 18.1.4.0.0.180125.3.
- Each of the two nodes is used as the driving system for the update on the other one.

1. Gather the environment details.
   
   a. **SSH to node1 as root** and run the following command to determine the version of Exadata:

      ```
      [root@node1]# imageinfo -ver
      12.2.1.1.4.171128
      ```

   b. **Switch to the grid user, and identify all computes in the cluster.**

      ```
      [root@node1 .ssh]# su - grid
      [grid@node1]$ olsnodes
      node1
      node1
      ```

2. Configure the driving system.
   
   a. **Switch back to the root user on node1, check whether a root ssh key pair (id_rsa and id_rsa.pub) already exists. If not, then generate it.**

      ```
      [root@node1 .ssh]# ls /root/.ssh/id_rsa*
      ls: cannot access /root/.ssh/id_rsa*: No such file or directory
      [root@node1 .ssh]# ssh-keygen -t rsa
      ```
Generating public/private rsa key pair.
Enter file in which to save the key (/root/.ssh/id_rsa):
Enter passphrase (empty for no passphrase): Enter same passphrase again:
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
root@node1.fraad1client.exadataclientne.oraclevcn.com
The key's randomart image is:

b. Distribute the public key to the target nodes, and verify this step. In this example, the only target node is node2.

```
[root@node1 .ssh]# scp -i ~opc/.ssh/id_rsa ~root/.ssh/id_rsa.pub
opc@node2:/tmp/id_rsa.node1.pub

[root@node2 ~]# ls -al /tmp/id_rsa.node1.pub
-rw-r--r-- 1 opc opc 442 Feb 28 03:33 /tmp/id_rsa.node1.pub

[root@node2 ~]# date
Wed Feb 28 03:33:45 UTC 2018
```
c. On the target node (node2, in this example), add the root public key of node1 to the root authorized_keys file.

```
[root@node2 ~]# cat /tmp/id_rsa.node1.pub >> ~root/.ssh/authorized_keys
```
d. Download dbserver.patch.zip as p21634633_12*_Linux-x86-64.zip onto the driving system (node1, in this example), and unzip it. See dbnodeupdate.sh and dbserver.patch.zip: Updating Exadata Database Server Software using the DBNodeUpdate Utility and patchmgr (Doc ID 1553103.1) for information about the files in this .zip.

```
[root@node1 patch]# mkdir /root/patch
[root@node1 patch]# cd /root/patch
[root@node1 patch]# unzip p21634633_181400_Linux-x86-64.zip
Archive:  p21634633_181400_Linux-x86-64.zip  creating: dbserver_patch_5.180228.2/
creating: dbserver_patch_5.180228.2/ibdiagtools/

```
e. Create the `dbs_group` file that contains the list of compute nodes to update. Include the nodes listed after running the `olsnodes` command in step 1 except for the driving system node. In this example, `dbs_group` should include only `node2`.

```
[root@node1 patch]# cd /root/patch/dbserver_patch_5.180228
```
3. Run a patching precheck operation.

```
patchmgr -dbnodes dbs_group -precheck -yum_repo <yum_repository> -target_version <target_version> -nomodify_at_prereq
```

**Important:**

You must run the precheck operation with the `-nomodify_at_prereq` option to prevent any changes to the system that could impact the backup you take in the next step. Otherwise, the backup might not be able to roll back the system to its original state, should that be necessary.

The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes
dbs_group -precheck -yum_repo http://yum-phx.oracle.com/repo/
EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_version
18.1.4.0.0.180125.3 -nomodify_at_prereq
************************************************************************************************************
NOTE  patchmgr release: 5.180228 (always check MOS 1553103.1 for the
latest release of dbserver.patch.zip)
NOTE
WARNING Do not interrupt the patchmgr session.
WARNING Do not resize the screen. It may disturb the screen layout.
WARNING Do not reboot database nodes during update or rollback.

verify SSH equivalence for the root user to node2
precheck on node(s).
node(s).
```

4. Back up the current system.

```
patchmgr -dbnodes dbs_group -backup -yum_repo <yum_repository> -target_version <target_version> -allow_active_network_mounts
```

**Important:**

This is the proper stage to take the backup, before any modifications are made to the system.

The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes
dbs_group -backup -yum_repo http://yum-phx.oracle.com/repo/
EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_version
18.1.4.0.0.180125.3 -allow_active_network_mounts
************************************************************************************************************

---

5. Remove all custom RPMs from the target compute nodes that will be updated. Custom RPMs are reported in precheck results. They include RPMs that were manually installed after the system was provisioned.

**Note:**
- If you are updating the system from version 12.1.2.3.4.170111, and the precheck results include krb5-workstation-1.10.3-57.el6.x86_64, remove it. (This item is considered a custom RPM for this version.)
- **Do not** remove exadata-sun-vm-computenode-exact or oracle-ofed-release-guest. These two RPMs are handled automatically during the update process.

6. Run the `nohup` command to perform the update.

```
nohup patchmgr -dbnodes dbs_group -upgrade -nobackup -
yum_repo <yum_repository> -target_version <target_version> -
allow_active_network_mounts &
```

The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]# nohup ./patchmgr -dbnodes
dbs_group -upgrade -nobackup -
yum_repo http://yum-phx.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0.180125.3 -target_version
18.1.4.0.0.180125.3 -allow_active_network_mounts &
```

**NOTE** patchmgr release: 5.180228 (always check MOS 1553103.1 for the latest release of dbserver.patch.zip)

**NOTE** Database nodes will reboot during the update process.

**WARNING** Do not interrupt the patchmgr session.

**WARNING** Do not resize the screen. It may disturb the screen layout.

**WARNING** Do not reboot database nodes during update or rollback.

**WARNING** Do not open logfiles in write mode and do not try to alter them.

7. After the update operation completes, verify the version of the kernel on the compute node that was updated.

   [root@node2 ~]# imageinfo -ver
   18.1.4.0.0.180125.3

8. If the driving system is a compute node that needs to be updated (as in this example), repeat steps 2 through 7 of this procedure using an updated compute node as the driving system to update the remaining compute node. In this example update, you would use `node2` to update `node1`.

9. On each compute node, run the `uptrack-install` command as root to install the available ksplice updates.

   uptrack-install --all --y

**Updating Tooling on an Exadata Cloud Service Instance**

You can update the cloud-specific tooling included on an Exadata Cloud Service compute node by downloading and applying an RPM file containing the latest version of the tools.

**Note:**

Oracle highly recommends that you maintain the same version of cloud tooling across your Exadata Cloud Service environment. Perform the following procedure on every compute node in the Exadata Cloud Service instance.

**Prerequisite**

The compute nodes in the Exadata Cloud Service instance must be configured to access the Oracle Cloud Infrastructure Object Storage service. For more information, see [Node Access to Object Storage: Static Route](#) on page 1236.

**Updating the Cloud Tooling on Each Compute Node Manually**

The method for updating the tooling depends on the tooling release that is currently installed on the compute node.
To check the installed tooling release

1. Connect to the compute node as the opc user.
2. Start a root-user command shell.
   
   ```
   $ sudo -s
   #
   ```
3. Use the following command to display information about the installed cloud tooling and note the release label, shown in red in the example that follows.
   
   ```
   # rpm -qa|grep -i dbaastools_exa
   dbaastools_exa-1.0-1+18.1.2.1.0_180511.0801.x86_64
   ```

   In this example, the release version is 18.1.2.1.0_180511.0801.

To update the tooling if the release label is higher than 17430

You use the `patch tools` subcommand of the `dbaascli` utility to update the cloud tooling.

**Important:**

If you are updating the tooling on an Exadata Cloud Service instance that includes a Data Guard configuration, you must perform these steps on both the primary database's system and on the standby database's system.

1. Connect as the opc user to the compute node.
2. Start a root-user command shell:
   
   ```
   $ sudo -s
   #
   ```
3. Check whether any cloud tooling updates are available:
   
   ```
   # dbaascli patch tools list
   ```

   Example output:

   ```
   [root@exacs-node1 ]# dbaascli patch tools list
   DBAAS CLI version 19.4.1.0.0
   Executing command patch tools list
   Checking tools on all nodes
   Current Patchid on stb-elbdc1: 19.4.1.0.0_190822.1034
   Available Patches
   Patchid : 19.4.1.0.0_190827.1034
   Patchid : 19.4.1.0.0_190912.0440 (LATEST)
   Install tools patch using
dbaascli patch tools apply --patchid 19.4.1.0.0_190912.0440 or
dbaascli patch tools apply --patchid LATEST
   All Nodes have the same tools version
   ```
4. In the command response, locate the patch ID of the cloud tooling update. The patch ID is listed as the "Patchid" value. If multiple patches are listed, choose the latest one.
5. Apply the patch containing the latest cloud tooling update by using one of the following methods:
   - Specify the patch ID of the latest patch:
     ```
     # dbaascli patch tools apply --patchid <patch_ID>
     ```
   - Specify the patch ID as LATEST:
     ```
     # dbaascli patch tools apply --patchid LATEST
     ```
   - Run the update process in the background:
     ```
     # dbaascli patch tools apply --patchid LATEST &
     ```

6. Reset the backup configuration:
   ```
   # /var/opt/oracle/ocde/assistants/bkup/bkup
   ```

7. Exit the root-user command shell and disconnect from the compute node:
   ```
   # exit
   $ exit
   ```

8. If you are updating cloud tooling on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) Exadata Cloud Service instance.

   **To update the tooling if the release label is 17430 or lower**

   1. Download the RPM file using the Swift object storage API endpoint URL for your region.
      ```
      wget <swift_API_endpoint>/v1/exadata/patches/dbaas_patch/shome/dbaastools_exa.rpm
      ```
      The following example downloads the RPM file from the US West (Phoenix).
      ```
      wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/exadata/patches/dbaas_patch/shome/dbaastools_exa.rpm
      ```
      See [API Reference and Endpoints](#) for the Swift API endpoint for your region.

   2. Apply the RPM file.
      ```
      # rpm -ev dbaastools_exa
      # rpm -ivh dbaastools_exa.rpm
      ```

   3. Repeat the previous steps on each compute node in the Exadata Cloud Service instance.

   **Configuring Automatic Cloud Tooling Updates**

   You can configure automatic cloud tooling updates for Exadata Cloud Service instance. When you configure these updates, an entry is added to the `/etc/crontab` file to regularly check for cloud tooling updates and apply new updates to the compute node when they become available.

   **Note:**
   These procedures apply only if the release label is higher than 17430.

   **To disable automatic cloud tooling updates for an Exadata Cloud Service instance**

   1. Connect to the compute node as the opc user.
   2. Start a root-user command shell:
      ```
      $ sudo -s
      ```
3. Use the following command to disable automatic tooling updates:

```
# dbaascli patch tools auto disable
```

4. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

5. If you are disabling automatic cloud tooling updates on an Exadata Cloud Service instance hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) system.

**To integrate customer-managed key management into Exadata Cloud Service**

If you choose to encrypt databases in an Exadata Cloud Service instance using encryption keys that you manage, then you may update the following two packages (using Red Hat Package Manager) to enable DBAASTOOLS to interact with the APIs that customer-managed key management uses.

**KMS TDE CLI**

To update the KMS TDE CLI package, you must complete the following task on all nodes in the Exadata Cloud Service instance:

1. Deinstall current KMS TDE CLI package, as follows:

```
rpm -ev kmstdecli
```

2. Install the updated KMS TDE CLI package, as follows:

```
rpm -ivh kms_tde_cli
```

**LIBKMS**

LIBKMS is a library package necessary to synchronize a database with customer-managed key management through PKCS11. When a new version of LIBKMS is installed, any databases converted to customer-managed key management continue to use the previous LIBKMS version, until the database is stopped and restarted.

To update the LIBKMS package, you must complete the following task on all nodes in the Exadata Cloud Service instance:

1. Confirm that the LIBKMS package is already installed, as follows:

```
rpm -qa --last | grep libkmstdepkcs11
```

2. Install a new version of LIBKMS, as follows:

```
rpm -ivh libkms
```

3. Use SQL*Plus to stop and restart all databases converted to customer-managed key management, as follows:

```
shutdown immediate;
startup;
```

4. Ensure that all converted databases are using the new LIBKMS version, as follows:

```
for pid in $(ps aux | grep "<dbname>" | awk '{print $2;}'); do echo $pid;
    sudo lsof -p $pid | grep kms | grep "pkcs11_[0-9A-Za-z.]*" | sort -u;
done | grep pkcs11
```

5. Deinstall LIBKMS packages that are no longer being used by any database, as follows:

```
rpm -ev libkms
```
Patching an Exadata Cloud Service Instance

This topic explains how to perform patching operations on Exadata Cloud Service resources by using the Console, API, or the CLI.

Tip:
Oracle recommends patching databases by moving them to a Database Home that uses the target patching level. See To patch a database by moving it to another Database Home on page 1287 for instructions on this method of database patching.

For information and instructions on patching the system by using the dbaascli utility, see Patching an Exadata Cloud Service Instance Manually on page 1289.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

About Patching Exadata Cloud Service Resources
Patching an Exadata Cloud Service instance updates the components on all the compute nodes in the instance. A VM cluster or DB system patch updates the Oracle Grid Infrastructure (GI) on the resource.

Note:
The cloud Exadata resource model the instance is using determines whether you patch the Grid Infrastructure on a DB system resource or a cloud VM cluster resource. VM clusters are used by the new resource model. DB systems can be easily migrated to the new resource model with no system downtime.

A Database Home patch updates the Oracle Database software shared by the databases in that home. Thus, you patch a database by either moving it to a Database Home that has the correct patch version or you patch the Database Home the database is currently in.

Consider the following best practices:
• Back up your databases before you apply any patches. For information about backing up the databases, see Managing Exadata Database Backups on page 1320.
• Patch a VM cluster or an Exadata DB system before you patch the Databases Homes and databases on that resource.
• Before you apply any patch, run the precheck operation to ensure your VM cluster, Exadata DB system, or Database Home meets the requirements for that patch.
• To patch a database to a version other than the database version of the current home, move the database to a Database Home running the target version. This technique requires less downtime and allows you to easily roll back the database to the previous version by moving it back to the old Database Home. See To patch a database by moving it to another Database Home on page 1287.
• For the Oracle Database and Oracle Grid Infrastructure major version releases available in Oracle Cloud Infrastructure, patches are provided for the current version plus the two most recent older versions (\(N\) through \(N\) - 2). For example, if an instance is using Oracle Database 19c, and the latest version of 19c offered is 19.8.0.0.0, patches are available for versions 19.8.0.0.0, 19.7.0.0 and 19.6.0.0.
Prerequisites

The Exadata Cloud Service instance requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for Exadata Cloud Service Instances on page 1232: For information about setting up your VCN for the Exadata Cloud Service instance, including the service gateway.
- Object Storage FAQ: For information about the Swift endpoints to use.

Important:

In addition to the prerequisites listed, ensure that the following conditions are met to avoid patching failures:

- The /u01 directory on the database host file system has at least 15 GB of free space for the execution of patching processes.
- The Oracle Clusterware is up and running on the Exadata Cloud Service instance.
- All nodes of the instance are up and running.

Using the Console

You can use the Console to view the history of patch operations on Exadata Cloud Service instances, apply patches, and monitor the status of patch operations.

Patching Exadata Instances That Use the DB System Resource Model

The tasks in this section describe how to apply patches and monitor the status of patch operations on Exadata DB systems and their Database Homes.

To patch the Oracle Grid Infrastructure on an Exadata DB system

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. In the list of DB systems, click the name of the Exadata DB system you want to patch to display the DB system details.
4. Under DB System Version, click the View link beside the Latest Patch Available field.
5. Review the list of available patches for the DB system.
6. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - Run Precheck: Check for any prerequisites to make sure that the patch can be successfully applied.
   - Apply: Applies the selected patch. Oracle highly recommends that you run the precheck operation for a patch before you apply it.
7. Confirm when prompted.

The patch list displays the status of the operation. While a patch is being applied, the patch's status displays as Patching and the DB system's status displays as Updating. Lifecycle operations on the DB system and its resources might be temporarily unavailable. If patching completes successfully, the patch's status changes to Applied and the status of the DB system changes to Available. You can view more details about an individual patch operation by clicking Patch History.

To patch the Oracle Database software in a Database Home (DB system)

Note:

This patching procedure updates the Oracle Database software for all databases located in the Database Home. To patch an individual database, you can move it to another Database Home that uses the desired Oracle Database software configuration.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. In the list of DB systems, click the name of the Exadata DB system with the Database Home you want to patch to display the DB system details.

4. Under Resources, click Database Homes.

5. Click the name of the Database Home you want to patch to display the Database Home details.

7. Review the list of available patches for the Database Home.

8. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - **Precheck**: Check for any prerequisites to make sure that the patch can be successfully applied.
   - **Apply**: Applies the selected patch. Oracle highly recommends that you run the precheck operation for a patch before you apply it.

9. Confirm when prompted.

   The patch list displays the status of the operation. While a patch is being applied, the status of the patch displays as **Patching** and the status of the Database Home and the databases in it display as **Updating**. During the operation, each database in the home is stopped and then restarted. If patching completes successfully, the patch's status changes to **Applied** and the Database Home's status changes to **Available**. You can view more details about an individual patch operation by clicking **Patch History**.

   **Patching Exadata Instances That use the New Resource Model**

   The tasks in this section describe how to apply patches and monitor the status of patch operations on cloud VM clusters and their Database Homes.

   **To patch the Oracle Grid Infrastructure on an Exadata cloud VM cluster**

   1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
   2. Choose your **Compartment**.
   3. Click **Exadata VM Clusters**.
   4. In the list of cloud VM clusters, click the name of the cluster you want to patch to display the cluster details.
   5. Under **Version**, click the **View Patches** link beside the **Updates Available** field.
   6. Review the list of available patches for the cloud VM cluster.
   7. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
      - **Run Precheck**: Check for any prerequisites to make sure that the patch can be successfully applied.
      - **Update Grid Infrastructure**: Applies the selected patch. Oracle highly recommends that you run the precheck operation for a patch before you apply it.
   8. Confirm when prompted.

      The patch list displays the status of the operation. While a patch is being applied, the patch's status displays as **Patching** and the cloud VM cluster's status displays as **Updating**. Lifecycle operations on the cluster and its resources might be temporarily unavailable. If patching completes successfully, the patch's status changes to **Applied** and the status of the cluster changes to **Available**. You can view more details about an individual patch operation by clicking **Update History**.

   **To patch the Oracle Database software in a Database Home (cloud VM cluster)**

   **Note:**

   This patching procedure updates the Oracle Database software for all databases located in the Database Home. To patch an individual database, you can move it to another Database Home that uses the desired Oracle Database software configuration.

   1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
   2. Choose your **Compartment**.
   3. Click **Exadata VM Clusters**.
   4. In the list of cloud VM clusters, click the name of the cluster you want to patch to display the cluster details.
   5. Under **Resources**, click **Database Homes**.
6. Click the name of the Database Home you want to patch to display the Database Home details.
7. Under **Latest Patch Available**, click **View**.
8. Review the list of available patches for the Database Home.
9. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - **Precheck**: Check for any prerequisites to make sure that the patch can be successfully applied.
   - **Apply**: Applies the selected patch. Oracle highly recommends that you run the precheck operation for a patch before you apply it.
10. Confirm when prompted.

The patch list displays the status of the operation. While a patch is being applied, the status of the patch displays as **Patching** and the status of the Database Home and the databases in it display as **Updating**. During the operation, each database in the home is stopped and then restarted. If patching completes successfully, the patch’s status changes to **Applied** and the Database Home's status changes to **Available**. You can view more details about an individual patch operation by clicking **Update History**.

**Patching Individual Oracle Databases in an Exadata Cloud Service Instance**

This task explains how to patch a single Oracle Database in your Exadata Cloud Service instance by moving it to another Database Home. For information on patching Database Homes, see To patch the Oracle Database software in a Database Home (cloud VM cluster) on page 1286 and To patch the Oracle Database software in a Database Home (DB system) on page 1285.

To patch a database by moving it to another Database Home

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system that contains the database you want to move.
   - **Cloud VM clusters (new resource model)**: Under Exadata at Oracle Cloud, click **Exadata VM Clusters**. In the list of VM clusters, click the name of the VM cluster that contains the database you want to move.
   - **DB systems**: Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, click the name of the DB system that contains the database you want to move.
4. In the list of databases on the details page of the VM cluster or DB system, click the name of the database you want to move to view the Database Details page.
5. Click **Move to Another Home**.
6. Select the target Database Home.
7. Click **Move Database**.
8. Confirm the move operation.

The database will be stopped in the current home and then restarted in the destination home. While the database is being moved, the Database Home status displays as **Moving Database**. When the operation completes, Database Home is updated with the current home. If the operation is unsuccessful, the status of the database displays as **Failed**, and the Database Home field provides information about the reason for the failure.

**Viewing Patch History**

Each patch history entry represents an attempted patch operation and indicates whether the operation was successful or failed. You can retry a failed patch operation. Repeating an operation results in a new patch history entry.

Patch history views in the Console do not show patches that were applied by using command line tools such as **dbaascli**.

If your service instance uses the **new resource model**, the patch history available by navigating to the VM Cluster Details page. If your service instance uses the DB system resource model, the patch history is available by navigating to the DB System Details page.

To view the patch history of a cloud VM cluster

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Click **Exadata VM Clusters**.
4. In the list of cloud VM clusters, click the name of the cluster you want to patch to display the cluster details.
5. Under **Version**, click the **View Patches** link beside the **Updates Available** field.
6. Click **Update History**.

   The Update History page displays the history of patch operations for that cloud VM cluster and for the Database Homes on that cloud VM cluster.

To view the patch history of a DB system

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, click the name of the Exadata DB system with the information you want to view to display the DB system details.
4. Under **DB System Version**, click the **View** beside the **Latest Patch Available** field.
5. Click **Patch History**.

   The Patch History page displays the history of patch operations for that DB system and for the Database Homes on that DB system.

To view the patch history of a Database Home

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system that contains the Database Home.

   * **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   * **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Under **Resources**, click **Database Homes**.
5. Click the name of the Database Home you want to view to display the Database Home details.
7. Click **Patch History** (DB systems) or **Update History** (cloud VM clusters).

   The history page displays the history of patch operations for that Database Home and for the cloud VM cluster or DB system to which it belongs.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage patching the following Exadata resources: cloud VM clusters, DB systems, databases, and Database Homes.

**Cloud VM clusters (for systems using the new resource model):**

- ListCloudVmClusterUpdates
- ListCloudVmClusterUpdateHistoryEntries
- GetCloudVmClusterUpdate
- GetCloudVmClusterUpdateHistoryEntry
- UpdateVmCluster

**DB systems:**

- ListDbSystemPatches
- ListDbSystemPatchHistoryEntries
- GetDbSystemPatch
- GetDbSystemPatchHistoryEntry
- **UpdateDbSystem**

**Databases:**
- **UpdateDatabase** - Use this operation to patch a database by moving it to another Database Home

**Database Homes:**
- **ListDbHomePatches**
- **ListDbHomePatchHistoryEntries**
- **GetDbHomePatch**
- **GetDbHomePatchHistoryEntry**
- **UpdateDbHome**

For the complete list of APIs for the Database service, see Database Service API.

### Patching an Exadata Cloud Service Instance Manually

This topic explains how to use the `dbaascli` utility to perform patching operations for Oracle Grid Infrastructure and Oracle Database on an Exadata Cloud Service instance. The utility requires root or sudo administration privileges.

**Note:**
You must update the cloud specific tooling on all the compute nodes in your Exadata Cloud Service instance before performing the following procedures. For more information, see Updating an Exadata Cloud Service Instance on page 1274.

**Prerequisites**

Patches are stored in Oracle Cloud Infrastructure Object Storage, so the Exadata Cloud Service instance requires access to that service. To enable this access, Oracle recommends using a service gateway with the VCN. For more information, see Network Setup for Exadata Cloud Service Instances on page 1232. In that topic, pay particular attention to:

- **Service Gateway for the VCN** on page 1237
- **Node Access to Object Storage: Static Route** on page 1236
- **Backup egress rule: Allows access to Object Storage** on page 1242

**Managing Patches**

To list available patches

You can produce a list of available patches using the `cswlib list` subcommand of the `dbaascli` utility:

- Connect to the compute node as the `opc` user.

For detailed instructions, see Connecting to an Exadata Cloud Service Instance on page 1269.

- Start a root-user command shell:

```bash
$ sudo -s
#
```

- Execute the following command:

```bash
# cswlib list
```

**Example:**

```bash
# dbaascli cswlib list
DBAAS CLI version 20.1.3.3.0
Executing command cswlib list
```
INFO : Log file => /var/opt/oracle/log/list/

INFO : dbimage fixup executed.

############ List of Available BP ############
-APR2020 (For DB Versions 18000 12201 12102 11204 19000)
-JUL2020 (For DB Versions 18000 12201 12102 11204 19000)
-OCT2020 (For DB Versions 18000 12201 12102 11204 19000)

############ List of Available NONCDB BP #######
-APR2020 (For DB Versions 12102 19000)
-JUL2020 (For DB Versions 12102 19000)
-OCT2020 (For DB Versions 12102 19000)

- Exit the root-user command shell.

# exit
$

To check prerequisites before applying a patch

You can perform the prerequisites-checking operation using the patch db prereq subcommand of the dbaascli utility:

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

   $ sudo -s
   #

3. Execute the following command:

   # dbaascli dbhome patch --oracleHome <dbhome_path> --targetVersion <Oracle_Database_version> --executePrereqs

where:

• --oracleHome identifies the path of the Database Home to be prechecked.
• --targetVersion specifies the target Oracle Database version to precheck.

Example:

# dbaascli dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.9.0.0 --executePrereqs
DBAAS CLI version 20.1.3.3.0
Executing command dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.9.0.0 --executePrereqs

To learn more about the `dbhome patch` subcommand, including available options, execute the following command:

```
# dbaascli dbhome patch ?
```

4. Exit the root-user command shell:

```
# exit
$ 
```

**To apply a patch to a database**

You can apply a patch by using the `dbhome patch` subcommand of the `dbaascli` utility.

The patching operation:

- Can be used to patch some or all of your compute nodes using one command.
- Coordinates multi-node patching in a rolling manner.
- Can execute patch-related SQL after patching all the compute nodes in the cluster.
- Can patch an empty Database Home, or a Database Home containing one or more databases.
Oracle recommends patching an empty Database Home and then moving databases into the home using the `dbaascli db move` command.

To patch a Database Home (dbhome):

1. Connect to the compute node as the `opc` user.
2. Start a root-user command shell:
   
   ```
   $ sudo -s
   #
   ```
3. Execute the following command:

   ```
   # dbaascli dbhome patch --oracleHome <dbhome_path> --targetVersion <Oracle_Database_version>
   ```

   where:
   - `--oracleHome` identifies the path of the Database Home to be patched.
   - `--targetVersion` specifies the target Oracle Database version to use for patching.
   - `--run_datasql 1` instructs the command to execute patch-related SQL commands.

   **Note:**
   - Patch-related SQL should only be executed after all of the compute nodes are patched. Therefore, take care not to specify this argument if you are patching a subset of nodes and further nodes remain to be patched.
   - This argument can only be specified in conjunction with a patching operation on a set of compute nodes. Therefore, if you have patched all of your nodes and you did not specify this argument, you will need to manually execute the SQL commands associated with the patch. Refer to the patch documentation for further details.

**Example:**

```bash
Example (Oracle Database):
# dbaascli dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.9.0.0
DBAAS CLI version 20.1.3.3.0
Executing command dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.9.0.0

To learn more about the dbhome patch subcommand, including available options, execute the following command:

```
# dbaascli dbhome patch ?
```

4. Exit the root-user command shell:

```
# exit
$
```

To apply a patch to the Oracle Grid Infrastructure

You can apply a patch to your Oracle Grid Infrastructure by using the patch db apply subcommand of the dbaascli utility.

To perform the patching operation:

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

```
$ sudo -s
  #
```

DBHome Patching Successful.

To apply a patch to the Oracle Grid Infrastructure

You can apply a patch to your Oracle Grid Infrastructure by using the patch db apply subcommand of the dbaascli utility.

To perform the patching operation:

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

```
$ sudo -s
  #
```

DBHome Patching Successful.

To apply a patch to the Oracle Grid Infrastructure

You can apply a patch to your Oracle Grid Infrastructure by using the patch db apply subcommand of the dbaascli utility.

To perform the patching operation:

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

```
$ sudo -s
  #
```

DBHome Patching Successful.
3. Execute the following command:

```
# dbaascli patch db apply --patchid <patchid> --dbnames grid
```

where:
- `--patchid` identifies the patch to be applied.
- `--dbnames` specifies "grid" to indicate that the Grid Infrastructure is to be patched.

Example:

```
# dbaascli patch db apply --patchid 29708703-GI --dbnames grid
```

To learn more about the `patch db apply` subcommand, including available options, execute the following command:

```
# dbaascli patch db apply ?
```

4. Exit the root-user command shell:

```
# exit
```

To list applied patches
You can produce a list of applied patches to determine which patches have been applied.

You can use the opatch utility to determine the patches that have been applied to an Oracle Database or Grid Infrastructure installation.

To produce a list of applied patches for an Oracle Database installation:

1. Connect to a compute node as the oracle user.
2. Go to the Oracle user's home directory:

```
$ cd
```

3. Ensure that you are in the Oracle user's home directory:

```
$ pwd
/home/oracle
```

4. Source the environment file.

Example (using the environment file for a database named "DB18"):

```
$ . DB18.env
```

5. Execute the opatch command with the `lspatches` option:

```
$ opatch lspatches
```

To produce a list of applied patches for Oracle Grid Infrastructure:

1. Connect to a compute node as the opc user.
2. Become the grid user:

```
$ sudo -s
# su - grid
```
3. Execute the opatch command with the lspatches option:

```shell
$ opatch lspatches
```

To roll back or resume a patching operation

You can roll back a patch by using the dbaascli utility's `dbaascli dbhome patch --rollback` operation. This operation:

- Can be used to roll back a patch on some or all of your compute nodes using one command.
- Coordinates multi-node operations in a rolling manner.
- Can execute rollback-related SQL after rolling back the patch on all the compute nodes in the cluster.

You can resume a patching operation by using the `dbaascli dbhome patch --resume` operation.

To perform a patch roll back operation:

1. Connect to the compute node as the `opc` user.
2. Start a root-user command shell:

```shell
$ sudo -s
#
```
3. Execute the following command:

```shell
dbaascli dbhome patch --oracleHome <dbhome_path> --targetVersion <Oracle_Database_version> --rollBack
```

where:

- `--oracleHome` identifies the path of the Database Home to be patched.
- `--targetVersion` specifies the target Oracle Database version to use for patching.
- `--instanceN` specifies a compute node and one or more Oracle home directories that are subject to the rollback operation. In this context, an Oracle home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.
- `--dbnames` specifies the name of the database you want to apply the switchback operation to.

Example:

```shell
# dbaascli dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.7.0.0 --rollBack
```

```shell
DBAAS CLI version 20.1.3.3.0
Executing command dbhome patch --oracleHome /u02/app/oracle/product/19.0.0.0/dbhome_2 --targetVersion 19.7.0.0 --rollBack
-----------------
Setting up parameters...
Patch Parameters setup successful.
-----------------
Validating Inputs.
Successfully Validated Inputs.
-----------------
```

```

**Upgrading Exadata Grid Infrastructure**

This topic describes how to upgrade the Oracle Grid Infrastructure (GI) on an Exadata cloud VM cluster using the Oracle Cloud Infrastructure Console or API. Upgrading allows you to provision Oracle Database Homes and databases that use the most current Oracle Database software. For more information on Exadata cloud VM clusters and the new Exadata resource model, see [Overview of X8M Scalable Exadata Infrastructure](#) on page 1227.
Database

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

Prerequisites

To upgrade your GI to Oracle Database 19c, you must be using the Oracle Linux 7 operating system for your VM cluster. For more information on upgrading the operating system, see the following documentation:

- How to update the Exadata System Software (DomU) to 19 from 18 on the Exadata Cloud Service in OCI (My Oracle Support Doc ID 2521053.1).

About Upgrading Grid Infrastructure

Upgrading the Oracle Grid Infrastructure (GI) on a VM cluster involves upgrading all the compute nodes in the instance. The upgrade is performed in a rolling fashion, with only one node being upgraded at a time.

- Oracle recommends running an upgrade precheck to identify and resolve any issues that would prevent a successful upgrade.
- You can monitor the progress of the upgrade operation by viewing the associated work requests.
- If you have an Exadata infrastructure maintenance operation scheduled to start within the next 24 hours, the GI upgrade feature is not available.
- During the upgrade, you cannot perform other management operations such as starting, stopping or rebooting nodes, scaling CPU, provisioning or managing Database Homes or databases, restoring a database, or editing IORM settings. The following Data Guard operations are not allowed on the VM cluster undergoing a GI upgrade:
  - Enable Data Guard
  - Switchover
  - Failover to the database using the VM cluster (a failover operation to a standby on another VM cluster is possible)

Using the Console

You can use the Console to perform a precheck prior to upgrading your Oracle Grid Infrastructure (GI), and to perform the GI upgrade operation.

To precheck your cloud VM cluster prior to upgrading

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Click Exadata VM Clusters.
4. In the list of cloud VM clusters, click the name of the cluster you want to patch to display the cluster details.
5. Under Version, click the View Patches link beside the Updates Available field.
6. Click Updates to view the list of available patches and upgrades.
7. Click the Actions icon (three dots) at the end of the row listing the Oracle Grid Infrastructure (GI) upgrade, then click Run Precheck.
8. In the Confirm dialog, confirm you want to upgrade to begin the precheck operation.

To upgrade the Oracle Grid Infrastructure of a cloud VM cluster

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Click Exadata VM Clusters.
4. In the list of cloud VM clusters, click the name of the cluster you want to patch to display the cluster details.

5. Under Version, click the View Patches link beside the Updates Available field.

6. Click Updates to view the list of available patches and upgrades.

7. Click the Actions icon (three dots) at the end of the row listing the Oracle Grid Infrastructure (GI) upgrade, then click Upgrade Grid Infrastructure.

8. In the Upgrade Grid Infrastructure dialog, confirm you want to upgrade the GI by clicking Upgrade Grid Infrastructure. If you haven't run a precheck, you have the option of clicking Run Precheck in this dialog to precheck your cloud VM cluster prior to the upgrade.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use these API operations to upgrade the Oracle Grid Infrastructure in a cloud VM clusters and view the cluster's update history.

- ListCloudVmClusterUpdates
- ListCloudVmClusterUpdateHistoryEntries
- GetCloudVmClusterUpdate
- GetCloudVmClusterUpdateHistoryEntry
- UpdateVmCluster

For the complete list of APIs for the Database service, see Database Service API.

Upgrading Exadata Databases

Note: This topic applies only to Exadata Cloud Service instances using the new resource model. For information on converting an Exadata DB system to the new resource model, see Switching an Exadata DB System to the New Resource Model and APIs on page 1228.

This topic describes the procedures to upgrade an Exadata database instance to Oracle Database 19c (Long Term Release) by using the Console and the API. The upgrade is accomplished by moving the Exadata database to a Database Home that uses the target software version.

Prerequisites

The following are required in order to upgrade an Exadata Oracle Database instance:

- The Exadata Cloud Service instance system software must use Oracle Linux 7 (OL7). See How to update the Exadata System Software (DomU) to 19 from 18 on the Exadata Cloud Service in OCI for instructions on manually updating the operating system.
- The Oracle Grid Infrastructure must be version 19c. See Upgrading Exadata Grid Infrastructure on page 1299 for instructions on using the Oracle Cloud Infrastructure Console or API to upgrade Grid Infrastructure. If patches are available for your Grid Infrastructure, Oracle recommends applying them prior to performing a database upgrade.
- You must have an available Oracle Database Home that uses the two most recent version of Oracle Database 19c available in Oracle Cloud Infrastructure. See To create a new Database Home in an existing Exadata Cloud Service instance on page 1330 for information on creating a Database Home. You can use Oracle-published software images or a custom database software image based on your patching requirements to create Database Homes.
- You must ensure that all pluggable databases in the container database that is being upgraded can be opened. Pluggable databases that cannot be opened by the system during the upgrade can cause an upgrade failure.

Your Oracle database must be configured with the following settings in order to upgrade:

- The database must be in archivelog mode
- The database must have flashback enabled
See the Oracle Database documentation for your database's release version to learn more about these settings.

**About Upgrading a Database**

For database software version upgrades, note the following:

- Database upgrades involve database downtime. Keep this in mind when scheduling your upgrade.
- Oracle recommends that you back up your database and test the new software version on a test system or a cloned version of your database before you upgrade a production database. See To create an on-demand full backup of a database on page 1322 for information on creating an on-demand manual backup.
- Oracle recommends running an upgrade precheck operation for your database prior to attempting an upgrade so that you can discover any issues that need mitigation prior to the time you plan to perform the upgrade. The precheck operation does not affect database availability and can be performed at any time that is convenient for you.
- If your databases uses Data Guard, you will need to disable or remove the Data Guard association prior to upgrading.
- An upgrade operation cannot take place while an automatic backup operation is underway. Before upgrading, Oracle recommends disabling automatic backups and performing a manual backup. See To configure automatic backups for a database on page 1322 and To create an on-demand full backup of a database on page 1322 for more information.
- After upgrading, you cannot use automatic backups taken prior to the upgrade to restore the database to an earlier point in time.
- If you are upgrading an database that uses version 11.2 software, the resulting version 19c database will be a non-container database (non-CDB).

**How the Upgrade Operation Is Performed by the Database Service**

During the upgrade process, the Database service does the following:

- Executes an automatic precheck. This allows the system to identify issues needing mitigation and to stop the upgrade operation.
- Sets a guaranteed restore point, enabling it to perform a flashback in the event of an upgrade failure.
- Moves the database to a user-specified Oracle Database Home that uses the desired target software version.
- Runs the Database Upgrade Assistant (DBUA) software to perform the upgrade.

**Rolling Back an Unsuccessful Upgrade**

If your upgrade does not complete successfully, you have the option of performing a rollback. Details about the failure are displayed on the Database Details page in the Console, allowing you to analyze and resolve the issues causing the failure. A rollback resets your database to the state prior to the upgrade. All changes to the database made during and after the upgrade will be lost. The rollback option is provided in a banner message displayed on the database details page of a database following an unsuccessful upgrade operation. See To roll back a failed database upgrade on page 1303 for more information.

**After Your Upgrade Is Complete**

After a successful upgrade, note the following:

- Check that automatic backups are enabled for the database if you disabled them prior to upgrading. See To configure automatic backups for a database on page 1322 for more information.
- Edit the Oracle Database COMPATIBLE parameter to reflect the new Oracle Database software version. See What Is Oracle Database Compatibility? for more information.
- If your database uses a <database_name>.env file, ensure that the variables in the file have been updated to point to the 19c Database Home. These variables should be automatically updated during the upgrade process.
- If you are upgrading a non-container database to Oracle Database version 19c, you can convert the database to a pluggable database after converting. See How to Convert Non-CDB to PDB (Doc ID 2288024.1) for instruction on converting your database to a pluggable database.
• If your old Database Home is empty and will not be reused, you can remove it. See To delete a Database Home on page 1332 for more information.

**Using the Console**

You can use the Console to:
• Upgrade your database
• Roll back an unsuccessful upgrade
• View the update history of a database that has been upgraded

Oracle recommends that you use the precheck action to ensure that your database has met the requirements for the upgrade operation.

*To upgrade or precheck an Exadata database*

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, click the name of the VM cluster that contains the database you want to upgrade.

**Note:**
If your database is in an Exadata Cloud Service instance that does not use the new Exadata resource model, you will need to switch the instance to the new model before you can upgrade your database.

4. In the list of databases on the details page of the VM cluster, click the name of the database you want to upgrade to view the Database Details page.
5. Click More Actions, then Upgrade.
6. In the Upgrade Database dialogue, select the following:
   • **Oracle Database version:** The drop-down selector lists only Oracle Database versions that are compatible with an upgrade from the current software version the database is using. The target software version must be higher than the database's current version.
   • **Target Database Home:** Select a Database Home for your database. The list of Database Homes is limited to those homes using the most recent versions of Oracle Database 19c software. Moving the database to the new Database Home results in the database being upgraded to the major release version and patching level of the new Database Home.

7. Click one of the following:
   • **Run Precheck:** This option starts an upgrade precheck to identify any issues with your database that need mitigation before you perform an upgrade.
   • **Upgrade database:** This option starts upgrade operation. Oracle recommends performing an upgrade only after you have performed a successful precheck on the database.

*To roll back a failed database upgrade*

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, click the name of the VM cluster that contains the database with the failed upgrade.
4. Find the database that was unsuccessfully upgraded, and click its name to display details about it. The database should display a banner at the top of the details page that includes a Rollback button and details about what issues caused the upgrade failure.
5. Click Rollback. In the Confirm rollback dialog, confirm that you want to initiate a rollback to the previous Oracle Database version by clicking Rollback.

*To view the upgrade history of a database*

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Under Exadata at Oracle Cloud, click **Exadata VM Clusters**. In the list of VM clusters, click the name of the VM cluster that contains the database you want to upgrade.

   **Note:**
   If your database is in an Exadata Cloud Service instance that does not use the new Exadata resource model, you will need to switch the instance to the new model before you can upgrade your database.

4. In the list of databases on the details page of the VM cluster, click the name of the database for which you want to view the upgrade history.

5. On the Database Details page, under **Database Version**, click the View link that is displayed for databases that have been upgraded. This link does not appear for databases that have not been updated.

   The **Updates History** page is displayed. The table displayed on this page shows precheck and upgrade operations performed on the database.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs to manage database upgrades:

- ListDatabaseUpgradeHistoryEntries
- UpgradeDatabase

For the complete list of APIs for the Database service, see Database Service API.

   **Note:**
   When using the UpgradeDatabase API to upgrade an Exadata Cloud Service database, you must specify DB_HOME as the upgrade source.

**Monitoring an Exadata Cloud Service Database**

This topic explains how to access Enterprise Manager Database Express and Enterprise Manager Database Control, which are web-based tools for managing Oracle Database.

**Accessing Enterprise Manager Database Express 12c**

Enterprise Manager Database Express 12c (EM Express) is available on Exadata Cloud Service databases created using Oracle Database 12c Release 1 (12.1) or later.

How you access EM Express depends on whether you want to manage a CDB or PDB.

- **To manage the CDB.** When a database is created, the Database service automatically sets port 5500 on the deployment’s compute nodes for EM Express access to the CDB.
- **To manage a PDB.** For a database using Oracle Database 12.2 or later, a single port (known as the global port) is automatically set on the compute nodes. The global port lets you use EM Express to connect to all of the PDBs in the CDB using the HTTPS port for the CDB.

   For a database using Oracle Database 12.1, you must manually set a port on the compute nodes for each PDB you want to manage using EM Express.

For both CDBs and PDBs, you must add the port to a security list as described in Updating the Security List on page 1305.

To confirm the port that is in use for a specific database, connect to the database as a database administrator and execute the query shown in the following example:

```
SQL> select dbms_xdb_config.getHttpsPort() from dual;
```

```
DBMS_XDB_CONFIG.GETHTTPS_PORT()
```
Setting the Port for EM Express to Manage a PDB (Oracle Database 12.1 Only)

In Oracle Database 12c Release 1, a unique HTTPS port must be configured for the root container (CDB) and each PDB that you manage using EM Express.

To configure a HTTPS port so that you can manage a PDB with EM Express:

1. Invoke SQL*Plus and log in to the PDB as the SYS user with SYSDBA privileges.
2. Execute the `DBMS_XDB_CONFIG.SETHTTPSPORT` procedure.

   ```sql
   SQL> exec dbms_xdb_config.sethttpsport(port-number)
   ```

Accessing EM Express

Before you access EM Express, add the port to the security list. See Updating the Security List on page 1305.

After you update the security list, you can access EM Express by directing your browser to the URL `https://<node-ip-address>:<port>/em`, where `node-ip-address` is the public IP address of the compute node hosting EM Express, and `port` is the EM Express port used by the database.

Accessing Enterprise Manager 11g Database Control

Enterprise Manager 11g Database Control (Database Control) is available on Exadata Cloud Service databases created using Oracle Database 11g Release 2. Database Control is allocated a unique port number for each database deployment. By default, access to Database Control is provided using port 1158 for the first deployment. Subsequent deployments are allocated ports in a range starting with 5500, 5501, 5502, and so on.

You can confirm the Database Control port for a database by searching for `REPOSITORY_URL` in the `$ORACLE_HOME/host_sid/sysman/config/emd.properties` file.

Before you access Database Control, add the port for the database to the security list associated with the Exadata DB system's client subnet. For more information, see Updating the Security List on page 1305.

After you update the security list, you can access Database Control by directing your browser to the URL `https://<node-ip-address>:<port>/em`, where `node-ip-address` is the public IP address of the compute node hosting Database Control, and `port` is the Database Control port used by the database.

Updating the Security List

Before you can access EM Express or Database Control, you must add the port for the database to the security list associated with the data (client) subnet used by the cloud VM cluster (for systems using the new resource model) or the DB system. To update an existing security list, complete the following steps using the Console:

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system contains the security list you want to update:
   - **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster in which you want to manage and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system in which you want to manage, and then click its name to display details about it.
4. Note Client Subnet name of the cloud VM cluster or the DB system and click its Virtual Cloud Network.
5. Locate the subnet in the list, and then click its security list under Security Lists.
6. Click Edit All Rules and add an ingress rule with source type=CIDR, source CIDR=<source CIDR>, protocol=TCP, and port=<port number or port range>.

The source CIDR should be the CIDR block that includes the ports you open for the client connection.
Creating and Managing Exadata Databases

This topic describes creating and managing Oracle Databases on an Exadata Cloud Service instance.

When you create a Exadata Cloud Service instance, an initial Database Home and database are created. You can create additional Database Homes and databases at any time by using the Console or the Oracle Cloud Infrastructure API.

When you add a database to a VM cluster or a DB system resource on an Exadata instance, the database versions you can select from depend on the current patch level of that resource. You may have to patch your VM cluster or DB system to add later database versions.

After you provision a database, you can move it to another Database Home. Consolidating databases under the same home can facilitate management of these resources. All databases in a given Database Home share the Oracle Database binaries and therefore, have the same database version. The Oracle-recommended way to patch a database to a version that is different from the current version is to move the database to a home running the target version. For information about patching, see Patching an Exadata Cloud Service Instance on page 1284.

**Note:**

When provisioning databases, make sure your VM cluster or DB system has enough OCPUs enabled to support the total number of database instances on the system. Oracle recommends the following general rule: for each database, enable 1 OCPU per node. See To scale CPU cores in an Exadata Cloud Service cloud VM cluster or DB system on page 1258 for information on scaling your OCPU count up or down.

When you create an Exadata database, you can choose to encrypt the database using your own encryption keys that you manage. You can rotate encryption keys, periodically, to maintain security compliance and, in cases of personnel changes, to disable access to a database.

**Note:**

- The encryption key you use must be AES-256.
- To ensure that your Exadata database uses the most current versions of the Vault encryption key, rotate the key from the database details page on the Oracle Cloud Infrastructure Console. Do not use the Vault service.
- You can only use Oracle-managed encryption keys if your database is enabled with Oracle Data Guard.

If you want to use your own encryption keys to encrypt a database that you create, then you must create a dynamic group and assign specific policies to the group for customer-managed encryption keys. See Managing Dynamic Groups on page 2422 and Let security admins manage vaults, keys, and secrets on page 2151. Additionally, see To integrate customer-managed key management into Exadata Cloud Service on page 1283 if you need to update customer-managed encryption libraries for the Vault service.

You can also add and remove databases, and perform other management tasks on a database by using command line utilities. For information and instructions on how to use these utilities, see Creating and Managing Exadata Databases Manually on page 1313.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.
To enable management of customer-managed encryption keys, you must create a policy in the tenancy that allows a particular dynamic group to do so, similar to the following:

```
allow dynamic-group dynamic_group_name to manage keys in tenancy
```

If you are new to policies, then see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want more information about writing policies for databases, then see Details for the Database Service on page 2240.

**Using the Console**

*To create a database in an existing Exadata Cloud Service instance*

**Note:**

If IORM is enabled on the Exadata Cloud Service instance, the default directive will apply to the new database and system performance might be impacted. Oracle recommends that you review the IORM settings and make applicable adjustments to the configuration after the new database is provisioned.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to create the database in:

   *Cloud VM clusters (new resource model):* Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   *DB systems:* Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Click Create Database.
5. In the Create Database dialog, enter the following:

   - **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
   - **Database version:** The version of the database. You can mix database versions on the Exadata DB system.
   - **PDB name:** *(Optional)* For Oracle Database 12c (12.1.0.2) and later, you can specify the name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of eight alphanumeric characters. The only special character permitted is the underscore (_).
   - **Database Home:** The Oracle Database Home for the database. Choose the applicable option:

     - **Select an existing Database Home:** The Database Home display name field allows you to choose the Database Home from the existing homes for the database version you specified. If no Database Home with that version exists, you must create a new one.

     - **Create a new Database Home:** A database home will be created using the database version and the Database Home display name you specified.

   - **Create administrator credentials:** A database administrator SYS user will be created with the password you supply.
     - **Username:** SYS
     - **Password:** Supply the password for this user. The password must meet the following criteria:

       - A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The
special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm password:** Re-enter the SYS password you specified.
- **Select workload type:** Choose the workload type that best suits your application:
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  - **Enable automatic backup:** Check the check box to enable automatic incremental backups for this database. If you are creating a database in a security zone compartment, you must enable automatic backups.
  - **Backup retention period:** If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Automatic Incremental Backups for more information.

6. Click **Show Advanced Options** to specify advanced options for the database:

   - **Character set:** The character set for the database. The default is AL32UTF8.
   - **National character set:** The national character set for the database. The default is AL16UTF16.
   - If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
   - If you are creating a database in an Exadata Cloud Service VM cluster, then you can choose to use encryption based on encryption keys that you manage. By default, the database is configured using Oracle-managed encryption keys. To configure the database with encryption based on encryption keys you manage:
     a. Click the Encryption tab.
     b. Select Use customer-managed keys. You must have a valid encryption key in Oracle Cloud Infrastructure Vault service. See Let security admins manage vaults, keys, and secrets on page 2151.

       **Note:**

       Oracle only supports AES-256 encryption keys.

     c. Choose a vault from the Vault in compartment drop-down. You can change the compartment by clicking the CHANGE COMPARTMENT link.
     d. Select an encryption key from the Master encryption key in compartment drop-down. You can change the compartment containing the encryption key you want to use by clicking the CHANGE COMPARTMENT link.
     e. If you want to use an encryption key that you import into your vault, then select Choose the key version and enter the OCID of the key you want to use in the Key version OCID field.

       **Note:**

       - Oracle supports customer-managed keys on databases after Oracle Database 11g release 2 (11.2.0.4).
       - If you choose to provide an OCID for the valid key version, then ensure that the OCID corresponds to the key version you want to use.

7. Click **Create Database**.

After database creation is complete, the status changes from **Provisioning** to **Available**, and on the database details page for the new database, the Encryption section displays the encryption key name and the encryption key OCID.
Caution:
Do not delete the encryption key from the vault. This causes any database protected by the key to become unavailable.

To create a database from a backup
Before you begin, note the following:

• When you create a database from a backup, the availability domain is the same as the availability domain that hosts the backup.
• The Oracle Database software version you specify must be the same or later version as that of the backed-up database.
• If you are creating a database from an automatic backup, then you can choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Using the Console on page 1321
• If the backup being used to create a database is in a security zone compartment, the database cannot be created in a compartment that is not in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to a backup.
   • Standalone backups: Click Standalone Backups under Bare Metal, VM, and Exadata.
   • Automatic backups: Navigate to the Database Details page of the database associated with the backup:
     • Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
     • DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

   Click the name of the database associated with the backup that you will use to create the new database. Locate the backup in the list of backups on the Database Details page.
4. Click the Actions icon (three dots) for the backup you chose.
5. Click Create Database. On the Create Database from Backup page, configure the database as follows.
6. In the Configure your DB system section:
   • Backups created in cloud VM clusters: Choose a cloud VM cluster to run the database from the Select a VM cluster drop-down list.
   • Backups created in DB systems: Choose a shape from the Select a shape drop-down list, then choose a DB system to run the database from the Select a DB system drop-down list.
7. In the Configure Database Home section:
   • Select an existing Database Home: If you choose this option, make a selection from the Select a Database Home drop-down list.
   • Create a new Database home: If you choose this option, enter a name for the new Database Home in the Database Home display name field.
8. In the Configure database section:
   • In the Database name field, accept the default name or name the database.
     The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
   • In the Password and Confirm password fields, enter and re-enter a password.
     A strong password for SYS administrator must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password
must not contain the user name (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reverse order and regardless of casing.

9. In the **Enter the source database’s TDE wallet or RMAN password** field, enter a password that matches either the Transparent Data Encryption (TDE) wallet password or RMAN password for the source database.

10. Click **Create Database**.

To navigate to a list of backups for a particular database:

1. Click the DB system name that contains the specific database to display the DB System Details page.
2. From the list of databases, click the database name associated with the backup you want to use to display a list of backups on the database details page. You can also access the list of backups for a database by clicking **Backups in the Resources section**.

To navigate to the list of standalone backups for your current compartment:

1. Click **Standalone Backups** under **Bare Metal, VM, and Exadata**.
2. In the list of standalone backups, find the backup you want to use to create the database.

**To move a database to another Database Home**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the database:
   
   - **Cloud VM clusters (new resource model)**: Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   
   - **DB systems**: Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Click **Move to Another Home**.
5. Select the target Database Home.
6. Click **Move Database**.
7. Confirm the move operation.

The database will be stopped in the current home and then restarted in the destination home. While the database is being moved, the Database Home status displays as **Moving Database**. When the operation completes, Database Home is updated with the current home. If the operation is unsuccessful, the status of the database displays as **Failed**, and the Database Home field provides information about the reason for the failure.

**To terminate a database**

You'll get the chance to back up the database prior to terminating it. This creates a standalone backup that can be used to create a database later. We recommend that you create this final backup for any production (non-test) database.

**Note:**

Terminating a database removes all automatic incremental backups of the database from Oracle Cloud Infrastructure Object Storage. However, all full backups that were created on demand, including your final backup, will persist as standalone backups.

You cannot terminate a database that is assuming the primary role in a Data Guard association. To terminate it, you can switch it over to the standby role.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the database.

   **X8M systems**: Under Exadata at Oracle Cloud, click **Exadata VM Clusters**. In the list of cloud VM clusters, find the VM cluster containing the database you want to manage and click its highlighted name to view the details page for the cluster.

   In the list of databases, click the highlighted name of the database you wish to manage. The Database Details page is displayed.

   **X6, X7, or X8 systems**: Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system containing the database you want to manage and click its highlighted name to view the details page for the DB system.

   In the list of databases, click the highlighted name of the database you wish to manage. The Database Details page is displayed.

4. Click **More Actions**, and then click **Terminate**.

5. In the confirmation dialog, indicate whether you want to back up the database before terminating it, and type the name of the database to confirm the termination.

6. Click **Terminate Database**.

   The database's status indicates Terminating.

### To administer Vault encryption keys

After you provision a database in an Exadata DB system or VM cluster, you can rotate the Vault encryption key or change the encryption management configuration for that database.

**Note:**

- To ensure that your Exadata database uses the most current version of the Vault encryption key, rotate the key from the database details page on the Oracle Cloud Infrastructure Console. Do not use the Vault service.
- You can rotate Vault encryption keys only on databases that are configured with customer-managed keys.
- You can change encryption key management from Oracle-managed keys to customer-managed keys but you cannot change from customer-managed keys to Oracle-managed keys.
- If the database for which you are changing encryption key management is using Oracle-managed keys and is enabled with Oracle Data Guard, then you cannot change to customer-managed keys.
- Oracle supports administering encryption keys on databases after Oracle Database 11g release 2 (11.2.0.4).

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your compartment from the **Compartment** drop-down.

3. Navigate to the cloud VM cluster or DB system that contains the database for which you want to change encryption management or to rotate a key.

   **Cloud VM clusters**: Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, locate the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems**: Under **Bare Metal, VM, and Exadata**, click **DB Systems**. In the list of DB systems, locate the Exadata DB system you want to access and click its name to display its details page.

4. In the **Databases** section, click the name of the database for which you want to change encryption management or to rotate a key to display its details page.

5. Click the **More Actions** drop-down.
6. Click **Administer Encryption Key**.

   To rotate an encryption key on a database using customer-managed keys:
   a. Click **Rotate Encryption Key** to display a confirmation dialog.
   b. Click **Rotate Key**.

   To change key management type from Oracle-managed keys to customer-managed keys:
   a. Click **Change Key Management Type**.
   b. Select **Use customer-managed keys**.

   You must have a valid encryption key in Oracle Cloud Infrastructure Vault service and provide the information in the subsequent steps. See Key and Secret Management Concepts on page 3953.
   c. Choose a vault from the **Vault in compartment** drop-down. You can change the compartment by clicking the **CHANGE COMPARTMENT** link.
   d. Select an encryption key from the **Master encryption key in compartment** drop-down. You can change the compartment containing the encryption key you want to use by clicking the **CHANGE COMPARTMENT** link.
   e. If you want to use an encryption key that you import into your vault, then select **Choose the key version** and enter the OCID of the key you want to use in the **Key version OCID** field.

   **Note:**
   Changing key management causes the database to become briefly unavailable.

   **Caution:**
   After changing key management to customer-managed keys, do not delete the encryption key from the vault as this can cause the database to become unavailable.

7. Click **Apply**.

   On the database details page for this database, the **Encryption** section displays the encryption key name and the encryption key OCID.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage databases.

- ListDatabases
- GetDatabase
- CreateDatabase
- UpdateDatabase - Use this operation to move a database to another Database Home
- DeleteDatabase

For the complete list of APIs for the Database service, see Database Service API.

**Changing the Database Passwords**

The password that you specify in the Database Admin Password field when you create a new Exadata Cloud Service instance or database is set as the password for the SYS, SYSTEM, TDE wallet, and PDB Admin credentials. Use the following procedures if you need to change passwords for an existing database.

Note that if you are enabling Data Guard for a database, the SYS password and the TDE wallet password of the primary and standby databases must all be the same.

*To change the SYS password for an Exadata Cloud Service database*

1. Log onto the cloud VM cluster or DB system host as opc.
2. Run the following command:

```
sudo dbaascli database changepassword --dbname <database_name>
```

To change the TDE wallet password for an Exadata Cloud Service database

1. Log onto the cloud VM cluster or DB system host as opc.
2. Run the following command:

```
sudo dbaascli tde changepassword --dbname <database_name>
```

## Creating and Managing Exadata Databases Manually

Exadata Cloud Service instances include these command line tools for performing various tasks to manage individual databases:

- **dbaasapi** - For adding and removing databases from the Exadata Cloud Service instance. See Using dbaasapi on page 1313.
- **dbaascli** - For a variety of life-cycle and administration operations such as:
  - Starting and stopping a database
  - Starting and stopping the Oracle Net listener
  - Viewing information about Oracle Homes
  - Moving a database to another Oracle Home
  - Deleting an unused Oracle Home
  - Performing database configuration changes
  - Managing Oracle Database software images
  - Managing pluggable databases (PDBs)
  - Performing database recovery
  - Rotating the master encryption key

For details about how to use this CLI, see The dbaascli Utility.

### Using dbaasapi

You can use the dbaasapi command line utility to create and delete databases on an Exadata DB system. The utility operates like a REST API. It reads a JSON request body and produces a JSON response body in an output file.

The utility is located in the `/var/opt/oracle/dbaasapi/` directory on the compute nodes and must be run as the root user.

To learn how to add or remove Exadata databases by using the Oracle Cloud Infrastructure Console or API instead, see Creating and Managing Exadata Databases on page 1306.

### Note:

- You must update the cloud-specific tooling on all the compute nodes in your Exadata Cloud Service instance before performing the following procedures. For more information, see Updating an Exadata Cloud Service Instance on page 1274.
- Only one dbaasapi operation can execute at a given time. We recommend that you check the status of an operation to ensure it completed before you run another operation.
- Databases that you create by using dbaasapi are visible in the Console and through the API and CLI only if you create the database across all nodes in the cluster. However, it can take up to 5 hours before you see them.
Prerequisites

If you plan to create a database and store its backups in the Oracle Cloud Infrastructure Object Storage, refer to the prerequisites in Managing Exadata Database Backups on page 1320, and ensure that the system meets the networking requirements for backing up to Object Storage. Review Create Database Parameters on page 1316 and gather the information you'll need to supply in the input file you create for the dbaasapi operation.

Caution:

We recommend that you avoid specifying parameter values that include confidential information when you use the dbaasapi commands.

Creating a Database

The following procedure creates directory called dbinput, a sample input file called myinput.json, and a sample output file called createdb.out.

1. SSH to a compute node in the Exadata DB system.

   ```
   ssh -i <private_key_path> opc@<node_ip_address>
   ```

2. Log in as opc and then sudo to the root user.

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Make a directory for the input file and change to the directory.

   ```
   [root@dbsys ~]# mkdir -p /home/oracle/dbinput
   # cd /home/oracle/dbinput
   ```

4. Create the input file in the directory. The following sample file will create a database configured to store backups in an existing bucket in Object Storage. For parameter descriptions, see Create Database Parameters on page 1316.

   ```json
   {
     "object": "db",
     "action": "start",
     "operation": "createdb",
     "params": {
       "nodelist": "",
       "dbname": "exadb",
       "edition": "EE_EP",
       "version": "12.1.0.2",
       "ohome_name": "oradbhome1",
       "adminPassword": "<password>",
       "sid": "exadb",
       "pdbName": "PDB1",
       "charset": "AL32UTF8",
       "ncharset": "AL16UTF16",
       "backupDestination": "OSS",
       "cloudStorageContainer": "https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/mycompany/DBBackups",
       "cloudStorageUser": "<name@example.com>",
       "cloudStoragePwd": "<auth_token>"
     },
     "outputfile": "/home/oracle/createdb.out",
     "FLAGS": ""
   }
   ```
5. Run the utility and specify the input file.

```
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i myinput.json
```

6. Check the output file and note the ID.

```
[root@dbsys ~]# cat /home/oracle/createdb.out
{
  "msg": "",
  "object": "db",
  "status": "Starting",
  "errmsg": "",
  "outputfile": "/home/oracle/createdb.out",
  "action": "start",
  "id": "170",
  "operation": "createdb",
  "logfile": "/var/opt/oracle/log/gsa1/dbaasapi/db/createdb/1.log"
}
```

7. Create a JSON file to check the database creation status. Note the action of "status". Replace the ID and the dbname with the values from the previous steps.

```
{
  "object": "db",
  "action": "status",
  "operation": "createdb",
  "id": 170,
  "params": {
    "dbname": "exadb"
  },
  "outputfile": "/home/oracle/createdb.out",
  "FLAGS": ""
}
```

8. Run the utility with the status file as input and then check the utility output.

Rerun the status action regularly until the response indicates that the operation succeeded or failed.

```
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i db_status.json
[root@dbsys ~]# cat /home/oracle/createdb.out
{
  "msg": "Sync sqnet file...[done]\n##Done executing tde\nWARN: Could not register elogger_parameters: elogger.pm::_init: /var/opt/oracle/dbaas_acfs/events does not exist\n##Invoking assistant bkup\nUsing cmd : /var/opt/oracle/ocde/assistants/bkup/bkup -out /var/opt/oracle/ocde/res/bkup.out -sid="exadb1" -reco_grp="RECOC1" -hostname="ed1db01.data.customer1.oraclevcn.com" -oracle_home="/u02/app/oracle/product/12.1.0/dbhome_5" -dbname="exadb" -dbtype="exarac" -exabm="\n

```

Oracle Cloud Infrastructure User Guide 1315
### Create Database Parameters

Use the following parameters to create a database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>The value &quot;db&quot;.</td>
</tr>
<tr>
<td>action</td>
<td>The value &quot;start&quot;.</td>
</tr>
<tr>
<td>operation</td>
<td>The value &quot;createdb&quot;.</td>
</tr>
<tr>
<td>nodelist</td>
<td>The value &quot;&quot; (an empty string). The database will be created across all nodes in the cluster. <strong>Note:</strong> If you specify only a subset of nodes, then the database you create will not be visible in the Oracle Cloud Infrastructure interfaces (Console, API, and CLI).</td>
</tr>
<tr>
<td>dbname</td>
<td>The database name, in quotes.</td>
</tr>
<tr>
<td>edition</td>
<td>The value &quot;EE_EP&quot;. (Only Enterprise Edition - Extreme Performance is supported.)</td>
</tr>
<tr>
<td>version</td>
<td>The database version as 18.0.0.0, 12.2.0.1, 12.1.0.2, or 11.2.0.4, in quotes.</td>
</tr>
<tr>
<td>ohome_name</td>
<td>The name of the Oracle Database Home to use for the new database, in quotes.</td>
</tr>
<tr>
<td>adminPassword</td>
<td>The administrator (SYS and SYSTEM) password to use for the new database, in quotes. The password must be nine to thirty characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -.</td>
</tr>
<tr>
<td>sid</td>
<td>The SID of the database, in quotes.</td>
</tr>
<tr>
<td>pdbName</td>
<td>The name of the pluggable database, in quotes.</td>
</tr>
<tr>
<td>charset</td>
<td>The database character set, in quotes. For allowed values, see Allowed Create Database Charset Values on page 1318.</td>
</tr>
<tr>
<td>ncharset</td>
<td>The database national character set. The value AL16UTF16 or UTF8, in quotes.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>backupDestination</td>
<td>The database backup destination, in quotes. You can configure the following backup destinations.</td>
</tr>
<tr>
<td></td>
<td>NONE No backup destination is configured.</td>
</tr>
<tr>
<td></td>
<td>DISK Configure database backups to the local disk Fast Recovery Area.</td>
</tr>
<tr>
<td></td>
<td>OSS Configure database backups to an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You must specify all the cloudStorage parameters.</td>
</tr>
<tr>
<td></td>
<td>BOTH Configure database backups to both local disk and an existing bucket in Object Storage. You must specify all the cloudStorage parameters.</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>&quot;backupDestination&quot;:&quot;BOTH&quot;</td>
</tr>
<tr>
<td>cloudStorageContainer</td>
<td>Required if you specify a backup destination of OSS or BOTH. The Object Storage URL, your Oracle Cloud Infrastructure tenant, and an existing bucket in the object store to use as the backup destination, in the following format:</td>
</tr>
<tr>
<td></td>
<td><a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1/&lt;tenant&gt;/&lt;bucket&gt;</td>
</tr>
<tr>
<td></td>
<td>See Regions and Availability Domains on page 180 to look up the region name string.</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>&quot;cloudStorageContainer&quot;:&quot;<a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1/&lt;company_name&gt;/DBBackups&quot;</td>
</tr>
<tr>
<td>cloudStorageUser</td>
<td>Required if you specify a backup destination of OSS or BOTH. The user name for the Oracle Cloud Infrastructure user account, for example:</td>
</tr>
<tr>
<td></td>
<td>&quot;cloudStorageUser&quot;:&quot;<a href="mailto:name@company.com">name@company.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td>This is the user name you use to sign in to the Console. The user name must be a member of the Administrators group, as described in Prerequisites on page 1314.</td>
</tr>
<tr>
<td>cloudStoragePwd</td>
<td>Required if you specify a backup destination of OSS or BOTH. The auth token generated by using the Console or IAM API, in quotes, for example:</td>
</tr>
<tr>
<td></td>
<td>&quot;cloudStoragePwd&quot;:&quot;&lt;auth_token&gt;&quot;</td>
</tr>
<tr>
<td></td>
<td>For more information, see Managing User Credentials on page 2456.</td>
</tr>
<tr>
<td></td>
<td>This is not the password for the Oracle Cloud Infrastructure user.</td>
</tr>
</tbody>
</table>
Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>outputfile</td>
<td>The absolute path for the output of the request, for example, &quot;outputfile&quot;: &quot;/home/oracle/createdb.out&quot;.</td>
</tr>
</tbody>
</table>

| FLAGS | The value "" (an empty string). |

**Allowed Create Database Charset Values**

**Deleting a Database**

We recommend that you create a final backup before you delete any production (non-test) database. See Managing Exadata Database Backups by Using bkup_api on page 1323 to learn how to back up an Exadata database.

1. SSH to a compute node (virtual machine) in the Exadata cloud VM cluster or DB system.

   ```
   ssh -i <private_key_path> opc@<node_ip_address>
   ```

2. Log in as opc and then sudo to the root user.

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Make a directory for the input file and change to the directory.

   ```
   [root@dbsys ~]$ mkdir -p /home/oracle/dbinput
   
   # cd /home/oracle/dbinput
   ```

4. Create the input file in the directory and specify the database name to delete and an output file. For more information, see Delete Database Parameters on page 1320.

   ```
   {  
   "object": "db",  
   "action": "start",  
   "operation": "deletedb",  
   "params": {  
   "dbname": "exadb"
   },
   ```
5. Run the utility and specify the input file.

```bash
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i myinput.json
```

6. Check the output file and note the ID.

```bash
[root@ed1db01 ~]# cat /home/oracle/delete_exadb.out
```

7. Create a JSON file to check the database deletion status. Note the action of "status" in the sample file below. Replace the ID and the dbname with the values from the previous steps.

```json
{
  "object": "db",
  "action": "status",
  "operation": "deletedb",
  "id": 17,
  "params": {
    "dbname": "exadb"
  },
  "outputfile": "/home/oracle/deletedb.out",
  "FLAGS": ""
}
```

8. Run the utility with the status file as input and then check the utility output.

Rerun the status action regularly until the response indicates that the operation succeeded.

```bash
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i db_status.json
```

```bash
[root@dbsys ~]# cat /home/oracle/deletedb.out
```

```json
{
  "msg": "Using cmd : su - root -c "/var/opt/oracle/ocde/assistants/dg/dgcc -dbname exadb -action delete" \n\n##Done executing dg\n\nWARN: Could not register elogger_parameters: elogger.pm::_init: /var/opt/oracle/dbaas_acfs/events does not exist\n\n##Invoking assistant bkup\nUsing cmd : /var/opt/oracle/ocde/assistants/bkup/bkup -out /var/opt/oracle/ocde/res/bkup.out -bkup_oss_url="bkup_oss_url" -bkup_daily_time="0:13" -bkup_oss_user="bkup_oss_user" -dbname="exadb" -dctype="exarac" -exabm="yes" -firstrun="no" -action="delete" -bkup_cfg_files="no" -bkup_oss="no" -bkup_disk="no" -action=delete \n\n##Done executing bkup\n\nWARN: Could not register elogger_parameters: elogger.pm::_init: /var/opt/oracle/dbaas_acfs/events does not exist\n\n##Invoking assistant dbda\nUsing cmd : /var/opt/oracle/ocde/assistants/dbda\n```

```bash
```

```
```
Delete Database Parameters

Use the following parameters to delete a database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>The value &quot;db&quot;.</td>
</tr>
<tr>
<td>action</td>
<td>The value &quot;start&quot;.</td>
</tr>
<tr>
<td>operation</td>
<td>The value &quot;deletedb&quot;.</td>
</tr>
<tr>
<td>dbname</td>
<td>The database name, in quotes.</td>
</tr>
<tr>
<td>outputfile</td>
<td>The absolute path for the output of the request, for example, &quot;/home/oracle/deletedb.out&quot;.</td>
</tr>
<tr>
<td>FLAGS</td>
<td>The value &quot;&quot; (an empty string).</td>
</tr>
</tbody>
</table>

Managing Exadata Database Backups

This topic explains how to work with Exadata database backups managed by Oracle Cloud Infrastructure. You do this by using the Console or the API. (For unmanaged backups, see Managing Exadata Database Backups by Using bkup_api on page 1323.)

**Important:**

If you previously used bkup_api to configure backups and then you switch to using the Console or the API for backups:

- A new backup configuration is created and associated with your database. This means that you can no longer rely on your previously configured unmanaged backups to work.
- bkup_api uses cron jobs to schedule backups. These jobs are not automatically removed when you switch to using managed backups.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you’re new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Prerequisites**

- Review the information and instructions in Configuring a Static Route for Accessing the Object Store on page 1254 and ensure that you configure the static route for the backup subnet on each compute node (for DB systems) or virtual machine (for cloud VM clusters) in the Exadata Cloud Service instance.
Your Exadata Cloud Service instance must have connectivity to the applicable Swift endpoint for Object Storage. See https://www.oracle.com/cloud/storage/object-storage-faq.html for information about the Swift endpoints to use.

**Important:**

To avoid backup failures, ensure that the database's archiving mode is set to `ARCHIVELOG` (the default).

**Using the Console**

You can use the Console to enable automatic incremental backups, create full backups on demand, and view the list of managed backups for a database. You can also use the Console to delete manual (on-demand) backups.

**Note:**

- The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `bkup_api`).
- All backups are encrypted with the same master key used for Transparent Data Encryption (TDE) wallet encryption.
- Backups for a particular database are listed on the details page for that database. The **Encryption Key** column displays either **Oracle-Managed Key** or a key name if you are using your own encryption keys to protect the database. See **Backing Up Vaults and Keys** on page 4003 for more information.

**Caution:**

Do not delete any necessary encryption keys from the vault because this causes databases and backups protected by the key to become unavailable.

The database and infrastructure (the VM cluster or DB system) must be in an “Available” state for a backup operation to run successfully. Oracle recommends that you avoid performing actions that could interfere with availability (such as patching operations) while a backup operation is in progress. If an automatic backup operation fails, the Database service retries the operation during the next day’s backup window. If an on-demand full backup fails, you can try the operation again when the Exadata Cloud Service instance and database availability are restored.

**Automatic Incremental Backups**

When you enable the Automatic Backup feature, the service creates daily incremental backups of the database to Object Storage. The first backup created is a level 0 backup. Then, level 1 backups are created every day until the next weekend. Every weekend, the cycle repeats, starting with a new level 0 backup.

**Backup Retention**

If you choose to enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The system automatically deletes your incremental backups at the end of your chosen retention period.

**Backup Scheduling**

The automatic backup process starts at any time during your daily backup window. You can optionally specify a 2-hour scheduling window for your database during which the automatic backup process will begin. There are 12 scheduling windows to choose from, each starting on an even-numbered hour (for example, one window runs from 4:00-6:00 AM, and the next from 6:00-8:00 AM). Backups jobs do not necessarily complete within the scheduling window.

The default backup window of 00:00 to 06:00 in the time zone of the Exadata Cloud Service instance's region is assigned to your database if you do not specify a window. Note that the default backup scheduling window is six hours long, while the windows you specify are two hours long.
**Note:**

- **Data Guard** - You can enable the Automatic Backup feature on a database with the standby role in a Data Guard association. However, automatic backups for that database will not be created until it assumes the primary role.
- **Retention Period Changes** - If you shorten your database’s automatic backup retention period in the future, existing backups falling outside the updated retention period are deleted by the system.
- **Object Storage Costs** - Automatic backups incur Object Storage usage costs.

**On-Demand Full Backups**

You can create a full backup of your database at any time.

**Standalone Backups**

When you terminate an Exadata Cloud Service instance, a database, all of its resources are deleted, along with any automatic backups. Full backups remain in Object Storage as standalone backups. You can use a standalone backup to create a new database.

**To configure automatic backups for a database**

When you create an Exadata Cloud Service instance, you can optionally enable automatic backups for the initial database. Use this procedure to enable or disable automatic backups after the database is created.

**Note:**

Databases in a security zone compartment must have automatic backups enabled. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system containing the database you want to configure:

   - **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. In the list of databases, find the database for which you want to enable or disable automatic backups, and click its name to display database details. The details indicate whether automatic backups are enabled.
5. Click Configure Automatic Backups.
6. In the Configure Automatic Backups dialog, check or uncheck Enable Automatic Backup, as applicable. If you are enabling automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
7. Click Save Changes.

**To create an on-demand full backup of a database**

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system containing the database you want to back up:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. In the list of databases, find the database for which you want to create an on-demand full backup and click its name to display database details.

5. Under Resources, click Backups.

   A list of backups is displayed.

6. Click Create Backup.

To delete full backups from Object Storage

Note:

You cannot explicitly delete automatic backups. Unless you terminate the database, automatic backups remain in Object Storage for 30 days, after which time they are automatically deleted.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Choose your Compartment.

3. Navigate to the cloud VM cluster or DB system containing the database backup you want to delete:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. In the list of databases, find the database you are interested in and click its name to display database details.

5. Under Resources, click Backups.

   A list of backups is displayed.

6. Click the Actions icon (three dots) for the backup you are interested in, and then click Delete.

7. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage database backups:

- ListBackups
- GetBackup
- CreateBackup
- DeleteBackup
- UpdateDatabase - To enable and disable automatic backups.

For the complete list of APIs for the Database service, see Database Service API.

What's Next?

See Recovering an Exadata Database from Object Storage on page 1328.

Managing Exadata Database Backups by Using bkup_api

You can use Exadata's backup utility, bkup_api, to back up databases on an Exadata Cloud Service instance to an existing bucket in the Oracle Cloud Infrastructure Object Storage service and to the local disk Fast Recovery Area.
For backups managed by Oracle Cloud Infrastructure, see Managing Exadata Database Backups on page 1320.

This topic explains how to:

• Create a backup configuration file that indicates the backup destination, when the backup should run, and how long backups are retained. If the backup destination is Object Storage, the file also contains the credentials to access the service.
• Associate the backup configuration file with a database. The database will be backed up as scheduled, or you can create an on-demand backup.

**Note:**
You must update the cloud-specific tooling on all the compute nodes in your Exadata Cloud Service instance before performing the following procedures. For more information, see Updating an Exadata Cloud Service Instance on page 1274.

**Prerequisites**

• The Exadata Cloud Service instance requires access to the Oracle Cloud Infrastructure Object Storage service. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see Network Setup for Exadata Cloud Service Instances on page 1232. In that topic, pay particular attention to:
  • Service Gateway for the VCN on page 1237
  • Node Access to Object Storage: Static Route on page 1236
  • Backup egress rule: Allows access to Object Storage on page 1242
• An existing Object Storage bucket to use as the backup destination. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets on page 3398.
• An auth token generated by Oracle Cloud Infrastructure. You can use the Console or the IAM API to generate the password. For more information, see Working with Auth Tokens.
• The user name specified in the backup configuration file must have tenancy-level access to Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access to all of the cloud services. Instead, an administrator should create a policy like the following that limits access to only the required resources in Object Storage for backing up and restoring the database:

```
Allow group <group_name> to manage objects in compartment <compartment_name> where target.bucket.name = '<bucket_name>'
Allow group <group_name> to read buckets in compartment <compartment_name>
```

For more information about adding a user to a group, see Managing Groups on page 2419. For more information about policies, see Getting Started with Policies on page 2135.

**Default Backup Configuration**

The backup configuration follows a set of Oracle best-practice guidelines:

• Full (level 0) backup of the database followed by rolling incremental (level 1) backups on a seven-day cycle (a 30-day cycle for the Object Storage destination).
• Full backup of selected system files.
• Automatic backups daily at a specific time set during the database deployment creation process.

Retention period:

• Both Object Storage and local storage: 30 days, with the 7 most recent days' backups available on local storage.
• Object Storage only: 30 days.
• Local storage only: Seven days.

Encryption:

• Both Object Storage and local storage: All backups to cloud storage are encrypted.
• Object Storage only: All backups to cloud storage are encrypted.
Managing Backups

To create a backup configuration file

**Important:**

The following procedure must be performed on the first compute node in the Exadata Cloud Service instance's VM cluster or DB system resource. To determine the first compute node, connect to any compute node as the grid user and execute the following command:

```
$ $ORACLE_HOME/bin/olsnodes -n
```

The first node has the number 1 listed beside the node name.

1. SSH to the first compute node in the VM cluster or DB system resource.

```bash
ssh -i <private_key_path> opc@<node_1_ip_address>
```

2. Log in as opc and then sudo to the root user.

```bash
login as: opc
[opc@dbsys ~]$ sudo su -
```

3. Create a new backup configuration file in `/var/opt/oracle/ocde/assistants/bkup/` as shown in the sample configuration file below. This example uses the file name `bkup.cfg`, but you can provide your own file name. The following file schedules a backup to both local storage and an existing bucket in Object Storage.

The parameters are described below this procedure.

```bash
[root@dbsys ~]$ cd /var/opt/oracle/ocde/assistants/bkup/
vi bkup.cfg
bkup_disk=yes
bkup_oss=yes
bkup_oss_url=https://swiftobjectstorage.<region>.oraclecloud.com/v1/ companyabc/DBBackups
bkup_oss_user=<oci_user_name>
bkup_oss_passwd=<password>
bkup_oss_recovery_window=7
bkup_daily_time=06:45
```

4. Change the permissions of the file.

```bash
[root@dbsys bkup]# chmod 600 bkup.cfg
```

5. Use the following command to install the backup configuration, configure the credentials, schedule the backup, and associate the configuration with a database name.

```bash
[root@dbsys bkup]# ./bkup -cfg bkup.cfg -dbname=<database_name>
```

The backup is scheduled via cron and can be viewed at `/etc/crontab`.

When the scheduled backup runs, you can check its progress with the following command.

```bash
[root@dbsys bkup]# /var/opt/oracle/bkup_api/bkup_api bkup_status
```

The backup configuration file parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bkup_disk=[yes</td>
<td>no]</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bkup_oss=[yes</td>
<td>no]</td>
</tr>
<tr>
<td>bkup_oss_url=&lt;swift_url&gt;</td>
<td>Required if bkup_oss=yes. The Object Storage URL including the tenant and bucket you want to use. The URL is: <a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1/&lt;tenant&gt;/&lt;bucket&gt; where &lt;tenant&gt; is the lowercase tenant name (even if it contains uppercase characters) that you specify when signing in to the Console and &lt;bucket&gt; is the name of the existing bucket you want to use for backups.</td>
</tr>
<tr>
<td>bkup_oss_user=&lt;oci_user_name&gt;</td>
<td>Required if bkup_oss=yes. The user name for the Oracle Cloud Infrastructure user account. This is the user name you use to sign in to the Oracle Cloud Infrastructure Console. For example, <a href="mailto:jsmith@example.com">jsmith@example.com</a> for a local user or &lt;identity_provider&gt;/jsmith@example.com for a federated user. To determine which type of user you have, see the following topics: • Managing Users on page 2414 (for information on local users) • Federating with Identity Providers on page 2362 (for information on federated users) Note that the user must be a member of the Administrators group, as described in Prerequisites on page 1324.</td>
</tr>
<tr>
<td>bkup_oss_passwd=&lt;auth_token&gt;</td>
<td>Required if bkup_oss=yes. The auth token generated by using the Console or IAM API, as described in Prerequisites on page 1324. This is not the password for the Oracle Cloud Infrastructure user.</td>
</tr>
<tr>
<td>bkup_oss_recovery_window=n</td>
<td>Required if bkup_oss=yes. The number of days for which backups and archived redo logs are maintained in the Object Storage bucket. Specify 1 to 30 days.</td>
</tr>
<tr>
<td>bkup_daily_time=hh:mm</td>
<td>The time at which the daily backup is scheduled, specified in hours and minutes (hh:mm), in 24-hour format.</td>
</tr>
</tbody>
</table>

To create an on-demand backup

You can use the `bkup_api` utility to create an on-demand backup of a database.
1. SSH to the first compute node in the Exadata VM cluster or DB system resource.

   ```
   ssh -i <private_key_path> opc@<node_1_ip_address>
   ```

   To determine the first compute node, connect to any compute node as the `grid` user and execute the following command:

   ```
   $ $ORACLE_HOME/bin/olsnodes -n
   ```

   The first node has the number 1 listed beside the node name.

2. Log in as opc and then sudo to the root user.

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. You can let the backup follow the current retention policy, or you can create a long-term backup that persists until you delete it:

   - To create a backup that follows the current retention policy, enter the following command:

     ```
     # /var/opt/oracle/bkup_api/bkup_api bkup_start --dbname=<database_name>
     ```

   - To create a long-term backup, enter the following command:

     ```
     # /var/opt/oracle/bkup_api/bkup_api bkup_start --keep --dbname=<database_name>
     ```

4. Exit the root-user command shell and disconnect from the compute node:

   ```
   # exit
   $ exit
   ```

   By default, the backup is given a timestamp-based tag. To specify a custom backup tag, add the `--tag` option to the `bkup_api` command; for example, to create a long-term backup with the tag "monthly", enter the following command:

   ```
   # /var/opt/oracle/bkup_api/bkup_api bkup_start --keep --tag=monthly
   ```

   After you enter a `bkup_api bkup_start` command, the `bkup_api` utility starts the backup process, which runs in the background. To check the progress of the backup process, enter the following command:

   ```
   # /var/opt/oracle/bkup_api/bkup_api bkup_status --dbname=<database_name>
   ```

   To remove the backup configuration

   A backup configuration can contain the credentials to access the Object Storage bucket. For this reason, you might want to remove the file after successfully configuring the backup.

   ```
   [root@dbsys bkup]# rm bkup.cfg
   ```

   To delete a local backup

   To delete a backup of a database deployment on the Exadata Cloud Service instance, use the `bkup_api` utility.
1. Connect to the first compute node in your Exadata VM cluster or DB system resource as the opc user.
   To determine the first compute node, connect to any compute node as the grid user and execute the following command:

   ```bash
   $ $ORACLE_HOME/bin/olsnodes -n
   ```

   The first node has the number 1 listed beside the node name.

2. Start a root-user command shell:

   ```bash
   $ sudo -s#
   ```

3. List the available backups:

   ```bash
   # > /var/opt/oracle/bkup_api/bkup_api recover_list --dbname=<database_name>
   ```

   where dbname is the database name for the database that you want to act on.
   A list of available backups is displayed.

4. Delete the backup you want:

   ```bash
   # /var/opt/oracle/bkup_api/bkup_api bkup_delete --bkup=<backup-tag> --dbname=<database_name>
   ```

   where backup-tag is the tag of the backup you want to delete.

5. Exit the root-user command shell:

   ```bash
   # exit$
   ```

To delete a backup in Object Storage

Use the RMAN delete backup command to delete a backup from the Object Store.

What Next?

If you used Object Storage as a backup destination, you can display the backup files in your bucket in the Console on the Storage page, by selecting Object Storage.

You can manually restore a database backup by using the RMAN utility. For information about using RMAN, see the Oracle Database Backup and Recovery User's Guide for Release 18.1, 12.2, 12.1, or 11.2.

Recovering an Exadata Database from Object Storage

This topic explains how to recover an Exadata database from a backup stored in Object Storage by using the Console or the API. The Object Storage service is a secure, scalable, on-demand storage solution in Oracle Cloud Infrastructure. For information on backing up your databases to Object Storage, see Managing Exadata Database Backups on page 1320.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Using the Console

You can use the Console to restore the database from a backup in the Object Storage that was created by using the Console or the API. You can restore to the last known good state of the database, or you can specify a point in time or an existing System Change Number (SCN).
**Note:**

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `bkup_api`).

## Restoring an Existing Database

**To restore a database**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system containing the database you want to restore:
   - **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. In the list of databases, find the database you want to restore, and click its name to display details about it.
5. Click **Restore**.
6. Select one of the following options, and click **Restore Database**:
   - **Restore to the latest:** Restores the database to the last known good state with the least possible data loss.
   - **Restore to the timestamp:** Restores the database to the timestamp specified.
   - **Restore to System Change Number (SCN):** Restores the database using the SCN specified. This SCN must be valid.

   **Tip:**
   
   You can determine the SCN number to use either by accessing and querying your database host, or by accessing any online or archived logs.

7. Confirm when prompted.

   If the restore operation fails, the database will be in a "Restore Failed" state. You can try restoring again using a different restore option. However, Oracle recommends that you review the RMAN logs on the host and fix any issues before reattempting to restore the database. These log files can be found in subdirectories of the `/var/opt/oracle/log` directory.

**To restore a database using a specific backup from Object Storage**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system containing the database you want to restore:
   - **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. In the list of databases, find the database you want to restore, and click its name to display details about it.
5. Under **Resources**, click **Backups**.

   A list of backups is displayed.
6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Restore**.
7. Confirm when prompted.

## Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.
Use these API operations to recover a database:

- ListBackups
- GetBackup
- RestoreDatabase

For the complete list of APIs for the Database service, see Database Service API.

**Recovering an Exadata Database by Using RMAN**

If you backed up your Exadata database by using `bkup_api`, you can manually restore that database backup by using the Oracle Recovery Manager (RMAN) utility. For information about using RMAN, see the *Oracle Database Backup and Recovery User's Guide* for Release 18.1, 12.2, 12.1, or 11.2.

To restore an Exadata database from a managed backup, see Recovering an Exadata Database from Object Storage on page 1328.

**Creating Oracle Database Homes on an Exadata Cloud Service Instance**

You can add Oracle Database Homes (referred to as "Database Homes" in Oracle Cloud Infrastructure) to an existing Exadata Cloud Service instance by using the Oracle Cloud Infrastructure Console, the API, or the CLI.

A Database Home is a directory location on the Exadata database compute nodes that contains Oracle Database software binary files. Compute nodes are also referred to as virtual machines in the Oracle Cloud Infrastructure Console.

After you provision the Exadata Cloud Service instance, you can create one or more Database Homes in the instance, and add databases to any of the Database Homes.

You can also add and remove Database Homes, and perform other management tasks on a Database Home by using the dbaascli utility. For information and instructions, see Managing Oracle Database Homes Manually on page 1333.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

**Using the Console**

To create a new Database Home in an existing Exadata Cloud Service instance:

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the cloud VM cluster or DB system you want to create the new Database Home on:

   - Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.
   - DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Under Resources, click Database Homes.
   A list of Database Homes is displayed.
5. Click Create Database Home.
6. In the **Create Database Home** dialog, enter the following:

   - **Database Home display name**: The display name for the Database Home. Avoid entering confidential information.
   - **Database image**: Determines what Oracle Database version is used for the database. You can mix database versions on the DB system, but not editions. By default, the latest Oracle-published database software image is selected.

   Click **Change Database Image** to use an older Oracle-published image or a custom database software image that you have created in advance, then select an **Image Type**:

     - **Oracle Provided Database Software Images**: These images contain generally available versions of Oracle Database software.
     - **Custom Database Software Images**: These images are created by your organization and contain customized configurations of software updates and patches. Use the **Select a compartment** and **Select a Database version** selectors to limit the list of custom database software images to a specific compartment or Oracle Database software major release version.

   After choosing a software image, click **Select** to return to the Create Database dialog.

   - Click **Show Advanced Options** to specify advanced options for the Database Home.

     - **Tags**: If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

7. Click **Create**.

When the Database Home creation is complete, the status changes from Provisioning to Available.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the **CreateDbHome** API operation to create Database Homes.

For the complete list of APIs for the Database service, see **Database Service API**.

**Managing Oracle Database Homes on an Exadata Cloud Service Instance**

You can delete or view information about Oracle Database Homes (referred to as "Database Homes" in Oracle Cloud Infrastructure) by using the Oracle Cloud Infrastructure Console, the API, or the CLI.

For information on how to perform these tasks manually, see **Managing Oracle Database Homes Manually** on page 1333.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: The policy in **Let database admins manage Oracle Cloud database systems** on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142. If you want to dig deeper into writing policies for databases, see **Details for the Database Service** on page 2240.

**Using the Console**

*To view information about a Database Home*

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Navigate to the cloud VM cluster or DB system containing the Database Home:

   **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. On the DB System Details page, under Resources, click **Database Homes**.

5. In the list of Database Homes, find the Database Home you are interested in, and then click its name to display details about it.

   **To delete a Database Home**

You cannot delete a Database Home that contains databases. You must first terminate the databases to empty the Database Home. See **To terminate a database** on page 1310 to learn how to terminate a database.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.

3. Navigate to the cloud VM cluster or DB system containing the Database Home you want to delete:

   **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. On the DB System Details page, under Resources, click **Database Homes**.

5. In the list of Database Homes, find the Database Home you want to delete, and then click its name to display details about it.

6. On the Database Home Details page, click **Delete**.

   If the Database Home contains databases, you will not be able to proceed. You must cancel the deletion, empty the Database Home as applicable, and then retry the deletion.

   **To manage tags for your Database Home**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.

3. Navigate to the cloud VM cluster or DB system containing the Database Home:

   **Cloud VM clusters (new resource model):** Under **Exadata at Oracle Cloud**, click **Exadata VM Clusters**. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click **DB Systems**. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Under **Resources**, click **Database Homes**.

5. In the list of Database Homes, find the Database Home you want to administer.

6. Click the the Actions icon (three dots) on the row listing the Database Home, and then click **Add Tags**.

   For more information, see **Resource Tags** on page 211.

   **Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage Database Homes:

- **ListDbHomes**
- **GetDbHome**
- **DeleteDbHome**
Managing Oracle Database Homes Manually

This topic describes how to manage Oracle Database Homes (also called "Oracle Homes" or "Database Homes") by using the `dbaascli` utility.

An Oracle Database Home is a directory location on the compute nodes that contains Oracle Database binaries. Exadata Cloud Service instances enable multiple databases to share a set of Oracle Database binaries in a shared Oracle Home directory location.

For information on how to manage Database Homes by using the Oracle Cloud Infrastructure Console, the API, or the CLI, see Managing Oracle Database Homes on an Exadata Cloud Service Instance on page 1331.

Viewing Information About Oracle Homes

You can view information about Oracle Home directory locations by using the `dbhome info` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata Cloud Service Instance on page 1269.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```
3. Execute the `dbaascli` command with the `dbhome info` subcommand:

   ```
   # dbaascli dbhome info
   ```
4. When prompted, press Enter to view information about all Oracle Homes registered in your Exadata Cloud Service instance, or specify an Oracle Home name to view information only about that Oracle Home.
5. Exit the root-user command shell:

   ```
   # exit
   $```

Moving a Database to Another Oracle Home

Moving a database to another Oracle Home enables you to consolidate existing Oracle Homes and manage the storage that they consume. You can move a database to another Oracle Home by using the `database move` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata Cloud Service Instance on page 1269.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```
3. Ensure that all database instances associated with the database deployment are up and running.

   ```
   # dbaascli database status --dbname <dbname>
   ```

   In the preceding command, `<dbname>` specifies the name of the database that you want to check.
   Restart any database instances that are not running and open.
4. Execute the `dbaascli` command with the `database move` subcommand:

```
# dbaascli database move --dbname <dbname> --ohome <oracle_home>
```

In the preceding command:
- `<dbname>` — specifies the name of the database that you want to move.
- `<oracle_home>` — specifies the path to an existing Oracle Home directory location, which you want the specified database to use.

When performing a move operation to an Oracle Home with a different patch level, if the database is part of a Data Guard association, then ensure that you move the standby database to the new patchset before you move the primary database.

5. Exit the root-user command shell:

```
# exit
```

Creating an Oracle Home

You can create an Oracle Home directory location and software installation, without creating a database, by using the `dbhome create` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the opc user.
   
   For detailed instructions, see Connecting to an Exadata Cloud Service Instance on page 1269.

2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Run the `dbaascli` command with the `dbhome create` subcommand:

```
# dbaascli dbhome create --version <software_version>
```

In the preceding command, `<software_version>` specifies an Oracle Database software version. For example, 19000, 18000, 12201, 12102, or 11204. The latest available bundle patch for the specified software version is automatically used.

To see information about Oracle Database software images that are available in your Exadata Cloud Service instance, including software version and bundle patch details, use the `dbaascli dbimage list` command.

When prompted, type `yes` to confirm that the installation is based on a local software image.

4. Exit the root-user command shell:

```
# exit
```

Deleting an Oracle Home

If an Oracle Home directory does not support any databases, you can delete it by using the `dbhome purge` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the opc user.

   For detailed instructions, see Connecting to an Exadata Cloud Service Instance on page 1269.

2. Start a root-user command shell:

```
$ sudo -s
#
```
3. Execute the dbaascli command with the dbhome purge subcommand:

```
# dbaascli dbhome purge
```

4. When prompted, enter:

- 1 — if you want to specify the Oracle Home name for the location being purged.
- 2 — if you want to specify the Oracle Home directory path for the location being purged.

5. When next prompted, enter the Oracle Home name or directory path for the location being purged.

If your entries are valid and the Oracle Home is not associated with a database, then the Oracle binaries are removed from the Oracle Home directory location and the associated metadata is removed from the system.

6. Exit the root-user command shell:

```
# exit
```

---

**Monitoring and Managing Exadata Storage Servers with ExaCLI**

The ExaCLI command line utility allows you to perform monitoring and management functions on Exadata storage servers in an Exadata Cloud Service instance. ExaCLI offers a subset of the commands found in the on-premises Exadata command line utility CellCLI. The utility runs on the database compute nodes in the Exadata Cloud Service instance.

See the [ExaCLI Command Reference](#) on page 1337 in this topic to learn what commands are available.

**Username and Password**

You need a username and password to connect to the Exadata Storage Server. On Exadata Cloud@Customer, the preconfigured user is `cloud_user_clustername`, where `clustername` is the name of the virtual machine (VM) cluster that is being used. You can determine the name of the VM cluster by running the following command as the `grid` user on any cluster node:

```
$ crsctl get cluster name
```

The password for `cloud_user_clustername` is initially set to the administration password that you specify when creating the starter database deployment on the VM cluster.

**Command Syntax**

For Exadata Storage Server targets, ExaCLI supports the same command syntax as CellCLI. Construct your commands using the syntax that follows. Note that the syntax example assumes you are the `opc` user on a compute node.

```
exacli -c [username@]remotehost[:port] [-l username] [--xml] [--cookie-jar filename] [-e {command | 'command; command' | @batchfile}]
```

**Example 1**

This example shows the user on an Exadata compute node issuing the command to log in to ExaCLI start an interactive ExaCLI session on a storage server:

```
[opc@exacs-node1 ~]$ exacli -l cloud_user_clustername -c 192.168.136.7
```

See [Connecting to a Storage Server with ExaCLI](#) for information on determining your storage server's IP address.

Once logged in, run additional commands as follows:

```
exacli cloud_user_clustername@192.168.136.7> LIST DATABASE
ASM
HRCDB
```
Example 2

This example shows a single command issued on a compute node that does the following:

- Connects to a storage server
- Performs a LIST action
- Exits the session (specified with the "-e" flag)

```
[opc@exacs-node1 ~]$ exacli -l cloud_user_clustername -c 192.168.136.7 --xml --cookie-jar -e list griddisk detail
```

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-c [username@]remotehost</code> or <code>-connect [username@]remotehost[:port]</code></td>
<td>Specifies the remote node to which you want to connect. ExaCLI prompts for the user name if not specified.</td>
</tr>
<tr>
<td><code>-l username</code> or <code>-login-name username</code></td>
<td>Specifies the user name to log into the remote node. The preconfigured user is <code>cloud_user_clustername</code>.</td>
</tr>
<tr>
<td><code>--xml</code></td>
<td>Displays the output in XML format.</td>
</tr>
<tr>
<td><code>--cookie-jar [filename]</code></td>
<td>Specifies the filename of the cookie jar to use. If filename is not specified, the cookie is stored in a default cookie jar located at <code>HOME/.exacli/cookiejar</code>, where <code>HOME</code> is the home directory of the OS user running the ExaCLI command. The presence of a valid cookie allows the ExaCLI user to execute commands without requiring to login in subsequent ExaCLI sessions.</td>
</tr>
<tr>
<td><code>-e command</code> or <code>-e 'command[; command]'</code> or <code>-e @batchFile</code></td>
<td>Specifies either the ExaCLI commands to run or a batch file. ExaCLI exits after running the commands. If specifying multiple commands to run, enclose the commands in single quotes to prevent the shell from interpreting the semi-colon. Omit this option to start an interactive ExaCLI session.</td>
</tr>
<tr>
<td><code>--cert-proxy proxy[:port]</code></td>
<td>Specifies the proxy server to use when downloading certificates. If <code>port</code> is omitted, port 80 is used by default.</td>
</tr>
<tr>
<td><code>-n</code> or <code>--no-prompt</code></td>
<td>Suppresses prompting for user input.</td>
</tr>
</tbody>
</table>

Usage Notes

- Notes for the `--cookie-jar` option:
  - The user name and password are sent to the remote node for authentication. On successful authentication, the remote node issues a cookie (the login credentials) that is stored in the specified `filename` on the database.
node. If filename is not specified, the cookie is stored in a default cookie jar located at HOME/.exacli/cookiejar, where HOME is the home directory of the operating system user running the ExaCLI command. For the opc user, the home is /home/opc.

- The operating system user running the ExaCLI command is the owner of the cookie-jar file.
- A cookie jar can contain multiple cookies from multiple users on multiple nodes in parallel sessions.
- Cookies are invalidated after 24 hours.
- If the cookie is not found or is no longer valid, ExaCLI prompts for the password. The new cookie is stored in the cookie jar identified by filename, or the default cookie jar if filename is not specified.
- Even without the --cookie-jar option, ExaCLI still checks for cookies from the default cookie jar. However, if the cookie does not exist or is no longer valid, the new cookie will not be stored in the default cookie jar if the --cookie-jar option is not specified.

Notes for the -e option:

- ExaCLI exits after running the commands.
- If specifying multiple commands to run, be sure to enclose the commands in single quotes to prevent the shell from interpreting the semi-colon.
- The batch file is a text file that contains one or more ExaCLI commands to run.

Notes for the -n (--no-prompt) option:

- If ExaCLI needs additional information from the user, for example, if ExaCLI needs to prompt the user for a password (possibly because there were no valid cookies in the cookie-jar) or to prompt the user to confirm the remote node’s identity, then ExaCLI prints an error message and exits.

Connecting to a Storage Server with ExaCLI

To use ExaCLI on storage servers, you will need to know your target storage server's IP address. If you do not know the IP address of the node you want to connect to, you can find it by viewing the contents of the cellip.ora file.

The following example illustrates how to do so on the UNIX command line for a quarter rack system. (Note that a quarter rack has three storage cells, and each cell has two connections, so a total of six IP addresses are shown.)

```
[root@exacs-node1 ~]# cat /etc/oracle/cell/network-config/cellip.ora
cell="192.168.136.5;cell="192.168.136.6"
cell="192.168.136.7;cell="192.168.136.8"
cell="192.168.136.9;cell="192.168.136.10"
```

If you are connecting to a storage cell for the first time using ExaCLI, you may be prompted to accept an SSL certificate. The ExaCLI output in this case will look like the following:

```
[opc@exacs-node1 ~]$ exacli -l cloud_user_clustername -c 192.168.136.7 --cookie-jar
No cookies found for cloud_user_clustername@192.168.136.7
Password: *********
EXA-30016: This connection is not secure. You have asked ExaCLI to connect to cell 192.168.136.7 securely. The identity of 192.168.136.7 cannot be verified.
Got certificate from server:
C=US,ST=California,L=Redwood City,O=Oracle Corporation,OU=Oracle Exadata,CN=ed1cl03clu01-priv2.usdc2.oraclecloud.com
Do you want to accept and store this certificate? (Press y/n)
```

Accept the self-signed Oracle certificate by pressing "y" to continue using ExaCLI.

ExaCLI Command Reference

You can execute various ExaCLI commands to monitor and manage Exadata Storage Servers associated with your Oracle Cloud Infrastructure Exadata DB system. ExaCLI allows you to get up-to-date, real-time information about your Exadata Cloud Service.

Use the LIST command with the following services and objects:
• **ACTIVERQUEST** - Lists all active requests that are currently being served by the storage servers.

• **ALERTDEFINITION** - Lists all possible alerts and their sources for storage servers.

• **ALERTHISTORY** - Lists all alerts that have been issues for the storage servers.

• **CELL** - Used to list the details of a specific attribute of the storage servers or storage cells. The syntax is as follows: LIST CELL ATTRIBUTES A, B, C, with A, B, and C being attributes. To see all cell attributes, use the LIST CELL ATTRIBUTES ALL command.

• **CELLDISK** - Lists the attributes of the cell disks in the storage servers. Use the following syntax to list the cell disk details: LIST CELLDISK cell_disk_name DETAIL.

• **DATABASE** - Lists details of the databases. Uses the regular LIST command syntax: LIST DATABASE and LIST DATABASE DETAIL. You can also use this command to show an individual attribute with the following syntax: LIST DATABASE ATTRIBUTES NAME.

• **FLASHCACHE** - Lists the details of the Exadata system's flash cache. For this object, you can use the following syntax patterns: LIST FLASHCACHE DETAIL or LIST FLASHCACHE ATTRIBUTES attribute_name.

• **FLASHCACHECONTENT** - Lists the details of all objects in the flash cache, or the details of a specified object ID. To list all the details of all objects, use LIST FLASHCACHECONTENT DETAIL. To list details for a specific object, use a where clause as follows: LIST FLASHCACHECONTENT WHERE objectNumber=12345 DETAIL

  **Note:** To find the object ID of a specific object, you can query user_objects using the object's name to get the data_object_id of a partition or table.

• **FLASHLOG** - Lists the attributes for the Oracle Exadata Smart Flash Log.

• **GRIDDISK** - Lists the details of a particular grid disk. The syntax is similar to the CELLDISK command syntax. To view all attributes: LIST GRIDDISK grid_disk_name DETAIL. To view specified attributes of the grid disk: LIST GRIDDISK grid_disk_name ATTRIBUTES size, name.

• **IBPORT** - Lists details of the InfiniBand ports. Syntax is LIST IBPORT DETAIL.

• **IORMPROFILE** - Lists any IORM profiles that have been set on the storage servers. You can also refer back to the profile attribute on the DATABASE object if a database has an IORM profile on it. Syntax is LIST IORMPROFILE.

• **LUN** - The LUN (logical unit number) object returns the number and the detail of the physical disks in the storage servers. List the LUNs of the disks with LIST LUN. List the details of each LUN with LIST LUN lun_number DETAIL.

• **METRICCURRENT** - Lists the current metrics for a particular object type. Syntax is LIST METRICCURRENT WHERE objectType = 'CELLDISK'. This command also allows for sorting and results limits as seen in the following example:

  ```
  LIST METRICCURRENT attributes name, metricObjectName ORDER BY metricObjectName asc, name desc LIMIT 5
  ```

• **METRICDEFINITION** - Lists metric definitions for the object that you can then get details for. With the command LIST metricDefinition WHERE objectType=cell, you can get all the metrics for that object type. You can then use the metric definition object again to get details for one of those specific metrics just listed: LIST metricDefinition WHERE name= IORM_MODE DETAIL.

• **METRICHISTORY** - List metrics over a specified period of time. For example, with the command LIST METRICHISTORY WHERE ageInMinutes < 30, you can list all the metrics collected over the past 30 minutes. You can also use the predicate collectionTime to set a range from a specific time. Use collectionTime as shown in the follow example: LIST METRICHISTORY WHERE collectionTime > '2018-04-01T21:12:00-10:00'. The metric history object can also be used to see a specific metric using the object’s name (for example, LIST METRICHISTORY CT_FD_IO_RQ_SM) or with a "where" clause to get objects with similar attributes like name (for example, LIST METRICHISTORY WHERE name like 'CT_.*').

• **OFFLOADGROUP** - Lists the attributes for the offload group that are running on your storage servers. You can list all details for all groups with LIST OFFLOADGROUP DETAIL, or list the attributes for a specific group, as shown in the following example: LIST OFFLOADGROUP offloadgroup4. List specific attributes with LIST OFFLOADGROUP ATTRIBUTES name.

• **PHYSICALDISK** - Lists all physical disks. Use the results of LIST PHYSICALDISK to identify a specific disk for further investigation, then list the details of that disk using the command as follows: LIST PHYSICALDISK
To list the details of flash disks, use the command as follows:

```bash
LIST PHYSICALDISK FLASH_1_0 DETAIL
```

- **PLUGGABLEDATABASE** - Lists all PDBs. View the details of a specific PDB with

  ```bash
  LIST PLUGGABLEDATABASE pdb_name.
  ```

- **QUARANTINE** - Lists all SQL statements that you prevented from using Smart Scans. The syntax is

  ```bash
  LIST QUARANTINE DETAIL. You can also use a "where" clause on any of the available attributes.
  ```

Use the ExaCLI **CREATE, ALTER, DROP**, and **LIST** commands to act on the following Exadata Storage Server objects:

- **DIAGPACK** - Lists the diagnostic packages and their status in your Exadata system. The syntax is

  ```bash
  LIST DIAGPACK [DETAIL], with DETAIL being an optional attribute. Use CREATE DIAGPACK with the packStartTime attribute to gather logs and trace files into a single compressed file for downloading, as in the following example:
  ```

  ```bash
  CREATE DIAGPACK packStartTime=2019_12_15T00_00_00.
  ```

  You can also use the value "now" with packStartTime:

  ```bash
  CREATE DIAGPACK packStartTime=now
  ```

To download a diagnostic package, use

```bash
DOWNLOAD DIAGPACK package_name local_directory.
```

For example, the following command downloads a diagnostic package to the /tmp directory:

```bash
DOWNLOAD DIAGPACK cfclcx2647_diag_2018_06_03T00_44_24_1 /tmp
```

- **IORMPLAN** - You can List, create, alter, and drop IORM plans using ExaCLI. To see the details of all IORM plans, use

  ```bash
  LIST IORMPLAN DETAIL.
  ```

  You can also use the command to create and alter IORM plans, and to apply plans to storage servers.

**Example query: finding the object_id value of an object**

```bash
select object_name, data_object_id from user_objects where object_name = 'BIG_CENSUS';
```

<table>
<thead>
<tr>
<th>OBJECT_NAME</th>
<th>DATA_OBJECT_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG_CENSUS</td>
<td>29152</td>
</tr>
</tbody>
</table>

**Using Oracle Data Guard with Exadata Cloud Service**

**Note:**

This procedure is only applicable to Exadata Cloud Service instances. To use Oracle Data Guard with bare metal and virtual machine DB systems, see Using Oracle Data Guard on page 1461.

This topic explains how to use the Oracle Cloud Infrastructure (OCI) Console or the API to manage Oracle Data Guard associations in your Exadata Cloud Service instances. This topic does not apply to Data Guard configurations created by accessing the host directly and setting up Oracle Data Guard manually.

When you use the Oracle Cloud Infrastructure Console or API to enable Oracle Data Guard for an Exadata Cloud Service database:

- The standby database is a physical standby.
- The peer databases (primary and standby) are:
  - in the same compartment
  - both Exadata system shapes
  - identical database versions
- You are limited to one standby database for each primary database.
- You must use Oracle-managed encryption keys.

To configure Oracle Data Guard between on-premises and OCI Exadata Cloud Service instances, or to configure your database with multiple standbys, you must access the database host directly and set up Oracle Data Guard manually.

For complete information on Oracle Data Guard, see the Data Guard Concepts and Administration documentation in the Oracle Help Center.
**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you are new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Prerequisites**

An Exadata Cloud Service Oracle Data Guard implementation requires two existing Exadata Cloud Service instances: one containing an existing database that is to be duplicated by Data Guard, and one that will house the new standby database by Data Guard. When enabling Data Guard, you can create a new Database Home on the standby Exadata instance to house the new standby database during the enable Data Guard operation. Alternately, you can choose to provision the standby database in an existing Database Home on the standby instance. For information on creating the required resources for the standby system, see the following topics:

- To create a cloud Exadata infrastructure resource on page 1245
- To create a cloud VM cluster resource on page 1246
- To create a new Database Home in an existing Exadata Cloud Service instance on page 1330

You can use a custom database software image that contains the necessary patches for your databases when creating a Database Home on either the primary or the standby Exadata instance. See Oracle Database Software Images on page 1567 for information on working with custom Oracle Database software images.

If you choose to provision a standby database in an existing Database Home, ensure that the target Database Home on the standby instance has all required patches that are in use for the primary database before you provision the standby database. See the following topics for more information on patching an existing Database Home:

- To patch the Oracle Database software in a Database Home (cloud VM cluster) on page 1286
- To patch the Oracle Database software in a Database Home (DB system) on page 1285

**Network Requirements**

Ensure that your environment meets the following network requirements:

- If you want to configure Oracle Data Guard across regions, then you must configure remote virtual cloud network (VCN) peering between the primary and standby databases. Networking is configured on the cloud VM cluster resource for systems using the new Exadata resource model, and on the DB system resource for system using the old resource model. See Remote VCN Peering (Across Regions) on page 3280.

  For Exadata Data Guard configurations, OCI supports the use of hub-and-spoke network topology for the VCNs within each region. This means that the primary and standby databases can each utilize a "spoke" VCN that passes network traffic to the "hub" VCN that has a remote peering connection. See Spoke-to-Spoke: Remote Peering with Transit Routing for information on setting up this network topology.

- To set up Oracle Data Guard within a single region, both Exadata Cloud Service instances must use the same VCN. When setting up Data Guard within the same region, Oracle recommends that the instance containing the standby database be in a different availability domain from the instance containing the primary database to improve availability and disaster recovery.

- Configure the ingress and egress security rules for the subnets of both Exadata Cloud Service instances in the Oracle Data Guard association to enable TCP traffic to move between the applicable ports. Ensure that the rules you create are stateful (the default).

  For example, if the subnet of the primary Exadata Cloud Service instance uses the source CIDR 10.0.0.0/24 and the subnet of the standby instance uses the source CIDR 10.0.1.0/24, then create rules as shown in the subsequent example.

  ```
  Note:
  The egress rules in the example show how to enable TCP traffic only for port 1521, which is a minimum requirement for Oracle Data Guard to
  ```
Database

If TCP traffic is already enabled for all destinations (0.0.0.0/0) on all of your outgoing ports, then you need not explicitly add these specific egress rules.

Security Rules for Subnet of Primary Exadata Cloud Service instance

**Ingress Rules:**

- Stateless: No
- Source: 10.0.1.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

**Egress Rules:**

- Stateless: No
- Destination: 10.0.1.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

Security Rules for Subnet of Standby Exadata Cloud Service instance

**Ingress Rules:**

- Stateless: No
- Source: 10.0.0.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

**Egress Rules:**

- Stateless: No
- Destination: 10.0.0.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

For information about creating and editing rules, see Security Lists on page 2850.

**Password Requirements**

For Oracle Data Guard operations to work, the SYS password and the TDE wallet password of the primary and standby databases must all be the same. If you change any one of these passwords, then you must update the rest of the passwords to match. See Changing the Database Passwords on page 1312 to learn how to change the SYS password or the TDE wallet password.

If you make any change to the TDE wallet (such as adding a master key for a new PDB or changing the wallet password), then you must copy the wallet from the primary database to the standby database so that Oracle Data Guard can continue to operate. For Oracle Database versions prior to Oracle Database 12c release 2 (12.2), if you change the SYS password on one of the peers, then you must manually sync the password file between the DB systems.
Working with Oracle Data Guard

Oracle Data Guard ensures high availability, data protection, and disaster recovery for enterprise data. The Oracle Cloud Infrastructure Database Data Guard implementation requires two databases: one in a primary role and one in a standby role. The two databases compose an Oracle Data Guard association. Most of your applications access the primary database. The standby database is a transactionally consistent copy of the primary database.

Oracle Data Guard maintains the standby database by transmitting and applying redo data from the primary database. If the primary database becomes unavailable, then you can use Oracle Data Guard to switch or failover the standby database to the primary role.

Switchover

A switchover reverses the primary and standby database roles. Each database continues to participate in the Oracle Data Guard association in its new role. A switchover ensures no data loss. Performing planned maintenance on an Exadata Cloud Service instance with an Oracle Data Guard association is typically done by switching the primary database to the standby role, performing maintenance on the standby database, and then switching the standby database back to the primary role.

Failover

A failover transitions the standby database into the primary role after the existing primary database fails or becomes unreachable. A failover might result in some data loss when you use Maximum Performance protection mode.

Reinstate

Reinstates a database into the standby role in an Oracle Data Guard association. You can use the reinstate command to return a failed database into service after correcting the cause of failure.

Note:

You cannot terminate a primary database that has an Oracle Data Guard association with a peer (standby) database. Delete the standby database first. Alternatively, you can switch over the primary database to the standby role, and then terminate it.

You cannot terminate an Exadata cloud VM cluster or DB system that includes Oracle Data Guard-enabled databases. You must first remove the Oracle Data Guard association by terminating the standby database.

Using the Console

Use the Console to enable an Oracle Data Guard association between databases, change the role of a database in an Oracle Data Guard association using either a switchover or a failover operation, and reinstate a failed database.

When you enable Oracle Data Guard, a separate Oracle Data Guard association is created for the primary and the standby database.

To enable Oracle Data Guard on an Exadata Cloud Service instance

Note:

If you use customer-managed encryption keys to protect this database, then enabling Oracle Data Guard for this database is not available.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains the Exadata Cloud Service instance with the database for which you want to enable Oracle Data Guard.
3. Navigate to the cloud VM cluster or DB system that contains a database you want to assume the primary role:

*Cloud VM clusters (new resource model)*: Under *Exadata at Oracle Cloud*, click *Exadata VM Clusters*. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

*DB systems*: Under Bare Metal, VM, and Exadata, click *DB Systems*. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. On the VM cluster or DB system details page, in the *Databases* section, click the name of the database you want to make primary.

5. On the Database Details page, in the *Resources* section, click *Data Guard Associations*.

6. In the *Data Guard Associations* section, click *Enable Data Guard*.

7. On the *Enable Data Guard* page, configure the Oracle Data Guard association.

   - The settings in the *Data Guard association details* section are read only and cannot be changed.

   - **Protection mode**: The protection mode used for this Oracle Data Guard association is set to *Maximum Performance*.
   - **Transport type**: The redo transport type used for this Oracle Data Guard association is set to *Async* (asynchronous).

   - In the *Select peer DB system* section, provide the following information for the standby database to obtain a list of available DB systems in which to locate the standby database:

     - **Region**: Select a region where you want to locate the standby database. The region where the primary database is located is selected, by default. You can choose to locate the standby database in a different region. The hint text associated with this field tells you in which region the primary database is located.
     - **Availability domain**: Select an availability domain for the standby database. The hint text associated with this field tells you in which availability domain the primary database is located.
     - **Shape**: Select the shape of the standby DB system. The shape must be an Exadata DB system shape.
     - **Data Guard peer resource type**: Select *DB System* or *VM Cluster*.

   - Select a DB system or cloud VM cluster from the drop-down list.

   - In the *Choose Database Home* section, choose one of the following:

     - **Select an existing Database Home**: If you use this option, select a home from the *Database Home display name* drop-down list.
     - **Create a new Database Home**: Use this option to provision a new Database Home for your Data Guard peer database.

   Click *Change Database Image* to use an older Oracle-published image or a custom database software image that you have created in advance, then select an *Image Type*:

     - **Oracle Provided Database Software Images**: These images contain generally available versions of Oracle Database software.
     - **Custom Database Software Images**: These images are *created by your organization* and contain customized configurations of software updates and patches. Use the *Select a compartment* and *Select a Database version* selectors to limit the list of custom database software images to a specific compartment or Oracle Database software major release version.

   - In the *Configure standby database* section, enter the database administrator password of the primary database in the *Database password* field. Use this same database administrator password for the standby database.

   **Note:**

   The administrator password and the TDE wallet password must be identical. If the passwords are not identical, then follow the instructions in *Changing the Database Passwords* on page 1312 to ensure that they are.
8. Click Enable Data Guard.

When you create the association, the details for a database and its peer display their respective roles as Primary or Standby.

To perform a database switchover

You initiate a switchover operation by using the Data Guard association of the primary database.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains the Exadata Cloud Service instance with the database for which you want to enable Oracle Data Guard.
3. Navigate to the cloud VM cluster or DB system that contains the Data Guard association:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Under Resources, click Data Guard Associations.
5. For the Data Guard association on which you want to perform a switchover, click the Actions icon (three dots), and then click Switchover.
6. In the Switchover Database dialog box, enter the database admin password, and then click OK.

   This database should now assume the role of the standby, and the standby should assume the role of the primary in the Data Guard association.

To perform a database failover

You initiate a failover operation by using the Data Guard association of the standby database.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains the Exadata Cloud Service instance with the database for which you want to enable Oracle Data Guard.
3. Navigate to the cloud VM cluster or DB system that contains the Data Guard association:

   Cloud VM clusters (new resource model): Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   DB systems: Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.
4. Under Resources, click Data Guard Associations.
5. For the Data Guard association on which you want to perform a failover, click Failover.
6. In the Failover Database dialog box, enter the database admin password, and then click OK.

   This database should now assume the role of the primary, and the old primary's role should display as Disabled Standby.

To reinstate a database

After you fail over a primary database to its standby, the standby assumes the primary role and the old primary is identified as a disabled standby. After you correct the cause of failure, you can reinstate the failed database as a functioning standby for the current primary by using its Data Guard association.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains the Exadata Cloud Service instance with the database for which you want to enable Oracle Data Guard.
3. Navigate to the cloud VM cluster or DB system that contains the Data Guard association:

   **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. Under Resources, click Data Guard Associations.

5. For the Data Guard association on which you want to reinstate this database, click the Actions icon (three dots), and then click Reinstate.

6. In the Reinstate Database dialog box, enter the database admin password, and then click OK.

   This database should now be reinstated as the standby in the Data Guard association.

To terminate a Data Guard association on an Exadata Cloud Service instance

On an Exadata Cloud Service instance, you remove a Data Guard association by terminating the standby database.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.

2. Choose the Compartment that contains the Exadata Cloud Service instance with the database for which you want to enable Oracle Data Guard.

3. Navigate to the cloud VM cluster or DB system that contains the standby database:

   **Cloud VM clusters (new resource model):** Under Exadata at Oracle Cloud, click Exadata VM Clusters. In the list of VM clusters, find the VM cluster you want to access and click its highlighted name to view the details page for the cluster.

   **DB systems:** Under Bare Metal, VM, and Exadata, click DB Systems. In the list of DB systems, find the Exadata DB system you want to access, and then click its name to display details about it.

4. For the standby database you want to terminate, click the Actions icon (three dots), and then click Terminate.

5. In the Terminate Database dialog box, enter the name of the database, and then click OK.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage Data Guard associations on an Exadata Cloud Service instance:

- CreateDataGuardAssociation
- GetDataGuardAssociation
- ListDataGuardAssociations
- SwitchoverDataGuardAssociation
- FailoverDataGuardAssociation
- ReinstateDataGuardAssociation
- DeleteDatabase - To terminate an Exadata Cloud Service instance Data Guard association, you delete the standby database.

For the complete list of APIs for the Database service, see Database Service API.

Configuring Oracle Database Features for Exadata Cloud Service

This topic describes how to configure Oracle Multitenant, tablespace encryption, and Huge Pages for use with your Exadata Cloud Service instance.

Using Oracle Multitenant on an Exadata Cloud Service Instance

When you create an Exadata Cloud Service instance that uses Oracle Database 12c or later, an Oracle Multitenant environment is created.

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes zero, one, or many pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects,
Database

and non-schema objects that appears to an Oracle Net Services client as a non-CDB. All Oracle databases using versions earlier than Oracle Database 12c are non-CDBs.

To use Oracle Transparent Data Encryption (TDE) in a pluggable database (PDB), you must create and activate a master encryption key for the PDB.

In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers.

You must export and import the master encryption key for any encrypted PDBs you plug into your Exadata Cloud Service instance CDB.

If your source PDB is encrypted, you must export the master encryption key and then import it.

You can export and import all of the TDE master encryption keys that belong to the PDB by exporting and importing the TDE master encryption keys from within a PDB. Export and import of TDE master encryption keys support the PDB unplug and plug operations. During a PDB unplug and plug, all of the TDE master encryption keys that belong to a PDB, as well as the metadata, are involved.

See "ADMINISTER KEY MANAGEMENT" in Oracle Database SQL Language Reference for Release 19, 18, 12.2 or 12.1.

To determine if you need to create and activate an encryption key for the PDB

1. Invoke SQL*Plus and log in to the database as the SYS user with SYSDBA privileges.
2. Set the container to the PDB:

   ```sql
   SQL> ALTER SESSION SET CONTAINER = pdb;
   ```

3. Query V$ENCRYPTION_WALLET as follows:

   ```sql
   SQL> SELECT wrl_parameter, status, wallet_type FROM v$encryption_wallet;
   ```

   If the STATUS column contains a value of OPEN_NO_MASTER_KEY, you need to create and activate the master encryption key.

To create and activate the master encryption key in a PDB

1. Set the container to the PDB:

   ```sql
   SQL> ALTER SESSION SET CONTAINER = pdb;
   ```
2. Create and activate a master encryption key in the PDB by executing the following command:

```
SQL> ADMINISTER KEY MANAGEMENT SET KEY USING TAG 'tag' FORCE KEYSTORE IDENTIFIED BY keystore-password WITH BACKUP USING 'backup_identifier';
```

In the previous command:

- `keystore-password` is the keystore password. By default, the keystore password is set to the value of the administration password that is specified when the database is created.
- The optional `USING TAG 'tag'` clause can be used to associate a tag with the new master encryption key.
- The `WITH BACKUP` clause, and the optional `USING 'backup_identifier'` clause, can be used to create a backup of the keystore before the new master encryption key is created.

See also `ADMINISTER KEY MANAGEMENT` in *Oracle Database SQL Language Reference for Release 19, 18 or 12.2*.

**Note:**

To enable key management operations while the keystore is in use, Oracle Database 12c Release 2, and later, includes the `FORCE KEYSTORE` option to the `ADMINISTER KEY MANAGEMENT` command. This option is also available for Oracle Database 12c Release 1 with the October 2017, or later, bundle patch.

If your Oracle Database 12c Release 1 database does not have the October 2017, or later, bundle patch installed, you can perform the following alternative steps:

a. Close the keystore.
b. Open the password-based keystore.
c. Create and activate a master encryption key in the PDB by using `ADMINISTER KEY MANAGEMENT` without the `FORCE KEYSTORE` option.
d. Update the auto-login keystore by using `ADMINISTER KEY MANAGEMENT` with the `CREATE AUTO_LOGIN KEYSTORE FROM KEYSTORE` option.

3. Query `V$ENCRYPTION_WALLET` again to verify that the `STATUS` column is set to `OPEN`:

```
SQL> SELECT wrl_parameter, status, wallet_type FROM v$encryption_wallet;
```

4. Query `V$INSTANCE` and take note of the value in the `HOST_NAME` column, which identifies the database server that contains the newly updated keystore files:

```
SQL> SELECT host_name FROM v$instance;
```
5. Copy the updated keystore files to all of the other database servers.

To distribute the updated keystore, you must perform the following actions on each database server that does not contain the updated keystore files:

a. Connect to the root container and query \texttt{V$ENCRYPTION\_WALLET}. Take note of the keystore location contained in the \texttt{WRL\_PARAMETER} column:

\begin{verbatim}
SQL> SELECT wrl_parameter, status FROM v$encryption_wallet;
\end{verbatim}

b. Copy the updated keystore files.

You must copy all of the updated keystore files from a database server that is already updated. Use the keystore location observed in the \texttt{WRL\_PARAMETER} column of \texttt{V$ENCRYPTION\_WALLET}.

Open the updated keystore:

\begin{verbatim}
SQL> ADMINISTER KEY MANAGEMENT SET KEYSTORE open FORCE KEYSTORE IDENTIFIED BY keystore-password CONTAINER=all;
\end{verbatim}

\textbf{Note:}

To enable key management operations while the keystore is in use, Oracle Database 12c Release 2, and later, includes the \texttt{FORCE KEYSTORE} option to the \texttt{ADMINISTER KEY MANAGEMENT} command. This option is also available for Oracle Database 12c Release 1 with the October 2017, or later, bundle patch.

If your Oracle Database 12c Release 1 database does not have the October 2017, or later, bundle patch installed, you can perform the following alternative steps:

a. Close the keystore before copying the updated keystore files.

b. Copy the updated keystore files.

c. Open the updated keystore by using \texttt{ADMINISTER KEY MANAGEMENT} without the \texttt{FORCE KEYSTORE} option.

6. Query \texttt{GV$ENCRYPTION\_WALLET} to verify that the \texttt{STATUS} column is set to \texttt{OPEN} across all of the database instances:

\begin{verbatim}
SQL> SELECT wrl_parameter, status, wallet_type FROM gv$encryption_wallet;
\end{verbatim}

\textbf{To export and import a master encryption key}

1. Export the master encryption key.

a. Invoke SQL*Plus and log in to the PDB.

b. Execute the following command:

\begin{verbatim}
SQL> ADMINISTER KEY MANAGEMENT EXPORT ENCRYPTION KEYS WITH SECRET "secret" TO 'filename' IDENTIFIED BY keystore-password;
\end{verbatim}

2. Import the master encryption key.

a. Invoke SQL*Plus and log in to the PDB.

b. Execute the following command:

\begin{verbatim}
SQL> ADMINISTER KEY MANAGEMENT IMPORT ENCRYPTION KEYS WITH SECRET "secret" FROM 'filename' IDENTIFIED BY keystore-password;
\end{verbatim}

\textbf{Managing Tablespace Encryption}

By default, all new tablespaces that you create in an Exadata database are encrypted.
However, the tablespaces that are initially created when the database is created may not be encrypted by default.

- For databases that use Oracle Database 12c Release 2 or later, only the USERS tablespaces initially created when the database was created are encrypted. No other tablespaces are encrypted including the non-USERS tablespaces in:
  - The root container (CDB$ROOT).
  - The seed pluggable database (PDB$SEED).
  - The first PDB, which is created when the database is created.
- For databases that use Oracle Database 12c Release 1 or Oracle Database 11g, none of the tablespaces initially created when the database was created are encrypted.

For further information about the implementation of tablespace encryption in Exadata, along with how it impacts various deployment scenarios, see Oracle Database Tablespace Encryption Behavior in Oracle Cloud.

Creating Encrypted Tablespaces

User-created tablespaces are encrypted by default.

By default, any new tablespaces created by using the SQL CREATE TABLESPACE command are encrypted with the AES128 encryption algorithm. You do not need to include the USING 'encrypt_algorithm' clause to use the default encryption.

You can specify another supported algorithm by including the USING 'encrypt_algorithm' clause in the CREATE TABLESPACE command. Supported algorithms are AES256, AES192, AES128, and 3DES168.

Managing Tablespace Encryption

You can manage the software keystore (known as an Oracle wallet in Oracle Database 11g), the master encryption key, and control whether encryption is enabled by default.

Managing the Master Encryption Key

Tablespace encryption uses a two-tiered, key-based architecture to transparently encrypt (and decrypt) tablespaces. The master encryption key is stored in an external security module (software keystore). This master encryption key is used to encrypt the tablespace encryption key, which in turn is used to encrypt and decrypt data in the tablespace.

When a database is created on an Exadata Cloud Service instance, a local software keystore is created. The keystore is local to the compute nodes and is protected by the administration password specified during the database creation process. The auto-login software keystore is automatically opened when the database is started.

You can change (rotate) the master encryption key by using the ADMINISTER KEY MANAGEMENT SQL statement. For example:

```
SQL> ADMINISTER KEY MANAGEMENT SET ENCRYPTION KEY USING TAG 'tag'
       IDENTIFIED BY password WITH BACKUP USING 'backup';
keystore altered.
```

Controlling Default Tablespace Encryption

The ENCRYPT_NEW_TABLESPACES initialization parameter controls the default encryption of new tablespaces. In Exadata databases, this parameter is set to CLOUD_ONLY by default.

Values of this parameter are as follows.
### Database

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALWAYS</td>
<td>During creation, tablespaces are transparently encrypted with the AES128 algorithm unless a different algorithm is specified in the ENCRYPTION clause.</td>
</tr>
<tr>
<td>CLOUDONLY</td>
<td>Tablespace created in an Exadata database are transparently encrypted with the AES128 algorithm unless a different algorithm is specified in the ENCRYPTION clause. For non-cloud databases, tablespaces are only encrypted if the ENCRYPTION clause is specified. ENCRYPTION is the default value.</td>
</tr>
<tr>
<td>DDL</td>
<td>During creation, tablespaces are not transparently encrypted by default, and are only encrypted if the ENCRYPTION clause is specified.</td>
</tr>
</tbody>
</table>

**Note:**

With Oracle Database 12c Release 2 (12.2), or later, you can no longer create an unencrypted tablespace in an Exadata database. An error message is returned if you set ENCRYPT_NEW_TABLESPACES to DDL and issue a CREATE TABLESPACE command without specifying an ENCRYPTION clause.

### Managing Huge Pages

Huge Pages provide considerable performance benefits for Oracle Database on systems with large amounts of memory. Oracle Database on an Exadata Cloud Service instance hosted in Oracle Cloud Infrastructure provides configuration settings that make use of Huge Pages by default; however, you can make manual adjustments to optimize the configuration of Huge Pages.

Huge Pages is a feature integrated into the Linux kernel 2.6. Enabling Huge Pages makes it possible for the operating system to support large memory pages. Using Huge Pages can improve system performance by reducing the amount of system CPU and memory resources required to manage Linux page tables, which store the mapping between virtual and physical memory addresses. For Oracle Databases, using Huge Pages can drastically reduce the number of page table entries associated with the System Global Area (SGA).

On Exadata Cloud Service instances hosted in Oracle Cloud Infrastructure, a standard page is 4 KB, while a Huge Page is 2 MB by default. Therefore, an Oracle Database on an Exadata DB system with a 50 GB SGA requires 13,107,200 standard pages to house the SGA, compared with only 25,600 Huge Pages. The result is much smaller page tables, which require less memory to store and fewer CPU resources to access and manage.

### Adjusting the Configuration of Huge Pages

The configuration of Huge Pages for Oracle Database is a two-step process:

- At the operating system level, the overall amount of memory allocated to Huge Pages is controlled by the `vm.nr_hugepages` entry in the `/etc/sysctl.conf` file. This setting is made on each compute node in the environment and it is strongly recommended that the setting is consistent across all of the compute nodes. To alter the Huge Page allocation, you can execute the following command on each compute node as the root user:

  ```
  # sysctl -w vm.nr_hugepages=value
  
  where value is the number of Huge Pages that you want to allocate.
  ```

On Exadata Cloud Service instances hosted in Oracle Cloud Infrastructure, each Huge Page is 2 MB by default. Therefore, to allocate 50 GB of memory to Huge Pages you can execute the following command:

```
# sysctl -w vm.nr_hugepages=25600
```
At the Oracle Database level, the use of Huge Pages is controlled by the `USE_LARGE_PAGES` instance parameter setting. This setting applies to each database instance in a clustered database. Oracle strongly recommends a consistent setting across all of the database instances associated with a database. The following options are available:

- **TRUE** — specifies that the database instance can use Huge Pages if they are available. For all versions of Oracle Database after 11.2.0.3, Oracle allocates as much of the SGA as it can, using Huge Pages. When the Huge Page allocation is exhausted, standard memory pages are used.
- **FALSE** — specifies that the database instance does not use Huge Pages. This setting is generally not recommended if Huge Pages are available.
- **ONLY** — specifies that the database instance must use Huge Pages. With this setting, the database instance fails to start if the entire SGA cannot be accommodated in Huge Pages.

If you make any adjustments at either the operating system or Oracle Database level, ensure that the overall configuration works.

For more information, see the *Oracle Database Administrator's Reference for Linux and UNIX-Based Operating Systems* for Release 19, 18, 12.1, or 11.2 for a general overview of Huge Pages and more information about configuring Huge Pages. Also, see `USE_LARGE_PAGES` in the *Oracle Database Reference* for Release 12.2, 12.1, or 11.2.

### Exadata Fixed Hardware Shapes: X6, X7, X8 and Exadata Base

This topic describes the available fixed-size Exadata Cloud Service hardware shapes in Oracle Cloud Infrastructure.

**Note:**

For information on the flexible X8M shape, see [Overview of X8M Scalable Exadata Infrastructure](#) on page 1227.

Exadata X8 shapes:

- **Exadata.Quarter3.100**: Provides a 2-node Exadata DB system with up to 100 CPU cores, and 149 TB of usable storage.
- **Exadata.Half3.200**: Provides a 4-node Exadata DB system with up to 200 CPU cores, and 299 TB of usable storage.
- **Exadata.Full3.400**: Provides an 8-node Exadata DB system with up to 400 CPU cores, and 598 TB of usable storage.

Exadata X7 shapes:

- **Exadata.Quarter2.92**: Provides a 2-node Exadata DB system with up to 92 CPU cores, and 106 TB of usable storage.
- **Exadata.Half2.184**: Provides a 4-node Exadata DB system with up to 184 CPU cores, and 212 TB of usable storage.
- **Exadata.Full2.368**: Provides an 8-node Exadata DB system with up to 368 CPU cores, and 424 TB of usable storage.

Exadata X6 shapes:

- **Exadata.Quarter1.84**: Provides a 2-node Exadata DB system with 22 enabled CPU cores, with up to 62 additional CPU cores, and 84 TB of usable storage.
- **Exadata.Half1.168**: Provides a 4-node Exadata DB system with 44 enabled CPU cores, with up to 124 additional CPU cores, and 168 TB of usable storage.
- **Exadata.Full1.336**: Provides an 8-node Exadata DB system with 88 enabled CPU cores, with up to 248 additional CPU cores, and 336 TB of usable storage.

Exadata base system:

- **Exadata.Base.48**: Provides a 2-node Exadata DB system with up to 48 CPU cores, and 74 TB of usable storage.
All Exadata shapes provide unlimited I/O, and support only Enterprise Edition - Extreme Performance. All Exadata shapes provide 720 GB RAM per node except for Exadata base systems, which provide 360 GB RAM per node. For more details about Exadata shapes, see Exadata Shape Configurations on page 1223.

For information on provisioning an Exadata Cloud Service instance, see Creating an Exadata Cloud Service Instance on page 1243.

**The X8M Virtual Machine File System Structure**

Exadata Cloud Service X8M systems use the following file system organization on the virtual machine nodes.

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Mounted On</th>
</tr>
</thead>
<tbody>
<tr>
<td>devtmpfs</td>
<td>/dev</td>
</tr>
<tr>
<td>tmpfs</td>
<td>/dev/shm</td>
</tr>
<tr>
<td>tmpfs</td>
<td>/run</td>
</tr>
<tr>
<td>tmpfs</td>
<td>/sys/fs/cgroup</td>
</tr>
<tr>
<td>tmpfs</td>
<td>/run/user/0</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbSys1</td>
<td>/</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbOra1</td>
<td>/u01</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbTmp</td>
<td>/tmp</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbVar1</td>
<td>/var</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbVarLog</td>
<td>/var/log</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDb-LVDbHome</td>
<td>/home</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDbDisk.u02_extra.img-LVDBDisk</td>
<td>/u02</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDbDisk.varLogAudit</td>
<td>/var/log/audit</td>
</tr>
<tr>
<td>/dev/sda1</td>
<td>/boot</td>
</tr>
<tr>
<td>/dev/mapper/VGExaDbDisk.grid19.0.0.0.200414.img-LVDBDisk</td>
<td>/u01/app/19.0.0.0/grid</td>
</tr>
<tr>
<td>/dev/asm/acfsvol01-142</td>
<td>/acfs01</td>
</tr>
</tbody>
</table>

**Bare Metal and Virtual Machine DB Systems**

Oracle Cloud Infrastructure offers single-node DB systems on either bare metal or virtual machines, and 2-node RAC DB systems on virtual machines. If you need to provision a DB system for development or testing purposes, a special fast-provisioning single-node virtual machine system is available.

You can manage these systems by using the Console, the API, the Oracle Cloud Infrastructure CLI, the Database CLI (DBCLI), Enterprise Manager, Enterprise Manager Express, or SQL Developer.

**Note:**

This documentation is intended for Oracle database administrators and assumes familiarity with Oracle databases and tools. If you need additional information, see the product documentation available at [http://docs.oracle.com/en/database/](http://docs.oracle.com/en/database/).
Supported Database Editions and Versions

All single-node Oracle RAC DB systems support the following Oracle Database editions:

- Standard Edition
- Enterprise Edition
- Enterprise Edition - High Performance
- Enterprise Edition - Extreme Performance

Two-node Oracle RAC DB systems require Oracle Enterprise Edition - Extreme Performance.

For standard provisioning of DB systems (using Oracle Automatic Storage Management (ASM) as your storage management software), the supported database versions are:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 18c (18.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)
- Oracle Database 11g Release 2 (11.2)

For fast provisioning of single-node virtual machine database systems (using Logical Volume Manager as your storage management software), the supported database versions are:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 18c

**Tip:**

Your DB system's operating system will periodically need to be updated, just as your Oracle Database software will need to be updated. Before attempting an OS update, be sure to read the information in Updating a DB System on page 1397 and back up your DB system's databases.

Upgrading the Oracle Database Software in Your DB System

You can upgrade database instances that use Oracle Database 18c and earlier to Oracle Database 19c (Long Term Release). For information on prerequisites and upgrade instructions see Upgrading a Database on page 1424.

Oracle Database Preview Version Availability

Oracle Cloud Infrastructure periodically offers preview software versions of Oracle Database for testing purposes. You can provision a virtual machine DB system using preview version software to test applications before the general availability of the software in the Database service. When you provision a DB system with preview version software, the system remains available to you until you decide to terminate it.

Preview version DB systems are provisioned in the same manner as non-preview systems. If available, preview version software is displayed as one of the choices in the Database version selector in the Create DB System dialog. See To create a DB system on page 1372 for instructions on provisioning a virtual machine DB system using preview version software.

**Current Preview Version Software**

There is no Oracle Database preview software version available at this time for bare metal and virtual machine DB systems in Oracle Cloud Infrastructure.

**Oracle Database Preview Version Restrictions**

Preview version software cannot be used for production databases. The following restrictions apply to preview version software:
• Only available for non-RAC virtual machine DB systems. Preview software is not available for bare metal systems, Exadata systems, or virtual machine systems using RAC.
• Uses Logical Volume Manager (LVM) storage management software only. Automatic Storage Management (ASM) is not available.
• Patching and database version upgrades (including upgrades to the generally available release of the preview software) are not available.
• You cannot create a new DB system from a backup of a database that uses preview version software.
• Standalone backups cannot be created.
• Data Guard is not available.
• Preview version software DB systems cannot be created from backups. In-place restores are supported.

Availability of Older Database Versions for Virtual Machine DB Systems

For virtual machine DB systems, Oracle Cloud Infrastructure also supports the creation of DB systems using older database versions. For each shape, the latest version and the two prior versions of the release are available at provisioning.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
</table>

If you need to launch your DB system with an older database version, see Critical Patch Updates for information on known security issues with your chosen database version. You will also need to analyze and patch known security issues for the operating system included with the older database version. See Securing Database on page 3685 for information on security best practices for databases in Oracle Cloud Infrastructure.

Per-Second Billing for Bare Metal and Virtual Machine Database Resources

For databases using bare metal and virtual machine infrastructure, Oracle Cloud Infrastructure uses per-second billing. This means that OCPU and storage usage is billed by the second, with a minimum usage period of 1 minute for virtual machine DB systems and 1 hour for bare metal DB systems.

Bare Metal DB Systems

Bare metal DB systems consist of a single bare metal server running Oracle Linux 6.8, with locally attached NVMe storage. If the node fails, you can simply launch another system and restore the databases from current backups.

When you launch a bare metal DB system, you select a single Oracle Database edition that applies to all the databases on that DB system. The selected edition cannot be changed. Each DB system can have multiple database homes, which can be different versions. Each database home can have only one database, which is the same version as the database home.

Shapes for Bare Metal DB Systems

When you launch a DB system, you choose a shape, which determines the resources allocated to the DB system. The available shapes for a bare metal DB system are:

• **BM.DenseIO2.52:** Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.

• **BM.DenseIO1.36:** Limited availability. Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.

*Note:* BM.DenseIO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
Bare Metal DB System Storage Considerations

The shape you choose for a bare metal DB system determines its total raw storage, but other options, like 2- or 3-way mirroring and the space allocated for data files, affect the amount of usable storage on the system. The following table shows how various configurations affect the usable storage for bare metal DB systems.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Raw Storage</th>
<th>Usable Storage with Normal Redundancy (2-way Mirroring)</th>
<th>Usable Storage with High Redundancy (3-way Mirroring)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BM.DenseIO2.52</td>
<td>51.2 TB NVMe</td>
<td>DATA 16 TB, RECO 4 TB</td>
<td>DATA 9 TB, RECO 2.3 TB</td>
</tr>
<tr>
<td>BM.DenseIO1.36</td>
<td>28.8 TB NVMe</td>
<td>DATA 9.4 TB, RECO 1.7 TB</td>
<td>DATA 5.4 TB, RECO 1 TB</td>
</tr>
</tbody>
</table>

Note: BM.DenseIO1.36 availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the us-phoenix-1, us-ashburn-1, and eu-frankfurt-1 regions.

Virtual Machine DB Systems

There are two types of DB systems on virtual machines:

- A 1-node virtual machine DB system consists of one virtual machine.
- A 2-node virtual machine DB system consists of two virtual machines.

When you launch a virtual machine DB system, you select the Oracle Database edition and version that applies to the database on that DB system. The selected edition cannot be changed. Depending on your selected Oracle Database edition and version, your DB system can support multiple pluggable databases (PDBs). See the following Oracle Database licensing topics for information about the maximum number of pluggable and container databases available for your selected Oracle Database version:

- Oracle Database 18c: Permitted Features, Options, and Management Packs by Oracle Database Offering
- Oracle Database 19c: Permitted Features, Options, and Management Packs by Oracle Database Offering

Unlike a bare metal DB system, a virtual machine DB system can have only a single Database Home, which in turn can have only a single database. The databases will be the same version as the Database Home.

Virtual machine DB systems also differ from bare metal DB systems in the following ways:

- A virtual machine DB system database uses Oracle Cloud Infrastructure block storage instead of local storage. You specify a storage size when you launch the DB system, and you can scale up the storage as needed at any time.
- To change the number of CPU cores on an existing virtual machine DB system, you must change the shape of that DB system. See To change the shape of a virtual machine DB system on page 1384 for more information.

Note:
The shape-changer operation takes place in a rolling fashion for multi-node DB systems, allowing you to change the shape with no database downtime.

Fast Provisioning Option for Single-Node Virtual Machine DB Systems

For 1-node virtual machine DB systems, Oracle Cloud Infrastructure provides have a "fast provisioning" option that allows you to create your DB system using Logical Volume Manager as your storage management software. The alternative ("standard provisioning") is to provision with Oracle Automatic Storage Management (ASM).

Note:
- When using the fast provisioning option, the number and size of the block volumes specified during provisioning determines the maximum total

- Multi-node Virtual Machine DB systems require Oracle Automatic Storage Management and cannot be created using the fast-provisioning option.
- You can clone virtual machine DB systems that have been created using the fast provision option. See Cloning a Virtual Machine DB System on page 1388 for instructions.
- You cannot use a custom database software image when provisioning a system with logical volume manager storage software.

Cloning a Fast-Provisioned Virtual Machine DB System

You can create a clone of a virtual machine DB system that was created using the "fast provisioning" option (these are single-node systems that use Logical Volume Manager storage management software). For more information and instructions, see Cloning a Virtual Machine DB System on page 1388.

Fault Domain Considerations for Two-Node Virtual Machine DB Systems

When you provision a 2-node RAC DB systems, the system assigns each node to a different fault domain by default. Using the Advanced Options link in the provisioning dialog, you can select the fault domain(s) to be used for your 2-node RAC DB systems and the system will assign the nodes to your selected fault domains. Oracle recommends that you place each node of a 2-node RAC DB system in a different fault domain. For more information on fault domains, see Fault Domains on page 182.

Rebooting a Virtual Machine DB System Node for Planned Maintenance

Virtual machine DB system nodes use underlying physical hosts that periodically need to undergo maintenance. When such maintenance is needed, Oracle Cloud Infrastructure schedules a reboot of your virtual machine DB system node and notifies you of the upcoming reboot. The reboot allows your virtual machine DB system node to be migrated to a new physical host which is not in need of maintenance. (Stopping and starting the node will also result in the migration to a new physical host.) The only impact to your virtual machine DB system node is the reboot itself. The planned maintenance of the original physical hardware takes place after your node has been migrated to its new host, and has no impact on your DB system.

If your virtual machine DB system node is scheduled for a maintenance reboot, you can proactively reboot your node (by stopping and starting it) using the Console or the API. This lets you control how and when your node experiences downtime. If you choose not to reboot before the scheduled time, then Oracle Cloud Infrastructure will reboot and migrate your node at the scheduled time.

To identify the virtual machine DB system nodes that you can proactively reboot, navigate to your system's DB System Details page in the Console and check the Node Maintenance Reboot field. If the instance has a maintenance reboot scheduled and can be proactively rebooted, this field displays the date and start time for the reboot. When the Maintenance Reboot field does not display a date, your virtual machine DB system has no scheduled node maintenance events.

To check for scheduled maintenance events using the API, use the GetDbNode operation to check the timeMaintenanceWindowEnd field of the DbNode resource. This field specifies when the system will initiate the next scheduled node reboot.

To make it easier to locate nodes that have scheduled maintenance reboots, you can use the Search service with a predefined query to find all DB systems that have a maintenance reboot scheduled.

For instructions on using the Console to reboot a node, see To start, stop, or reboot a database system on page 1383.

Shapes for Virtual Machine DB Systems

When you launch a virtual machine DB system, you choose a shape, which determines the resources allocated to the DB system. After you provision the system, you can change the shape to adapt to new processing capacity requirements.

The following table shows the available shapes in the X7 series for a virtual machine DB system.
## Database

<table>
<thead>
<tr>
<th>Shape</th>
<th>CPU Cores</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard2.1</td>
<td>1</td>
<td>15 GB</td>
</tr>
<tr>
<td>VM.Standard2.2</td>
<td>2</td>
<td>30 GB</td>
</tr>
<tr>
<td>VM.Standard2.4</td>
<td>4</td>
<td>60 GB</td>
</tr>
<tr>
<td>VM.Standard2.8</td>
<td>8</td>
<td>120 GB</td>
</tr>
<tr>
<td>VM.Standard2.16</td>
<td>16</td>
<td>240 GB</td>
</tr>
<tr>
<td>VM.Standard2.24</td>
<td>24</td>
<td>320 GB</td>
</tr>
</tbody>
</table>

The following table shows the available shapes in the X5 series for a virtual machine DB system.

### Note:

Availability of X5 shapes is limited to monthly universal credit customers existing on or before November 9th, 2018, in the us-phoenix-1, us-ashburn-1, and eu-frankfurt-1 regions.

<table>
<thead>
<tr>
<th>Shape</th>
<th>CPU Cores</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard1.1</td>
<td>1</td>
<td>7 GB</td>
</tr>
<tr>
<td>VM.Standard1.2</td>
<td>2</td>
<td>14 GB</td>
</tr>
<tr>
<td>VM.Standard1.4</td>
<td>4</td>
<td>28 GB</td>
</tr>
<tr>
<td>VM.Standard1.8</td>
<td>8</td>
<td>56 GB</td>
</tr>
<tr>
<td>VM.Standard1.16</td>
<td>16</td>
<td>112 GB</td>
</tr>
</tbody>
</table>

## Storage Options for Virtual Machine DB Systems

Virtual machine DB systems use Oracle Cloud Infrastructure block storage. The following table shows details of the storage options for a virtual machine DB system. Total storage includes available storage plus recovery logs.

<table>
<thead>
<tr>
<th>Available Storage (GB)</th>
<th>Total Storage (GB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>256</td>
<td>712</td>
</tr>
<tr>
<td>512</td>
<td>968</td>
</tr>
<tr>

</tr>
<tr>
<td>32768</td>
<td>39520</td>
</tr>
<tr>
<td>34816</td>
<td>41980</td>
</tr>
<tr>
<td>36864</td>
<td>44436</td>
</tr>
<tr>
<td>38912</td>
<td>46896</td>
</tr>
<tr>
<td>40960</td>
<td>49352</td>
</tr>
</tbody>
</table>

For 2-node RAC virtual machine DB systems, storage capacity is shared between the nodes.

**Security Hardening Tool for Virtual Machine DB systems**

Oracle Cloud Infrastructure virtual machine DB systems provisioned using Oracle Linux 7 include a python script, referred to as the Security Technical Implementation Guide (STIG) tool, that you can use to perform security hardening for your virtual machine DB system. See Security Technical Implementation Guide (STIG) Tool for Virtual Machine DB systems on page 1555 and Enabling FIPS, SE Linux, and STIG on Bare Metal or Virtual Machine DB System Components on page 1556 for more information.

**Boot Volume Backups**

Oracle maintains a weekly boot volume backup of your virtual machine DB system so that the system can be easily restored in the event of a serious error or system failure. Boot volume backups are currently not accessible to users (there is no Console, API, or CLI access to a DB system boot volume backup), and Oracle bears the cost of keeping and maintaining the backup. In the event of a system failure, contact My Oracle Support to request that Oracle perform a restore of your system from the boot volume backup.

**Database Backups, Restoring from a Backup, and Creating a Database or DB System from a backup**

**Backup Options**

Oracle Cloud Infrastructure offers you the ability to create and store automatic daily backups and on-demand full backups. You can store backups in your DB system's local storage, or in Oracle Cloud Infrastructure Object Storage. See Backing Up a Database on page 1435 for information about the backup storage options you have for your cloud databases. See Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435 for information about managed automatic backups in Oracle Cloud Infrastructure.

**Restoring from a Backup**

See Recovering a Database from Object Storage on page 1446 for information on restoring a database from a backup in Object Storage.

**Creating a Database or DB System Using a Backup**

See To create a DB system from a backup and To create a database from a backup in an existing DB system for information about creating a database or DB system from the following sources:

- Daily automatic backups or on-demand full backups.
• The last archived redo log backup. Requires that you have automatic backups enabled. This backup combines data from the most recent daily automatic backup and data from archived redo logs, and represents the most current backup available.
• Daily automatic backup data used to create a point-in-time copy of the source database based on a specified timestamp.
• Standalone Backups on page 1438

Moving Databases to Oracle Cloud DB Systems Using Zero Downtime Migration

Oracle now offers the Zero Downtime Migration service, a quick and easy way to move on-premises Oracle Databases and Oracle Cloud Infrastructure Classic databases to Oracle Cloud Infrastructure. You can migrate databases to the following types of Oracle Cloud Infrastructure systems: Exadata, Exadata Cloud@Customer, bare metal, and virtual machine.

Zero Downtime Migration leverages Oracle Active Data Guard to create a standby instance of your database in an Oracle Cloud Infrastructure system. You switch over only when you are ready, and your source database remains available as a standby. Use the Zero Downtime Migration service to migrate databases individually or at the fleet level. See Move to Oracle Cloud Using Zero Downtime Migration for more information.

Network Setup for DB Systems

Note:
This topic is not applicable to Exadata DB systems. For information on the network setup for an Exadata DB system, see Network Setup for Exadata Cloud Service Instances on page 1232.

Before you set up a bare metal or virtual machine DB system, you must set up a virtual cloud network (VCN) and other Networking service components. This topic describes the recommended configuration for the VCN.

VCN and Subnets

To launch a DB system, you must have:

• A VCN in the region where you want the DB system
• At least one subnet in the VCN (either a public subnet or a private subnet)

In general, Oracle recommends using regional subnets, which span all availability domains in the region. For a bare metal or virtual machine DB system, either a regional subnet or AD-specific subnet works. For more information, see Overview of VCNs and Subnets on page 2822.

You will create a custom route table. You will also create security rules to control traffic to and from the DB system's compute notes. More information follows about that.

Certain details of the VCN and subnet configuration depend on your choice for DNS resolution within the VCN. For more information, see DNS for the DB System on page 1362.

Option 1: Public Subnet with Internet Gateway

This option can be useful when doing a proof-of-concept or development work. You can use this setup in production if you want to use an internet gateway with the VCN, or if you have services that run only on a public network and need access to the database. See the following diagram and description.
You set up:

- **Public subnet.**
- **Internet gateway.**
- **Service gateway** to reach Object Storage for database backups and patching. Also see Option 1: Service Gateway Access Only to Object Storage on page 1366.
- **Route table**: A custom route table for the subnet, with two rules:
  - A rule for 0.0.0.0/0, and target = internet gateway.
  - A rule for the service CIDR label called **OCI <region> Object Storage**, and target = the service gateway. Also see Option 1: Service Gateway Access Only to Object Storage on page 1366.
- **Security rules** to enable the desired traffic to and from the DB system nodes. See Security Rules for the DB System on page 1367.

**Important:**

See this known issue for information about configuring route rules with service gateway as the target on route tables associated with public subnets.
**Option 2: Private Subnet**

Oracle recommends this option for a production system. The subnet is private and cannot be reached from the internet. See the following diagram and description.

![Diagram of Private Subnet]

You set up:

- Private subnet.
- Gateways for the VCN:
  - Dynamic routing gateway (DRG), with a FastConnect or IPSec VPN to your on-premises network.
  - Service gateway to reach Object Storage for database backups and patching, and to reach Oracle YUM repos for OS updates. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos on page 1366.
  - NAT gateway (to reach public endpoints not supported by the service gateway).
- Route table: A custom route table for the subnet, with these rules:
  - A route for the on-premises network's CIDR, and target = DRG.
  - A rule for the service CIDR label called All `<region>` Services in Oracle Services Network, and target = the service gateway. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos on page 1366.
  - If you want to access the Oracle YUM repos through the NAT gateway, add a route rule for the regional YUM repo's public IP address, and target = the NAT gateway. If you just use the next rule only, the traffic to the
YUM repo would still be routed to the service gateway, because the service gateway route is more specific than 0.0.0.0/0.

- A rule for 0.0.0.0/0, and target = NAT gateway.
- Security rules to enable the desired traffic to and from the DB system nodes. See Security Rules for the DB System on page 1367.

Requirements for IP Address Space

If you are setting up DB systems (and thus VCNs) in more than one region, make sure the IP address space of the VCNs does not overlap.

The subnet you create for a bare metal or virtual machine DB system cannot overlap with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance.

The following table lists the minimum required subnet size.

<table>
<thead>
<tr>
<th>DB System Type</th>
<th># Required IP Addresses</th>
<th>Minimum Subnet Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-node bare metal or virtual machine</td>
<td>1 + 3 reserved in subnet = 4</td>
<td>/30 (4 IP addresses)</td>
</tr>
<tr>
<td>2-node RAC virtual machine</td>
<td>(2 addresses * 2 nodes) + 3 for SCANs + 3 reserved in subnet = 10</td>
<td>/28 (16 IP addresses)</td>
</tr>
</tbody>
</table>

VCN Creation Wizard: Not for Production

The Networking section of the Console includes a handy wizard that creates a VCN along with related resources. It can be useful if you just want to try launching an instance. However, the wizard automatically creates a public subnet and an internet gateway. You may not want this for your production network, so Oracle recommends you create the VCN and other resources individually yourself instead of using the wizard.

DNS for the DB System

There are two choices for DNS and hostname resolution for the DB system:

- Recommended: Use the default DNS functionality in the VCN (called the Internet and VCN Resolver)
- Use a custom DNS resolver of your choice

The following table shows which choices are supported with each type of DB system, and the endpoints that need to be resolved for the DB system to function.

<table>
<thead>
<tr>
<th>DB System Type</th>
<th>Supported DNS Choices</th>
<th>Endpoints to BeResolved</th>
</tr>
</thead>
</table>
| 1-node bare metal or virtual machine | - Recommended: Default (Internet and VCN Resolver)  
|                                   | - Custom DNS resolver of your choice |  
| | | - Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints)  
| | | - Oracle YUM repo endpoints |
| 2-node RAC virtual machine      | - Default (Internet and VCN Resolver) |  
| | | - Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints)  
| | | - Oracle YUM repo endpoints  
| | | - Single Client Access Names (SCANs) |
The following sections give more details about the DNS choices.

**Default (Internet and VCN Resolver)**

See the preceding table for the types of DB systems that support the Internet and VCN Resolver.

Oracle recommends using the Internet and VCN Resolver for DNS. It's the default, built-in DNS functionality that comes with each VCN. It enables hosts in a VCN to resolve these items:

- Hostnames of other hosts in the same VCN
- Hostnames that are publicly published on the Internet

For general information about the Internet and VCN Resolver, see *DNS in Your Virtual Cloud Network* on page 2910.

For a DB system, the Internet and VCN Resolver handles resolution of all necessary endpoints: Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints), YUM repos, and SCANs (SCANs are used only with 2-node RAC systems).

By default, each VCN is configured to use the Internet and VCN Resolver. If you plan to use a custom DNS resolver, you must configure the VCN in a different way. For more information, see *To use a custom DNS resolver with your DB system* on page 1364.

**To use the Internet and VCN Resolver with your DB System**

As part of the overall network setup, perform these tasks:

1. Create the VCN with the required DNS settings:
   - When creating the VCN, select the check box for **Use DNS Hostnames in this VCN**.
   - Specify a DNS label for the VCN. See the restrictions in *Hostname restrictions for using the Internet and VCN Resolver* on page 1363.
   - Notice that you cannot change these VCN DNS settings after you create the VCN.

2. Create each subnet with the required DNS settings:
   - When creating a subnet in the VCN, select the check box for **Use DNS Hostnames in this Subnet**.
   - Specify a DNS label for the subnet. See the restrictions in *Hostname restrictions for using the Internet and VCN Resolver* on page 1363.
   - Notice that you cannot change these subnet DNS settings after you create the subnet.

3. Use the default set of DHCP options that come with the VCN:
   - When creating each subnet, configure it to use the VCN's default set of DHCP options.
   - By default, the default set of DHCP options is configured to use the Internet and VCN Resolver.

4. Create the DB system with a hostname prefix:
   - Later, when creating the DB system, specify a value in the **Hostname Prefix** field. See the restrictions in *Hostname restrictions for using the Internet and VCN Resolver* on page 1363.
   - Notice that the DB system's **Host Domain Name** value is automatically assigned based on the VCN and subnet DNS labels.

The resulting DB system has a fully qualified domain name (FQDN) based on the hostname prefix, VCN label, and subnet label you specify.

**Hostname restrictions for using the Internet and VCN Resolver**

When you create the VCN, subnet, and DB system, you must carefully set the following identifiers, which are related to DNS in the VCN:

- VCN DNS label
- Subnet DNS label
- Hostname prefix for the DB system

These values make up the node's fully qualified domain name (FQDN):
For RAC systems only, the Database service automatically appends a node number after the hostname prefix.

For example:
- Node 1: `dbsys1.ad1.acmevcniad.oraclevcn.com`
- Node 2: `dbsys2.ad1.acmevcniad.oraclevcn.com`

Requirement for the DB system's hostname prefix:
- Recommended maximum: 16 characters. For more information, see the example under the following section, "Requirements for the VCN and subnet DNS labels", for more details.
- Must start with an alphabetical character.
- Cannot be the string `localhost`.

Requirements for the VCN and subnet DNS labels:
- Recommended maximum: 15 characters.
- No hyphens or underscores.
- Recommended: Include the region name in the VCN's name, and include the availability domain name in the subnet's name.
- The FQDN has a maximum total limit of 63 characters, so set the VCN and subnet DNS labels short enough to meet that requirement. Here is a safe general rule:

  `<16_chars_max>\.<15_chars_max>\.<15_chars_max>.oraclevcn.com`

- The recommended maximums are not enforced when you create the VCN and subnets. However, the DB system deployment fails if the FQDN has more than 63 characters.

**Custom DNS Resolver**

See the preceding table for the types of DB systems that support the use of a custom DNS resolver.

A custom DNS resolver is a DNS server that you set up in your on-premises network and maintain yourself. It must resolve the endpoints required by the DB system.

By default, the VCN is configured to use the Internet and VCN Resolver. Therefore, if you instead want to use a custom DNS resolver, you must configure the VCN and DHCP options in a different way. See the following process.

**To use a custom DNS resolver with your DB system**

As part of the overall network setup, perform these tasks:

1. Create the VCN with the recommended DNS settings:
   - When creating the VCN, Oracle recommends that you select the check box for **Use DNS Hostnames in this VCN** and then specify a DNS label for the VCN. See the restrictions listed in Hostname restrictions when using a custom DNS resolver on page 1365.
   - Notice that you cannot change the preceding VCN DNS settings after you create the VCN. They are optional for a custom DNS server, but required if you use the Internet and VCN Resolver. Therefore, Oracle recommends that you configure them now in case you later want to use the Internet and VCN Resolver.

2. Create each subnet with the recommended DNS settings:
   - When creating a subnet in the VCN, Oracle recommends that you select select the check box for **Use DNS Hostnames in this Subnet** and then specify a DNS label for the subnet. See the restrictions listed in Hostname restrictions when using a custom DNS resolver on page 1365.
   - Notice that you cannot change the preceding subnet DNS settings after you create the subnet. They are optional for a custom DNS server, but required if you use the Internet and VCN Resolver. Therefore, Oracle recommends that you configure them now in case you later want to use the Internet and VCN Resolver.
3. Edit the default set of DHCP options to use a custom resolver:
   • When creating each subnet, configure it to use the VCN’s default set of DHCP options.
   • Edit the default set of DHCP options so that **DNS Type** is set to **Custom Resolver**. Provide the IP address for at least one DNS server (maximum three). Optionally provide a single search domain (which will automatically be added to the host's `/etc/resolv.conf` file).

4. Create the DB system with required DNS entries:
   • Later, when creating the DB system, specify a **Hostname Prefix**.
   • For the **Host Domain Name**: If you selected the check box for **Use DNS Hostnames** in the preceding steps, the **Host Domain Name** is automatically generated from the VCN and subnet DNS labels. Otherwise, you must provide a value for the **Host Domain Name**. See the restrictions listed in **Hostname restrictions when using a custom DNS resolver** on page 1365.
   • Notice that when launching the DB system, the Database service automatically assigns an IP address from the VCN’s CIDR block and resolves the address locally based on the host's `/etc/hosts` file. Your custom DNS resolver does not need to resolve the hostname in advance for the DB system launch to succeed.

**Hostname restrictions when using a custom DNS resolver**

Requirement for the DB system's hostname prefix:
   • Recommended maximum: 16 characters. For more information, see the example under the next section, **Requirements for the VCN and subnet DNS labels**.
   • Must start with an alphabetical character.
   • Cannot be the string `localhost`.

Requirements for the VCN and subnet DNS labels:
   • You can provide a value for the DNS labels only if you select the check box for **Use DNS Hostnames** when creating the VCN and subnets. The resulting FQDN for the DB system follows this format:
     <hostname_prefix>.<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com
   • Recommended maximum for each DNS label: 15 characters.
   • No hyphens or underscores.
   • Recommended: Include the region name in the VCN's name, and include the availability domain name in the subnet's name.
   • The FQDN has a maximum total limit of 63 characters, so set the VCN and subnet DNS labels short enough to meet that requirement. Here is a safe general rule:
     <16_chars_max>.<15_chars_max>.<15_chars_max>.oraclevcn.com
   • The recommended maximums are not enforced when you create the VCN and subnets. However, the DB system deployment fails if the FQDN has more than 63 characters.

Requirements for the DB system's host domain name:
   • You can provide a value in the **Host Domain Name** field only if you did not select the check box for **Use DNS Hostnames** when creating the VCN and subnets.
   • No hyphens or underscores.
   • Ensure that the value results in an FQDN that is no longer than 63 characters. Otherwise the DB system deployment will fail.

**DNS: Between On-Premises Network and VCN**

If you are using the Internet and VCN Resolver and want to enable the use of hostnames when on-premises hosts and VCN resources communicate with each other, you can set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see **Hybrid DNS Configuration**.

**Service Gateway for the VCN**

Your VCN needs access to both Object Storage (for backing up databases, patching, and updating the cloud tooling on a DB system) and Oracle YUM repos for OS updates.
Depending on whether you use option 1 or option 2 described previously, you use the service gateway in different ways. See the next two sections.

**Option 1: Service Gateway Access Only to Object Storage**

You configure the subnet to use the service gateway for access only to Object Storage. As a reminder, here's the diagram for option 1:

In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called `OCI <region> Object Storage`.
- In the task for updating routing, add a route rule to the subnet's custom route table. For the destination service, use `OCI <region> Object Storage` and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the DB system's custom network security group (NSG) or security list. Here you set up a security rule with the destination service set to `OCI <region> Object Storage`. See Custom Security Rules on page 1368.

**Option 2: Service Gateway Access to Both Object Storage and YUM Repos**

You configure the subnet to use the service gateway for access to the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos.
Important:

See this known issue for information about accessing Oracle YUM services through the service gateway.

As a reminder, here's the diagram for option 2:

In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called All <region> Services in Oracle Services Network.
- In the task for updating routing in the subnet, add a rule to the subnet's custom route table. For the destination service, use All <region> Services in Oracle Services Network and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the subnet's custom network security group (NSG) or security list. Here you set up a security rule with the destination service set to All <region> Services in Oracle Services Network. See Custom Security Rules on page 1368.

Security Rules for the DB System

This section lists the security rules to use with your DB system. Security rules control the types of traffic allowed in and out of the DB system's compute nodes. The rules are divided into two sections.

There are different ways to implement these rules. For more information, see Ways to Implement the Security Rules on page 1370.
Important:
Your instances running Oracle-provided DB system images also have firewall rules that control access to the instance. Make sure that both the instance's security rules and firewall rules are set correctly. Also see Opening Ports on the DB System on page 1433.

General Rules Required for Basic Connectivity

This section has several general rules that enable essential connectivity for hosts in the VCN.

If you use security lists to implement your security rules, be aware that the rules that follow are included by default in the default security list. Update or replace the list to meet your particular security needs. The two ICMP rules (general ingress rules 2 and 3) are required for proper functioning of network traffic within the Oracle Cloud Infrastructure environment. Adjust the general ingress rule 1 (the SSH rule) and the general egress rule 1 to allow traffic only to and from hosts that require communication with resources in your VCN.

General ingress rule 1: Allows SSH traffic from anywhere
- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: 0.0.0.0/0
- **IP Protocol**: TCP
- **Source Port Range**: All
- **Destination Port Range**: 22

General ingress rule 2: Allows Path MTU Discovery fragmentation messages
This rule enables hosts in the VCN to receive Path MTU Discovery fragmentation messages. Without access to these messages, hosts in the VCN can have problems communicating with hosts outside the VCN.
- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: 0.0.0.0/0
- **IP Protocol**: ICMP
- **Type**: 3
- **Code**: 4

General ingress rule 3: Allows connectivity error messages within the VCN
This rule enables the hosts in the VCN to receive connectivity error messages from each other.
- **Stateless**: No (all rules must be stateful)
- **Source Type**: CIDR
- **Source CIDR**: Your VCN's CIDR
- **IP Protocol**: ICMP
- **Type**: 3
- **Code**: All

General egress rule 1: Allows all egress traffic
- **Stateless**: No (all rules must be stateful)
- **Destination Type**: CIDR
- **Destination CIDR**: 0.0.0.0/0
- **IP Protocol**: All

Custom Security Rules
The following rules are necessary for the DB system's functionality.
Important:

Custom ingress rules 1 and 2 only cover connections initiated from within the VCN. If you have a client that resides outside the VCN, Oracle recommends setting up two additional similar rules that instead have the Source CIDR set to the public IP address of the client.

Custom ingress rule 1: Allows ONS and FAN traffic from within the VCN

This rule is recommended and enables the Oracle Notification Services (ONS) to communicate about Fast Application Notification (FAN) events.

- Stateless: No (all rules must be stateful)
- Source Type: CIDR
- Source CIDR: VCN's CIDR
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 6200
- Description: An optional description of the rule.

Custom ingress rule 2: Allows SQL*NET traffic from within the VCN

This rule is for SQL*NET traffic and is required only if you need to enable client connections to the database.

- Stateless: No (all rules must be stateful)
- Source Type: CIDR
- Source CIDR: VCN's CIDR
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Description: An optional description of the rule.

Custom egress rule 1: Allows outbound SSH access

This rule enables SSH access between nodes in a 2-node DB system. It is redundant with the general egress rule in General Rules Required for Basic Connectivity (and in the default security list). It is optional but recommended in case the general rule (or default security list) is inadvertently changed.

- Stateless: No (all rules must be stateful)
- Destination Type: CIDR
- Destination CIDR: 0.0.0.0/0
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 22
- Description: An optional description of the rule.

Custom egress rule 2: Allows access to Object Storage and YUM repos

This rule enables the DB system to communicate with Object Storage alone (for option 1), or with the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos (for option 2). It is redundant with the general egress rule in General Rules Required for Basic Connectivity on page 1368 (and in the default security list). It is optional but recommended in case the general rule (or default security list) is inadvertently changed.

- Stateless: No (all rules must be stateful)
- Destination Type: Service
- Destination Service:
  - For option 1, use the service CIDR label called OCI <region> Object Storage
  - For option 2, use the service CIDR label called All <region> Services in Oracle Services Network
- IP Protocol: TCP
• **Source Port Range:** All
• **Destination Port Range:** 443 (HTTPS)
• **Description:** An optional description of the rule.

**Ways to Implement the Security Rules**

The Networking service offers two ways to implement security rules within your VCN:

• **Network security groups**
• **Security lists**

For a comparison of the two methods, see [Comparison of Security Lists and Network Security Groups](#) on page 2833.

*If you use network security groups*

If you choose to use network security groups (NSGs), here is the recommended process:

1. Create a network security group for DB systems. Add the following security rules to that NSG:
   - The rules listed in [General Rules Required for Basic Connectivity](#) on page 1368
   - The rules listed in [Custom Security Rules](#) on page 1368
2. When the database administrator creates the DB system, they must choose several networking components (for example, which VCN and subnet to use). They can also choose which NSG or NSGs to use. Make sure they choose the NSG you created.

You could instead create one NSG for the general rules and a separate NSG for the custom rules. Then when the database administrator chooses which NSGs to use for the DB system, make sure they choose both NSGs.

*If you use security lists*

If you choose to use security lists, here is the recommended process:

1. Configure the subnet to use the required security rules:
   a. Create a custom security list for the subnet and add the rules listed in [Custom Security Rules](#) on page 1368.
   b. Associate the following two security lists with the subnet:
      - VCN's default security list with all its default rules. This automatically comes with the VCN.
      - The new custom security list you created for the subnet
2. Later when the database administrator creates the DB system, they must choose several networking components. When they select the subnet that you have already created and configured, the security rules are automatically enforced for the compute nodes created in the subnet.

**Caution:**

Do not remove the default egress rule from the default security list. If you do, instead make sure to include the following replacement egress rule in the subnet's custom security list:

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

**Creating Bare Metal and Virtual Machine DB Systems**

This topic explains how to create a bare metal or virtual machine DB system, and set up DNS for a single-node or two-node Oracle RAC DB system.

When you create a DB system using the Console, the API, or the CLI, the system is provisioned to support Oracle databases, and an initial database is created based on the options you provide and some default options described later in this topic.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more information about writing policies for databases, see Details for the Database Service on page 2240.

Prerequisites

You'll need the following items to create any DB system:

- The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the DB System via SSH. A sample public key, abbreviated for readability, is shown below.

  ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA...lo/gKMLVM2xzc1xJr/
  Hc26biw3TXWGEakrK1OQ== rsa-key-20160304

  For more information, see Managing Key Pairs on Linux Instances on page 693.

- A correctly configured virtual cloud network (VCN) to launch the DB system in. Its related networking resources (gateways, route tables, security lists, DNS, and so on) must also be configured as necessary for the DB system. For more information, see Network Setup for DB Systems on page 1359.

- If you plan to back up your DB system to Object Storage or to use the managed patching feature, then Oracle recommends using a service gateway to enable access to Object Storage. For more information, see Service Gateway for the VCN on page 1365.

- For a two-node Oracle RAC DB system, ensure that port 22 is open for both ingress and egress on the subnet, and that the security rules you create are stateful (the default), otherwise, the DB system might fail to provision successfully.

Default Options for the Initial Database

To simplify creating a DB system in the Console, and when using the API, the following default options are used for the initial database and for any additional databases that you create. (Several advanced options, such as time zone, can be set when you can use the dbcli command line interface to create databases.)

- **Console Enabled**: False
- **Create Container Database**: False for Oracle Database 11g (11.2.0.4) databases. Otherwise, true.
- **Create Instance Only (for standby and migration)**: False
- **Database Home ID**: Creates a new database home
- **Database Language**: AMERICAN
- **Database Sizing Template**: odb2
- **Database Storage**: Oracle Automatic Storage Management Cluster File System (ACFS) for Oracle Database 11g (11.2.0.4) databases. Otherwise, Automatic Storage Management (ASM) for all bare metal and multi-node virtual machine DB systems. Single-node VM systems can optionally be provisioned using Logical Volume Manager for faster provisioning.
- **Database Territory**: AMERICA
- **Database Unique Name**: The user-specified database name and a system-generated suffix, for example, dbtst_phx1cs.
- **PDB Admin Name**: pdbuser (Not applicable for Oracle Database 11g (11.2.0.4) databases.)

For a list of the database options that you can set, see To create a DB system on page 1372.
Using a Backup to Create the Initial Database

When creating a new DB system using a backup stored in Object Storage as the source of the initial database, you have the following options:

- **Daily automatic backup**. Requires that you have automatic backups enabled and an available backup to use. If you are creating a database from an automatic backup, you can choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Oracle Cloud Infrastructure Managed Backup Features on page 1436.
- **On-demand full backup**. See To create an on-demand full backup of a database on page 1439 for information on creating an on-demand backup.
- **Standalone backup**. For more information, see Standalone Backups on page 1438.
- **Last archived redo log backup**. Requires that you have automatic backups enabled. This backup combines data from the most recent daily automatic backup and data from archived redo logs, and represents the most current backup available. The time of the last archived redo log backup is visible on the database details page in the Last Backup Time field.
- **Point-in-time out of place restore**. Specify a timestamp to create a new copy of the database that included data up to a specified point in time. The timestamp must be earlier or equal to the Last Backup Time time displayed on the database details page. Note the following limitations when performing a point-in-time out of place restore:
  - The timestamp must be within the recovery window of the database
  - The timestamp must be available within the database incarnation of the available automatic backups
  - The timestamp cannot fall within two overlapping database incarnations
  - The create database operation will fail if the database has undergone structural changes since the specified timestamp. Structural changes include operations such as creating or dropping a tablespace.
  - The create database operation cannot be started if another point-in-time database copy operation is in progress.

Custom IP Addresses for Non-RAC DB Systems

When creating a new non-RAC DB system or cloning an existing VM DB system, you can optionally define the IP address of the DB system being provisioned. This is useful in development contexts where you create and delete the same DB system over and over, and you need each new iteration of the DB system to use the same IP address.

**Using the Console**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

To create a DB system

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Click Create DB System.
3. On the **Create DB System** page, provide the basic information for the DB system:

- **Select a compartment**: By default, the DB system is created in your current compartment and you can use the network resources in that compartment.
- **Name your DB system**: A non-unique, display name for the DB system. An Oracle Cloud Identifier (OCID) uniquely identifies the DB system. Avoid entering confidential information.
- **Select an availability domain**: The availability domain in which the DB system resides.
- **Select a shape type**: The shape type you select sets the default shape and filters the shape options in the next field.
- **Select a shape**: The shape determines the type of DB system created and the resources allocated to the system. To specify a shape other than the default, click **Change Shape**, and select an available shape from the list.

**Bare metal shapes**

- **BM.DenseIO2.52**: Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.
- **BM.DenseIO1.36**: Limited availability. Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.

*Note*: BM.DenseIO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

**Virtual machine shapes**

Virtual machine X7 shapes:

- **VM.Standard2.1**: Provides a 1-node DB system with 1 core.
- **VM.Standard2.2**: Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard2.4**: Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard2.8**: Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard2.16**: Provides a 1- or 2-node DB system with 16 cores.
- **VM.Standard2.24**: Provides a 1- or 2-node DB system with 24 cores.

Virtual machine X5 shapes:

- **VM.Standard1.1**: Provides a 1-node DB system with 1 core.
- **VM.Standard1.2**: Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard1.4**: Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard1.8**: Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard1.16**: Provides a 1- or 2-node DB system with 16 cores.

*Note*: X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

- **VM.Standard1.1** and **VM.Standard2.1** shapes cannot be used for 2-node RAC clusters.

**Configure the DB system**: Specify the following:

- **Total node count**: The number of nodes in the DB system, which depends on the shape you select. For virtual machine DB systems, you can specify either one or two nodes, except for **VM.Standard2.1** and **VM.Standard1.1**, which are single-node DB systems.
- **Oracle Database software edition**: The database edition supported by the DB system. For bare metal systems, you can mix supported database releases on the DB system to include older database versions, but
not editions. The database edition cannot be changed and applies to all the databases in this DB system. Virtual machine systems support only one database.

- **CPU core count:** Displays only for bare metal DB systems to allow you to specify the number of CPU cores for the system. (Virtual machine DB system shapes have a fixed number of CPU cores.) The text below the field indicates the acceptable values for that shape. For a multi-node DB system, the core count is evenly divided across the nodes.

  
  **Note:**
  After you provision the DB system, you can increase the CPU cores to accommodate increased demand. On a bare metal DB system, you scale the CPU cores directly. For virtual machine DB systems, you change the number of CPU cores by changing the shape.

- **Choose Storage Management Software:** Select Oracle Grid Infrastructure to use Oracle Automatic Storage Management (recommended for production workloads). Select Logical Volume Manager to quickly provision your DB system using Logical Volume Manager storage management software. Note that the Available storage (GB) value you specify during provisioning determines the maximum total storage available through scaling. The total storage available for each choice is detailed in the Storage Scaling Considerations for Virtual Machine Databases Using Fast Provisioning on page 1555 topic.

  See Fast Provisioning Option for 1-node Virtual Machine DB Systems for more information about this feature.

- **Configure storage:** Specify the following:

  - **Available storage (GB):** Virtual machine only. The amount of Block Storage in GB to allocate to the virtual machine DB system. Available storage can be scaled up or down as needed after provisioning your DB system.
  
  - **Total storage (GB):** Virtual machine only. The total Block Storage in GB used by the virtual machine DB system. The amount of available storage you select determines this value. Oracle charges for the total storage used.
  
  - **Cluster name:** (Optional) A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.
  
  - **Data storage percentage:** Bare metal only. The percentage (40% or 80%) assigned to DATA storage (user data and database files). The remaining percentage is assigned to RECO storage (database redo logs, archive logs, and recovery manager backups).

- **Add public SSH keys:** The public key portion of each key pair you want to use for SSH access to the DB system. You can browse or drag and drop .pub files, or paste in individual public keys. To paste multiple keys, click + Another SSH Key, and supply a single key for each entry.

- **Choose a license type:** The type of license you want to use for the DB system. Your choice affects metering for billing.

  - **License Included** means the cost of this Oracle Cloud Infrastructure Database service resource will include both the Oracle Database software licenses and the service.
  
  - **Bring Your Own License (BYOL)** means you will use your organization’s Oracle Database software licenses for this Oracle Cloud Infrastructure Database service resource. See Bring Your Own License for more information.

4. **Specify the network information:**

  - **Virtual cloud network:** The VCN in which to create the DB system. Click Change Compartment to select a VCN in a different compartment.
  
  - **Client Subnet:** The subnet to which the DB system should attach. For 1- and 2-node RAC DB systems: Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private
interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

Click **Change Compartment** to select a subnet in a different compartment.

- **Network Security Groups:** Optionally, you can specify one or more network security groups (NSGs) for your DB system. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your DB system. A maximum of five NSGs can be specified. For more information, see Network Security Groups on page 2841 and Network Setup for DB Systems on page 1359.

Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs.

**To use network security groups**

a. Check the **Configure Network Security Groups** check box. Note that you must have a virtual cloud network selected to be able to assign NSGs to your DB system.

b. Specify the NSG to use with the DB system. You might need to use more than one NSG. If you're not sure, contact your network administrator.

c. To use additional NSGs, click **+ Another Network Security Group**.

- **Hostname prefix:** Your choice of host name for the bare metal or virtual machine DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

  **Important:**

  The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

- **Host domain name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, then this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

- **Host and domain URL:** Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

- **Private IP address:** Optionally, for non-RAC DB systems, you can define the IP address of the new DB system. This is useful in development contexts where you create and delete a DB system over and over, and you need each new iteration of the DB system to use the same IP address. If you specify an IP address that is currently in use within the subnet, the provisioning operation will fail with an error message regarding the invalid IP address.

5. Click **Show Advanced Options** to specify advanced options for the DB system:

- **Disk redundancy:** *For bare metal systems only.* The type of redundancy configured for the DB system.
  - **Normal** is 2-way mirroring, recommended for test and development systems.
  - **High** is 3-way mirroring, recommended for production systems.

- **Fault domain:** The fault domain(s) in which the DB system resides. You can choose which fault domain to use for your DB system. For two-node Oracle RAC DB systems, you can specify which two fault domains to use. Oracle recommends that you place each node of a two-node Oracle RAC DB system in a different fault domain. For more information on fault domains, see About Regions and Availability Domains on page 180.

- **Time zone:** The default time zone for the DB system is UTC, but you can specify a different time zone. The time zone options are those supported in both the Java.util.TimeZone class and the Oracle Linux operating system. For more information, see DB System Time Zone on page 1575.

  **Tip:**

  If you want to set a time zone other than UTC or the browser-detected time zone, and if you do not see the time zone you want, try selecting "Miscellaneous" in the **Region or country** list.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more
6. After you complete the network configuration and specify any advanced options, click **Next**.

7. Provide information for the initial database:

   - **Database name**: The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
   - **Database image**: This controls the version of the initial database created on the DB system. By default, the latest available Oracle Database version is selected. You can also choose an older Oracle Database version, or choose a customized database software image that you have previously created in your current region with your choice of updates and one-off (interim) patches. See Oracle Database Software Images on page 1567 for information on creating and working with database software images.

   To use an older Oracle-published software image:

   a. Click **Change Database Image**.
   b. In the Select a Database Software Image dialog, select **Oracle-published Database Software Images**.
   c. In the Oracle Database Version list, check the version you wish to use to provision the initial database in your DB system. If you are launching a DB system with a virtual machine shape, you have option of selecting an older database version.

   Display all available versions: Use this switch to include older database updates in the list of database version choices. When the switch is activated, you will see all available PSUs and RUs. The most recent release for each major version is indicated with "(latest)". See Availability of Older Database Versions for Virtual Machine DB Systems on page 1354 for more information.

   d. Click **Select**.

To use a user-created database software image:

   a. Click **Change Database Image**.
   b. In the Select a Database Software Image dialog, select **Custom Database Software Images**.
   c. Select the compartment that contains your database software image.
   d. Select the Oracle Database version that your database software image uses.
   e. A list of database software images is displayed for your chosen Oracle Database version. Check the box beside the display name of the image you want to use.

   After the DB system is active, you can create additional databases for bare metal systems. You can mix database versions on the DB system, but not editions. Virtual machine DB systems are limited to a single database.

   - **PDB name**: Not applicable to Oracle Database 11g (11.2.0.4). The name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of eight alphanumeric characters. The only special character permitted is the underscore (_).
   - **Create administrator credentials**: A database administrator SYS user will be created with the password you supply.

     - **Username**: SYS
     - **Password**: Supply the password for this user. The password must meet the following criteria:

       A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The
special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm password:** Re-enter the SYS password you specified.
- **Use the administrator password for the TDE wallet:** When this option checked, the password entered for the SYS user is also used for the TDE wallet. To set the TDE wallet password manually, uncheck this option and enter the TDE wallet password.
- **Select workload type:** Choose the workload type that best suits your application:
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  - **Enable automatic backup:** Check the check box to enable automatic incremental backups for this database. If you are creating a database in a security zone compartment, you must enable automatic backups.
  - **Backup retention period:** If you enable automatic backups, then you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  - **Backup Scheduling:** If you enable automatic backups, then you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, then the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Backup Scheduling for more information.
- **Click Show Advanced Options** to specify advanced options for the initial database:
  - **Character set:** The character set for the database. The default is AL32UTF8.
  - **National character set:** The national character set for the database. The default is AL16UTF16.

8. Click **Create DB System**. The DB system appears in the list with a status of Provisioning. The DB system's icon changes from yellow to green (or red to indicate errors).

After the DB system's icon turns green, with a status of Available, you can click the highlighted DB system name to display details about the DB system. Note the IP addresses. You'll need the private or public IP address, depending on network configuration, to connect to the DB system.

**To create a DB system from a backup**

You can create a new DB system from a backup. See Using a Backup to Create the Initial Database on page 1372 in this topic for details on backup source options.

Before you begin, note the following:

- When you create a DB system from a backup, the availability domain is the same as where the backup is hosted.
- The shape you specify must be the same type as the database from which the backup was taken. For example, if you are using a backup of a single-node database, then the DB system you select as your target must also be a single-node DB system.
- The Oracle database software version you specify must be an equal or greater version than that of the backed up database.
- If you specify a virtual machine DB system shape, then the Available Storage Size will default to the data size of the backup, rounded up to the closest storage size option. However, you can specify a larger storage size.
- If you are creating a new DB system from an automatic backup, you may choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Oracle Cloud Infrastructure Managed Backup Features on page 1436.
- If the backup being used to create a DB system is in a security zone compartment, the DB system cannot be created in a compartment that is not in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.

   A list of DB systems is displayed.

3. Navigate to the backup or standalone backup you want to use to create the new DB system:

   **Tip:**
   
   If you are creating a database from an automatic backup, you may choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Oracle Cloud Infrastructure Managed Backup Features on page 1436.

   **To select a daily automatic backup or on-demand full backup as the source**
   
   a. Click the DB system name that contains the specific database to display the DB System Details page.
   b. From the Databases list, click the database name associated with the backup you want to use.
   c. Find your desired backup in the Backups list. If you don't see the backups list on the database details page, click Backups in the Resources menu.
   d. Click the Actions icon (three dots) for the backup, and then click Create Database.

   **To select the last archived redo log automatic backup as the source**
   
   a. Find the DB system where the database is located, and click the system name to display details about it.
   b. Find the database associated with the backup you wish to use, and click its name to display details about it.
   c. On the database details page, click Create Database from Last Backup.
   d. In the Create Database from Backup dialog, select Create database from last backup.

   **To specify a timestamp for a point-in-time copy of the source**
   
   a. Click the DB system name that contains the specific database to display the DB System Details page.
   b. From the Databases list, click the database name associated with the backup data you want to use as the source for the initial database in your new DB system.
   c. On the database details page, click Create Database from Last Backup.
   d. In the Create Database from Backup dialog, select Create database from specified timestamp.

   **To select a standalone backup as the source**
   
   a. Click Standalone Backups under Bare Metal, VM, and Exadata.
   b. In the list of standalone backups, find the backup you want to use to create the database.
   c. Click the Actions icon (three dots) for the backup you are interested in, and then click Create Database.
4. In the **Create Database from Backup** dialog, enter the following:

**DB System Information**

- **DB System Information**: Select **Launch New DB System**.
- **Display Name**: A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system. Avoid entering confidential information.
- **Shape**: The shape to use to launch the DB system. The shape determines the type of DB system and the resources allocated to the system.

The selected shape must support the same number of nodes as the DB system from which the backup was created.

**Bare metal shapes**

- **BM.DenseIO2.52**: Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.
- **BM.DenseIO1.36**: Limited availability. Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.

**Note:** BM.DenseIO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

**Virtual machine shapes**

Virtual machine X7 shapes:

- **VM.Standard2.1**: Provides a 1-node DB system with 1 core.
- **VM.Standard2.2**: Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard2.4**: Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard2.8**: Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard2.16**: Provides a 1- or 2-node DB system with 16 cores.
- **VM.Standard2.24**: Provides a 1- or 2-node DB system with 24 cores.

Virtual machine X5 shapes:

- **VM.Standard1.1**: Provides a 1-node DB system with 1 core.
- **VM.Standard1.2**: Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard1.4**: Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard1.8**: Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard1.16**: Provides a 1- or 2-node DB system with 16 cores.

**Note:**

- X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- **VM.Standard1.1** and **VM.Standard2.1** shapes cannot be used for 2-node RAC clusters.

**Total Node Count**: *Virtual machine DB systems only*. The number of nodes in the DB system. The number depends on the shape you select. You can specify 1 or 2 nodes for virtual machine DB systems, except for **VM.Standard2.1** and **VM.Standard1.1**, which are single-node DB systems.

**Oracle Database Software Edition**: The database edition supported by the DB system. For bare metal systems, you can mix supported database releases on the DB system to include older database versions, but not
editions. The database edition cannot be changed and applies to all the databases in this DB system. Virtual machine systems support only one database.

- **Available Storage Size:** *Virtual machine DB systems only.* The amount of Block Storage you wish to allocate to the virtual machine DB system.
- **Cluster Name:** A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.
- **License Type:** The type of license you want to use for the DB system. Your choice affects metering for billing.
  - **License included** means the cost of this Oracle Cloud Infrastructure Database service resource will include both the Oracle Database software licenses and the service.
  - **Bring Your Own License (BYOL)** means you will use your organization’s Oracle Database software licenses for this Oracle Cloud Infrastructure Database service resource. See Bring Your Own License for more information.
- **SSH Public Key:** The public key portion of the key pair you want to use for SSH access to the DB system. To provide multiple keys, paste each key on a new line. Make sure each key is on a single, continuous line. The length of the combined keys cannot exceed 10,000 characters.
- **Data Storage Percentage:** *For bare metal DB systems only.* The percentage (40% or 80%) assigned to DATA storage (user data and database files). The remaining percentage is assigned to RECO storage (database redo logs, archive logs, and recovery manager backups).
- **Available Storage Size:** *For virtual machine DB systems only.* The amount of block storage to allocate to the virtual machine DB system. Available storage can be scaled up or down as needed after provisioning your DB system.

If you are creating a DB system from a backup, the minimum value for available storage is determined by the size of the backup.

- **Advanced Options:**
  - **Disk redundancy:** *For bare metal systems only.* The type of redundancy configured for the DB system.
    - **Normal** is 2-way mirroring, recommended for test and development systems.
    - **High** is 3-way mirroring, recommended for production systems.
  - **Fault Domain:** The fault domain(s) in which the DB system resides. You can choose which fault domain to use for your DB system. For 2-node RAC DB systems, you can specify which two fault domains are to be used. Oracle recommends that you place each node of a 2-node RAC DB system in a different fault domain. For more information on fault domains, see Fault Domains on page 182.

**Network Information**

- **Virtual Cloud Network:** The VCN in which to launch the DB system.
- **Client Subnet:** The subnet to which the bare metal or virtual machine DB system should attach. *For 1- and 2-node RAC DB systems:* Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.
- **Network Security Groups:** Optionally, you can specify one or more network security groups (NSGs) for your DB system. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules
to your DB system. A maximum of five NSGs can be specified. For more information, see Network Security Groups on page 2841 and Network Setup for DB Systems on page 1359.

To use network security groups

a. Check the Configure Network Security Groups check box. Note that you must have a virtual cloud network selected to be able to assign NSGs to your DB system.

b. Specify the NSG to use with the DB system. You might need to use more than one NSG. If you're not sure, contact your network administrator.

c. To use additional NSGs, click + Another Network Security Group.

- **Hostname Prefix:** Your choice of host name for the bare metal or virtual machine DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.</td>
</tr>
</tbody>
</table>

- **Private IP address:** Optionally, for non-RAC DB systems, you can define the IP address of the new DB system. This is useful in development contexts where you create and delete a DB system over and over, and you need each new iteration of the DB system to use the same IP address. If you specify an IP address that is currently in use within the subnet, the provisioning operation will fail with an error message regarding the invalid IP address.

**Database Information**

- **Database Name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.

- **Database Admin Password:**
  
  A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be , #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm Database Admin Password:** Re-enter the Database admin password you specified.

- **Password for Transparent Data Encryption (TDE) Wallet or RMAN Encryption:**
  
  Enter either the TDE wallet password or the RMAN encryption password for the backup, whichever is applicable. The TDE wallet password is the SYS password provided when the database was created by using the Oracle Cloud Infrastructure Console, API, or CLI. The RMAN encryption password is typically required instead if the password was subsequently changed manually.

5. Click **Create Database**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create DB system components.

**DB systems:**

- ListDbSystems
- GetDbSystem
- LaunchDbSystem

**Database homes:**

- ListDbHomes
- GetDbHome
- CreateDbHome
- DeleteDbHome
Databases:

- ListDatabases
- GetDatabase

Shapes and database versions:

- ListDbSystemShapes
- ListDbVersions

For the complete list of APIs for the Database service, see Database Service API.

Setting up DNS for a DB System

DNS lets you use host names instead of IP addresses to communicate with a DB system. You can use the Internet and VCN Resolver (the DNS capability built into the VCN) as described in DNS in Your Virtual Cloud Network on page 2910.

Alternatively, you can use your choice of DNS server. You associate the host name and domain name to the public or private IP address of the DB system. You can find the host and domain names and IP addresses for the DB system in the Oracle Cloud Infrastructure Console on the Database page.

To associate the host name to the DB system's public or private IP address, contact your DNS administrator and request a custom DNS record for the DB system’s IP address. For example, if your domain is example.com and you want to use clouddb1 as the host name, you would request a DNS record that associates clouddb1.example.com to your DB system's IP address.

If you provide the public IP address to your DNS administrator as described above, you should also associate a custom domain name to the DB system's public IP address:

1. Register your domain name through a third-party domain registration vendor, such as register.com.
2. Resolve your domain name to the DB system's public IP address, using the third-party domain registration vendor console. For more information, refer to the third-party domain registration documentation.

Managing Bare Metal and Virtual Machine DB Systems

This topic explains how to perform a variety of management tasks for a bare metal or virtual machine database system. Tasks include:

- Starting, stopping, rebooting, and terminating a DB system
- Scaling the CPU count and storage
- Changing the shape of a virtual machine DB system
- Managing network security groups (NSGs) for your system
- Managing licenses for your DB system
- Checking the system status
- Moving a system to another compartment
- Creating a serial console connection to your DB system nodes
- Managing tags for your system
- Viewing work requests related to your system

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.
Using the Console

To check the status of a DB system

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.

   A list of database systems is displayed.
3. In the list of DB systems, find the system you're interested in and check its icon. The color of the icon and the text next to it indicates the status of the system.
   - **Provisioning**: Yellow icon. Resources are being reserved for the DB system, the system is booting, and the initial database is being created. Provisioning can take several minutes. The system is not ready to use yet.
   - **Available**: Green icon. The DB system was successfully provisioned. A few minutes after the system enters this state, you can SSH to it and begin using it.
   - **Terminating**: Gray icon. The DB system is being deleted by the terminate action in the Console or API.
   - **Terminated**: Gray icon. The DB system has been deleted and is no longer available.
   - **Failed**: Red icon. An error condition prevented the provisioning or continued operation of the DB system.

To view the status of a database node, under Resources, click Nodes to see the list of nodes. In addition to the states listed for a DB system, a node's status can be one of the following:
   - **Starting**: Yellow icon. The database node is being powered on by the start or reboot action in the Console or API.
   - **Stopping**: Yellow icon. The database node is being powered off by the stop or reboot action in the Console or API.
   - **Stopped**: Yellow icon. The database node was powered off by the stop action in the Console or API.

You can also check the status of database systems and database nodes by using the ListDbSystems or ListDbNodes API operations, which return the lifecycleState attribute.

To start, stop, or reboot a database system

DB system nodes are stopped, started, or rebooted individually. For multi-node DB systems, you may need to act on only one node (as in the case of proactively rebooting a virtual machine node with scheduled maintenance).

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.

   A list of database systems is displayed.
3. In the list of database systems, find the DB system you want to stop or start, and then click its name to display details about it.
4. In the list of nodes, click the Actions icon (three dots) for a node and then click one of the following actions:
   - **Start**: Restarts a stopped node. After the node is restarted, the **Stop** action is enabled.
   - **Stop**: Shuts down the node. After the node is powered off, the **Start** action is enabled.
   - **Reboot**: Shuts down the node, and then restarts it.

**Note:**

- Resource billing differs between bare metal and virtual machine DB systems as follows:
  - **Bare metal DB systems** - The **Stop** state has no effect on the resources you consume. Billing continues for nodes that you stop, and related resources continue to apply against any relevant quotas. You must **Terminate** a DB system to remove its resources from billing and quotas.
  - **Virtual machine DB systems** - Stopping a node stops billing for all OCPUs associated with that node. Billing resumes if you restart the node.
After you restart or reboot a node, the floating IP address might take several minutes to be updated and display in the Console.

To scale the CPU cores for a bare metal DB system

If a bare metal DB system requires more compute node processing power, you can scale up (increase) the number of enabled CPU cores in the system without impacting the availability of that system.

Note:
You cannot change the number of CPU cores for a virtual machine DB system in the same way. Instead, you must change the shape to one with a different number of OCPUs. See To change the shape of a virtual machine DB system on page 1384 to learn how.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of database systems is displayed.
3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click Scale CPU Cores, and then change the number in the CPU Core Count field. The text below the field indicates the acceptable values, based on the shape used when the DB system was launched.
5. Click Update.

To change the shape of a virtual machine DB system

After you provision a virtual machine DB system, you can change the shape at any time to adapt to changes in performance needs. For example, you might require a system with a higher number of OCPUs, or you might want to reduce costs by reducing the number of OCPUs. See Virtual Machine DB Systems on page 1355 for resource details for each shape in a series.

Note:
The shape-changer operation takes place in a rolling fashion for multi-node DB systems, allowing you to change the shape with no database downtime.

Changing the shape does not impact the amount of storage available to the DB system. However, the new shape can have different memory and network bandwidth characteristics, and you might need to reapply any customizations to these aspects after the change.

Prerequisites:
• DB system and database are in the Available state
• DB system is registered with the Cluster Ready Services (CRS) Grid Infrastructure stack. By default, virtual machine DB systems use CRS.
• Database can be successfully restarted
• Database is configured to use SPFILE (server parameter file), not PFILE. By default, databases in virtual machine DB systems use the SPFILE configuration.
• The SGA_TARGET parameter for Automatic Shared Memory Management (ASMM) has a non-zero value. By default, virtual machine DB systems use this ASMM configuration.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of database systems is displayed.
3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click Change Shape.
5. Select the new shape from the list of compatible and available shapes, and click **Change Shape**. Compatible shapes are those shapes within the same series. For example, if the current shape is VM.Standard 2.2, you can select another X7 shape that has not reached its usage limit in the selected availability domain.

   **Note:**

   If the current shape supports Oracle RAC, then you can only change that shape to another shape that also supports Oracle RAC. For example, you cannot change the shape from VM.Standard2.2 to VM.Standard2.1.

6. Review the information on the confirmation dialog, and proceed as applicable.

   **Tip:**

   If your shape change operation is not successful, see the troubleshooting tips in [Shape Change Failures for Virtual Machine DB Systems](#) on page 1663.

**To scale up the storage for a virtual machine DB system**

If a virtual machine DB system requires more block storage, you can increase the storage at any time without impacting the system.

   **Note:**

   This procedure does not apply to bare metal DB systems.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.

   A list of database systems is displayed.

3. In the list of DB systems, find the system you want to scale up and click its highlighted name.

   The system details are displayed.

4. Click **Scale Storage Up**, and then select the new available storage size from the drop-down list.

   The new total storage size displays in the total storage field. Oracle charges for the total storage used.

5. Click **Update**.

**To move a DB system to another compartment**

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.

   A list of database systems is displayed.

3. In the list of DB systems, find the system you want to move and click its highlighted name.

   The system details are displayed.

4. Click **Move Resource**.

5. Select the new compartment.

6. Click **Move Resource**.

   For information about dependent resources for Database resources, see [Moving Database Resources to a Different Compartment](#) on page 1141.
To terminate a DB system

Terminating a DB system permanently deletes it and any databases running on it.

**Note:**

The database data is local to the DB system and will be lost when the system is terminated. Oracle recommends that you back up any data in the DB system prior to terminating it.

Terminating a DB system removes all automatic incremental backups of all databases in the DB system from Oracle Cloud Infrastructure Object Storage. Full backups remain in Object Storage as standalone backups which you can use to create a new database. See Creating Databases on page 1414 for information on creating a new database from a backup.

**Important:** If your DB system has Data Guard enabled, you must terminate the standby DB system before terminating the primary DB system. If you try to terminate a primary DB system that has a standby, the terminate operation will not complete.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   
   A list of database systems is displayed.
3. For the DB system you want to terminate, click the Actions icon (three dots) and then click Terminate.
4. Confirm when prompted.
   
   The database system's icon indicates Terminating.

At this point, you cannot connect to the system and any open connections will be terminated.

To edit the network security groups (NSGs) for your DB system

Your DB system can use up to five network security groups (NSGs). Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs. For more information, see Network Security Groups on page 2841 and Network Setup for DB Systems on page 1359.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   
   A list of database systems is displayed.
3. In the list of DB systems, find the system you want to manage and click its highlighted name.
   
   The system details are displayed.
4. In the Network details, click the Edit link to the right of the Network Security Groups field.
5. In the Edit Network Security Groups dialog, click + Another Network Security Group to add an NSG to the DB system.
   
   To change an assigned NSG, click the drop-down menu displaying the NSG name, then select a different NSG.
   
   To remove an NSG from your DB system, click the X icon to the right of the displayed NSG name.
6. Click Save.

To manage your BYOL database licenses on your bare metal DB system

If you want to control the number of database licenses that you run at any given time on a bare metal system, you can scale up or down the number of OCPUs on the instance. These additional licenses are metered separately.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   
   A list of database systems is displayed.
3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click **Scale CPU Cores**, and then change the number.

*To change the license type of a bare metal or virtual machine DB system*

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, find the DB system you want to administer and click its highlighted name.
4. On the DB system details page, click **Update License Type**.
   The dialog displays the options with your current license type selected.
5. Select the new license type.
6. Click **Save**.

See **Known Issue**.

*To manage tags for your DB systems and database resources*

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Find the DB system or database resource you're interested in, and click the name.
4. Click the **Tags** tab to view or edit the existing tags. Or click **More Actions** and then **Apply Tags** to add new ones.

For more information, see **Resource Tags** on page 211.

*To view a work request for your DB systems and database resources*

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of database systems is displayed.
3. Find the DB system or database resource you're interested in, and click the name.
4. In the **Resources** section, click **Work Requests**. The status of all work requests appears on the page.
5. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the **More information** section.
   For associated resources, you can click the Actions icon (three dots) next to a resource to copy the resource’s OCID.

For more information, see **Work Requests** on page 258.

*To create a serial console connection to your database system*

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of database systems is displayed.
3. Find the DB system or database resource you're interested in, and click the name.
4. In the **Resources** section, click **Console Connections**.
5. Click **Create Console Connection**. Note that if all nodes currently have existing console connections, this button will be disabled.
6. In the **Create Console Connection** dialog, specify the following:
   - The DB system node. For multi-node DB systems, select which node or nodes you wish to create a connection for. No node selector will display if the DB system has only one node, or if there is only one node in a multi-node system that currently lacks a connection.
   - The SSH key. You can browse or drag and drop .pub files, or paste in individual public keys.
7. Click **Create Console Connection**.
To delete a serial console connection to your database system

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of database systems is displayed.
3. Find the DB system or database resource you're interested in, and click the name.
4. In the Resources section, click Console Connections. Your current console connections are displayed.
5. To delete a connection, click the Actions icon (three dots) in the row listing the connection, then click Delete.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage DB system components.

- **database systems:**
  - ListDbSystems
  - GetDbSystem
  - UpdateDbSystem
  - ChangeDbSystemCompartment
  - TerminateDbSystem

- **Database homes:**
  - ListDbHomes
  - GetDbHome
  - DeleteDbHome

- **Databases:**
  - ListDatabases
  - GetDatabase

- **Nodes:**
  - DbNodeAction: Use this operation to power cycle a node in the database system.
  - ListDbNodes
  - GetDbNode

For the complete list of APIs for the Database service, see Database Service API.

Cloning a Virtual Machine DB System

This topic explains how to clone a virtual machine DB system that uses Logical Volume Manager storage management software. See Fast Provisioning Option for Single-Node Virtual Machine DB Systems on page 1355 for more information on these virtual machine DB systems.

Cloning creates a copy of a source DB system as it exists at the time of the cloning operation, including the storage configuration software and database volumes. When creating a clone, you can specify a new SSH key and ADMIN password.

Note:

- Cloning is not supported for bare metal DB systems or virtual machine systems using Oracle Automatic Storage Management.
- You can't clone a virtual machine DB system in a security zone to create a virtual machine DB system that isn't in a security zone. See the Security Zone Policies topic for a full list of policies that affect Database service resources.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more information about writing policies for databases, see Details for the Database Service on page 2240.

Using the Console to Clone a Virtual Machine DB System

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the compartment where the source DB system is located.
3. In the list of DB systems, find the virtual machine DB system you want to clone and click its highlighted name.
   Note that only system using Logical Volume Manager storage management software can be cloned.
4. On the DB System Details page of your source DB system, click Clone. This opens the Clone DB System dialog.
5. Select a compartment: By default, the DB system is created in your current compartment and you can use the network resources in that compartment.
6. Display name: A non-unique, display name for the DB system. An Oracle Cloud Identifier (OCID) uniquely identifies the DB system. Avoid entering confidential information.
7. Add public SSH keys: The public key portion of each key pair you want to use for SSH access to the DB system.
   You can browse or drag and drop .pub files, or paste in individual public keys. To paste multiple keys, click + Another SSH Key, and supply a single key for each entry.
   The clone will use the SSH keys specified during the cloning operation, and the source DB system will continue to use the SSH keys that were in place prior to the cloning operation.
8. Choose a license type: The type of license you want to use for the DB system. Your choice affects metering for billing.
   - License Included means the cost of this Oracle Cloud Infrastructure Database service resource will include both the Oracle Database software licenses and the service.
   - Bring Your Own License (BYOL) means you will use your organization's Oracle Database software licenses for this Oracle Cloud Infrastructure Database service resource. See Bring Your Own License for more information.
   Note that this license selection only applies to the clone, and does not affect the source DB system.
9. Specify the network information:
   - Virtual cloud network: The VCN in which to create the DB system. Click Change Compartment to select a VCN in a different compartment. Note that the clone can use a different VCN and subnet from the source DB system.
   - Client Subnet: The subnet to which the DB system should attach. For 1- and 2-node RAC DB systems:
     Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.
     Click Change Compartment to select a subnet in a different compartment.
   - Network Security Groups: Optionally, you can specify one or more network security groups (NSGs) for your DB system. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules
to your DB system. A maximum of five NSGs can be specified. For more information, see Network Security Groups on page 2841 and Network Setup for DB Systems on page 1359.

Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs.

- **Hostname prefix:** Your choice of host name for the bare metal or virtual machine DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

  \[\text{Important:}\]
  
  The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision. If the clone is created in a different subnet from the source, the same host name can be used for both the clone and the source DB system.

- **Host domain name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, then this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

- **Host and domain URL:** Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

- **Private IP address:** Optionally, you can define the IP address of the clone. This is useful in development contexts where you create and delete clones of the same source DB system over and over, and you need each new iteration of the clone to use the same IP address. If you specify an IP address that is currently in use within the subnet, the cloning operation will fail with an error message regarding the invalid IP address.

10. **Fault domain:** The fault domain in which the DB system resides. You can choose which fault domain to use for your DB system. For more information on fault domains, see About Regions and Availability Domains on page 180.

11. Provide information for the initial database of the clone:

- **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted. You can use the same database name that is used in the source DB system.

- **Password:** A strong password for the SYS user. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS or SYSTEM) or the word "oracle" either in forward or reversed order and regardless of casing. The password will be used for the SYS and SYSTEM administrator accounts.

  \[\text{Important:}\] The TDE wallet password is inherited from the source DB system.

- **Confirm password:** Re-enter the password you specified.

12. Clicking **Show Advanced Options** allows you to configure the following:

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

13. Click **Clone DB System**.

**Connecting to a DB System**

This topic explains how to connect to an active DB system. How you connect depends on the client tool or protocol you use, the purpose of the connection, and how your cloud network is set up. You can find information on various networking scenarios in Networking Overview on page 2748, but for specific recommendations on how you should connect to a database in the cloud, contact your network security administrator.
Prerequisites
This section describes prerequisites you'll need to perform various tasks in this topic.

- To use the Console or the API to get the default administration service connection strings, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

- To connect to the database, you'll need the public or private IP address of the DB system.

Use the private IP address to connect to the system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the Exadata system’s public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console as follows:

- Cloud VM clusters (new resource model): On the Exadata VM Cluster Details page, click Virtual Machines in the Resources list.
- DB systems: On the DB System Details page, click Nodes in the Resources list.

The values are displayed in the Public IP Address and Private IP Address & DNS Name columns of the table displaying the Virtual Machines or Nodes of the Exadata Cloud Service instance.

- For Secure Shell (SSH) access to the DB system, you'll need the full path to the file that contains the private key associated with the public key used when the DB system was launched.

If you have problems connecting, see Troubleshooting Connection Issues on page 1396.

Database Services and Connection Strings
Database services allow you to control client access to a database instance depending on the functionality needed. For example, you might need to access the database for administration purposes only or you might need to connect an application to the database. Connection strings are specific to a database service.

When you provision a DB system, a default database administration service is automatically created. For 12c and later Oracle Databases, this service is for administrating the database at the CDB level. Because this service provides limited functionality, it is not suitable for connecting an application. Oracle recommends that you create a default application service for the initial database after you create your DB system. For 12c and later Oracle Databases, application services connect at the PDB level. Here are some important functions an application service can provide:

- Workload identification
- Load balancing
- Application continuity and Transaction Guard
- Fast Application Notification
- Resource assignment based on the service name

For details about these and other High Availability capabilities, see Client Failover Best Practices for Highly Available Oracle Databases.

Creating an Application Service
You use the srvctl utility to create an application service. Before you can connect to the service, you must start it.

To create an application service for a PDB or an 11g Oracle database

1. Log in to the DB system host as opc.
2. Switch to the oracle user, and set your environment to the Oracle Database you want to administer.

```bash
$ sudo su - oracle
$ . oraenv
ORACLE_SID = [oracle] ? <database_name>
```
The Oracle base has been set to /u01/app/oracle

3. Create the application service for the database. Include the pdb option only if you are creating an application service for a PDB.

```bash
$ srvctl add service
   -db <DB_unique_name>
   -pdb <PDB_name>
   -service <app_service_name>
   -role PRIMARY
   -notification TRUE
   -session_state dynamic
   -failovertype transaction
   -failovermethod basic
   -commit_outcome TRUE
   -failoverretry 30
   -failoverdelay 10
   -replay_init_time 900
   -clbgoal SHORT
   -rlbgoal SERVICE_TIME
   -preferred <rac_node1>,<rac_node2>
   -retention 3600
```

Note that the preferred option is required only for multi-node databases to specify the hostname of the node in the RAC.

4. Start the application service.

```bash
$ srvctl start service -db <DB_unique_name> -s <app_service_name>
```

For more information about services for a PDB, see Managing Services for PDBs.

**Database Connection Strings**

You must use the appropriate connection string to access a database administration or application service. You can use the Console or the API to get the string for connecting to the default administration service from within a VCN. For 12c and later Oracle Databases, this service is for administrating the database at the CDB level. The string is provided in both the Easy Connect and in the full connect descriptor (long) format. Use the long format for the connection if hostname resolution is not available. You can also use the long format to create an alias in the tnsnames.ora file.

For accessing a database service within the VCN, the connection string for a Real Application Cluster (RAC) DB system uses the Single Client Access Name (SCAN) while the connection string for single instance DB system uses the hostname instead.

The private SCAN name is a Round Robin DNS entry created when you launch a 2-node RAC DB system. The private SCAN name is resolvable only within the VCN. If the client and the database are in the same VCN, the connection mechanism is the same as an on-premises RAC database; all the features provided by VIPs and SCAN VIPs, such as server side load balancing and VIP failover, are available.

**Note:**

If you manually change the DB_UNIQUE_NAME, DB_DOMAIN, or listener port on the DB system, the connection strings you see in the Console or API will not reflect your changes. Ensure that you use the actual values of these parameters when you make a connection.

To get the connection strings for the default administration service

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Find the DB system you're interested in, and click the name.
4. Click **DB Connection**.
5. Click the applicable link to view or copy the connection string.

You can derive the connection strings for other database services by replacing part of the default application service connection string with the applicable values.

**To derive the connection string for a PDB administration service or an application service**

1. Follow the procedure to get the Easy Connect string for the default administration service. That string should have the following format:

   ```
   <hostname|SCAN>:1521/<DB_unique_name>.<DB_domain>
   ```

2. Make the appropriate substitution:
   - For the PDB administration service, replace **DB_unique_name** with the PDB name.
     ```
     <hostname|SCAN>:1521/<PDB_name>.<DB_domain>
     ```
   - For an application service, replace **DB_UNIQUE_NAME** with the name of the application service.
     ```
     <hostname|SCAN>:1521/<app_service_name>.<DB_domain>
     ```

### Connecting to a Database Service by Using SQL*Net

This section describes how to connect to a database service from a computer that has a SQL*Net client installed. Port 1521 must be open to support the SQL*Net protocol.

#### Connecting from Within the VCN

For security reasons, Oracle recommends that you connect to your database services from within the VCN. You can use this method whether you are connecting to an administration service or to an application service.

To connect using SQL*Plus, you run the following command using the applicable connection string:

```
sqlplus system/<password>@<connection_string>
```

Consider the following:

- If your system is not using the VCN Resolver, ensure that the DB system's hostname (for single-node systems) or SCAN name (for multi-node systems) can be resolved. See [DNS in Your Virtual Cloud Network](#) on page 2910 for information about DNS name resolution.
- For connecting to the administration service of a PDB, ensure that the PDB is open or the service will not be available.
- For connecting to an application service, ensure that the service is started. For Fast Application Notification to work, ensure that port 6200 can be reached. See [Client Failover Best Practices for Highly Available Oracle Databases](#) for information about Fast Application Notification.

#### Connecting from the Internet

Although Oracle does not recommend connecting to your database from the Internet, you can connect to a database service by using a public IP address if port 1521 is open to the public for ingress.

To use this method, you run the following command using the public IP address instead of the hostname or SCAN in the connection string:

```
sqlplus system/<password>@<public_IP>:1521/<service_name>.<DB_domain>
```

Consider the following:

- SCANs and hostnames are not resolvable on the Internet, therefore load balancing and failover for multi-node DB systems, which rely on these names, cannot work.
• For multi-node DB systems, which normally use SCANs, you must specify the IP address of one of the RAC hosts to access the database.

**Important:**

Do not use this method to connect to the database from within the VCN. Doing so negatively impacts performance because traffic to the database is routed out of the VCN and back in through the public IP address.

**Example: Connecting in SQL Developer Using SQL*Net**

**Prerequisites:**

• Ensure that port 1521 is open for the Oracle default listener. (You can do this by checking the DB system's security list.)
• If port 1521 is open only to hosts in the VCN, then you must run your SQL Developer client from a machine that has direct access to the VCN. If you are connecting to the database from the Internet instead, then the public IP address of your computer must be granted access to port 1521 in the security list. (Alternatively, the security list can grant full access to port 1521, however, this is not recommended for security reasons.) You must use the public IP address of the host because connecting from the Internet does not support SCAN name resolution.

**To connect from within the VCN using a private IP address**

After the prerequisites are met, start SQL Developer and create a connection by supplying the following connection details:

• **Username:** sys as sysdba
• **Password:** The Database Admin Password that was specified in the Launch DB System dialog in the Console.
• **Hostname:** The hostname as it appears in the Easy Connect format of the connection string. (See Database Connection Strings on page 1392 for help with getting the connection string and identifying the hostname.)
• **Port:** 1521
• **Service name:** The concatenated name of the service and host domain name, for example, `db1_phx1tv.example.com`. You can identify this value as the last part of the Easy Connect string, `<service_name>.<DB_domain>`.

**Connecting to a Database with a Public IP by Using SSH Tunneling**

You can access the services of DB system databases with public IP addresses by using SSH tunneling. The main advantage of this method is that port 1521 does not need to be opened to the public internet. However, just like accessing the database with a public IP using a SQL*Net client, load balancing and failover for multi-node DB systems cannot work because they rely on SCANs and hostnames.

Oracle SQL Developer and Oracle SQLcL and are two tools that facilitate the use of tunneling for Oracle Database access.

To open a tunnel, and then connect to a database service by using SQLcL, you run commands like the following:

```
SQL> sshtunnel opc@<public_IP> -i <private_key> -L <local_port>:<private_IP>:1521
Using port:22
SSH Tunnel connected
SQL> connect
system/<password>@localhost:<local_port>/<service_name>.<DB_domain>
```

See Oracle SQL Developer and Oracle SQLcL for information about these tools.

**Connecting to a Database by Using SSH and the Bequeath Protocol**

This method allows you to connect to the database without using the network listener. It should be used to connect only for administration purposes.

When connecting to a multi-node DB system, you'll SSH to each individual node in the cluster.
To connect from a UNIX-style system

Use the following SSH command to access the DB system: $ ssh -i <private_key> 
opc@<DB_system_IP_address>

<private_key> is the full path and name of the file that contains the private key associated with the DB system you want to access.

Use the DB system’s private or public IP address depending on your network configuration. For more information, see Prerequisites on page 1391.

To connect from a Windows system

1. Open putty.exe.

2. In the Category pane, select Session and enter the following fields:
   - Host Name (or IP address): opc@<DB_system_IP_address>
     Use the DB system’s private or public IP address depending on your network configuration. For more information, see Prerequisites on page 1391.
   - Connection type: SSH
   - Port: 22

3. In the Category pane, expand Connection, expand SSH, and then click Auth, and browse to select your private key.

4. Optionally, return to the Session category screen and save this session information for reuse later.

5. Click Open to start the session.

To access a database after you connect

1. Log in as opc and then sudo to the grid user.

   login as: opc
   [opc@ed1db01 ~]$ sudo su - grid

2. List all the databases on the system.

   root@ed1db01 ]# srvctl config database -v
cdbm01 /u02/app/oracle/product/12.1.0/dbhome_2 12.1.0.2.0
exadb /u02/app/oracle/product/11.2.0/dbhome_2 11.2.0.4.0
mmdb /u02/app/oracle/product/12.1.0/dbhome_3 12.1.0.2.0

3. Connect as the oracle user and get the details about one of the databases by using the srvctl command.

   [root@ed1db01 ~]$ su - oracle
   [oracle@ed1db01 ~]$ . oraenv
   ORACLE_SID = [oracle] ? cdbm01
   The Oracle base has been set to /u02/app/oracle
   [oracle@ed1db01 ~]$ srvctl config database -d cdbm01
   Database unique name: cdbm01 <<== DB unique name
   Database name: Oracle home: /u02/app/oracle/product/12.1.0/dbhome_2
   Oracle user: oracle
   Spfile: +DATAC1/cdbm01/spfilecdbm01.ora
   Password file: +DATAC1/cdbm01/PASSWORD/passwd
   Domain: data.customer1.oraclevcn.com
   Start options: open
   Stop options: immediate
   Database role: PRIMARY
   Management policy: AUTOMATIC
   Server pools:
   Disk Groups: DATAC1,RECO1
Mount point paths:
Services:
Type: RAC
Start concurrency:
Stop concurrency:
OSDBA group: dba
OSOPER group: racoper
Database instances: cdbm011,cdbm012 <== SID
Configured nodes: ed1db01,ed1db02
Database is administrator managed

4. Set the ORACLE_SID and ORACLE_UNIQUE_NAME using the values from the previous step.

[oracle@ed1db01 ~]$ export ORACLE_UNIQUE_NAME=cdbm01
[oracle@ed1db01 ~]$ export ORACLE_SID=cdbm011
[oracle@ed1db01 ~]$ sqlplus / as sysdba

SQL*Plus: Release 12.1.0.2.0 Production on Wed Apr 19 04:10:12 2017

With the Partitioning, Real Application Clusters, Automatic Storage
Management, Oracle Label Security, OLAP, Advanced Analytics and Real Application Testing options

Serial Console Access for Troubleshooting and Managing a Bare Metal or VM System
You can create and delete serial console connections to your bare metal or virtual machine DB system in the Oracle
Cloud Infrastructure Console. This allows you to manage and troubleshoot your system in single-user mode using an
SSH connection. See the following topics for more information:

- To create a serial console connection to your database system on page 1387
- To delete a serial console connection to your database system on page 1388

Using the API
For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on
page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the GetDatabase API operation to get the default administration service connection strings.

Troubleshooting Connection Issues
The following issues might occur when connecting to a DB system or database.

ORA-28365: Wallet is Not Open Error
For a 1-node DB system or 2-node RAC DB system, regardless of how you connect to the DB system, before
you use OS authentication to connect to a database (for example, sqlplus / as sysdba) be sure to set
the ORACLE_UNQNAME variable. Otherwise, commands that require the TDE wallet will result in the error
ORA-28365: wallet is not open.

Note that this is not an issue when using a TNS connection because ORACLE_UNQNAME is automatically set in the
database CRS resource.

SSH Access Stops Working
If the DB system’s root volume becomes full, you might lose the ability to SSH to the system (the SSH command
will fail with permission denied errors). Before you copy a large amount of data to the root volume, for example, to
migrate a database, use the dbcli create-dbstorage command to set up storage on the system’s NVMe drives.
and then copy the database files to that storage. For more information, see Setting Up Storage on the DB System on page 1637.

**What Next?**

Before you begin updating your DB system, review the information in Updating a DB System on page 1397.

For information about setting up an Enterprise Manager console to monitor your databases, see Monitoring a Database on page 1427.

**Updating a DB System**

---

**Note:**

This topic is not applicable to Exadata DB systems. For information on how to update an Exadata DB system, see Updating an Exadata Cloud Service Instance on page 1274.

This topic includes information and instructions on how to update the OS of a bare metal or virtual machine DB system.

---

**Caution:**

- Review all of the information before you begin updating the system. Updating the operating system through methods not described on this page can cause permanent loss of access.
- Always back up your databases prior to updating your DB system's operating system.

**Bash Profile Updates**

Do not add interactive commands such as `oraenv`, or commands that might return an error or warning message, to the `.bash_profile` file for the grid or oracle users. Adding such commands can prevent Database service operations from functioning properly.

**Essential Firewall Rules**

For a 1-node DB system or 2-node RAC DB system, do not remove or modify the following firewall rules in `/etc/sysconfig/iptables`:

- The firewall rules for ports 1521, 7070, and 7060 allow the Database service to manage the DB system. Removing or modifying them can result in the Database Service no longer operating properly.
- The firewall rules for 169.254.0.2:3260 and 169.254.0.3:80 prevent non-root users from escalating privileges and tampering with the system’s boot volume and boot process. Removing or modifying these rules can allow non-root users to modify the system's boot volume.

**OS Updates**

Before you update the OS, review the following important guidelines and information:

- Back up your DB system's databases prior to attempting an OS update.
- Do not remove packages from a DB system. However, you might have to remove custom RPMs (packages that were installed after the system was provisioned) for the update to complete successfully.

---

**Caution:**

Do not install NetworkManager on the DB system. Installing this package and reboots the system results in severe loss of access to the system.

- Oracle recommends that you test any updates thoroughly before updating a production system.
- The image used to launch a DB system is updated regularly with the necessary patches. After you launch a DB system, you are responsible for applying the required OS security updates published through the Oracle public YUM server.
To apply OS updates, the DB system's VCN must be configured to allow access to the YUM repository. For more information, see Network Setup for DB Systems on page 1359.

**To update an OL7 OS on a DB system host**

You can update the OS on 2-node RAC virtual machine DB systems in a rolling fashion.

*Note:* Ensure the Oracle Clusterware (CRS) is completely shut down before performing the OS kernel updates.

1. Log on to the DB system host as opc, and then sudo to the root user.

   ```bash
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ``

2. If your DB system uses an image with the kernel version 4.1.12-124.27.1.el7uek (used with older images), then change the bootefi label before updating the OS.

3. Identify the host region by running the following command:

   ```bash
   # curl -s http://169.254.169.254/opc/v1/instance/ | grep region
   ``

4. With the region noted from the previous step, determine the region name, and perform the following two steps.

   See Regions and Availability Domains on page 180 to look up the region name.

   **a.** Download the repo.

   ```bash
   # wget https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol7repo -O /tmp/oci_dbaas_ol7repo
   ``

   This example output assumes the region is us-phoenix-1 (PHX).

   ```bash
   # wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol7repo -O /tmp/oci_dbaas_ol7repo
   Resolving swiftobjectstorage.us-phoenix-1.oraclecloud.com...
   129.146.13.177, 129.146.13.180, 129.146.12.235, ...
   Connecting to swiftobjectstorage.us-phoenix-1.oraclecloud.com|129.146.13.177|:443... connected.
   HTTP request sent, awaiting response... 200 OK
   Length: 1394 (1.4K) [binary/octet-stream]
   Saving to: `/tmp/oci_dbaas_ol7repo'
   100%[==============================================] 1,394 --.-K/s in 0s
   ```
b. Download the version lock files.

```bash
# wget https://swiftobjectstorage.<region_name>.oraclecloud.com/
v1/dbaaspatchstore/DBaaSOSPatches/versionlock_ol7.list -O /tmp/
versionlock.list
```

This example output assumes the region is us-phoenix-1 (PHX).

```bash
# wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/
v1/dbaaspatchstore/DBaaSOSPatches/versionlock_ol7.list -O /tmp/
versionlock.list
```

5. Copy the repo file to the `/etc/yum.repos.d` directory.

```bash
cp /tmp/oci_dbaas_ol7repo /etc/yum.repos.d/ol7.repo
```

6. Copy and overwrite the existing version lock file.

```bash
cp /etc/yum/pluginconf.d/versionlock.list /etc/yum/pluginconf.d/
versionlock.list-`date +%Y%m%d`
cp /tmp/versionlock.list /etc/yum/pluginconf.d/versionlock.list
```

The initial version lock file should be empty. However, it is a good practice to back it up in case it is not and you need to refer to it later.

7. Run the update command.

```bash
|  18 MB 00:00 |
# yum update
Loaded plugins: kernel-update-handler, ulninfo, versionlock
Excluding 250 updates due to versionlock (use "yum versionlock status" to show them)

Installing : kernel-uek-firmware-4.1.12-124.28.5.el7uek.noarch 1/6
Updating   : libtalloc-2.1.13-1.el7.x86_64 2/6
Updating : pytalloc-2.1.13-1.el7.x86_64 3/6
Installing : kernel-uek-4.1.12-124.28.5.el7uek.x86_64 4/6
Cleanup    : pytalloc-2.1.10-1.el7.x86_64 5/6
Cleanup    : libtalloc-2.1.10-1.el7.x86_64 6/6

Note:
• Ignore the error activating message that results from running the update.
• An update will occur only if a versionlock file has a valid update available to apply to the DB system.

8. Restart the system.

$ sudo su -
# reboot

9. Run the following command to validate the update:

# uname -r
4.1.12-124.28.5

In this example, then new kernel version is 4.1.12-124.28.5.

To check the kernel version
Run the following command.

$ uname -r

Example response indicating kernel version 4.1.12-124.27.1.el7uek:

4.1.12-124.27.1.el7uek.x86_64

If you have kernel version 4.1.12-124.27.1.el7uek, then proceed to change the bootefi label.

To change the bootefi label (each node)

1. Edit /etc/fstab: Change the label bootefi to BOOTEFI (uppercase).

Example:

LABEL=BOOTEFI             /boot/efi             vfat    defaults        1

2. Restart the DB node.

3. Run the following command to ensure that the required link is created.

$ sudo ls -lrt /etc/grub2-efi.cfg

Example response indicating that the required link exists:

lrwxrwxrwx 1 root root 31 Sep  4 11:49 /etc/grub2-efi.cfg -> ../boot/efi/EFI/redhat/grub.cfg

To update an OL6 OS on a DB system host
You can update the OS on 2-node RAC virtual machine DB systems in a rolling fashion.
Note:
Ensure the Oracle Clusterware (CRS) is completely shut down before performing the OS kernel updates.

1. Log on to the DB system host as opc, and then sudo to the root user.
   
   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

2. Identify the host region by running the following command:
   
   ```
   # curl -s http://169.254.169.254/opc/v1/instance/ | grep region
   ```

3. With the region you noted from the previous step, determine the region name, and perform the following two steps.
   
   See Regions and Availability Domains on page 180 to look up the region name.

   a. Download the repo.
      
      ```
      # wget https://swiftobjectstorage.<region_name>.oraclecloud.com/
      v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol6repo -O /tmp/
      oci_dbaas_ol6repo
      ```
      
      This example output assumes the region is us-phoenix-1 (PHX).

      ```
      # wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/
      v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol6repo -O /tmp/
      oci_dbaas_ol6repo
      Resolving swiftobjectstorage.us-phoenix-1.oraclecloud.com... 129.146.13.177, 129.146.13.180, 129.146.12.235, ...

      ```

   b. Download the version lock files.
      
      ```
      # wget https://swiftobjectstorage.<region_name>.oraclecloud.com/
      v1/dbaaspatchstore/DBaaSOSPatches/versionlock_ol6.list -O /tmp/
      versionlock.list
      ```
      
      This example output assumes the region is us-phoenix-1 (PHX).

      ```
      # wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/
      v1/dbaaspatchstore/DBaaSOSPatches/versionlock_ol6.list -O /tmp/

4. Enable the repo for your region.
   a. Copy the repo file to the /etc/yum.repos.d directory.

```bash
cp /tmp/oci_dbaas_ol6repo /etc/yum.repos.d/ol6.repo
```

b. Modify the ol6.repo file to enable the repo for your region.

```bash
vi /etc/yum.repos.d/ol6.repo
```

```bash
[ol6_latest_PHX]
name=Oracle Linux $releasever Latest ($basearch)
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1 <= Enabled.

[ol6_UEKR4_PHX]
name=Latest Unbreakable Enterprise Kernel Release 4 for Oracle Linux $releasever ($basearch)
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1 <= Enabled.
```

5. Install yum-plugin-versionlock.

```bash
$ sudo su -
# yum repolist
Loaded plugins: kernel-update-handler, security, ulninfo
ol6_UEKR4
ol6_UEKR4/primary
ol6_UEKR4
588/588
ol6_latest
ol6_latest/primary
ol6_latest
39825/39825
repo id repo name
status
ol6_UEKR4 Latest Unbreakable Enterprise Kernel Release 4 for Oracle Linux 6Server (x86_64) 588
```
[root@jigsosupg ~]# yum install yum-plugin-versionlock
Loaded plugins: kernel-update-handler, security, ulninfo
Setting up Install Process
Resolving Dependencies

Warning: RPMDB altered outside of yum.
** Found 4 pre-existing rpmdb problem(s), 'yum check' output follows:
oda-hw-mgmt-12.2.0.1.0_LINUX.X64_170614.TR1221-1.x86_64 has missing requires of /usr/local/bin/perl
oda-hw-mgmt-12.2.0.1.0_LINUX.X64_170614.TR1221-1.x86_64 has missing requires of libnfsodm12.so()(64bit)
oda-hw-mgmt-12.2.0.1.0_LINUX.X64_170614.TR1221-1.x86_64 has missing requires of perl(GridDefParams)
oda-hw-mgmt-12.2.0.1.0_LINUX.X64_170614.TR1221-1.x86_64 has missing requires of perl(s_GridSteps)
Installing : yum-plugin-versionlock-1.1.30-40.0.1.el6.noarch
1/1
Verifying : yum-plugin-versionlock-1.1.30-40.0.1.el6.noarch
1/1
Installed:
  yum-plugin-versionlock.noarch 0:1.1.30-40.0.1.el6

Complete!

**Note:**

Ignore the RPMDB warning messages that refer to oda-hw-mgmt.

6. Copy and overwrite the existing version lock file.

```bash
cp /etc/yum/pluginconf.d/versionlock.list /etc/yum/pluginconf.d/
    versionlock.list-`date +%Y%m%d`

cp /tmp/versionlock.list /etc/yum/pluginconf.d/versionlock.list
```

The initial version lock file should be empty. However, it is a good practice to back it up in case it is not and you need to refer to it later.

7. Run the update command.

```bash
# yum update
Loaded plugins: kernel-update-handler, security, ulninfo, versionlock
Setting up Update Process
---> Running transaction check

Uploading /tmp/tmp5HjrRUcmdline to http://169.254.0.3/cmdline

Error activating kernel/initrd/cmdline: 502 - <html>
<head><title>502 Bad Gateway</title></head>
<body bgcolor="white">
<center><h1>502 Bad Gateway</h1></center>
</body>
</html>

Note:

- Ignore the error activating message that results from running the update.
- An update will occur only if a versionlock file has a valid update available to apply to the DB system.

8. Restart the system.

   $ sudo su -
   # reboot

9. Run the following command to validate the update:

   # uname -r
   4.1.12-112.14.13

In this example, then new kernel version is 4.1.12-112.14.13.

For information about applying Oracle database patches to a DB system, see Patching a DB System on page 1407.
**Configuring a DB System**

This topic provides information to help you configure your DB system.

**Network Time Protocol**

Oracle recommends that you run a Network Time Protocol (NTP) daemon on your 1-node DB systems to keep system clocks stable during rebooting. If you need information about an NTP daemon, see Setting Up “NTP (Network Time Protocol) Server” in RHEL/CentOS 7.

Oracle recommends that you configure NTP on both nodes in a 2-node RAC DB system to synchronize time across the nodes. If you do not configure NTP, then Oracle Clusterware configures and uses the Cluster Time Synchronization Service (CTSS), and the cluster time might be out-of-sync with applications that use NTP for time synchronization.

For information about configuring NTP on a version 12c database, see Setting Network Time Protocol for Cluster Time Synchronization. For a version 11g database, see Network Time Protocol Setting.

**Transparent Data Encryption**

All user-created tablespaces in a DB system database are encrypted by default, using Transparent Data Encryption (TDE).

- For version 12c databases, if you don’t want your tablespaces encrypted, you can set the `ENCRYPT_NEW_TABLESPACES` database initialization parameter to `DDL`.
- On a 1- or 2-node RAC DB system, you can use the TDE Commands on page 1542 command to update the master encryption key for a database.
- You must create and activate a master encryption key for any PDBs that you create. After creating or plugging in a new PDB on a 1- or 2-node RAC DB System, use the `dbcli update-tdekey` command to create and activate a master encryption key for the PDB. Otherwise, you might encounter the error `ORA-28374: typed master key not found in wallet when attempting to create tablespaces in the PDB`. In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers. For more information, see “Overview of Managing a Multitenant Environment” in the Oracle Database Administrator’s Guide.
- For information about encryption on Exadata DB systems, see Using Tablespace Encryption in Exadata Cloud Service.
- For information on changing an existing TDE wallet password using the Oracle Cloud Infrastructure Console, see To manage administrator and TDE wallet passwords on page 1419.

For detailed information about database encryption, see the Oracle Database Security White Papers.

**Patching a DB System**

This topic describes the procedures to patch bare metal and virtual machine DB systems and database homes by using the Console, the API, or the database CLI (dbcli Integration Cloud). For information on patching or performing a version upgrade on databases within a bare metal or virtual machine DB system, see Patching a Database on page 1421.

**Note:**

This topic is not applicable to Exadata Cloud Service instances. For information and instructions on Exadata patching in Oracle Cloud Infrastructure, see the following topics:

- Patching an Exadata Cloud Service Instance on page 1284
- Patching an Exadata Cloud Service Instance Manually on page 1289.

For information about operating system updates, see OS Updates on page 1397.

Required IAM Policy

You must have the required type of access in a policy to use Oracle Cloud Infrastructure, whether you're using the Console or the REST API with an SDK, CLI, or other tool. When running a command, if you see an error message that says you don’t have permission or are unauthorized, contact your administrator. Confirm the type of access you’ve been granted, and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 enables the specified group to do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. Details about writing policies for databases are located in Details for the Database Service on page 2240.

About Patching DB Systems

Planning and Preparation

Patching a DB system requires a reboot, which can take several minutes. To minimize the impact on users, run the patch at a time when the system has the fewest users. To avoid system interruption, consider implementing a high availability strategy such as Oracle Data Guard. For more information, see Using Oracle Data Guard with the Database CLI on page 1469.

Oracle recommends that you back up your database and test the patch on a test system before you apply the patch. See Backing Up a Database on page 1435 for more information.

Always patch a DB system before you patch the databases within that system. The Console displays the latest DB system patch and the previous patch. You can use either of these patches, but we recommend using the latest patch when possible.

Patch Availability for Older Oracle Database Software Versions

For the Oracle Database and Oracle Grid Infrastructure major version releases available in Oracle Cloud Infrastructure, patches are provided for the current version plus the two most recent older versions (N through N - 2). For example, if an instance is using Oracle Database 19c, and the latest version of 19c offered is 19.8.0.0.0, patches are available for versions 19.8.0.0.0, 19.7.0.0 and 19.6.0.0.
Prerequisites

DB systems require access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. We recommend using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for DB Systems on page 1359. This topic describes the procedure to set up your VCN for the DB system, including the service gateway.
- https://cloud.oracle.com/infrastructure/storage/object-storage/faq. This topic explains which Swift endpoints to use.

**Important:**

In addition to the prerequisites listed in this section, ensure that the following conditions are met to avoid patching failures:

- The `/u01` directory on the database host file system has at least 15 GB of free space to execute patching processes.
- The Oracle Cluster ware is running on the DB system.
- All DB system nodes are running.

See Patching Failures on Bare Metal and Virtual Machine DB Systems on page 1659 for details on problems that can result from not following these guidelines.

Using the Console

You can use the Console to:

- View the patch history of a DB system or an individual database.
- Apply patches
- Monitor the status of an operation.

We recommend that you use the pre-check action to ensure that your DB system or database home has met the requirements for the patch you want to apply.

**To patch a DB system**

1. Open the navigation menu. Click > Database > Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   
   A list of DB systems is displayed.
3. Find the DB system that you plan to patch.
4. Click the DB system name to display details about it.
5. Click Resources > Patches.
6. Review the list of patches.
7. Click Actions (three dots) for the patch you are interested in, and then select one of the following actions:
   - Pre-check: Check for any prerequisites to ensure that the patch can be successfully applied.
   - Apply: Performs the pre-check, and then applies the patch.
8. Confirm when prompted.
9. In the list of patches, click the patch name to display its patch request. Then monitor the progress of the patch operation.

   While a patch is being applied, the patch status displays as Applying and the DB system status displays as Updating. If the operation completes successfully, the patch's status changes to Applied and the DB system's status changes to Available.

**To view the patch history of a DB system**

1. Open the navigation menu. Click > Database > Bare Metal, VM, and Exadata.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. To display details about the system you are interested in, locate the system name and click it.
4. Under **Resources**, click **Patch History**.
   The history of patch operations for that DB system is displayed.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs to manage patching DB systems:

- `ListDbSystemPatches`
- `ListDbSystemPatchHistoryEntries`
- `GetDbSystemPatch`
- `GetDbSystemPatchHistoryEntry`
- `UpdateDbSystem`

For the complete list of APIs for the Database service, see Database Service API.

**Using the Database CLI**

This topic explains how to use the command line interface on the DB system to patch a DB system. Patches are available from the Oracle Cloud Infrastructure Object Storage service. You use the `DBCLI` commands to download and apply patches to some or all components in your system.

**Prerequisites**

To connect to the DB system via SSH, you need the path to private key associated with the public key used when the DB system was launched.

You also need the public or private IP address of the DB system.

Use the private IP address to connect to the system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the Exadata system's public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console as follows:

- **Cloud VM clusters (new resource model):** On the Exadata VM Cluster Details page, click Virtual Machines in the **Resources** list.
- **DB systems:** On the DB System Details page, click **Nodes** in the **Resources** list.

The values are displayed in the **Public IP Address** and **Private IP Address & DNS Name** columns of the table displaying the **Virtual Machines** or **Nodes** of the Exadata Cloud Service instance.

To update the CLI with the latest commands

Update the CLI to ensure you have the latest patching commands (older DB systems might not include them).

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as `opc` and then sudo to the root user. Use `sudo su` – with a hyphen to invoke the root user’s profile, which will set the `PATH` to the `dbcli` directory (`/opt/oracle/dcs/bin`).

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```
3. Update the CLI by using the CLI Update Command on page 1483 command.

```bash
[root@dbsys ~]# cliadm update-dbcli
{
    "jobId" : "dc9ce73d-ed71-4473-99cd-9663b9d79bfd",
    "status" : "Created",
    "message" : "Dcs cli will be updated",
    "reports" : [ ],
    "createTimestamp" : "January 18, 2017 10:19:34 AM PST",
    "resourceList" : [ ],
    "description" : "dbcli patching",
    "updatedTime" : "January 18, 2017 10:19:34 AM PST"
}
```

4. Wait for the update job to complete successfully. Check the status of the job by using the Job Commands on page 1525 command.

```bash
[root@dbsys ~]# dbcli list-jobs
ID                                   Description    Created    Status
------------------------------------ -------------- --------- ----------
----------------------------------- ----------
dc9ce73d-ed71-4473-99cd-9663b9d79bfd dbcli patching January 18, 2017 10:19:34 AM PST    Success
```

To check for installed and available patches

1. SSH to the DB System.

```bash
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use sudo su - with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).

```bash
login as: opc
[opc@dbsys ~]$ sudo su -
```

3. Display the installed patch versions by using the Component Command on page 1504 command. If the Available Version column indicates a version number for a component, you should update the component.

```bash
[root@dbsys ~]# dbcli describe-component
System Version
-------------
12.1.2.10.0

Component Name        Installed Version    Available Version
--------------------- -------------------- --------------------
OAK                   12.1.2.10.0          up-to-date
GI                    12.1.0.2.161018      up-to-date
ORADB12102_HOME1      12.1.0.2.160719      12.1.0.2.161018
```

4. Display the latest patch versions available in Object Storage by using the Latestpatch Command on page 1527 command.

```bash
[root@dbsys ~]# dbcli describe-latestpatch
componentType   availableVersion
--------------- -------------------
gi               12.1.0.2.161018
db               11.2.0.4.161018
```
**To patch server components**

You can patch the Grid Infrastructure (GI) and storage management kit (OAK) server components.

1. SSH to the DB System.

   ```bash
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).

   ```bash
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Update the server components by using the Server Command on page 1540 command.

   ```bash
   [root@dbsys ~]$ dbcli update-server
   {
   "jobId" : "9a02d111-e902-4e94-bc6b-9b820ddf6ed8",
   "status" : "Created",
   "reports" : [ ],
   "createTimestamp" : "January 19, 2017 09:37:11 AM PST",
   "resourceList" : [ ],
   "description" : "Server Patching",
   "updatedTime" : "January 19, 2017 09:37:11 AM PST"
   }
   ```

   Note the job ID in the above example.

4. Check the job output by using the Job Commands on page 1525 command with the job ID.

   ```bash
   [root@dbsys ~]$ dbcli describe-job -i 9a02d111-e902-4e94-bc6b-9b820ddf6ed8
   ```

<table>
<thead>
<tr>

</tbody>
</table>
5. Verify that the server components were updated successfully by using the Component Command on page 1504 command. The Available Version column should indicate update-to-date.

To patch database home components

1. SSH to the DB System.

   \[ssh -i <private_key_path> opc@<db_system_ip_address>\]

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

   login as: opc

   [opc@dbsys ~]$ sudo su -

3. Get the ID of the database home by using the Dbhome Commands on page 1518 command.

   [root@dbsys ~]# dbcli list-dbhomes

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>DB Version</th>
<th>Home</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>---------------------</td>
<td>------------</td>
<td>------------------</td>
</tr>
<tr>
<td>---------</td>
<td>---------------------</td>
<td>------------</td>
<td>------------------</td>
</tr>
<tr>
<td>b727bf80-c99e-4846-ac1f-28a81a725df6</td>

<td>12.1.0.2</td>
<td>/u01/app/orauser/product/12.1.0.2/dbhome_1</td>
</tr>
</tbody>
</table>

4. Update the database home components by using the Dbhome Commands on page 1518 command and providing the ID from the previous step.

   [root@dbsys ~]# dbcli update-dbhome -i b727bf80-c99e-4846-ac1f-28a81a725df6

   \{"jobId": "31b38f67-f993-4f2e-b7eb-5bccda9901ae",
   "status": "Created",
   "message": null,
   "reports": [],
   "createTimestamp": "January 20, 2017 10:08:48 AM PST",
   "resourceList": [],
   "description": "DB Home Patching: Home Id is b727bf80-c99e-4846-ac1f-28a81a725df6",
   "updatedTime": "January 20, 2017 10:08:48 AM PST"
   \}

   Note the job ID in the above example.

5. Check the job output by using the Job Commands on page 1525 command with the job ID.

   [root@dbsys ~]# dbcli describe-job -i 31b38f67-f993-4f2e-b7eb-5bccda9901ae

   Job details

   ID: 31b38f67-f993-4f2e-b7eb-5bccda9901ae
   Description: DB Home Patching: Home Id is b727bf80-c99e-4846-ac1f-28a81a725df6
   Status: Success
   Created: January 20, 2017 10:08:48 AM PST
6. Verify that the database home components were updated successfully by using the Component Command on page 1504 command. The Available Version column should indicate update-to-date.

Creating Databases

**Note:**

- This topic applies only to bare metal DB systems. Virtual machine DB systems can only contain a single database, which is created when the DB system is provisioned.
- Database backups on virtual machine DB systems can only be restored to an existing bare metal DB system or a newly-created virtual machine or bare metal DB system.

When you launch a bare metal DB system, an initial database is created in that system. After provisioning your system, you can create additional databases at any time by using the Console or the API. The database edition will be the edition of the DB system in which the database is created, and each new database is created in a separate database home. You can create an empty database or reproduce a database by using a backup.

**Options for Creating a Database from a Backup**

When creating a new database using a backup stored in Object Storage as the source, you have the following backup source options:

- **Daily automatic backup.** Requires that you have automatic backups enabled and an available backup to use. If you are creating a database from an automatic backup, you can choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Oracle Cloud Infrastructure Managed Backup Features on page 1436.
- **On-demand full backup.** See To create an on-demand full backup of a database on page 1439 for information on creating an on-demand backup.
- **Standalone backup.** For more information, see Standalone Backups on page 1438.
- **Last archived redo log backup.** Requires that you have automatic backups enabled. This backup combines data from the most recent daily automatic backup and data from archived redo logs, and represents the most current backup available. The time of the last archived redo log backup is visible on the database details page in the Last Backup Time field.
• **Point-in-time out of place restore.** Specify a timestamp to create a new copy of the database that included data up to a specified point in time. The timestamp must be earlier or equal to the **Last Backup Time** time displayed on the database details page. Note the following limitations when performing a point-in-time out of place restore:
  - The timestamp must be within the recovery window of the database
  - The timestamp must be available within the database **incarnation** of the available automatic backups
  - The timestamp cannot fall within two overlapping database incarnations
  - The create database operation will fail if the database has undergone structural changes since the specified timestamp. Structural changes include operations such as creating or dropping a tablespace.
  - The create database operation cannot be started if another point-in-time database copy operation is in progress.

For information on configuring your DB system to back up to Object Storage, see **Backing Up a Database to Oracle Cloud Infrastructure Object Storage** on page 1435.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** you should work in.

For administrators: The policy in **Let database admins manage Oracle Cloud database systems** on page 2150 lets the specified group do everything with databases and related Database resources.

If you’re new to policies, see **Getting Started with Policies** on page 2135 and **Common Policies** on page 2142. If you want to dig deeper into writing policies for databases, see **Details for the Database Service** on page 2240.

**Using the Console**

*To create a new database in an existing DB system*

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• The database that you create will be the same edition as the initial database in your bare metal DB system.</td>
</tr>
<tr>
<td>• Virtual machine DB systems do not support the creation of additional databases after system provisioning.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   
   A list of DB systems is displayed.
3. In the list of DB systems, find the DB system in which you want to create the database, and then click its name to display details about it.
4. Click **Create Database**.
5. In the **Create Database** dialog, enter the following:

- **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
- **Database image:** Determines what Oracle Database version is used for the database. You can mix database versions on the DB system, but not editions. By default, the latest Oracle-published database software image is selected.

   Click **Change Database Image** to use an older Oracle-published image or a custom database software image that you have created in advance, then select an **Image Type**:

   - **Oracle Provided Database Software Images:** These images contain generally available versions of Oracle Database software.
   - **Custom Database Software Images:** These images are created by your organization and contain customized configurations of software updates and patches.

   After choosing a software image, click **Select** to return to the Create Database dialog.

- **PDB name:** (Optional) For version 12.1.0.2 and later, you can specify the name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).
- **Create administrator credentials:** A database administrator SYS user will be created with the password you supply.
  - **Username:** SYS
  - **Password:** Supply the password for this user. The password must meet the following criteria:
    - A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
  - **Confirm password:** Re-enter the SYS password you specified.
  - **Use the administrator password for the TDE wallet:** When this option checked, the password entered for the SYS user is also used for the TDE wallet. To set the TDE wallet password manually, uncheck this option and enter the TDE wallet password.
- **Select workload type:** Choose the workload type that best suits your application:
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  - **Enable automatic backup:** Check the check box to enable automatic incremental backups for this database. If you are creating a database in a security zone compartment, you must enable automatic backups.
  - **Backup Retention Period:** If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See **Backup Scheduling** for more information.

6. Click **Show Advanced Options** to specify the following options for the database:

- **Character set:** The character set for the database. The default is AL32UTF8.
- **National character set:** The national character set for the database. The default is AL16UTF16.
- **Tags:** If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Database**.

When the database creation is complete, the status changes from Provisioning to Available.

**To create a database from a backup in an existing DB system**

<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine DB systems do not support the creation of additional databases after system provisioning. To create a new virtual machine DB system from a backup, see <strong>To create a DB system from a backup</strong> on page 1377.</td>
</tr>
</tbody>
</table>

You can create a new database from a database backup. See **Options for Creating a Database from a Backup** on page 1414 for details on backup source options.

Before you begin, note the following:

- When you create a database from a backup, you can choose a different DB system and compartment. However, the availability domain will be the same as where the source database is hosted.

<table>
<thead>
<tr>
<th><strong>Tip:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You can use the <strong>GetBackup</strong> API to obtain information about the availability domain of the backup.</td>
</tr>
</tbody>
</table>

- The DB system you specify must support the same type as the system from which the backup was taken. For example, if the backup is from a single-node database, then the target DB system must be a single-node shape.

- The version of the target DB system must be the same or higher than the version of the backup.

- If the backup being used to create a database is in a security zone compartment, the database cannot be created in a compartment that is not in a security zone. See the **Security Zone Policies** topic for a full list of policies that affect Database service resources.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.

   A list of DB systems is displayed.
3. Navigate to the backup or standalone backup you want to use to create the new DB system:

<table>
<thead>
<tr>
<th><strong>Tip:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are creating a database from an automatic backup, you may choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic...</td>
</tr>
</tbody>
</table>
To select a daily automatic backup or on-demand full backup as the source

a. Click the DB system name that contains the specific database to display the DB System Details page.
b. From the Databases list, click the database name associated with the backup you want to use.
c. Find your desired backup in the Backups list. If you don't see the backups list on the database details page, click Backups in the Resources menu.
d. Click the Actions icon (three dots) for the backup, and then click Create Database.

To select the last archived redo log automatic backup as the source

a. Find the DB system where the database is located, and click the system name to display details about it.
b. Find the database associated with the backup you wish to use, and click its name to display details about it.
c. On the database details page, click Create Database from Last Backup.
d. In the Create Database from Backup dialog, select Create database from last backup.

To specify a timestamp for a point-in-time copy of the source

a. Click the DB system name that contains the specific database to display the DB System Details page.
b. From the Databases list, click the database name associated with the backup data you want to use as the source for the initial database in your new DB system.
c. On the database details page, click Create Database from Last Backup.
d. In the Create Database from Backup dialog, select Create database from specified timestamp.

To select a standalone backup as the source

a. Click Standalone Backups under Bare Metal, VM, and Exadata.
b. In the list of standalone backups, find the backup you want to use to create the database.
c. Click the Actions icon (three dots) for the backup you are interested in, and then click Create Database.

4. In the Create Database from Backup dialog, enter the following:

- **DB System:** The DB system in which you want to create the database. You must have the Use Existing DB System radio button selected to see the drop-down list of DB system choices.

  [Note:
  You cannot create a new database in the same DB system in which the database used to create the backup resides.]

- **Database Name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.

- **Database Admin Password:**
  A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

  A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm Database Admin Password:** Re-enter the Database admin password you specified.

- **Password for Transparent Data Encryption (TDE) Wallet or RMAN Encryption:**
  Enter either the TDE wallet password or the RMAN encryption password for the backup, whichever is applicable. The TDE wallet password is the SYS password provided when the database was created by using the Oracle Cloud Infrastructure Console, API, or CLI. The RMAN encryption password is typically required instead if the password was subsequently changed manually.

5. Click Create Database.
Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create databases on bare metal DB systems.

Database homes:
- ListDbHomes
- GetDbHome
- CreateDbHome
- DeleteDbHome

Databases:
- CreateDatabase

For the complete list of APIs for the Database service, see Database Service API.

Managing Databases

This topic describes the following administrative tasks for databases in bare metal and virtual machine DB systems:

- Updating the administrator and TDE wallet passwords of a database in a bare metal or virtual machine DB system
- Deleting a database in a DB system (bare metal systems only)

Note:

Virtual machine DB systems can only contain a single database, which is created when the DB system is provisioned. To delete a database in a virtual machine DB system, terminate the virtual machine DB system resource.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. If you want to dig deeper into writing policies for databases, see Details for the Database Service on page 2240.

Using the Console

To manage administrator and TDE wallet passwords

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
3. Navigate to the database:
   a. Click the DB system name that contains the specific database to display the DB System Details page.
   b. From the Databases list, click the database name you want to administer.
4. On the Database Details page, click More Actions, then Manage Passwords.
5. In the Manage Passwords dialog click Update Administrator Password or Update TDE Wallet Password, depending on which password you want to update.
6. Enter the new password:
   - For the administrator password, enter the new password in both the New administrator password and Confirm administrator password fields.
   - For the TDE wallet password, enter the current wallet password in the Enter existing TDE wallet password field, then enter the new password in both the New TDE wallet password and the Confirm TDE wallet password fields.

7. Click **Apply** to update your chosen password.

**To terminate a database**

When terminating a database in a bare metal DB system, you will be given the chance to back up the database prior to terminating it. This creates a standalone backup that can be used to create a database later. Oracle recommends that you create this final backup for any production (non-test) database.

![](Note)

Terminating a database removes all automatic incremental backups of the database from Oracle Cloud Infrastructure Object Storage. However, all full backups that were created on demand, including your final backup, will persist as standalone backups.

You cannot terminate a database that is assuming the primary role in a Data Guard association. To terminate it, you can switch it over to the standby role.

For information on terminating a database contained in a virtual machine DB system, see To terminate a DB system on page 1386. For virtual machine systems, a database can only be terminated as part of the terminate DB system operation.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**. A list of DB systems is displayed.
3. In the list of DB systems, find the DB system that contains the database you want to terminate, and then click its name to display details about it.
4. In the list of databases, find the database you want to terminate, and then click its name to display details about it.
5. Click **Actions**, and then click **Terminate**.
6. In the confirmation dialog, indicate whether you want to back up the database before terminating it, and type the name of the database to confirm the termination.
7. Click **Terminate Database**. The database's status indicates Terminating.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225. Use these API operations to manage databases.

Database homes:
- ListDbHomes
- GetDbHome
- UpdateDbHome
- DeleteDbHome

Databases:
- ListDatabases
- GetDatabase
- UpdateDatabase
Note:

See the DeleteDbHome API for information on deleting databases on bare metal DB systems. See the TerminateDbSystem for information on deleting virtual machine DB systems, including the database contained in the system.

For the complete list of APIs for the Database service, see Database Service API.

Additional Information

See the following topics for additional information on administering database resources in Oracle Cloud Infrastructure:

- Backing Up a Database on page 1435
- Recovering a Database on page 1446
- Patching a DB System on page 1407
- To patch a database on page 1422
- To view the patch history of a database on page 1422
- Using the Console to Clone a Virtual Machine DB System on page 1389

Patching a Database

This topic describes the procedures to apply patches to databases in bare metal and virtual machine DB systems by using the Console and the API. For information on patching DB systems and to see a list of currently available database patches, see Patching a DB System on page 1407.

Note:

This topic is not applicable to Exadata Cloud Service instances. For information and instructions on Exadata patching in Oracle Cloud Infrastructure, see the following topics:

- Patching an Exadata Cloud Service Instance on page 1284
- Patching an Exadata Cloud Service Instance Manually on page 1289.

Required IAM Policy

You must have the required type of access in a policy to use Oracle Cloud Infrastructure, whether you're using the Console or the REST API with an SDK, CLI, or other tool. When running a command, if you see an error message that says you don’t have permission or are unauthorized, contact your administrator. Confirm the type of access you’ve been granted, and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 enables the specified group to do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. Details about writing policies for databases are located in Details for the Database Service on page 2240.

About Patching Databases

For database patching, always patch a DB system before you patch the databases within that system. The Console displays the latest DB system patch and the previous patch. You can use either of these patches, but we recommend using the latest patch when possible. See Patching a DB System on page 1407 for more information.

You can also patch your database using a custom database software image. See Oracle Database Software Images on page 1567 for more information on creating and working with software images.

For a list of currently available database patches, see Currently Available Patches on page 1408.

Applying Interim Patches Using a Database Software Image

You can use custom database software images to easily apply interim (one-off) patches to virtual machine and bare metal DB systems in the Console. See the following topics for more information:
• Oracle Database Software Images on page 1567: An overview of the database software image feature.
• To create a database software image on page 1568 Provides information on how to create a custom image that includes one or more interim patches.
• To patch a database on page 1422: Once you have created a database software image with your interim patches, follow the instructions in this topic to patch using the image.

Using the Console

To patch a database

1. Open the navigation menu. Click > Database > Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database on which you want to perform the patch operation, and click its name to display details about it.
5. Under Resources, click Updates.
   The Oracle Provided Database Software Images tab displays generally-available Oracle Database software images that you can use to patch your database. Oracle images that can be used for patching have the update Type of "Patch".
   The Custom Database Software Images tab allows you to select a database software image that you have created in advance. Use the Select a Compartment selector to specify the compartment that contains the database software image. Custom images that can be used for patching have the update Type of "Patch".
6. Review the list of database software image s that you can use to patch your database. We recommend using the latest database software image patch when possible.
7. Click Actions (three dots) for the patch you are interested in, and then select one of the following actions:
   • Precheck: Check for any prerequisites to ensure that the patch can be successfully applied.
   • Apply: Performs the precheck, and then applies the patch.
8. Confirm when prompted.
9. In the list of patches, click the patch name to display its patch request and monitor the progress of the patch operation.
   While a patch is being applied, the patch's status displays as Applying and the database's status displays as Updating. If the operation completes successfully, the patch's status changes to Applied and the database's status changes to Available.

Viewing Patch History

Each patch history entry represents an attempted patch operation and indicates whether the operation was successful or failed. You can retry a failed patch operation. Repeating an operation results in a new patch history entry.

Patch history views in the Console do not show patches that were applied by using command line tools like dbcli or the Patch utility.

To view the patch history of a database

1. Open the navigation menu. Click > Database > Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of DB systems is displayed.
3. To display details about the DB system where the database is located, and click the system name.
   A list of databases is displayed.
4. To display details about the database you are interested in, locate the system name and click it.
5. Under **Resources**, click **Update History**.

   The history of patch and upgrade operations for that database is displayed.

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use the following APIs to manage database patching.

- ListDbHomePatches
- ListDbHomePatchHistoryEntries
- GetDbHomePatch
- GetDbHomePatchHistoryEntry
- UpdateDbHome
- UpdateDatabase

For the complete list of APIs for the Database service, see **Database Service API**.

### Applying Interim Patches Manually

**Note:**

This topic applies only to database homes in 1-node and 2-node RAC DB systems.

To apply an interim patch (previously known as a “one-off” patch) to fix a specific defect, follow the procedure in this section. Use the Opatch utility to apply an interim patch to a database home.

In the procedure example, the database home directory is `/u02/app/oracle/product/12.1.0.2/dbhome_1` and the patch number is `26543344`.

**To apply an interim patch to a database home**

1. Obtain the applicable interim patch from My Oracle Support.
2. Review the information in the patch README.txt file. This file might contain additional and/or custom instructions to follow to apply the patch successfully.
3. Use SCP or SFTP to place the patch on your target database.
4. Shut down each database that is running in the database home.

   ```bash
   srvctl stop database -db <db name> -stopoption immediate -verbose
   ```

5. Set the Oracle home environment variable to point to the target Oracle home.

   ```bash
   sudo su - oracle
   export ORACLE_HOME=/u02/app/oracle/product/12.1.0.2/dbhome_1
   ```

6. Change to the directory where you placed the patch, and unzip the patch.

   ```bash
   cd <work_dir_where_opatch_is_stored>
   unzip p26543344_122010_Linux-x86-64.zip
   ```

7. Change to the directory with the unzipped patch, and check for conflicts.

   ```bash
   cd 26543344
   $ORACLE_HOME/OPatch/opatch prereq CheckConflictAgainstOHWithDetail -ph ./
   ```

8. Apply the patch.

   ```bash
   $ORACLE_HOME/OPatch/opatch apply
   ```
9. Verify that the patch was applied successfully.

   `$ORACLE_HOME/OPatch/opatch lsinventory -detail -oh $ORACLE_HOME`

10. If the database home contains databases, restart them.

    `$ORACLE_HOME/bin/srvctl start database -db <db_name>`

Otherwise, run the following command as root user.

    `# /u01/app/<db_version>/grid/bin/setasmgidwrap o=/u01/app/oracle/product/<db_version>/dbhome_1/bin/oracle`

11. If the readme indicates that the patch has a sqlpatch component, run the datapatch command against each database.

    Before you run datapatch, ensure that all pluggable databases (PDBs) are open. To open a PDB, you can use SQL*Plus to execute `ALTER PLUGGABLE DATABASE <pdb_name> OPEN READ WRITE;` against the PDB.

    `$ORACLE_HOME/OPatch/datapatch`

### Upgrading a Database

This topic describes the procedures to upgrade databases in bare metal and virtual machine DB systems by using the Console and the API. Currently upgrades to Oracle Database 19c (Long Term Release) are available.

**Note:**
This topic is not applicable to Exadata Cloud Service instances.

**Required IAM Policy**

You must have the required type of access in a policy to use Oracle Cloud Infrastructure, whether you're using the Console or the REST API with an SDK, CLI, or other tool. When running a command, if you see an error message that says you don’t have permission or are unauthorized, contact your administrator. Confirm the type of access you’ve been granted, and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud database systems on page 2150 enables the specified group to do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. Details about writing policies for databases are located in Details for the Database Service on page 2240.

**Prerequisites**

The following are required in order to upgrade a database on a bare metal or virtual machine DB system:

- The DB system must use Oracle Linux 7 (OL7)
- If your DB System uses ASM storage management software, the system must use Oracle Grid Infrastructure 19c

For databases on DB systems not meeting the minimum software version requirements, you can upgrade only after using the backup and restore operations to restore the database to a DB system that uses OL7 and version 19c Grid Infrastructure. See the following topics for more information on restoring a database to another DB system by using an on-demand full backup:

- Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435
- To create an on-demand full backup of a database on page 1439
- To create a new database in an existing DB system on page 1415
- To create a DB system from a backup on page 1377

Your Oracle database must be configured with the following settings in order to upgrade:
• The database must be in archivelog mode
• The database must have flashback enabled

See the Oracle Database documentation for your database's release version to learn more about these settings.

About Upgrading a Database
For database software version upgrades, note the following:

• Database upgrades involve some database downtime. Keep this in mind when scheduling your upgrade.
• Oracle recommends that you back up your database and test the new software version on a test system before you upgrade. See Backing Up a Database on page 1435 for information on creating an on-demand manual backup.
• Oracle recommends running an upgrade precheck operation for your database prior to attempting an upgrade so that you can discover any issues that need mitigation prior to the time you plan to perform the upgrade.
• If your databases uses Data Guard, you will need to disable or remove the Data Guard association prior to upgrading.
• An upgrade operation cannot take place while an automatic backup operation is underway. Before upgrading, Oracle recommends disabling automatic backups and performing a manual backup. See To configure automatic backups for a database on page 1438 and To create an on-demand full backup of a database on page 1439 for more information.
• After upgrading, you cannot use automatic backups taken prior to the upgrade to restore the database to an earlier point in time.
• If you are upgrading an database that uses version 11.2 software, the resulting version 19c database will be a non-container database.
• The upgrade operation cannot be performed using the dbcli utility.

How the Upgrade Operation Is Performed by the Database Service
During the upgrade process, the Database service does the following:

• Executes an automatic precheck. This allows the system to identify issues needing mitigation and to stop the upgrade operation.
• Sets a guaranteed restore point, enabling it to perform a flashback in the event of an upgrade failure.
• Creates a new Oracle Database Home based on the specified Oracle-published or custom database software image.
• Runs the Database Upgrade Assistant (DBUA) software to perform the upgrade.

Rolling Back an Unsuccessful Upgrade (Oracle Database Enterprise Editions Only)
If your upgrade does not complete successfully on a system using one of the Enterprise software editions, you have the option of performing a rollback. A rollback resets your database to the state prior to the upgrade. All changes to the database made during and after the upgrade will be lost. The rollback option is provided in a banner message displayed on the database details page of a database following an unsuccessful upgrade operation. See To roll back a failed database upgrade on page 1427 for more information.

After Your Upgrade Is Complete
After a successful upgrade, note the following:

• Oracle recommends that you remove the old Oracle Database Home using the dbcli utility. See Dbhome Commands on page 1518 in the dbcli reference for more information.
• Check that automatic backups are enabled for the database if you disabled them prior to upgrading. See To configure automatic backups for a database on page 1438 for more information.
• Edit the Oracle Database COMPATIBLE parameter to reflect the new Oracle Database software version. See What Is Oracle Database Compatibility? for more information.
• On virtual machine DB Systems, ensure that the .bashrc file in the home directory of the Oracle User has been updated to point to the 19c Database Home.
Using the Console

You can use the Console to:

- Upgrade your database
- View the update history of your database
- Roll back an unsuccessful upgrade

Oracle recommends that you use the precheck action to ensure that your database has met the requirements for the upgrade operation.

To upgrade a database

1. Open the navigation menu. Select Bare Metal, VM, and Exadata, then select DB Systems.
2. Choose your Compartment.
   - A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   - A list of databases is displayed.
4. Find the database you want to upgrade, and click its name to display details about it.
5. Under Resources, click Updates.
   - The Oracle Provided Database Software Images tab displays generally-available Oracle Database software images that you can use to upgrade your database to a higher major release version. Oracle images that can be used for upgrading have the update Type of "Upgrade". Note that only the most recent patch level of Oracle Database 19c and the next-most recent patch level can be used for the upgrade operation.
   - The Custom Database Software Images tab allows you to select a database software image that you have created in advance. Use the Select a Compartment selector to specify the compartment that contains the database software image. Custom images that can be used for upgrading have the update Type of "Upgrade". Note that only the most recent patch level of Oracle Database 19c and the next-most recent patch level can be used for the upgrade operation.
6. Review the list of Oracle provided or custom database software images that you can use to upgrade your database, and identify an image you want to use for the upgrade.
7. Click Actions (three dots) on the row of the image you want to use for the upgrade, and then select one of the following actions:
   - Precheck: Check for any prerequisites to ensure that the upgrade can be successfully applied. Oracle recommends that you manually perform a precheck operation prior to upgrading to ensure that your database is ready to be upgraded.
   - Upgrade: Applies the selected database upgrade.
8. Confirm when prompted.
9. While an upgrade is being applied, the database’s status displays as Upgrading. If the operation completes successfully, the database’s status changes to Available.

To view the upgrade history of a database

1. Open the navigation menu. Select Bare Metal, VM, and Exadata, then select DB Systems.
2. Choose your Compartment.
   - A list of DB systems is displayed.
3. To display details about the DB system where the database is located, and click the system name.
   - A list of databases is displayed.
4. To display details about the database you are interested in, locate the system name and click it.
5. Under Resources, click Update History.
   - The history of patch and upgrade operations for that database is displayed.
To roll back a failed database upgrade

**Note:**

The upgrade rollback operation is only available for Enterprise software edition databases that were unsuccessfully upgraded and are currently in the "Failed" lifecycle state.

1. Open the navigation menu. Select **Bare Metal, VM, and Exadata**, then select **DB Systems**.
2. Choose your **Compartment**.
   
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   
   A list of databases is displayed.
4. Find the database that was unsuccessfully upgraded, and click its name to display details about it. The database should display a banner at the top of the details page that includes a **Rollback** button.
5. Click **Rollback**. In the **Confirm rollback** dialog, confirm that you want to initiate a rollback to the previous Oracle Database version by clicking **Rollback**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs to manage database upgrades:

- ListDatabaseUpgradeHistoryEntries
- UpgradeDatabase

For the complete list of APIs for the Database service, see Database Service API.

**Note:**

When using the UpgradeDatabase API to upgrade a database on a virtual machine or bare metal DB system, you must specify either DB_VERSION or DB_SOFTWARE_IMAGE as the upgrade source.

**Monitoring a Database**

This topic explains how to set up an:

- Enterprise Manager Express console to monitor a version 12.1.0.2 or later database
- Enterprise Manager Database Control console to monitor a version 11.2.0.4 database

Each console is a web-based database management tool inside the Oracle database. You can use the console to perform basic administrative tasks such as managing user security, memory, and storage, and view performance information.

**Required IAM Policy**

Some of the procedures below require permission to create or update security lists. For more information about security list policies, see Security Lists on page 2850.

**Monitoring a Database with Enterprise Manager Express**

On 1- and 2-node RAC DB Systems, by default, the EM Express console is not enabled on version 18.1.0.0, 12.2.0.1, and 12.1.0.2 databases. You can enable it for an existing database as described below, or you can enable it when you create a database by using the Database Commands on page 1505 command with the -co parameter.

You must also update the security list and iptables for the DB system as described later in this topic.

When you enable the console, you’ll set the port for the console. The procedure below uses port 5500, but each additional console enabled on the same DB system will have a different port.
To enable the EM Express console and determine its port number

1. SSH to the DB system, log in as opc, sudo to the oracle user, and log in to the database as SYS.

   ```
sudo su - oracle
. oraenv
<provide the database SID at the prompt>
sqlplus / as sysdba
   ```

2. Do one of the following:

   - To enable the console and set its port, use the following command.

     ```
     exec DBMS_XDB_CONFIG.SETHTTPSPORT(<port>);
     ```

     For example:

     ```
     SQL> exec DBMS_XDB_CONFIG.SETHTTPSPORT(5500);
     PL/SQL procedure successfully completed.
     ```

   - To determine the port for a previously enabled console, use the following command.

     ```
     select dbms_xdb_config.getHttpsPort() from dual;
     ```

     For example:

     ```
     SQL> select dbms_xdb_config.getHttpsPort() from dual;
     DBMS_XDB_CONFIG.GETHTTPSPORT()
     -----------------------------
     5500
     ```

3. Return to the operating system by typing `exit` and then confirm that the listener is listening on the port:

   ```
   lsnrctl status | grep HTTP
   ```

   (DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)(HOST=xxx.us.oracle.com)(PORT=5500))
   (Security=(my_wallet_directory=/u01/app/oracle/admin/prod/xdb_wallet))
   (Presentation=HTTP) (Session=RAW))

4. If you're using a 2-node RAC DB system, see To set the required permissions on a 2-node RAC DB system on page 1428.

5. Open the console's port as described in Opening Ports on the DB System on page 1433.

6. Update the security list for the console's port as described in Updating the Security List for the DB System on page 1434.

To set the required permissions on a 2-node RAC DB system

If you're using a 2-node RAC DB system, you'll need to add read permissions for the asmadmin group on the wallet directory on both nodes in the system.

1. SSH to one of the nodes in the DB system, log in as opc, sudo to the grid user.

   ```
   [opc@dbsysHost1 ~]$ sudo su - grid
   [grid@dbsysHost1 ~]$
   ```

   ORACLE_SID = [+ASM1] ?
   The Oracle base has been set to /u01/app/grid

2. Get the location of the wallet directory, shown in red below in the command output.

   ```
   [grid@dbsysHost1 ~]$ lsnrctl status | grep xdb_wallet
   ```
3. Return to the opc user, switch to the oracle user, and change to the wallet directory.

```
[opc@dbsysHost1 ~]$ sudo su - oracle
[oracle@dbsysHost1 ~]$ cd /u01/app/oracle/admin/dbsys12_phx3wm/xdb_wallet
```

4. List the directory contents and note the permissions.

```
[oracle@dbsysHost1 xdb_wallet]$ ls -ltr
total 8
-rw------- 1 oracle asadmin 3881 Apr  6 16:32 ewallet.p12
-rw------- 1 oracle asadmin 3926 Apr  6 16:32 cwallet.sso
```

5. Change the permissions:

```
[oracle@dbsysHost1 xdb_wallet]$ chmod 640 /u01/app/oracle/admin/dbsys12_phx3wm/xdb_wallet/*
```

6. Verify that read permissions were added.

```
[oracle@dbsysHost1 xdb_wallet]$ ls -ltr
total 8
-rw-r----- 1 oracle asadmin 3881 Apr  6 16:32 ewallet.p12
-rw-r----- 1 oracle asadmin 3926 Apr  6 16:32 cwallet.sso
```

7. Important! Repeat the steps above on the other node in the cluster.

To connect to the EM Express console

After you’ve enabled the console and opened its port in the security list and iptables, you can connect as follows:

1. From a web browser, connect to the console using the following URL format:

```
https://<ip_address>[:port]/em
```

For example, https://129.145.0.164:5500/em

Use the DB system’s private or public IP address depending on your network configuration.

Use the private IP address to connect to the system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the Exadata system’s public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console as follows:

- **Cloud VM clusters (new resource model)**: On the **Exadata VM Cluster Details** page, click **Virtual Machines** in the Resources list.
- **DB systems**: On the **DB System Details** page, click **Nodes** in the Resources list.

The values are displayed in the **Public IP Address** and **Private IP Address & DNS Name** columns of the table displaying the **Virtual Machines** or **Nodes** of the Exadata Cloud Service instance.
2. A login page is displayed and you can log in with any valid database credentials.

The Database Home page is displayed.

To learn more about EM Express, see Introduction to Oracle Enterprise Manager Database Express.

**Note:**

If you're using a 1-node DB system, and you are unable to connect to the EM Express console, see Database Known Issues.

**Monitoring a Database with Enterprise Manager Database Control**

By default, the Enterprise Manager Database Control console is not enabled on version 11.2.0.4 databases. You can enable the console:

- when you create a database by using the Database Commands on page 1505 with the `–co` parameter
- for an existing database as described here.

Port 1158 is the default port used for the first console enabled on the DB system, but each additional console enabled on the DB system will have a different port.
Note:
For a version 11.2.0.4 database on a 2-node RAC DB system, see To enable the console for a version 11.2.0.4 database on a multi-node DB system on page 1432.

To determine the port for the Enterprise Manager Database Control console

1. SSH to the DB system, log in as opc, and sudo to the oracle user.
   
   ```
   sudo su - oracle
   . oraenv
   <provide the database SID at the prompt>
   ```

2. Use the following command to get the port number.
   
   ```
   emctl status dbconsole
   ```

   The port is in the URL, as shown in the following example:

   ```
   [oracle@dbsys ~]$ emctl status dbconsole
   Oracle Enterprise Manager 11g Database Control Release 11.2.0.4.0
   Copyright (c) 1996, 2013 Oracle Corporation.  All rights reserved.
   https://dbprod:1158/em/console/aboutApplication
   Oracle Enterprise Manager 11g is running.
   _____________________________________________________________________
   Logs are generated in directory /u01/app/oracle/product/11.2.0.4/dbhome_2/
   dbprod_db11/sysman/log
   ```

3. Open the console's port as described in Opening Ports on the DB System on page 1433.
4. Update the security list for the console's port as described in Updating the Security List for the DB System on page 1434.

To connect to the Enterprise Manager Database Control console

After you've enabled the console and opened its port in the security list and iptables, you can connect as follows:

1. From a web browser, connect to the console using the following URL format:
   
   ```
   https://<ip_address>:<port>/em
   ```

   For example, https://129.145.0.164:1158/em

   Use the DB system's private or public IP address depending on your network configuration.

   Use the private IP address to connect to the system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the Exadata system’s public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console as follows:

   - **Cloud VM clusters (new resource model):** On the Exadata VM Cluster Details page, click Virtual Machines in the Resources list.
   - **DB systems:** On the DB System Details page, click Nodes in the Resources list.

   The values are displayed in the Public IP Address and Private IP Address & DNS Name columns of the table displaying the Virtual Machines or Nodes of the Exadata Cloud Service instance.

2. A login page will be displayed and you can log in with any valid database credentials.

To learn more about Enterprise Manager Database Control, see Introduction to Oracle Enterprise Manager Database Control.
To enable the console for a version 11.2.0.4 database on a multi-node DB system

A few extra steps are required to enable the console for a version 11.2.0.4 database on a multi-node DB system.

Configure SSH Equivalency Between the Two Nodes

You'll create SSH keys on each node and copy the key to the other node, so that each node has the keys for both nodes. The following procedure uses the sample names node1 and node2.

1. SSH to node1, log in as opc, and sudo to the oracle user.

   ```
   sudo su - oracle
   ```

2. Create a directory called .ssh, set its permissions, create an RSA key, and add the public key to the authorized_keys file.

   ```
   mkdir .ssh
   chmod 755 .ssh
   ssh-keygen -t rsa
   cat id_rsa.pub > authorized_keys
   ```

3. Repeat the previous steps on the other node in the cluster.

4. On each node, add the id_rsa.pub key for the other node to the authorized_keys file.

   When you're done, you should see both keys in authorized_keys on each node.

5. On node1, create the known_hosts file by doing the following:

   - SSH to node1 and reply yes to the authentication prompt.
   - SSH to node2 and reply yes to the authentication prompt.

6. On node2, create the known_hosts file by doing the following:

   - SSH to node2 and reply yes to the authentication prompt.
   - SSH to node1 and reply yes to the authentication prompt.

7. On node1, verify that SSH equivalency is now configured by using the following Cluster Verification Utility (CVU) command.

   ```
   cluvfy stage -pre crsinst -n all -verbose
   ```

Configure the Console

1. On node1, create a file called emca.rsp with the following entries.

   ```
   DB_UNIQUE_NAME=<pdb_unique_name>
   SERVICE_NAME=<db_unique_name>.<db_domain>
   PORT=<scan listener port>
   LISTENER_OH=$GI_HOME
   SYS_PWD=<admin password>
   DBSNMP_PWD=<admin password>
   SYSMAN_PWD=<admin password>
   CLUSTER_NAME=<cluster name>  
   ASM_OH=$GI_HOME
   ASM_SID=+ASM1
   ASM_PORT=<asm listener port>
   ASM_USER_NAME=ASMSNMP
   ASM_USER_PWD=<admin password>
   ```

2. On node1, run Enterprise Manager Configuration Assistant (EMCA) using the emca.rsp file as input.

   ```
   $ORACLE_HOME/bin/emca -config dbcontrol db -repos create -cluster -silent -respFile <location of response file above>
   ```
3. On node2, configure the console so the agent in node1 reports to the console in node1, and the agent in node2 reports to the console in node2.

```
$ORACLE_HOME/bin/emca -reconfig dbcontrol -silent -cluster -EM_NODE <node2 host> -EM_NODE_LIST <node2 host> -DB_UNIQUE_NAME <db_unique_name> -SERVICE_NAME <db_unique_name>.<db_domain>
```

4. On each node, verify that console is working properly.

```
$ export ORACLE_UNQNAME=<db_unique_name>
$ emctl status agent
```

Update iptables and Security List

1. On each node, edit iptables to open the console's port as described in Opening Ports on the DB System on page 1433.

2. Update the security list for the console's port as described in Updating the Security List for the DB System on page 1434.

Opening Ports on the DB System

Open the following ports as needed on the DB system:

- 6200 - For Oracle Notification Service (ONS).
- 5500 - For EM Express. 5500 is the default port, but each additional EM Express console enabled on the DB system will have a different port. If you're not sure which port to open for a particular console, see Monitoring a Database with Enterprise Manager Express on page 1427.
- 1158 - For Enterprise Manager Database Control. 1158 is the default port, but each additional console enabled on the DB system will have a different port. If you're not sure which port to open for a particular console, see Monitoring a Database with Enterprise Manager Database Control on page 1430.

For important information about critical firewall rules, see Essential Firewall Rules on page 1397.
To open ports on the DB system

1. SSH to the DB System.
   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user.
   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Save a copy of iptables as a backup.
   ```
   [root@dbsys ~]# iptables-save > /tmp/iptables.orig
   ```
   (If necessary, you can restore the original file by using the command `iptables-restore < /tmp/iptables.orig`.)

4. Dynamically add a rule to iptables to allow inbound traffic on the console port, as shown in the following sample. Change the port number and comment as needed.
   ```
   [root@dbsys ~]# iptables -I INPUT 8 -p tcp -m state --state NEW -m tcp --dport 5500 -j ACCEPT -m comment --comment "Required for EM Express."
   ```

5. Make sure the rule was added.
   ```
   [root@dbsys ~]# service iptables status
   ```

6. Save the updated file to `/etc/sysconfig/iptables`.
   ```
   [root@dbsys ~]# /sbin/service iptables save
   ```
   The change takes effect immediately and will remain in effect when the node is rebooted.

7. Update the DB system’s security list as described in Updating the Security List for the DB System on page 1434.

Updating the Security List for the DB System

Review the list of ports in Opening Ports on the DB System on page 1433 and for every port you open in iptables, update the security list used for the DB system, or create a new security list.

Note that port 1521 for the Oracle default listener is included in iptables, but should also be added to the security list.

To update an existing security list

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of DB systems is displayed.
3. Locate the DB system in the list.
4. Note the DB system’s Subnet name and click its Virtual Cloud Network.
5. Locate the subnet in the list, and then click its security list under Security Lists.
6. Click Edit All Rules and add an ingress rule with source type = CIDR, source CIDR=<source CIDR>, protocol=TCP, and port=<port number or port range>.
   The source CIDR should be the CIDR block that includes the ports you open for the client connection.

For detailed information about creating or updating a security list, see Security Lists on page 2850.
Database

Backing Up a Database

Backing up your DB system is a key aspect of any Oracle database environment. You can store backups in the cloud or in local storage. Each backup destination has advantages, disadvantages, and requirements that you should consider, as described below.

Object Storage (Recommended)
• Backups are stored in the Oracle Cloud Infrastructure Object Storage.
• Durability: High
• Availability: High
• Back Up and Recovery Rate: Medium
• Advantages: High durability, performance, and availability.

Local Storage
• Backups are stored locally in the Fast Recovery Area of the DB System.
• Durability: Low
• Availability: Medium
• Back Up and Recovery Rate: High
• Advantages: Optimized back up and fast point-in-time recovery.
• Disadvantages: If the DB System becomes unavailable, the backup is also unavailable.

Currently, Oracle Cloud Infrastructure does not provide the ability to attach block storage volumes to a DB System, so you cannot back up to network attached volumes.

For 1- and 2-node RAC DB Systems, see:
• Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435
• Backing Up a Database to Local Storage Using the Database CLI on page 1443

Backing Up a Database to Oracle Cloud Infrastructure Object Storage

Note:
This topic is not applicable to Exadata DB systems. For Exadata DB systems, see Managing Exadata Database Backups on page 1320.

This topic explains how to work with backups managed by Oracle Cloud Infrastructure. You do this by using the Console or the API. (For unmanaged backups, you can use RMAN or dbcli, and you must create and manage your own Object Storage buckets for backups. See Backing Up a Database to Object Storage Using RMAN on page 1440.)

Caution:
If you previously used RMAN or dbcli to configure backups and then you switch to using the Console or the API for backups, a new backup configuration is created and associated with your database. This means that you can no longer rely on your previously configured unmanaged backups to work.

Required IAM Policy
To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.
Prerequisites

The DB system requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- **Network Setup for DB Systems** on page 1359: For information about setting up your VCN for the DB system, including the service gateway.
- **Can I use Oracle Cloud Infrastructure Object Storage as a destination for my on-premises backups?**: For information about the Swift endpoints to use.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note that your database and DB system must be in an “Available” state for a backup operation to run successfully. Oracle recommends that you avoid performing actions that could interfere with availability (such as patching and Data Guard operations) while a backup operation is in progress. If an automatic backup operation fails, the Database service retries the operation during the next day’s backup window. If an on-demand full backup fails, you can try the operation again when the DB system and database availability are restored.</td>
</tr>
</tbody>
</table>

In addition to the prerequisites listed, ensure that the following conditions are met to avoid backup failures:

- The database's archiving mode is set to ARCHIVELOG (the default).
- The `/u01` directory on the database host file system has sufficient free space for the execution of backup processes.
- The `.bash_profile` file for the oracle user does not include any interactive commands (such as `oraenv` or one that could generate an error or warning message).
- (For automatic backups) No changes were made to the default `WALLET_LOCATION` entry in the `sqlnet.ora` file.
- No changes were made to `RMAN` backup settings by using standard `RMAN` commands.

See **Backup Failures on Bare Metal and Virtual Machine DB Systems** on page 1646 for details on problems that can result from not following these guidelines.

**Oracle Cloud Infrastructure Managed Backup Features**

The following information applies to managed backups configured using the Oracle Cloud Infrastructure Console or API.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Databases in a security zone compartment must have automatic backups enabled. See the <strong>Security Zone Policies</strong> topic for a full list of policies that affect Database service resources.</td>
</tr>
</tbody>
</table>

**Automatic Incremental and Archived Redo Log Backups**

When you enable the Automatic Backup feature for a database, the service creates the following on an on-going basis:

- Weekly level 0 backup, generally created on a specified weekend day. A level 0 backup is the equivalent of a full backup. Note that in the Console, weekly level 0 backups appear in the list of backups with backup type “incremental”, as do the daily level 1 backups.
• Daily level 1 backups, which are incremental backups created on each day for the six days following the level 0 backup day.

Level 0 and level 1 backups are stored in Object Storage and have an assigned OCID.

• Ongoing archived redo log backups (with a minimum frequency of every 60 minutes). The Last Backup Time field on the database details page in the Oracle Cloud Infrastructure Console displays the time of the last archived redo logs. This backup differs from the level 0 and level 1 automatic backups in that it is based on log data and does not have an assigned OCID. The last archived redo log backup can be used to create a new database or to recover a database with minimal data loss.

The automatic backup process used to create level 0 and level 1 backups can run at any time within the daily backup window (between midnight and 6:00 AM). See note for backup window time zone information. Automatic incremental backups (level 0 and level 1) are retained in Object Storage for 30 days by default.

Backup Retention

If you choose to enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The system automatically deletes your incremental backups at the end of your chosen retention period.

Audit and Trace File Retention for Databases Using Automatic Backups

Oracle Database writes audit and trace files to your database's local storage in the /u01 directory. These files are retained for 30 days by default, though you can change this interval. Once a day, audit and trace files older than 30 days (or the user-specified interval, if applicable) are discarded by a Oracle Scheduler job. You can also disable the Scheduler job if you want to retain these files permanently. Use the following dbcli commands to make changes to this Scheduler job.

• To change the retention period from the default setting of 30 days:

```
dbcli update-database -in <dbName> -lr <number_of_days_to_retain_files>
```

For example:

```
dbcli update-database -in inventorydb -lr 15
```

• To disable the daily discard Scheduler job for older audit and trace files:

```
dbcli update-schedule -i <schedulerID> -d
```

For example:

```
dbcli update-schedule -i 5678 -d
```

Backup Scheduling

The automatic backup process starts at any time during your daily backup window. You can optionally specify a 2-hour scheduling window for your database during which the automatic backup process will begin. There are 12 scheduling windows to choose from, each starting on an even-numbered hour (for example, one window runs from 4:00-6:00 AM, and the next from 6:00-8:00 AM). Backups jobs do not necessarily complete within the scheduling window.

The default backup window of 00:00 to 06:00 in the time zone of the DB system's region is assigned to your database if you do not specify a window. Note that the default backup scheduling window is six hours long, while the windows you specify are two hours long. See note for backup window time zone information.

```
Note:

• Backup Window Time Zone - Automatic backups enabled for the first time after November 20, 2018 on any database will run between midnight
```
and 6:00 AM in the time zone of the DB system's region. If you have enabled automatic backups on a database before this date, the backup window for the database will continue to be between midnight and 6:00 AM UTC. You can create a My Oracle Support service request to have your automatic backups run in a backup window of your choice.

- **Data Guard** - You can enable the Automatic Backup feature on a database with the standby role in a Data Guard association. However, automatic backups for that database will not be created until it assumes the primary role.
- **Retention Period Changes** - If you shorten your database’s automatic backup retention period in the future, existing backups falling outside the updated retention period are deleted by the system.
- **Object Storage Costs** - Automatic backups incur Object Storage usage costs.

**On-Demand Full Backups**

You can create a full backup of your database at any time unless your database is assuming the standby role in a Data Guard association.

**Standalone Backups**

When you terminate a DB system or a database, all of its resources are deleted, along with any automatic backups. Full backups remain in Object Storage as standalone backups. You can use a standalone backup to create a new database.

**Using the Console**

You can use the Console to enable automatic incremental backups, create full backups on demand, and view the list of managed backups for a database. The Console also allows you to delete full backups.

**Note:**

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using RMAN or dbcli).

All backups are encrypted with the same master key used for Transparent Data Encryption (TDE) wallet encryption.

To navigate to the list of standalone backups for your current compartment

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Click **Standalone Backups** under **Bare Metal, VM, and Exadata**.

To configure automatic backups for a database

When you launch a DB system, you can optionally enable automatic backups for the initial database. Use this procedure to configure or disable automatic backups after the database is created.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   
   A list of databases is displayed.
4. Find the database for which you want to enable or disable automatic backups, and click its name to display database details. The details indicate whether automatic backups are enabled. When backups are enabled, the details also indicate the chosen backup retention period.
5. Click **Configure Automatic Backups**.
6. In the **Configure Automatic Backups** dialog, check or uncheck **Enable Automatic Backup**, as applicable.

   If you are enabling automatic backups, you can choose to configure the following:

   • **Backup Retention Period**: If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, 60 days, or 90 days. The default selection is 30 days.
   • **Backup Scheduling**: If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See **Backup Scheduling** on page 1437 for more information.

7. Click **Save Changes**.

To create an on-demand full backup of a database

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, click the name of the system that contains the database that you want to work with.
4. On the DB system details page, find the database you want to work with in list of databases and click the display name of the database to view the database details.
5. Under **Resources**, click **Backups**.
   
   A list of backups is displayed.
6. Click **Create Backup**.

To delete full backups from Object Storage

   **Note:**

   You cannot explicitly delete automatic backups. Unless you terminate the database, automatic backups remain in Object Storage for 30 days, after which time they are automatically deleted.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   
   A list of DB systems is displayed.
3. Find the DB system where the database is located and click the DB system name to display details.
   
   A list of databases is displayed.
4. Find the database you are interested in and click its name to display database details.
5. Under **Resources**, click **Backups**.
   
   A list of backups is displayed.
6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Delete**.
7. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 4368 and **Security Credentials** on page 179. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 4225.

Use these API operations to manage database backups:

• **ListBackups**
• **GetBackup**
• **CreateBackup**
• **DeleteBackup**
• **UpdateDatabase** - To enable and disable automatic backups.

For the complete list of APIs for the Database service, see **Database Service API**.
What's Next?

See Recovering a Database from Object Storage on page 1446 for information on restoring your database.

See To create a database from a backup in an existing DB system on page 1417 for information on creating a new database from a backup. You have the choice of using a daily incremental backup, a Standalone Backups on page 1438, the latest archive redo log backup, or a timestamp for a point-in-time copy.

See To create a DB system from a backup on page 1377 for information on creating a new DB system using a backup as the source for the initial database. You have the choice of using a daily incremental backup, a Standalone Backups on page 1438, the latest archive redo log backup, or a timestamp for a point-in-time copy.

Backing Up a Database to Object Storage Using RMAN

This topic is not applicable to Exadata DB systems. For Exadata DB systems, see Managing Exadata Database Backups by Using bkup_api on page 1323.

This topic explains how to use Recovery Manager (RMAN) to manage backups of your Bare Metal or Virtual Machine DB system database to your own Object Storage. For backups managed by Oracle Cloud Infrastructure, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435.

To back up to the service you'll need to create an Object Storage bucket for the backups, generate a password for the service, install the Oracle Database Cloud Backup Module, and then configure RMAN to send backups to the service. The backup module is a system backup to tape (SBT) interface that’s tightly integrated with RMAN, so you can use familiar RMAN commands to perform backup and recovery operations.

You'll notice Swift mentioned in the Console and in the endpoint URL for the service. That's because the backup module is typically used to back up to the Oracle Database Backup Cloud Service, which is an OpenStack Swift object store.

Tip:

On a 1-node DB system, you can use the database command line interface (dbcli) to back up to Object Storage. This is an alternative to installing the backup module and using RMAN for backups. For more information, see Objectstoreswift Commands on page 1533. Note that the dbcli commands are not available for a 2-node RAC DB system.

Prerequisites

You'll need the following:

• A DB system and a database to back up. For more information, see Creating Bare Metal and Virtual Machine DB Systems on page 1370.

• The DB system's cloud network (VCN) must be configured with access to Object Storage:
  • For Object Storage access in the same region as the DB system: Oracle recommends using a service gateway. For more information, see Service Gateway for the VCN on page 1365.
  • For Object Storage access in a different region than the DB system: Use an internet gateway. Note that the network traffic between the DB system and Object Storage does not leave the cloud and never reaches the public internet. For more information, see Internet Gateway on page 3243.

• An existing Object Storage bucket to use as the backup destination. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets on page 3398.

• An auth token generated by Oracle Cloud Infrastructure. You can use the Console or the IAM API to generate the password. For more information, see Working with Auth Tokens.

• The user name (specified when you install and use the backup module) must have tenancy-level access to Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access...
to all of the cloud services. Instead, an administrator should create a policy like the following that limits access to only the required resources in Object Storage for backing up and restoring the database:

```plaintext
Allow group <group_name> to manage objects in compartment <compartment_name> where target.bucket.name = '<bucket_name>'
Allow group <group_name> to read buckets in compartment <compartment_name>
```

For more information about adding a user to a group, see Managing Groups on page 2419. For more information about policies, see Getting Started with Policies on page 2135.

**Installing the Backup Module on the DB System**

1. SSH to the DB system, log in as opc, and sudo to the oracle user.

   ```bash
   ssh -i <SSH_key_used_when-launching_the_DB_system> opc@<DB_system_IP_address_or_hostname> login as: opc sudo su - oracle
   ```

2. Change to the directory that contains the backup module `opc_install.jar` file.

   ```bash
   cd /opt/oracle/oak/pkgrepos/oss/odbcs
   ```

3. Use the following command syntax to install the backup module.

   ```bash
   java -jar opc_install.jar -opcId <user_id> -opcPass '<auth_token>' -container <bucket_name> -walletDir ~/hsbtwallet/ -libDir ~/lib/ -configfile ~/config - host https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>
   ```

The parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-opcId</code></td>
<td>The user name for the Oracle Cloud Infrastructure user account, for example: <code>opcId -opcId &lt;username&gt;@&lt;example&gt;.com</code> This is the user name you use to sign in to the Console. The user name must be a member of the Administrators group, as described in Prerequisites on page 1440. You can also specify the user name in single quotes. This might be necessary if the name contains special characters, for example: <code>opcId 'j~smith@example.com'</code> Make sure to use straight single quotes and not slanted apostrophes.</td>
</tr>
<tr>
<td><code>-opcPass</code></td>
<td>The auth token generated by using the Console or IAM API, in single quotes, for example: <code>opcPass -opcPass '&lt;password&gt;'</code> Make sure to use straight single quotes and not slanted apostrophes. For more information, see Managing User Credentials on page 2456. This is not the password for the Oracle Cloud Infrastructure user.</td>
</tr>
<tr>
<td><code>-container</code></td>
<td>The name of an existing bucket in Object Storage to use as the backup destination, for example: <code>container -container DBBackups</code></td>
</tr>
</tbody>
</table>
### Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| walletDir | The directory where the install tool will create an Oracle Wallet containing the Oracle Cloud Infrastructure user auth token. 
- `walletDir ~/hsbtwallet` creates the wallet in the current user (oracle) home directory. |
| libDir | The directory where the SBT library is stored. The directory must already exist before you run the command. This parameter causes the latest SBT library to be downloaded. 
- `libDir ~/lib/` downloads the `libopc.so` file to the current user's home directory, for example, `/home/oracle/lib/libopc.so`. |
| configfile | The name of the initialization parameter file that will be created by the install tool. This file will be referenced by your RMAN jobs. 
- `configfile ~/config` creates the file in the current user's home directory, for example, `/home/oracle/config`. |
| host | The endpoint URL to which backups are to be sent:

```text
https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>
```

where `<object_storage_namespace>` is your tenancy's Object Storage namespace. 
Do not add a slash after the Object Storage namespace. 
See [Regions and Availability Domains](#) on page 180 to look up the region name. |

### Configuring RMAN

This section describes how to configure RMAN to use the bucket as the default backup destination. The following assumes you are still logged in to the DB system.

1. On the DB system, set the ORACLE_HOME and ORACLE_SID environment variables using the oraenv utility.

   ```sql
   . oraenv
   ```

2. Connect to the database using RMAN.

   ```sql
   rman target /
   ```

3. Configure RMAN to use the SBT device and point to the `config` file that was created when you installed the backup module. A sample command for a version 12 database is shown here.

   ```sql
   RMAN> CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' PARMS 'SBT_LIBRARY=/home/oracle/lib/libopc.so, SBT_PARMS=(OPC_PFILE=/home/oracle/config)';
   ```

4. Configure RMAN to use SBT_TAPE by default. The following sample enables the controlfile and spfile autobackup to SBT_TAPE and configures encryption (recommended). There are other settings that may apply to your installation such as compression, number of backup and recovery channels to use, backup retention policy, archived log deletion policy, and more. See the Oracle Backup and Recovery documentation for your version of Oracle for more information on choosing the appropriate settings.

   ```sql
   RMAN> CONFIGURE DEFAULT DEVICE TYPE TO SBT_TAPE;
   RMAN> CONFIGURE BACKUP OPTIMIZATION ON;
   RMAN> CONFIGURE CONTROLFILE AUTOBACKUP ON;
   RMAN> CONFIGURE CONTROLFILE AUTOBACKUP FORMAT FOR DEVICE TYPE SBT_TAPE TO '%F';
   RMAN> CONFIGURE ENCRYPTION FOR DATABASE ON;
   ```
Once the RMAN configuration is complete, you can use the same RMAN commands that you regularly use for tape backups.

**Backing up the Database**

This section provides examples of commonly used backup commands.

1. Set the database encryption:

   ```
   RMAN> SET ENCRYPTION IDENTIFIED BY "password" ONLY;
   ```

   Note that this setting is not permanent; you must set it for each new RMAN session.

2. Back up the database and archivelogs. Below are some example commands. See the Oracle Backup and Recovery documentation for your version of Oracle for more information about choosing a back up procedure that meets your needs. Be sure to back up regularly to minimize potential data loss and always include a copy of the spfile and controlfile. Note that the example below uses multi-section incremental backups, which is a feature introduced in 12c. When using 11g, omit the `section size` clause.

   ```
   RMAN> BACKUP INCREMENTAL LEVEL 0 SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
   
   RMAN> BACKUP INCREMENTAL LEVEL 1 SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
   
   RMAN> BACKUP INCREMENTAL LEVEL 1 CUMULATIVE SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
   ```

3. Backup archivelogs frequently to minimize potential data loss, and keep multiple backup copies as a precaution.

   ```
   RMAN> BACKUP ARCHIVELOG ALL NOT BACKED UP 2 TIMES;
   ```

When the backup job completes, you can display the backup files in your bucket in the Console on the Storage page, by selecting Object Storage.

**What's Next?**

See Recovering a Database from Object Storage on page 1446.

**Backing Up a Database to Local Storage Using the Database CLI**

**Note:**

This topic is not applicable to virtual machine DB systems because they have no local storage. For Exadata DB systems, see Managing Exadata Database Backups on page 1320.

This topic explains how to back up to the local Fast Recovery Area on a bare metal DB system by using the database CLI (dbcli). Some sample dbcli commands are provided below. For complete command syntax, see the Oracle Database CLI Reference on page 1483.

**Note:**

Backing up to local storage is fast and provides for fast point-in-time recovery, however, if the DB system becomes unavailable, the backup also becomes unavailable. For information about more durable backup destinations, see Backing Up a Database on page 1435.
Database

**Backing Up the Database to Local Storage**

You’ll use the dbcli commands to create a backup configuration, associate the backup configuration with the database, initiate the backup operation, and then review the backup job.

1. **SSH to the DB System.**

   ```bash
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. **Log in as opc and then sudo to the root user. Use sudo su – with a hyphen to invoke the root user’s profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).**

   ```bash
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. **Create a backup configuration by using the Backupconfig Commands on page 1491 command and specify local disk storage as the backup destination.**

   The following example creates a backup configuration named prodbackup and specifies a disk backup destination and a disk recovery window of 5 (backups and archived redo logs will be maintained in local storage for 5 days).

   ```bash
   [root@dbsys ~]# dbcli create-backupconfig --name prodbackup --
   backupdestination disk --recoverywindow 5
   {
   "jobId" : "e7050756-0d83-48ce-9336-86592be59827",
   "status" : "Success",
   "message" : null,
   "reports" : [ {
   "taskId" : "TaskParallel_471",
   "taskName" : "persisting backup config metadata",
   "taskResult" : "Success",
   "startTime" : 1467774813141,
   "endTime" : 1467774813207,
   "status" : "Success",
   "taskDescription" : null,
   "parentTaskId" : "TaskSequential_467",
   "jobId" : "e7050756-0d83-48ce-9336-86592be59827",
   "reportLevel" : "Info",
   "updatedAt" : 1467774813207
   } ],
   "createTimestamp" : 1467774781851,
   "description" : "create backup config:prodbackup",
   "updatedAt" : 1467774813236
   }
   ``

   The example above uses full parameter names for demonstration purposes, but you can abbreviate the parameters like this:

   ```bash
   dbcli create-backupconfig -n prodbackup -d disk -w 5
   ```

4. **Get the ID of the database you want to back up by using the Database Commands on page 1505 command.**

   ```bash
   [root@dbsys ~]# dbcli list-databases
   ID           Class  Shape  Storage  Status       DB Name     DB Version     CDB
   ------------------------- ---------- ---------- ---------- --------- --- ---------- ----------
   71ec8335-113a-46e3-b81f-235f4db6fde prod 12.1.0.2 true
   OLTP  odb1 ACFS Configured
   ```
5. Get the ID of the backup configuration by using the **Backupconfig Commands** on page 1491 command.

   ```bash
   [root@dbsbackup backup]# /opt/oracle/dcs/bin/dbcli list-backupconfigs
   ID                      Name                      DiskRecoveryWindow BackupDestination createTime              
   ---------------        ---------------------      ------------------------------ ---------------
   78a2a5f0-72b1-448f-bd86-cf41b30b64ee prodbackup        5        Disk            July 6, 2016 3:13:01 AM UTC
   
   ID
   ---------------
   78a2a5f0-72b1-448f-bd86-cf41b30b64ee
   
   Name
   ---------------------
   prodbackup
   
   CreateTime
   ------------------------------
   July 6, 2016 3:13:01 AM UTC
   ```

6. Associate the backup configuration ID with the database ID by using the **Database Commands** on page 1505 command.

   ```bash
   [root@dbsys ~]# dbcli update-database --backupconfigid 78a2a5f0-72b1-448f-bd86-cf41b30b64ee --dbid 71ec8335-113a-46e3-b81f-235f4d1b6fde
   {
     "jobId": "2b104028-a0a4-4855-b32a-b97a37f5f9c5",
     "status": "Created",
     "message": null,
     "reports": [],
     "createTimestamp": 1467775842977,
     "description": "update database id:71ec8335-113a-46e3-b81f-235f4d1b6fde",
     "updatedTime": 1467775842978
   }
   
   You can view details about the update job by using the **Job Commands** on page 1525 command and specifying the job ID from the `dbcli update-database` command output, for example:

   ```bash
   dbcli describe-job --jobid 2b104028-a0a4-4855-b32a-b97a37f5f9c5
   ```

7. Initiate the database backup by using the **Backup Commands** on page 1487 command. The backup operation is performed immediately.

   The following example creates a backup of the specified database.

   ```bash
   [root@dbsys ~]# dbcli create-backup --dbid 71ec8335-113a-46e3-b81f-235f4d1b6fde
   {
     "createTimestamp": 1467792576854,
     "description": "Backup service creation with db name: prod",
     "jobId": "d6c9edaa-fc80-40a9-bcdd-056430c56c",
     "message": null,
     "reports": [],
     "status": "Created",
     "updatedTime": 1467792576855
   }
   
   Or you can abbreviate the command parameters like this:

   ```bash
   dbcli create-backup -i 71ec8335-113a-46e3-b81f-235f4d1b6fde
   
   You can view details about the backup job by using the **Job Commands** on page 1525 command and specifying the job ID from the `dbcli create-backup` command output, for example:

   ```bash
   dbcli describe-job --jobid d6c9edaa-fc80-40a9-bcdd-056430c56c
   ```

8. **Important!** Manually back up any TDE password-based wallets to your choice of a safe location, preferably not on the DB system. The wallets are required to restore the backup to a new host.
After the backup command completes, the database backup files are available in the Fast Recovery Area on the DB system.

**Recovering a Database**

For information on restoring a database on a bare metal or virtual machine DB system, see the following topics:

- Recovering a Database from Object Storage on page 1446
- Recovering a Database from the Oracle Cloud Infrastructure Classic Object Store on page 1452

**Recovering a Database from Object Storage**

Note:

This topic is not applicable to Exadata DB systems.

This topic explains how to recover a database from a backup stored in Object Storage. The service is a secure, scalable, on-demand storage solution in Oracle Cloud Infrastructure. For information on using Object Storage as a backup destination, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435.

You can recover a database using the Console, API, or by using RMAN.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142.

**Prerequisites**

The DB system requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for DB Systems on page 1359: For information about setting up your VCN for the DB system, including the service gateway.
- Can I use Oracle Cloud Infrastructure Object Storage as a destination for my on-premises backups?: For information about the Swift endpoints to use.

**Using the Console**

You can use the Console to restore the database from a backup in the Object Storage that was created by using the Console or the API. You can restore to the last known good state of the database, or you can specify a point in time or an existing System Change Number (SCN). You can also create a new database by using a standalone backup.

Note:

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using RMAN or dbcli).

Restoring a database with Data Guard enabled is not supported. You must first remove the Data Guard association by terminating the standby database before you can restore the database.

**Restoring an Existing Database**

To restore a database

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.

A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
   A list of backups is displayed in the default view of the database details. You can also access the list of backups for a database by clicking on Backups under Resources.
5. Click Restore.
6. Select one of the following options, and then click Restore Database:
   • Restore to the latest: Restores the database to the last known good state with the least possible data loss.
   • Restore to the timestamp: Restores the database to the timestamp specified.
   • Restore to System Change Number (SCN): Restores the database using the SCN specified. This SCN must be valid.
   
   **Tip:**
   You can determine the SCN number to use either by accessing and querying your database host, or by accessing any online or archived logs.
7. Confirm when prompted.
   If the restore operation fails, the database will be in a "Restore Failed" state. You can try restoring again using a different restore option. However, Oracle recommends that you review the RMAN logs on the host and fix any issues before reattempting to restore the database.

To restore a database using a specific backup from Object Storage
1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose your Compartment.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
5. Click Restore.
6. In the Restore Database dialog, select Restore to the latest, Restore to timestamp, or Restore to System Change Number (SCN). Specify a timestamp or System Change Number if you are using an option that requires either.
7. Click Restore Database.

**Creating a New Database from a Backup**

You can use a backup to create a database in an existing DB system or to launch a new DB system. See the following procedures for more information:
• To create a database from a backup in an existing DB system on page 1417
• To create a DB system from a backup on page 1377

**Using the API**

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to recover a database:
• ListBackups
• GetBackup
• RestoreDatabase
• CreateDbHome - For creating a DB system database from a standalone backup.

For the complete list of APIs for the Database service, see Database Service API.
Using an RMAN Backup

This topic explains how to recover a Recovery Manager (RMAN) backup stored in Object Storage.

Prerequisites

You’ll need the following:

- A new DB system to restore the database to (see assumptions below). For more information, see Creating Bare Metal and Virtual Machine DB Systems on page 1370.
- The Oracle Database Cloud Backup Module must be installed on the DB system. For more information, see Installing the Backup Module on the DB System on page 1441.

Assumptions

The procedures below assume the following:

- A new DB system has been created to host the restored database and no other database exists on the new DB system. It is possible to restore to a DB system that has existing databases, but that is beyond the scope of this topic.
- The original database is lost and all that remains is the latest RMAN backup. For virtual machine DB systems, the procedure assumes the DB system (inclusive of the database) no longer exists.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any data not included in the most recent backup will be lost.</td>
</tr>
</tbody>
</table>

- The Oracle Wallet and/or encryption keys used by the original database at the time of the last backup is available.
- The RMAN backup contains a copy of the control file and spfile as of the most recent backup as well as all of the datafile and archivelog backups needed to perform a complete database recovery.
- An RMAN catalog will not be used during the restore.

Setting Up Storage on the DB system

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. You can use an existing empty database home or create a new one for the restore. Use the applicable commands to help you complete this step.

   If you will be using an existing database home:

   - Use the Dbhome Commands on page 1518 command to list the database homes.

     ```
     [root@dbsys ~]# dbcli list-dbhomes
     ID   Home Location
     Name          DB Version
     ```

Oracle Cloud Infrastructure User Guide

1448
• Use the Database Commands on page 1505 command to ensure the database home is not associated with any database.

If necessary, use the Dbhome Commands on page 1518 command to create a database home for the restore.

4. Use the Dbstorage Commands on page 1521 to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the rectest database.

```bash
[root@dbsys ~]# dbcli create-dbstorage --dbname rectest --dataSize 10 --dbstorage ACFS
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When restoring a version 11.2 database, ACFS storage must be specified.</td>
</tr>
</tbody>
</table>

Performing the Database Restore and Recovery

1. SSH to the DB system, log in as opc, and then become the oracle user.

   ```bash
   sudo su - oracle
   ```

2. Create an entry in /etc/oratab for the database. Use the same SID as the original database.

   ```bash
dbl:/u01/app/oracle/product/12.1.0.2/dbhome_1:N
   ```

3. Set the ORACLE_HOME and ORACLE_SID environment variables using the oraenv utility.

   ```bash
   . oraenv
   ```

4. Obtain the DBID of the original database. This can be obtained from the file name of the controlfile autobackup on the backup media. The file name will include a string that contains the DBID. The typical format of the string is `c-DDDDDDDDDDDD-YYYYMMDD-NN` where `DDDDDDDDDDDD` is the `DBID`, `YYYYMMDD` is
the date the backup was created, and NN is a sequence number to make the file name unique. The DBID in the following examples is 1508405000. Your DBID will be different.

Use the following curl syntax to perform a general query of Object Storage. The parameters in red are the same parameters you specified when installing the backup module as described in Installing the Backup Module on the DB System on page 1441.

```
curl -u '<user_ID>.com:<auth_token>' -v https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/object_storage_namespace
```

See Regions and Availability Domains on page 180 to look up the region name.

For example:

```
curl -u 'djones@mycompany.com:1cnk!d0++ptETd&C;thR' -v https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/myobjectstoragenamespace
```

To get the DBID from the control file name, use the following syntax:

```
curl -u '<user_id>.com:<auth_token>' -v https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/object_storage_namespace/<bucket_name>?prefix=sbt_catalog/c-
```

For example:

```
curl -u 'djones@mycompany.com:1cnk!d0++ptETd&C;thR' -v https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/myobjectstoragenamespace/dbbackups/?prefix=sbt_catalog/c-
```

In the sample output below, 1508405000 is the DBID.

```
{
   "bytes": 1732,
   "content_type": "binary/octet-stream",
   "hash": "f1b61f08892734ed7af4f1d3a8be317",
   "last_modified": "2016-08-11T20:28:34.438000",
   "name": "sbt_catalog/c-1508405000-20160811-00/metadata.xml"
}
```

5. Run RMAN and connect to the target database. There is no need to create a spfile or spfile or use a backup controlfile. These will be restored in the following steps. Note that the target database is (not started). This is normal and expected at this point.

```
rman target /
```

RMAN target /
Recovery Manager: Release 12.1.0.2.0 - Production on Wed Jun 22 18:36:40 2016
Copyright (c) 1982, 2014, Oracle and/or its affiliates. All rights reserved.
connected to target database (not started)

6. Set the DBID using the value obtained above.

```
RMAN> set dbid 1508405000;
executing command: SET DBID
7. Run the STARTUP NOMOUNT command. If the server parameter file is not available, RMAN attempts to start the instance with a dummy server parameter file. The ORA-01078 and LRM-00109 errors are normal and can be ignored.

```
RMAN> STARTUP NOMOUNT

startup failed: ORA-01078: failure in processing system parameters
LRM-00109: could not open parameter file '/u01/app/oracle/product/12.1.0.2/dbhome_1/dbs/initdb1.ora'

starting Oracle instance without parameter file for retrieval of spfile
Oracle instance started

Total System Global Area 2147483648 bytes
Fixed Size 2944952 bytes
Variable Size 847249480 bytes
Database Buffers 1254096896 bytes
Redo Buffers 43192320 bytes
```

8. Restore the server parameter file from autobackup.

The SBT_LIBRARY is the same library specified with the -libDir parameter when the Backup Module was installed, for example /home/oracle/lib/.

The OPC_PFILE is the same file specified with the -configfile parameter when the Backup Module was installed, for example /home/oracle/config.

```
set controlfile autobackup format for device type sbt to '%F';
run {
    allocate channel c1 device type sbt PARMS 'SBT_LIBRARY=/home/oracle/lib/libopc.so, SBT_PARMS=(OPC_PFILE=/home/oracle/config)';
    restore spfile from autobackup;
}
```

9. Create the directory for audit_file_dest. The default is /u01/app/oracle/admin/$ORACLE_SID/adump.

You can see the setting used by the original database by searching the spfile for the string, audit_file_dest.

```
strings ${ORACLE_HOME}/dbs/spfile${ORACLE_SID}.ora | grep audit_file_dest
*.audit_file_dest='/u01/app/oracle/admin/db1/adump'
mkdir -p /u01/app/oracle/admin/db1/adump
```

10. If block change tracking was enabled on the original database, create the directory for the block change tracking file. This will be a directory under db_create_file_dest. Search the spfile for the name of the directory.

```
strings ${ORACLE_HOME}/dbs/spfile${ORACLE_SID}.ora | grep db_create_file_dest
*.db_create_file_dest='/u02/app/oracle/oradata/db1'
mkdir -p /u02/app/oracle/oradata/db1/<$ORA_UNQNAME if available or database name>/changetracking
```

11. Restart the instance with the restored server parameter file.

```
STARTUP FORCE NOMOUNT;
```

12. Restore the controlfile from the RMAN autobackup and mount the database.

```
set controlfile autobackup format for device type sbt to '%F';
run {
```
allocate channel c1 device type sbt PARMS 'SBT_LIBRARY=/home/oracle/lib/
libopc.so, SBT_PARMS=(OPC_PFILE=/home/oracle/config)';
  restore controlfile from autobackup;
  alter database mount;
}

13. Restore and recover the database.

    RESTORE DATABASE;
    RECOVER DATABASE;

14. RMAN will recover using archived redo logs until it can't find any more. It is normal for an error similar to the
    one below to occur when RMAN has applied the last archived redo log in the backup and can't find any more logs.

    unable to find archived log
    archived log thread=1 sequence=29
    RMAN-00571: =============== ERROR MESSAGE STACK FOLLOWS ===============
    RMAN-00569: -----------------------------------------
    RMAN-00571: -----------------------------------------
    RMAN-03002: failure of recover command at 06/28/2016 00:57:35
    RMAN-06054: media recovery requesting unknown archived log for thread 1
    with sequence 29 and starting SCN of 2349563

15. Open the database with resetlogs.

    ALTER DATABASE OPEN RESETLOGS;

The recovery is complete. The database will have all of the committed transactions as of the last backed up archived
redo log.

Recovering a Database from the Oracle Cloud Infrastructure Classic Object Store

Note:

This topic is not applicable to Exadata DB systems.

This topic explains how to recover a database using a backup created by the Oracle Database Backup Module and
stored in Oracle Cloud Infrastructure Object Storage Classic.

The following terms are used throughout this topic:

• Source database: The database backup in Object Storage Classic.
• Target database: The new database on a DB system in Oracle Cloud Infrastructure.

Prerequisites

You'll need the following:

• The service name, identity name, container, user name, and password for Oracle Cloud Infrastructure Object
  Storage Classic.
• The backup password if password-based encryption was used when backing up to Object Storage Classic.
• The source database ID, database name, database unique name (required for setting up storage).
• If the source database is configured with Transparent Data Encryption (TDE), you'll need a backup of the wallet
  and the wallet password.
• Tnsnames to setup for any database links.
• The output of Opatch lsinventory for the source database Oracle_home, for reference.
• A copy of the sqlpatch directory from the source database home. This is required for rollback in case the target
database does not include these patches.
**Setting Up Storage on the DB System**

1. SSH to the DB System.

   ```bash
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

   ```bash
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. Use the **Dbstorage Commands** on page 1521 command to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the tdetest database.

   ```bash
   [root@dbsys ~]$ dbcli create-dbstorage --dbname tdetest --dataSize 10 --dbstorage ACFS
   ```

   **Note:**
   When migrating a version 11.2 database, ACFS storage must be specified.

4. Use the **Dbstorage Commands** on page 1521 command to list the storage ID. You'll need the ID for the next step.

   ```bash
   [root@dbsys ~]$ dbcli list-dbstorages
   ID                  Type   DBUnique Name   Status
   ------------------- ------- ----------------- ------
   9dcdfb8e-e589-4d5f-861a-e5ba981616ed Acfs   tdetest   Configured
   ```

5. Use the **Dbstorage Commands** on page 1521 command with the storage ID from the previous step to list the DATA, RECO and REDO locations.

   ```bash
   [root@dbsys ~]$ dbcli describe-dbstorage --id 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
   DBStorage details
   --------------------------------------------------------
   ID: 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
   DB Name: tdetest
   DBUnique Name: tdetest
   DB Resource ID:
   Storage Type: Acfs
   DATA Location: /u02/app/oracle/oradata/tdetest
   RECO Location: /u03/app/oracle/fast_recovery_area/
   REDO Location: /u03/app/oracle/redo/
   State: ResourceState(status=Configured)
   Created: August 24, 2016 5:25:38 PM UTC
   UpdatedTime: August 24, 2016 5:25:53 PM UTC
   ```

6. Note the DATA, RECO and REDO locations. You'll need them later to set the `db_create_file_dest`, `db_create_online_log_dest`, and `db_recovery_file_dest` parameters for the database.

**Choosing an ORACLE_HOME**

Decide which ORACLE_HOME to use for the database restore and then switch to that home with the correct ORACLE_BASE, ORACLE_HOME, and PATH settings. The ORACLE_HOME must not already be associated with a database.
To get a list of existing ORACLE_HOMEs and to ensure that the ORACLE_HOME is empty, use the Dbhome Commands on page 1518 and the Database Commands on page 1505 commands, respectively. To create a new ORACLE_HOME, use the Dbhome Commands on page 1518 command.

**Copying the Source Database Wallets**

Skip this section if the source database is **not** configured with TDE.

1. On the DB system, become the oracle user:
   ```bash
   sudo su - oracle
   ```

2. Create the following directory, if it does not already exist:
   ```bash
   mkdir /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
   ```

3. Copy the ewallet.p12 file from the source database to the directory you created in the previous step.

4. On the target host, make sure that `$ORACLE_HOME/network/admin/sqlnet.ora` contains the following line:
   ```ora
   ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME))
   ```

   Add the line if it doesn't exist in the file. (The line might not be there if this is a new home and no database has been created yet on this host.)

5. Create the autologin wallet from the password-based wallet to allow auto-open of the wallet during restore and recovery operations.

   For a version 12.1 or later database, use the `ADMINISTER KEY MANAGEMENT` command:
   ```bash
   $ cat create_autologin_12.sh
   #!/bin/sh
   if [ $# -lt 2 ]; then
     echo "Usage: $0 <dbuniquename><remotewalletlocation>"
     exit 1;
   fi
   mkdir /opt/oracle/dcs/commonstore/wallets/tde/$1
   cp $2/ewallet.p12* /opt/oracle/dcs/commonstore/wallets/tde/$1
   rm -f autokey.ora
   echo "db_name=$1" > autokey.ora
   autokeystoreLog="autologinKeystore_`date +%Y%m%d_%H%M%S_%N`.log"
   echo "Enter Keystore Password:"
   read -s keystorePassword
   echo "Creating AutoLoginKeystore -> "
   sqlplus "/ as sysdba" <<EOF
   spool $autokeystoreLog
   set echo on
   startup nomount pfile=autokey.ora
   ADMINISTER KEY MANAGEMENT CREATE AUTO_LOGIN KEYSTORE
   FROM KEYSTORE '/opt/oracle/dcs/commonstore/wallets/tde/$1' -- Keystore location
   IDENTIFIED BY "$keystorePassword';
   shutdown immediate;
   EOF
   ```

   Adjust the `cwallet.sso` permissions from `oracle:asmadmin` to `oracle:oinstall`.
   ```bash
   $ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
   total 20
   ```
For a version 11.2 database, use the orapki command:

```
orapki wallet create -wallet wallet_location -auto_login [-pwd password]
```

### Installing the Oracle Database Backup Module

The backup module JAR file is included on the DB system but you need to install it.

1. SSH to the DB system, log in as opc, and then become the oracle user.

   ```
   ssh -i <path to SSH key used when launching the DB System> opc@<DB System IP address or hostname>
   sudo su - oracle
   ```

2. Change to the directory that contains the backup module opc_install.jar file.

   ```
   cd /opt/oracle/oak/pkgrepos/orapkgs/oss/＜version＞/
   ```

3. Use the command syntax described in Installing the Oracle Database Cloud Backup Module to install the backup module.

### Setting Environment Variables

Set the following environment variables for the RMAN and SQL*Plus sessions for the database:

```
ORACLE_HOME=<path of Oracle Home where the database is to be restored>
ORACLE_SID=<database instance name>
ORACLE_UNQNAME=<db_unique_name in lower case>
NLS_DATE_FORMAT="mm/dd/yyyy hh24:mi:ss"
```

### Allocating an RMAN SBT Channel

For each restore operation, allocate an SBT channel and set the SBT_LIBRARY parameter to the location of the libopc.so file and the OPC_FILE parameter to the location of the opc_sbt.ora file, for example:

```
ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U'
PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/<ORACLE_HOME>/dbs/opc_sbt.ora)';
```

(For more information about these files, see Files Created When the Backup Module is Installed.)

### Ensuring Decryption is Turned On

Make sure that decryption is turned on for all the RMAN restore sessions.

```
set decryption wallet open identified by <keystore password> ;
```

For more information, see Providing Password Required to Decrypt Encrypted Backups.

### Restoring Spfile

The following sample shell script restores the spfile. Set the $dbID variable to the dbid of the database being restored. By default, spfile is restored to $ORACLE_HOME/dbs/spfile$<sid>.ora.

```
 rman target / <<EOF
spool log to "\date +%Y%m%d%H%M%S\_dbid_$(dbID)_restore_spfile.log"
startup nomount
```
Setting the Database Parameters

1. Start the database in nomount mode.

   ```
   startup nomount
   ```

2. Update spfile and modify the following parameters.

   - If the database storage type is ACFS, use the DATA, RECO, and REDO locations obtained from the `dbcli describe-dbstorage` command output, as described in Setting Up Storage on the DB System on page 1453:

     ```
     alter system set db_create_file_dest='/u02/app/oracle/oradata/' scope = spfile;
     alter system set db_create_online_log_dest_1='/u03/app/oracle/redo' scope = spfile;
     alter system set db_recovery_file_dest='/u03/app/oracle/fast_recovery_area' scope = spfile;
     ```

   - If the database storage type is ASM:

     ```
     alter system set db_create_file_dest='+DATA' scope = spfile;
     alter system set db_create_online_log_dest_1='+RECO' scope = spfile;
     alter system set db_recovery_file_dest='+RECO' scope = spfile;
     ```

   - Set `db_recovery_file_dest_size` is not set or is set incorrectly:

     ```
     alter system set db_recovery_file_dest_size=<sizeG> scope=spfile;
     ```

   - Set `audit_file_dest` to the correct value:

     ```
     alter system set audit_file_dest=/u01/app/oracle/admin/<db_unique_name in lower case>/adump
     ```

3. Remove the `control_files` parameter. The Oracle Managed Files (OMF) parameters will be used to create the control file.

   ```
   alter system reset control_files scope=spfile;
   ```

4. Restart the database in nomount mode using the newly added parameters.

   ```
   shutdown immediate
   startup nomount
   ```

Restoring the Control File

Modify the following sample shell script for your environment to restore the control file. Set the `$dbID` variable to the dbid of the database being restored. Set `SBT_LIBRARY` to the location specified in the `-libDir` parameter when you installed the Backup Module. Set `OPC_PFILE` to the location specified in the `-configFile` parameter, which defaults to `ORACLE_HOME/dbs/opcSID.ora`.

```
rman target / <<EOF
spool log to "`date +%Y%m%d_%H%M%S_%N`_dbid_${dbID}_restore_controlfile.log"
```
Restoring the Database

1. Preview and validate the backup. The database is now mounted and RMAN should be able to locate the backup from the restored controlfile. This step helps ensure that the list of archivelogs is present and that the backup components can be restored.

   In the following examples, modify SBT_LIBRARY and OPC_PFILE as needed for your environment.

   ```
   rman target / <<EOF
   spool log to "`date +%Y%m%d_%H%M%S_%N`_restore_database_preview.log"
   set echo on
   run {
   ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c2 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c3 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   restore database validate header preview;
   }
   EOF
   ```

   Review the output and if there are error messages, investigate the cause of the problem.

2. Redirect the restore using `set newname` to restore the data files in OMF format and use `switch datafile all` to allow the control file to update with the new data file copies.

   ```
   rman target / <<EOF
   spool log to "`date +%Y%m%d_%H%M%S_%N`_restore_database_preview.log"
   set echo on
   run {
   ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c2 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c3 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   set newname for database to new;
   restore database;
   switch datafile all;
   switch tempfile all;
   recover database;
   ```
This recovery will attempt to use the last available archive log backup and then fail with an error, for example:

RMAN-00571: ===========================================================
RMAN-00569: =============== ERROR MESSAGE STACK FOLLOWS ===============
RMAN-00571: ===========================================================
RMAN-03002: failure of recover command at 07/20/2016 12:09:02
RMAN-06054: media recovery requesting unknown archived log for thread 1
with sequence 22 and starting SCN of 878327

3. To complete the incomplete recovery, run a recovery using the sequence number and thread number shown in the RMAN-06054 message, for example:

Recover database until sequence 22 thread 1;

Resetting the Logs
Reset the logs.

alter database open resetlogs;

Preparing to Register the Database
Before you register the database:

1. Make sure the database COMPATIBLE parameter value is acceptable. If the value is less than the minimum, the database cannot be registered until you upgrade the database compatibility.

   The minimum compatibility values are as follows:
   • For a version 18.1 database - 18.0.0.0
   • For a version 12.2 or 12.1 database - 12.1.0.2
   • For a version 11.2 database - 11.2.0.4

2. Verify that the database has registered with the listener and the service name.

   lsnrctl services

3. Make sure the password file was restored or created for the new database.

   ls -ltr $ORACLE_HOME/dbs/orapw<oracle sid>

   If the file does not exist, create it using the orapwd utility.

   orapwd file=$ORACLE_HOME/dbs/orapw<ORACLE_SID> password=<sys password>

4. Make sure the restored database if open in read write mode.

   select open_mode from v$database;

   The command output should indicate read write mode. The dbcli register-database command will attempt to run datapatch, which requires read write mode. If there are PDBs, they should also be in read write mode to ensure that datapatch runs on them.

5. From oracle home on the restored database, use the following command verify the connection to SYS:

   conn sys/<password>@//<hostname>:1521/<database service name>

   This connection is required to register the database later. Fix any connection issues before continuing.
6. Make sure the database is running on spfile by using the SQL*Plus command.

```
SHOW PARAMETERS SPFILE
```

7. (Optional) If you would like to manage the database backup with the dbcli command line interface, you can associate a new or existing backup configuration with the migrated database when you register it or after you register it. A backup configuration defines the backup destination and recovery window for the database. Use the following commands to create, list, and display backup configurations:

- **Backupconfig Commands** on page 1491
- **Backupconfig Commands** on page 1491
- **Backupconfig Commands** on page 1491

8. Copy the folder `$ORACLE_HOME/sqlpatch` from source database to the target database. This will enable the `dbcli register-database` command to roll back any conflicting patches.

```
Note:
If you are migrating a version 11.2 database, additional steps are required after you register the database. For more information, see **Rolling Back Patches on a Version 11.2 Database** on page 1459.
```

### Registering the Database on the DB System

The **Database Commands** on page 1505 command registers the restored database to the dcs-agent so it can be managed by the dcs-agent stack.

```
Note:
The dbcli register-database command is not available on 2-node RAC DB systems.
```

As the root user, use the `dbcli register-database` command to register the database on the DB system, for example:

```
[root@dbsys ~]# dbcli register-database --dbclass OLTP --dbshape odb1 --servicename tdetest --syspassword
Password for SYS:
{
   "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
   "status" : "Created",
   "message" : null,
   "reports" : [
   ],
   "createTimestamp" : "August 08, 2016 05:55:49 AM EDT",
   "description" : "Database service registration with db service name: tdetest",
   "updatedTime" : "August 08, 2016 05:55:49 AM EDT"
}
```

### Updating tnsnames.ora

Check the `tnsnames.ora` in the backup location, check the database links used in the cloned database, and then add any relevant connection strings to the cloned database file at `$ORACLE_HOME/network/admin/tnsnames.ora`.

### Rolling Back Patches on a Version 11.2 Database

For version 11.2 databases, the `sqlpatch` application is not automated, so any interim patches (previously known as a "one-off" patches) applied to the source database that are not part of the installed PSU must be rolled back manually in the target database. After registering the database, execute the `catbundle.sql` script and then the `postinstall.sql` script with the corresponding PSU patch (or the overlay patch on top of the PSU patch), as described below.
Tip:

Some interim patches may include files written to the $ORACLE_HOME/rdbms/admin directory as well as the $ORACLE_HOME/sqlpatch directory. Oracle recommends that you roll back these patches in the source database using the instructions in the patch read-me prior to migrating the database to OCI environment. Contact Oracle Support if you need assistance with rolling back these patches.

1. On the DB System, use the `dbcli list-dbhomes` command to find the PSU patch number for the version 11.2 database home. In the following sample command output, the PSU patch number is the second number in the DB Version column:

   ![Command Output]

   (The first patch number, 23054319 in the example above, is for the OCW component in the database home.)

2. Find the overlay patch, if any, by using the `lsinventory` command. In the following example, patch number 24460960 is the overlay patch on top of the 23054359 PSU patch.

   ![Inventory Output]

3. Start SQL*Plus and execute the `catbundle.sql` script, for example:

   ![SQL Execution]

4. Apply the sqlpatch, using the overlay patch number from the previous step, for example:

   ![SQL Execution]
Note:

If the source database has one-off patches installed and those patches are not part of the installed PSU in the cloud environment, then the SQL changes that correspond to those one-off patches need to be rolled back. To rollback the SQL changes, copy the $ORACLE_HOME/sqlpatch/<patch#>/postdeinstall.sql script from the source environment to the cloud environment and execute the postdeinstall.sql script.

Post Restore Checklist

After the database is restored and registered on the DB system, use the following checklist to verify the results and perform any post-restore customizations.

1. Make sure the database files were restored in OMF format.
2. Make sure the database is listed in the Database Commands on page 1505 command output.
3. Check for the following external references in the database and update them if necessary:
   - External tables: If the source database uses external tables, back up that data and migrate it to the target host.
   - Directories: Customize the default directories as needed for the restored database.
   - Database links: Make sure all the required TNS entries are updated in the tnsnames.ora file in ORACLE_HOME.
   - Email and URLs: Make sure any email addresses and URLs used in the database are still accessible from the DB system.
   - Scheduled jobs: Review the jobs scheduled in source database and schedule similar jobs as needed in the restored database.
4. If you associated a backup configuration when you registered the database, run a test back up using the Backup Commands on page 1487 command.
5. If the restored database contains a CDB and PDBs, verify that patches have been applied to all PDBs.

Using Oracle Data Guard

Note:

This procedure is only applicable to bare metal and virtual machine DB systems. To use Oracle Data Guard with Exadata, see Using Oracle Data Guard with Exadata Cloud Service on page 1339.

This topic explains how to use the Console to manage Oracle Data Guard associations in your DB system.

For complete information on Oracle Data Guard, see the Data Guard Concepts and Administration documentation in the Oracle Help Center.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

If you are new to policies, then see Getting Started with Policies on page 2135 and Common Policies on page 2142.

Prerequisites

An Oracle Data Guard implementation requires two DB systems, one containing the primary database and one containing the standby database. When you enable Oracle Data Guard for a virtual machine DB system database, a new DB system with the standby database is created and associated with the primary database. For a bare metal DB
system, the DB system with the database that you want to use as the standby must already exist before you enable Oracle Data Guard.

**Tip:**

An Oracle Data Guard configuration on the Oracle Cloud Infrastructure is limited to one standby database for each primary database.

Requirement details are as follows:

- Both DB systems must be in the same compartment.
- The DB systems must be the same shape type (for example, if the shape of the primary database is a virtual machine, then the shape of the standby database can be any other virtual machine shape).
- The database versions and editions must be identical. Oracle Data Guard does not support Oracle Database Standard Edition. (Active Data Guard requires Enterprise Edition - Extreme Performance.)
- The database version determines whether Active Data Guard is enabled. If you are using the BYOL licensing model and if your license does not include Active Data Guard, then you must either use Oracle Database Enterprise Edition - High Performance or set up Oracle Data Guard manually. See Using Oracle Data Guard with the Database CLI on page 1469.
- If your primary and standby databases are in the same region, then both must use the same virtual cloud network (VCN).
- If your primary and standby databases are in different regions, then you must peer the virtual cloud networks (VCNs) for each database. See Remote VCN Peering (Across Regions) on page 3280.
- Configure the security list ingress and egress rules for the subnets of both DB systems in the Oracle Data Guard association to enable TCP traffic to move between the applicable ports. Ensure that the rules you create are stateful (the default).

For example, if the subnet of the primary DB system uses the source CIDR 10.0.0.0/24 and the subnet of the standby DB system uses the source CIDR 10.0.1.0/24, then create rules as shown in the subsequent example.

**Note:**

The egress rules in the example show how to enable TCP traffic only for port 1521, which is a minimum requirement for Oracle Data Guard to work. If TCP traffic is already enabled on all of your outgoing ports (0.0.0.0/0), then you do not need to explicitly add these specific egress rules.

**Security List for Subnet on the Primary DB System**

**Ingress Rules:**

- Stateless: No
- Source: 10.0.1.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

**Egress Rules:**

- Stateless: No
- Destination: 10.0.1.0/24
- IP Protocol: TCP
- Source Port Range: All
- Destination Port Range: 1521
- Allows: TCP traffic for ports: 1521

**Security List for Subnet on the Standby DB System**

**Ingress Rules:**

- Stateless: No
For information about creating and editing rules, see Security Lists on page 2850.

**Availability Domain and Fault Domain Considerations for Oracle Data Guard**

Oracle recommends that the DB system that contains the standby database be in a different availability domain from that of the DB system containing the primary database to improve availability and disaster recovery. If you enable Oracle Data Guard for a database and your standby database is in the same availability domain as the primary database (either by choice, or because you are working in a single availability domain region), then Oracle recommends that you place the standby database in a different fault domain from that of the primary database.

**Note:**

If your primary and standby databases are two-node Oracle RAC databases and both are in the same availability domain, then only one of the two nodes of the standby database can be in a fault domain that does not include any other nodes from either the primary or standby database. This is because each availability domain has only three fault domains, and the primary and standby databases have a combined total of four nodes. For more information on availability domains and fault domains, see Regions and Availability Domains on page 180.

**Working with Oracle Data Guard**

Oracle Data Guard ensures high availability, data protection, and disaster recovery for enterprise data. The Oracle Cloud Infrastructure Database Data Guard implementation requires two databases: one in a primary role and one in a standby role. The two databases make an Oracle Data Guard association. Most of your applications access the primary database, while the standby database is a transactionally consistent copy of the primary database.

Oracle Data Guard maintains the standby database by transmitting and applying redo data from the primary database. If the primary database becomes unavailable, then you can use Oracle Data Guard to switch or fail over the standby database to the primary role.

**Tip:**

The standby databases in Oracle Cloud Infrastructure Database are physical standbys.

**Switchover**

A switchover reverses the primary and standby database roles. Each database continues to participate in the Oracle Data Guard association in its new role. A switchover ensures no data loss. Performing planned maintenance on a DB system with an Oracle Data Guard association is typically done by switching the primary database to the standby role, performing maintenance on the standby database, and then switching it back to the primary role.
Failover
A failover transitions the standby database into the primary role after the existing primary database fails or becomes unreachable. A failover might result in some data loss when you use Maximum Performance protection mode.

Reinstate
Reinstates a database into the standby role in an Oracle Data Guard association. You can use the reinstate command to return a failed database into service after correcting the cause of failure.

Note:
You cannot terminate a primary database that has an Oracle Data Guard association with a standby database until you first delete the standby database. Alternatively, you can switch over the primary database to the standby role, and then terminate it.
You cannot terminate a DB system that includes databases that have Oracle Data Guard enabled. To remove the Oracle Data Guard association:
• For a bare metal DB system database you can terminate the standby database.
• For a virtual machine DB system database you can terminate the standby DB system.

Terminating a DB System with Data Guard
If you want to terminate a DB system that has Data Guard enabled, you must terminate the standby DB system before terminating the primary DB system. If you try to terminate a primary DB system that has a standby, the terminate operation will not complete. See To terminate a DB system on page 1386 for instructions on terminating a DB system.

Using the Console
Use the Console to enable an Oracle Data Guard association between databases, change the role of a database in an Oracle Data Guard association using either a switchover or a failover operation, and reinstate a failed database.

When you enable Oracle Data Guard, a separate Oracle Data Guard association is created for the primary and the standby databases.

To enable Oracle Data Guard on a bare metal DB system

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains a DB system with a database for which you want to enable Oracle Data Guard.
3. Click the name of a DB system that contains a database you want to assume the primary role.
4. On the DB System Details page, in the Databases section, click the name of the database you want to make primary.
5. On the Database Details page, in the Resources section, click Data Guard Associations.
6. In the Data Guard Associations section, click Enable Data Guard.
7. On the **Enable Data Guard** page, configure the Oracle Data Guard association.
   - The settings in the **Data Guard association details** section are read only and cannot be changed.
   - **Protection mode**: The protection mode used for this Oracle Data Guard association is set to **Maximum Performance**.
   - **Transport type**: The redo transport type used for this Oracle Data Guard association is set to **Async** (asynchronous).
   - In the **Select peer DB system** section, provide the following information for the standby database to obtain a list of available DB systems in which to locate the standby database:
     - **Region**: Select a region where you want to locate the standby database. The region where the primary database is located is selected, by default. You can choose to locate the standby database in a different region. The hint text associated with this field tells you in which region the primary database is located.
     - **Availability domain**: Select an availability domain for the standby database. The hint text associated with this field tells you in which availability domain the primary database is located.

   **Note:**
   If your standby database is in a region with only one availability domain, or if you choose to provision your standby database in the same availability domain as your primary database, then the system asks you to specify a number of optional fault domains from the **Fault domain** drop-down for your standby database. Oracle recommends that you locate your standby database in a different fault domain from your primary database. For more information on fault domains, see **Regions and Availability Domains** on page 180.

     - **Shape**: Select the shape of the DB system in which to locate the standby database. The shape can be another bare metal DB system shape.
     - **Peer DB system**: Select a DB system in which to locate the standby database.
   - In the **Configure standby database** section, enter the database administrator password of the primary database in the **Database password** field. Use this same database administrator password for the standby database.

8. Click **Enable Data Guard**.

When you create the association, the details for a database and its peer display their respective roles as **Primary** or **Standby**.

### To enable Oracle Data Guard on a virtual machine DB system

If you do not already have a virtual machine DB system with a database that will assume the primary role, then create a database as described in **Creating Bare Metal and Virtual Machine DB Systems** on page 1370. A new DB system includes an initial database. When you enable Oracle Data Guard on the primary database, a virtual machine DB system gets created for the standby database.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains a DB system with a database for which you want to enable Oracle Data Guard.
3. Click the name of a DB system that contains a database you want to assume the primary role.
4. On the DB System Details page, in the **Databases** section, click the name of the database you want to make primary.
5. On the Database Details page, in the Resources section, click **Data Guard Associations**.
6. In the **Data Guard Associations** section, click **Enable Data Guard**.
7. On the **Enable Data Guard** page, configure your Oracle Data Guard association.

- The settings in the **Data Guard association details** section are read only and cannot be changed.
  - **Protection mode**: The protection mode used for this Oracle Data Guard association is set to **Maximum Performance**.
  - **Transport type**: The redo transport type used for this Oracle Data Guard association is set to **Async** (asynchronous).
- Specify the following values in the **Create peer DB system** section for the standby database:
  - **Display name**: Enter a non-unique display name for the DB system containing the standby database. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system. Avoid entering confidential information.
  - **Region**: Select a region where you want to locate the standby database. The region where the primary database is located is selected, by default. You can choose to locate the standby database in a different region. The hint text associated with this field tells you in which region the primary database is located.
  - **Availability domain**: Select an availability domain for the standby database. The hint text associated with this field tells you in which availability domain the primary database is located.

  **Note:**

  If your standby database is in a region with only one availability domain, or if you choose to provision your standby database in the same availability domain as your primary database, then the system asks you to specify a number of optional fault domains from the **Fault domain** drop-down for your standby database. Oracle recommends that you locate your standby database in a different fault domain from your primary database. For more information on fault domains, see **Regions and Availability Domains** on page 180.

  - **Select a shape**: Choose a shape to use to create the standby DB system. To specify a shape other than the default, click **Change Shape** and select an available virtual machine shape from the list.

  - In the **Specify the network information** section:
    - **Virtual cloud network in compartment**: Select a virtual cloud network from the drop-down in which to create the DB system containing the standby database. Click **Change Compartment** to select a virtual cloud network in a different compartment.
    - **Subnet in compartment**: The subnet to which the DB system containing the standby database attaches. Click **Change Compartment** to select a subnet in a different compartment.

      Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

    - **Configure network security groups (NSGs)**: Select to add a number of network security groups, which function as virtual firewalls, enabling you to apply a set of security rules that control inbound and outbound traffic for the DB system containing the standby database. For more information, see **Network Security Groups** on page 2841 and **Network Setup for DB Systems** on page 1359.

      **Note:**

      - If you choose a subnet with a security list, then the security rules for the DB system will be a combination of the rules in the security list and the network security groups.
      - You must select a virtual cloud network to be able to assign network security groups to your DB system.

    - **Hostname prefix**: Enter a host name prefix for the DB system that contains the standby database. The host name must begin with an alphabetic character, and can contain only alphanumeric characters.
and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

**Important:**

If the host name within the subnet is not unique, then provisioning of the DB system fails.

- **Host domain name:** The domain name for the DB system. If the subnet you selected uses the Oracle-provided internet and virtual cloud network resolver for DNS name resolution, then this field displays the domain name for the subnet, which you cannot change. Otherwise, you can enter a domain name. Hyphens (-) are not permitted.

- **Host and domain URL:** Combines the host and domain names to display the fully-qualified domain name for the database. The maximum length is 64 characters.

- In the **Configure standby database** section, enter the database administrator password of the primary database in the **Database password** field. Use this same database administrator password for the standby database.

- **Database Admin Password:** Enter the primary database admin password.

  The same password is used for the standby database.

- **Confirm Database Admin Password:** Re-enter the Database Admin Password you specified.

8. Click **Enable Data Guard**.

When you create the association, the details for a database and its peer display their respective roles as **Primary** or **Standby**.

**Virtual machine shapes**

**Virtual machine X7 shapes:**

- VM.Standard2.1: Provides a 1-node DB system with 1 core.
- VM.Standard2.2: Provides a 1- or 2-node DB system with 2 cores.
- VM.Standard2.4: Provides a 1- or 2-node DB system with 4 cores.
- VM.Standard2.8: Provides a 1- or 2-node DB system with 8 cores.
- VM.Standard2.16: Provides a 1- or 2-node DB system with 16 cores.
- VM.Standard2.24: Provides a 1- or 2-node DB system with 24 cores.

**Virtual machine X5 shapes:**

- VM.Standard1.1: Provides a 1-node DB system with 1 core.
- VM.Standard1.2: Provides a 1- or 2-node DB system with 2 cores.
- VM.Standard1.4: Provides a 1- or 2-node DB system with 4 cores.
- VM.Standard1.8: Provides a 1- or 2-node DB system with 8 cores.
- VM.Standard1.16: Provides a 1- or 2-node DB system with 16 cores.

**Note:**

- X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- VM.Standard1.1 and VM.Standard2.1 shapes cannot be used for 2-node RAC clusters.

**To perform a database switchover**

You initiate a switchover operation by using the Data Guard association of the primary database.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the primary database you want to switch over.
3. Click the DB system name, and then click the name of the primary database.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to perform a switchover, click the Actions icon (three dots), and then click **Switchover**.

6. In the **Switchover Database** dialog box, enter the database admin password, and then click **OK**.

   This database should now assume the role of the standby, and the standby should assume the role of the primary in the Data Guard association.

**To perform a database failover**

You initiate a failover operation by using the Data Guard association of the standby database.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose the **Compartment** that contains the DB system with the primary database's peer standby you want to fail over to.

3. Click the DB system name, and then click the name of the standby database.

4. Under **Resources**, click **Data Guard Associations**.

5. For the Data Guard association on which you want to perform a failover, click **Failover**.

6. In the **Failover Database** dialog box, enter the database admin password, and then click **OK**.

   This database should now assume the role of the primary, and the old primary's role should display as **Disabled Standby**.

**To reinstate a database**

After you fail over a primary database to its standby, the standby assumes the primary role and the old primary is identified as a disabled standby. After you correct the cause of failure, you can reinstate the failed database as a functioning standby for the current primary by using its Data Guard association.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before you can reinstate a 12.2 database, you must perform some steps on the database host to stop the database or start it in MOUNT mode.</td>
</tr>
<tr>
<td>Set your ORACLE_UNQNAME environment variable to the value of the Database Unique Name (as seen in the Console), and then run these commands:</td>
</tr>
<tr>
<td>srvctl stop database -d db-unique-name -o abort</td>
</tr>
<tr>
<td>srvctl start database -d db-unique-name -o mount</td>
</tr>
</tbody>
</table>

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose the **Compartment** that contains the DB system with the failed database you want to reinstate.

3. Click the DB system name, and then click the database name.

4. Under **Resources**, click **Data Guard Associations**.

5. For the Data Guard association on which you want to reinstate this database, click the Actions icon (three dots), and then click **Reinstate**.

6. In the **Reinstate Database** dialog box, enter the database admin password, and then click **OK**.

   This database should now be reinstated as the standby in the Data Guard association.

**To terminate a Data Guard association on a bare metal DB system**

On a bare metal DB system, you remove a Data Guard association by terminating the standby database.

1. Open the navigation menu. Under **Oracle Database**, click **Bare Metal, VM, and Exadata**.

2. Choose the **Compartment** that contains the DB system that includes the standby database you want to terminate.

3. Click the DB system name.

4. For the standby database you want to terminate, click the Actions icon (three dots), and then click **Terminate**.

5. In the **Terminate Database** dialog box, enter the name of the database, and then click **OK**.
To terminate a Data Guard association on a virtual machine DB system

On a virtual machine DB system, you remove a Data Guard association by terminating the standby DB system.

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
2. Choose the Compartment that contains the standby DB system that you want to terminate.
3. Click the DB system name, click the Actions icon (three dots), and then click Terminate.
4. Confirm when prompted.

The DB system's icon indicates Terminating.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage Data Guard associations:

• CreateDataGuardAssociation
• GetDataGuardAssociation
• ListDataGuardAssociations
• SwitchDataGuardAssociation
• FailoverDataGuardAssociation
• RevertDataGuardAssociation
• DeleteDbHome - To terminate a bare metal DB system Data Guard association, delete the standby database.
• TerminateDbSystem - To terminate a virtual machine DB system Data Guard association, terminate the standby DB system.

For the complete list of APIs for the Database service, see Database Service API.

Using Oracle Data Guard with the Database CLI

Oracle recommends that you use the Console instead of the database CLI to set up and work with Data Guard in Oracle Cloud Infrastructure. See Using Oracle Data Guard on page 1461 for information and instructions.

Note:

This topic is not applicable to Exadata DB systems. You can manually configure Data Guard on Exadata DB systems using native Oracle Database utilities and commands, however this topic explains how set up primary and standby databases using dbcli, which is not available on Exadata DB systems. For more information, see Data Guard Concepts and Administration for version 18.1, 12.2, 12.1, or 11.2.

This topic explains how to use the database CLI to set up Data Guard with Fast-Start Failover (FSFO) in Oracle Cloud Infrastructure. The following sections explain how to prepare the primary and standby databases, and then configure Data Guard to transmit redo data from the primary database and apply it to the standby database.

Note:

This topic assumes that you are familiar with Data Guard and FSFO. To learn more about them, see documentation at the Oracle Document Portal.

Prerequisites

To perform the procedures in this topic, you'll need the following information for the primary and standby databases.

• db_name (or oracle_sid)
• db_unique_name
• oracle home directory (or database home)
To find the database information

After you’ve launched the primary and standby DB systems and created databases as described later in this topic, you can use the CLI on those systems to find the needed database information.

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user’s profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).

   ```
   login as: opc
   [opc@dbsys ~]$ sudo su -
   ```

3. To find the db_name (or oracle_sid) and db_uniqueName, run the `dbcli list-databases -j` command.

   ```
   [root@dbsys ~]# dbcli list-databases -j
   [ {
   "id" : "80ad855a-5145-4f8f-a08f-406c5e4684ff",
   "name" : "dbtst",
   "dbName" : "dbtst",
   "databaseUniqueName" : "dbtst_phx1cs",
   "dbVersion" : "12.1.0.2",
   "dbHomeId" : "2efe7af7-0b70-4e9b-ba8b-71f1c6fe287",
   "instanceOnly" : false,
   .
   .
   }
   ```

4. To find the oracle home directory (or database home), run the `dbcli list-dbhomes` command. If there are multiple database homes on the DB system, use the one that matches the "dbHomeId" in the `dbcli list-databases -j` command output shown above.

   ```
   [root@dbtst ~]# dbcli list-dbhomes
   ID                                       Name                 DB Version     Home Location
   Status
   ----------- ------------------ ------------------ ------------------ 
   2efe7af7-0b70-4e9b-ba8b-71f1c6fe287     OraDB12102_home1   12.1.0.2.160719 (23739960, 23144544) /u01/app/oracle/product/12.1.0.2/dbhome_1 Configured

   ```

Creating a Primary DB System

If you don’t already have a primary DB system, create one as described in Creating Bare Metal and Virtual Machine DB Systems on page 1370. The DB system will include an initial database. You can create additional databases by using the Database Commands on page 1505 command available on the DB system.

Creating a Standby DB System

**Note:**

The standby database must have the same db_name as the primary database, but it must have a different db_unique_name. If you use the same database
name for the standby and primary, you will have to delete the database from the standby DB system by using the dbcli delete-database command before you can run the dbcli create-database command described below. Deleting and creating the database will take several minutes to complete. The dbcli commands must be run as the root user.

1. Create a standby DB system as described in Creating Bare Metal and Virtual Machine DB Systems on page 1370 and wait for the DB system to finish provisioning and become available.

   You can create the standby DB system in a different availability domain from the primary DB system for availability and disaster recovery purposes (this is strongly recommended). You can create the standby DB system in the primary DB system's cloud network so that both systems are in a single, routable network.

2. SSH to the DB System.

   ssh -i <private_key_path> opc@<db_system_ip_address>

3. Log in as opc and then sudo to the root user. Use sudo su - with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (/opt/oracle/dcs/bin).

   login as: opc
   [opc@dbsys ~]$ sudo su -

4. The DB system will include an initial database, but you'll need to create a standby database by using the dbcli create-database command with the --instanceonly parameter. This parameter creates only the database storage structure and starts the database in nomount mode (no other database files are created).

   When using --instanceonly, both the --dbname and --adminpassword parameters are required and they should match the dbname and admin password of the primary database to avoid confusion.

   The following sample command prompts for the admin password and then creates a storage structure for a database named dbname.

   [root@dbsys ~]# dbcli create-database --dbname <same as primary dbname> --databaseUniqueName <different from primary uniquename> --instanceonly --adminpassword

   If you are using pluggable databases, also specify the --cdb parameter.

   For complete command syntax, see Database Commands on page 1505.

5. Wait a few minutes for the dbcli create-database command to create the standby database.

   You can use the dbcli list-jobs command to verify that the creation job ran successfully, and then the dbcli list-databases command verify that the database is configured.

Preparing the Primary DB System

To prepare the primary DB system, you'll need to configure static listeners, update tnsnames.ora, and configure some database settings and parameters.

Configuring the Static Listeners

Create static listeners to be used by RMAN and Data Guard Broker.

1. SSH to the primary DB system, log in as the opc or root user, and sudo to the grid OS user.

   sudo su - grid
2. Edit `/u01/app/<version>/grid/network/admin/listener.ora` and add the following content to it. The first static listener shown here is optional. The second DGMGRL static listener is optional for version 12.1 or later databases, but required for version 11.2 databases.

```sql
SID_LIST_LISTENER=
 (SID_LIST=
  (SID_DESC=
   (GLOBAL_DBNAME = <primary_db_unique_name>,<primary_db_domain>)
   (SID_NAME = <primary_oracle_sid>)
   (ORACLE_HOME=<oracle_home_directory>)
   (ENVS="TNS_ADMIN=<oracle_home_directory>/network/admin")
  )
  (SID_DESC=
   (GLOBAL_DBNAME = <primary_db_unique_name>_DGMGRL,<primary_db_domain>)
   (SID_NAME = <primary_oracle_sid>)
   (ORACLE_HOME=<oracle_home_directory>)
   (ENVS="TNS_ADMIN=<oracle_home_directory>/network/admin")
  )
)
```

3. Save your changes and then restart the listener.

```
$ srvctl stop listener
$ srvctl start listener
```

### Adding Net Service Names to tnsnames.ora

As the oracle user, edit `$ORACLE_HOME/network/admin/tnsnames.ora` and add the standby database net service name to it.

```sql
<standby db_unique_name> =
 (DESCRIPTION =
   (SDU=65535)
   (ADDRESS = (PROTOCOL = TCP)(HOST = <standby_server>.<domain>) (PORT = 1521))
   (CONNECT_DATA =
     (SERVER = DEDICATED)
     (SERVICE_NAME = <standby db_unique_name>.<standby db_domain>)
   )
)
```

The sample above assumes that name resolution is working and that the `<standby_server>.<domain>` is resolvable at the primary database. You can also use the private IP address of the standby server if the IP addresses are routable within a single cloud network (VCN).

### Configuring Primary Database Parameters

**Tip:**

If the primary and standby hosts have different directory structures, you might need to set additional parameters that are not discussed here, such as the `log_file_name_convert` parameter. See the RMAN documentation for more information about how to create standbys for hosts with different directory structures.

1. As the oracle user, enable automatic standby file management.

```
SQL> alter system set standby_file_management=AUTO;
```
2. Identify the Broker configuration file names and locations. The commands used for this depend on the type of database storage. If you're not sure of the database storage type, use the Database Commands on page 1505 command on the DB system.

For ACFS database storage, use the following commands to set the Broker configuration files.

```
SQL> alter system set dg_broker_config_file1='/u02/app/oracle/oradata/<Primary db_unique_name>/dbs/dr1<Primary db_unique_name>.dat';
SQL> alter system set dg_broker_config_file2='/u02/app/oracle/oradata/<Primary db_unique_name>/dbs/dr2<Primary db_unique_name>.dat';
```

For ASM database storage, use the following commands to set the Broker configuration files.

```
SQL> alter system set dg_broker_config_file1='+DATA/<Primary db_unique_name>/dr1<db_unique_name>.dat';
SQL> alter system set dg_broker_config_file2='+DATA/<Primary db_unique_name>/dr2<db_unique_name>.dat';
```

3. Enable Broker DMON process for the database.

```
SQL> alter system set dg_broker_start=true;
```

4. Force database logging for all database transactions.

```
SQL> alter database force logging;
```

5. Add Standby Redo Logs (SRLs), based on the Online Redo Logs (ORLs). On a newly launched DB system, there will be three ORLs of size 1073741824, so create four SRLs of the same size.

You can use the query below to determine the number and size (in bytes) of the ORLs.

```
SQL> select group#, bytes from v$log;
GROUP#    BYTES
--------- ----------
1 1073741824
2 1073741824
```
All of the ORLs must be the same size.

The SRLs must be the same size as the ORLs, but there must be at least one more SRL than the ORLs. In the example above, there are three ORLs, so four SRLs are required. So specify the current redo logs plus one, and use the same size as the redo logs.

```
SQL> alter database add standby logfile thread 1 size <size>;
```

There should be only one member in the SRL group (by default, a DB system is created with only one member per SRL group). To ensure this, you can name the file with the following syntax.

```
alter database add standby logfile thread 1 group 4 (logfile name with full path) size 1073741824, group 5 (logfile name with full path) size 1073741824 ...
```

For ASM/OMF configurations, the above command uses the diskgroup instead of `logfile name with full path`.

```
alter database add standby logfile thread 1 group 4 (+RECO) size 1073741824, group 5 (+RECO) size 1073741824 ...
```

**Tip:**

ORLs and SRLs should be sized so that log switches do not occur more frequently than every 10 minutes. This requires knowledge of the application and may need to be adjusted after deployment. For more information, see Use Standby Redo Logs and Configure Size Appropriately.

6. Verify that you created the correct number of SRLs.

```
SQL> select group#, bytes from v$standby_log;
```

7. Make sure the database is in ARCHIVELOG mode.

```
SQL> archive log list
```

8. Enable database FLASHBACK. The minimum recommended value for db_flashback_retention_target is 120 minutes.

```
SQL> alter database flashback on;
SQL> alter system set db_flashback_retention_target=120;
```

9. Perform a single switch redo log to activate archiving if database is newly created. (At least one log must be archived prior to running the RMAN duplicate.)

```
SQL> alter system switch logfile;
```

**Preparing the Standby Database**

Before you prepare the standby database, make sure the database home on the standby is the same version as on the primary. (If the primary and standby databases are both newly created with the same database version, the database homes will be the same.) If it is not, create a database home that is the same version. You can use the `Dbhome Commands` on page 1518 command to verify the versions and the `Dbhome Commands` on page 1518 command to create a new database home as needed.

To prepare the standby DB system, you'll need to configure static listeners, update tnsnames.ora, configure TDE Wallet, create a temporary password file, verify connectivity, run RMAN DUPLICATE, enable FLASHBACK, and then create the database service.
Configuring the Static Listeners

Create static listeners to be used by RMAN and Data Guard Broker.

1. SSH to the standby DB system, log in as the opc or root user, and sudo to the grid OS user.

   ```
sudo su - grid
   ```

2. Append the following content to /u01/app/<db_version>/grid/network/admin/listener.ora.

   The first static listener shown below is required for RMAN DUPLICATE. The second DGMGRL static listener is optional for database versions 12.2.0.1 and 12.1.0.2, but required for database version 11.2.0.4.

   ```
SID_LIST_LISTENER=
   (SID_LIST=
     (GLOBAL_DBNAME = <standby db_unique_name>.<standby db_domain>)
     (SID_NAME = <standby oracle_sid>)
     (ORACLE_HOME=<oracle home directory>)
     (ENVS="TNS_ADMIN=<oracle home directory>/network/admin")
   )
   (SID_DESC=--
     (GLOBAL_DBNAME = <standby db_unique_name>_DGMGRL.<standby db_domain>)
     (SID_NAME = <standby oracle_sid>)
     (ORACLE_HOME=<oracle home directory>)
     (ENVS="TNS_ADMIN=<oracle home directory>/network/admin")
   )
   )
   ```

3. Restart the listener.

   ```
$ srvctl stop listener
$ srvctl start listener
   ```

4. Verify that the static listeners are available. The sample output below is for database version 12.1.0.2. Note that the ...status UNKNOWN messages are expected at this point.

   ```
$ lsnrctl status
LSNRCTL for Linux: Version 12.1.0.2.0 - Production on 29-SEP-2016 21:09:25
Copyright (c) 1991, 2014, Oracle. All rights reserved.
Connecting to (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=LISTENER)))

   (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=LISTENER)))
   (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=10.0.1.24)(PORT=1521)))
Services Summary...
   ```
Adding Net Service Names to tnsnames.ora

As the oracle user, add the standby database net service name to $ORACLE_HOME/network/admin/tnsnames.ora. $ORACLE_HOME is the database home where the standby database is running.

```xml
<Primary db_unique_name> =
  (DESCRIPTION =
    (SDU=65535)
    (ADDRESS = (PROTOCOL = TCP)(HOST = <primary_server>.<domain>) (PORT = 1521))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <primary db_unique_name>.<primary db_domain>)
    )
  )

<Standby db_unique_name> =
  (DESCRIPTION =
    (SDU=65535)
    (ADDRESS = (PROTOCOL = TCP)(HOST = <standby_server>.<domain>) (PORT = 1521))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <standby db_unique_name>.<db_domain>)
    )
  )
```

Copying the TDE Wallets to the Standby System

Copy the TDE wallet files from the primary DB system to standby DB system using SCP. The following sample command assumes the SCP command is being run by the oracle OS user and that the private key for oracle has been created and exists on the host where SCP is being run.

```bash
$ scp -i <private key> primary_server:/opt/oracle/dcs/commonstore/wallets/tde/<primary db_unique_name>/* standby_server:/opt/oracle/dcs/commonstore/wallets/tde/<standby db_unique_name>
```

Setting Up the Standby System Configuration

As the oracle user, create the following directory for database version 11.2.0.4. This step is optional for version 12.2.0.1 and version 12.1.0.2.

```bash
[oracle@dbsys ~]$ mkdir -pv /u03/app/oracle/redo/<standby db_unique_name>uppercase)/controlfile
```

Creating the Audit File Destination

As the oracle user, create the following directory to use as the audit file destination.

```bash
[oracle@dbsys ~]$ mkdir -p /u01/app/oracle/admin/<db_name>/adump
```

Otherwise, the RMAN duplicate command used later will fail.
Creating a Temporary Password File

As the oracle user, create a temporary password file.

```bash
[oracle@dbsys ~]$ orapwd file=$ORACLE_HOME/dbs/orapw<standby oracle_sid>
password=<admin password for primary> entries=5
```

The password **must** be the same as the admin password of the primary database. Otherwise, the RMAN duplicate step below will fail with: RMAN-05614: Passwords for target and auxiliary connections must be the same when using active duplicate.

Verifying the Standby Database is Available

1. As the oracle user, set the environment variables.

   ```bash
   [oracle@dbsys ~]$ . oraenv
   <enter the db_name>
   ```

2. Replace `$ORACLE_HOME/dbs/init<standby sid_name>.ora` with the following content:

   ```
   db_name=<Primary db_name>
   db_unique_name=<standby db_unique_name>
   db_domain=<standby db_domain>
   ```

3. Remove the spfile from the standby.

   ```bash
   /u02/app/oracle/oradata/<standby db_unique_name>/dbs/spfile
   $ORACLE_SID.ora
   ```

   The database needs to be started in nomount mode with no spfile specified, but the original init file contains an spfile parameter which will prevent the RMAN duplicate step from working.

4. Set the `ORACLE_UNQNAME` environment variable to point to your `DB_UNIQUE_NAME`.

   ```bash
   $ export ORACLE_UNQNAME =db_unique_name
   ```

   **Important:**
   If you do not perform this step, the wallet will not be opened, and running the RMAN DUPLICATE command in the subsequent step will fail.

5. The `dbcli create-database --instanceonly` command used earlier opens the standby database as a primary in read/write mode, so the database needs to be brought down before proceeding to the nomount step below.

   ```bash
   $ sqlplus / as sysdba
   SQL> shutdown immediate
   ```

6. Start the database in nomount mode.

   ```bash
   SQL> startup nomount
   ```

Verifying the Database Connections

Verify the connection between the primary and standby databases.

1. Make sure that the listener port 1521 is open in the security list(s) used for the primary and standby DB systems. For more information, see [Updating the Security List for the DB System](#) on page 1434.
2. From the primary database, connect to standby database.

   $ sqlplus sys/<password>@<standby net service name> as sysdba

3. From standby database, connect to primary database.

   $ sqlplus sys/<password>@<primary net service name> as sysdba

**Running the RMAN DUPLICATE Command**

Run the RMAN DUPLICATE command on the standby DB system, as the oracle user.

If the primary database is large, you can allocate additional channels to improve performance. For a newly installed database, one channel typically runs the database duplication in a couple of minutes.

Make sure that there are no errors generated by the RMAN DUPLICATE command. If errors occur, restart the database using the init.ora file (not spfile) in case it is generated under $ORACLE_HOME/dbs as part of RMAN DUPLICATE.

In the following examples, use lowercase for the `<Standby db_unique_name>` unless otherwise specified.

For ACFS storage layout, run the following commands.

```
$ rman target sys/<password>@<primary alias> auxiliary
sys/<password>@<standby alias> log=rman.out
RMAN> run { allocate channel prim1 type disk;
 allocate auxiliary channel sby type disk;
duplicate target database for standby from active database
dorecover
spfile
 parameter_value_convert '/<Primary db_unique_name>','/<Standby
db_unique_name>','<Primary db_unique_name uppercase>','/<Standby
db_unique_name uppercase>'
 set db_unique_name='<Standby db_unique_name>'
 set db_create_file_dest='/u02/app/oracle/oradata/<Standby
db_unique_name>'
 set dg_broker_config_file1='/u02/app/oracle/oradata/<Standby
db_unique_name>/dr1/<Standby db_unique_name>.dat'
 set dg_broker_config_file2='/u02/app/oracle/oradata/<Standby
db_unique_name>/dr2/<Standby db_unique_name>.dat'
 set dispatchers ='(PROTOCOL=TCP) (SERVICE=<Standby
db_unique_name>XDB)'
 set instance_name='<Standby db_unique_name>'
}
```

For ASM storage layout, run the following commands.

```
$ rman target sys/<password>@<primary alias> auxiliary
sys/<password>@<standby alias> log=rman.out
RMAN> run { allocate channel prim1 type disk;
 allocate auxiliary channel sby type disk;
duplicate target database for standby from active database
dorecover
spfile
 parameter_value_convert '/<Primary db_unique_name>','/<Standby
db_unique_name>','<Primary db_unique_name uppercase>','/<Standby
db_unique_name uppercase>'
 set db_unique_name='<Standby db_unique_name>'
 set dg_broker_config_file1='+DATA/<Standby db_unique_name>/dr1/<Standby
db_unique_name>.dat'
```
Enabling Database FLASHBACK

1. As a Data Guard best practice, enable flashback and set `db_flashback_retention_target` to at least 120 minutes on both the primary and standby databases.

   ```sql
   SQL> alter database flashback on;
   SQL> alter system set db_flashback_retention_target=120;
   ```

2. Verify that the standby database is created properly.

   ```sql
   SQL> select FORCE_LOGGING, FLASHBACK_ON, OPEN_MODE, DATABASE_ROLE, SWITCHOVER_STATUS, DATAGUARD_BROKER, PROTECTION_MODE from v$database ;
   ```

Creating a Database Service

Oracle recommends creating a database service for the standby database by using `srvctl`.

For ACFS storage layout.

1. Create a shared directory and copy the spfile file to it.

   ```sh
   $ mkdir -pv /u02/app/oracle/oradata/<Standby db_unique_name>/dbs
   $ cp $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora /u02/app/oracle/oradata/<Standby db_unique_name>/dbs
   ```

2. Stop and remove the existing database service.

   ```sh
   $ srvctl stop database -d <standby db_unique_name>
   $ srvctl remove database -d <standby db_unique_name>
   ```

3. Create the database service.

   ```sh
   $ srvctl add database -d <standby db_unique_name> -n <standby db_name> -o $ORACLE_HOME -c SINGLE -p '/u02/app/oracle/oradata/<Standby db_unique_name>/dbs/spfile<standby db_name>.ora' -x <standby hostname> -s "READ ONLY" -r PHYSICAL_STANDBY -i <db_name>
   $ srvctl setenv database -d <standby db_unique_name> -t "ORACLE_UNQNAME=<standby db_unique_name>"
   $ srvctl config database -d <standby db_unique_name>
   ```

4. Start the database service.

   ```sh
   $ srvctl start database -d <standby db_unique_name>
   ```

5. Clean up the files from $ORACLE_HOME/dbs.

   ```sh
   $ rm $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora
   $ rm $ORACLE_HOME/dbs/init<standby oracle_sid>.ora
   ```
6. Create the $ORACLE_HOME/dbs/init<standby oracle_sid>.ora file to reference the new location of the spfile file.

   SPFILE='/u02/app/oracle/oradata/<standby db_unique_name>/dbs/spfile<standby db_name>.ora'

7. Stop the standby database and then start it by using srvctl.

   srvctl stop database -d <standby db_unique_name>
srvctl start database -d <standby db_unique_name>

For ASM storage layout.

1. Consider generating the spfile file under +DATA.

   SQL> create pfile='init<standby oracle_sid>.ora' from spfile ;
   SQL> create spfile='+DATA' from pfile='init<standby oracle_sid>.ora' ;

2. Stop and remove the existing database service.

   $ srvctl stop database -d <standby db_unique_name>
   $ srvctl remove database -d <standby db_unique_name>

3. Create the database service.

   $ srvctl add database -d <standby db_unique_name> -n <standby db_name>
   -o $ORACLE_HOME -c SINGLE -p '+DATA/<standby db_unique_name>/PARAMETERFILE/spfile.xxx.xxxxxx'
   -x <standby hostname> -s "READ ONLY" -r PHYSICAL_STANDBY -i <db_name>
   $ srvctl setenv database -d <standby db_unique_name> -t "ORACLE_UNQNAME=<standby db_unique_name>"
   $ srvctl config database -d <standby db_unique_name>

4. Start the database service.

   $ srvctl start database -d <standby db_unique_name>

5. Clean up the files from $ORACLE_HOME/dbs.

   $ rm $ORACLE_HOME/dbs/init<standby oracle_sid>.ora
   $ rm $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora

6. Create $ORACLE_HOME/dbs/init<standby oracle_sid>.ora file to reference the new location of the spfile file.

   SPFILE='+DATA/<standby db_unique_name>/PARAMETERFILE/spfile.xxx.xxxxxx'

7. Stop the database and start the standby database by using srvctl.

   $ srvctl start database -d <standby db_unique_name>

Configuring Data Guard

Perform the following steps to complete the configuration of Data Guard and enable redo transport from the primary database and redo apply in the standby database.
1. Run the dgmgrl command line utility from either the primary or standby DB system and connect to the primary database using sys credentials.

   DGMGRL> connect sys/<sys password>@<primary tns alias>

2. Create the Data Guard configuration and identify for the primary and standby databases.

   DGMGRL> create configuration mystby as primary database is <primary db_unique_name>
   connect identifier is <primary tns alias>
   add database <standby db_unique_name> as connect identifier is <standby tns alias> maintained as physical;

3. Enable Data Guard configuration.

   DGMGRL> enable configuration;

4. Verify that Data Guard setup was done properly. Run the following SQL in both the primary and standby databases.

   SQL> select FORCE_LOGGING, FLASHBACK_ON, OPEN_MODE, DATABASE_ROLE,
   SWITCHOVER_STATUS, DATAGUARD_BROKER, PROTECTION_MODE from v$database;

5. Verify that Data Guard processes are initiated in the standby database.

   SQL> select PROCESS,PID,DELAY_MINS from V$MANAGED_STANDBY;

6. Verify parameter configuration on primary and standby.

   SQL> show parameter log_archive_dest_
   SQL> show parameter log_archive_config
   SQL> show parameter fal_server
   SQL> show parameter log_archive_format

7. Verify that the Data Guard configuration is working. Specifically, make sure redo shipping and redo apply are working and that the standby is not unreasonably lagging behind the primary.

   DGMGRL> show configuration verbose
   DGMGRL> show database verbose <standby db_unique_name>
   DGMGRL> show database verbose <primary db_unique_name>

   Any discrepancies, errors, or warnings should be resolved. You can also run a transaction on the primary and verify that it's visible in the standby.

8. Verify that the Data Guard configuration is functioning as expected by performing switchover and failover in both directions. Run show configuration after each operation and make sure there are no errors or warnings.

   Caution:

   This step is optional, based on your discretion. If for any reason the configuration is not valid, the switchover and/or failover will fail and it might be difficult or impossible to start the primary database. A recovery of the primary might be required, which will affect availability.

   DGMGRL> switchover to <standby db_unique_name>
   DGMGRL> switchover to <primary db_unique_name>
   #connect to standby before failover:

   DGMGRL> connect sys/<sys password>@<standby db_unique_name>
   DGMGRL> failover to <standby db_unique_name>
   DGMGRL> reinstate database <primary db_unique_name>
   #connect to primary before failover:
Configuring Observer (Optional)

The best practice for high availability and durability is to run the primary, standby, and observer in separate availability domains. The observer determines whether or not to failover to a specific target standby database. The server used for observer requires the Oracle Client Administrator software, which includes the Oracle SQL NET and Broker.

1. Configure TNS alias names for both the primary and standby databases as described previously, and verify the connection to both databases.

2. Change protection mode to either maxavailability or maxperformance (maxprotection is not supported for FSFO).

   To enable maxavailability:

   ```
   DGMGRL> edit database <standby db_unique_name> set property 'logXptMode'='SYNC';
   DGMGRL> edit database <primary db_unique_name> set property 'logXptMode'='SYNC';
   DGMGRL> edit configuration set protection mode as maxavailability;
   ```

   To enable maxperformance:

   ```
   DGMGRL> edit configuration set protection mode as maxperformance;
   DGMGRL> edit database <standby db_unique_name> set property 'logXptMode'='ASYNC';
   DGMGRL> edit database <primary db_unique_name> set property 'logXptMode'='ASYNC';
   ```

   For maxperformance, the FastStartFailoverLaglimit property limits the maximum amount of permitted data loss to 30 seconds by default.

3. The following properties should also be considered. Run `show configuration verbose` to see their current values.

   - FastStartFailoverPmyShutdown
   - FastStartFailoverThreshold
   - FastStartFailoverTarget
   - FastStartFailoverAutoReinstate

   (Running `show configuration` will result in the following error until the observer is started: Warning : ORA-16819: fast-start failover observer not started.)

4. Enable fast-start failover from Broker:

   ```
   DGMGRL> Enable fast_start failover
   ```

5. Verify the fast-start failover and associated settings.

   ```
   DGMGRL> show fast_start failover
   ```

6. Start the observer from Broker (it will run in the foreground, but can also be run in the background).

   ```
   DGMGRL> start observer
   ```

7. Verify fast-start failover is enabled and without errors or warnings.

   ```
   DGMGRL> show configuration verbose
   ```
8. Always test failover in both directions to ensure that everything is working as expected. Verify that FSFO is running properly by performing a shutdown abort of the primary database.

The observer should start the failover to the standby database. If protection mode is set to maxprotection, some loss of data can occur, based on the FastStartFailoverLaglimit value.

**Oracle Database CLI Reference**

The database CLI (dbcli) is a command line interface available on bare metal and virtual machine DB systems. After you connect to the DB system, you can use the database CLI to perform tasks such as creating Oracle database homes and databases.

**Note:**
The database CLI is **not** for use on Exadata DB systems.

**Operational Notes**

- The database CLI commands must be run as the root user.
- `dbcli` is in the `/opt/oracle/dcs/bin/` directory.
  This directory is included in the path for the root user's environment.
- Oracle Database maintains logs of the `dbcli` command output in the `dcscli.log` and `dcs-agent.log` files in the `/opt/oracle/dcs/log/` directory.
- The database CLI commands and most parameters are case sensitive and should be typed as shown. A few parameters are not case sensitive, as indicated in the parameter descriptions, and can be typed in uppercase or lowercase.

**Caution:**
Oracle recommends that you avoid specifying parameter values that include confidential information when you use the database CLI commands.

**Syntax**
The database CLI commands use the following syntax:

```
 dbcli command [parameters]
```

where:

- **command** is a verb-object combination such as `create-database`.
- **parameters** include additional options for the command. Most parameter names are preceded with two dashes, for example, `--help`. Abbreviated parameter names are preceded with one dash, for example, `-h`.
- User-specified parameter values are shown in red text within angle brackets, for example, `<db_home_id>`. Omit the angle brackets when specifying these values.
- The help parameter is available with every command.

The remainder of this topic contains syntax and other details about the commands.

**CLI Update Command**
Occasionally, new commands are added to the database CLI and other commands are updated to support new features. You can use the following command to update the database CLI:

```
 cliadm update-dbcli
```

Use the `cliadm update-dbcli` command to update the database CLI with the latest new and updated commands.
On RAC DB systems, execute the `cliadm update-dbcli` command on each node in the cluster.

**Syntax**

```
cliadm update-dbcli [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command updates the `dbcli`:

```
[root@dbsys ~]# cliadm update-dbcli
{
    "jobId": "dc9ce73d-ed71-4473-99cd-9663b9d79b7d",
    "status": "Created",
    "message": "Dcs cli will be updated",
    "reports": [],
    "createTimestamp": "January 18, 2017 10:19:34 AM PST",
    "resourceList": [],
    "description": "dbcli patching",
    "updatedTime": "January 18, 2017 10:19:34 AM PST"
}
```

**Agent Commands**

The following commands are available to manage agents:

- `dbcli ping-agent`
- `dbcli list-agentConfigParameters`
- `dbcli update-agentConfigParameters`

**dbcli ping-agent**

Use the `dbcli ping-agent` command to test the reachability of an agent.

**Syntax**

```
dbcli ping-agent [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
**dbcli list-agentConfigParameters**

Use the `dbcli list-agentConfigParameters` command to list agent configuration parameters.

**Syntax**

```
dbcli list-agentConfigParameters [-n] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>-name</td>
<td>(Optional) Parameter name.</td>
</tr>
</tbody>
</table>

**dbcli update-agentConfigParameters**

Use the `dbcli update-agentConfigParameters` command to update agent configuration parameters.

**Syntax**

```
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td>--append</td>
<td>(Optional) Appends the specified values to the specified parameters. Example with multiple parameter names and values: <code>-n p1 -v v1 -n p2 -v v2 -a</code></td>
</tr>
<tr>
<td>-c</td>
<td>--comment</td>
<td>(Optional) Adds a comment for the parameter. Default: []</td>
</tr>
<tr>
<td>-d</td>
<td>--description</td>
<td>(Optional) Adds a description for the parameter. Default: []</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--name</td>
<td>Parameter name. Example with multiple parameter names and values: <code>-n p1 -v v1 -n p2 -v v2 Default: []</code></td>
</tr>
<tr>
<td>-r</td>
<td>--reset</td>
<td>(Optional) Resets the parameter to the default value. Example resetting multiple parameters: <code>-n p1 -n p2 -r Default: false</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-u</td>
<td>--update</td>
<td>(Optional) Replaces the specified parameter values as directed. Example with multiple parameter names and values: <code>-n p1 -v v1 -n p2 -v v2 -u</code> Default: false</td>
</tr>
<tr>
<td>-v</td>
<td>--value</td>
<td>(Optional) Parameter value. Example with multiple parameter names and values: <code>-n p1 -v v1 -n p2 -v v2</code> Default: []</td>
</tr>
</tbody>
</table>

**Autologcleanpolicy Commands**

The following commands are available to manage policies for automatic cleaning (purging) of logs.

- `dbcli create-autoLogCleanPolicy`
- `dbcli list-autoLogCleanPolicy`

**dbcli create-autoLogCleanPolicy**

Use the `dbcli create-autoLogCleanPolicy` command to create policies for automatic cleaning (purging) of logs.

**Syntax**

```
dbcli create-autoLogCleanPolicy [-c {gi|database|dcs}] [-f <number>] [-o <number>] [-u {Day|Hour|Minute}] [-uMB <number>] [-uPer <number>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--components</td>
<td>(Optional) Components to purge. Possible values are gi, database, and dcs. Separate multiple values with commas. Example: <code>gi,dcs</code></td>
</tr>
<tr>
<td>-f</td>
<td>--freeSpaceBelowPercentage</td>
<td>(Optional) Purges logs when the free disk space is below the specified percentage of the total partition size. Valid range: 20-50. Default: 20.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-o</td>
<td>--olderthan</td>
<td>(Optional) Quantity portion of time interval. Default: 30. Cleans logs older than the specified time interval (<code>-o</code> and <code>-u</code>).</td>
</tr>
</tbody>
</table>
### Parameter List

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-u</td>
<td>--olderThanUnit</td>
<td>(Optional) Unit portion of time interval. Possible values: Day, Hour, or Minute. Default: Day. Cleans logs older than the specified time interval (-o and -u).</td>
</tr>
<tr>
<td>-uMB</td>
<td>--usageOverMB</td>
<td>(Optional) Purges logs when log usage exceeds the specified number of MegaBytes (MB). Valid range: 10 to 50% of total partition size.</td>
</tr>
<tr>
<td>-uPer</td>
<td>--usageOverPercentage</td>
<td>(Optional) Purges logs when log usage exceeds the specified percentage of the total partition size. Valid range: 10-50.</td>
</tr>
</tbody>
</table>

#### dbcli list-autoLogCleanPolicy

Use the `dbcli list-autoLogCleanPolicy` command to list policies for automatic cleaning of logs.

**Syntax**

```
  dbcli list-autoLogCleanPolicy [-c {gi|database|dcs}] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--components</td>
<td>(Optional) Components. Possible values are gi, database, and dcs. Separate multiple values with commas. Example: gi,dcs</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

#### Backup Commands

The following commands are available to back up databases:

- `dbcli create-backup`
- `dbcli getstatus-backup`
- `dbcli schedule-backup`

**Note:**

Instead of using `dbcli`, you can use the Console or the API to manage backing up your bare metal or virtual machine DB system databases to Object Storage. However, if you switch from using `dbcli` to using managed backups, a new backup configuration is created and associated with your database, and backups you created by using `dbcli` will not be accessible from the managed backup interfaces. For information about managed backups, see [Backing Up a Database to Oracle Cloud Infrastructure Object Storage](#) on page 1435.
Before you can back up a database by using the `dbcli create-backup` command, you'll need to:

1. Create a backup configuration by using the `dbcli create-backupconfig` command.
2. Associate the backup configuration with the database by using the `dbcli update-database` command.

After a database is associated with a backup configuration, you can use the `dbcli create-backup` command in a cron job to run backups automatically. You can use a cron utility such as CronMaker to help build expressions. For more information, see [http://www.cronmaker.com](http://www.cronmaker.com).

**dbcli create-backup**

Use the `dbcli create-backup` command to create a backup of a database.

**Syntax**

```
    dbcli create-backup -in <db_name> -i <db_id> [-bt {Regular-L0|Regular-L1|Longterm|ArchiveLog}] [-c {Database|TdeWallet}] [-k <n>] [-t <tag>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bt</td>
<td>--backupType</td>
<td>(Optional) Backup type. Possible values are Regular-L0, Regular-L1, Longterm, and ArchiveLog. Regular-L0 and Regular L1 correspond to incremental L0 and L1 backups. Longterm corresponds to Full backup. ArchiveLog corresponds to archived redo logs backup. The default value is Regular-L1. Values are not case-sensitive. If omitted, the default value is used.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-c</td>
<td>--component</td>
<td>(Optional) Component. Possible values are Database and TdeWallet. The default value is Database. The value TdeWallet backs up TDE wallets. Values are not case-sensitive. If omitted, the default value is used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>TDE wallets are automatically backed up in the following situations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A database is created with an Object Storage backup configuration.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A database that has an Object Storage backup configuration is updated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• An Object Storage backup configuration is updated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A backup of the type Longterm is created.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The TDE key for a database is rotated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A database is backed up and no TDE wallet backups exist yet.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>The ID of the database to back up. Use the <code>dbcli list-databases</code> command to get the database's ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>The name of the database to back up. Use the <code>dbcli list-databases</code> command to get the database's name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
### Examples

The following command creates a backup of the specified database using the database ID.

```
[root@dbsys ~]# dbcli create-backup -i 573cadb2-0cc2-4c1c-9c31-595ab8963d5b
```

The following command creates a backup of the specified database using the database name ("mydb").

```
[root@dbsys ~]# dbcli create-backup -in mydb
```

**dbcli getstatus-backup**

Use the `dbcli getstatus-backup` command to display the status of a backup.

**Syntax**

```
dbcli getstatus-backup -t <backup_type> [i <id>] [-in <name>] [-l] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbId</td>
<td>(Optional) Database Resource ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>(Optional) Database Resource Name.</td>
</tr>
</tbody>
</table>
Use the `dbcli schedule-backup` command to schedule a backup of a database.

### Syntax

```
dbcli schedule-backup -t <backup_type> -f <number> [i <id>] [-in <name>] [-h] [-j]
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>--frequency</td>
<td>Frequency in minutes.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbId</td>
<td>(Optional) Database Resource ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>(Optional) Database Resource Name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-t</td>
<td>--backupType</td>
<td>Backup type.</td>
</tr>
</tbody>
</table>

### Backupconfig Commands

A backup configuration determines the backup destination and recovery window for database backups. You create the backup configuration and then associate it with a database by using the `dbcli update-database` command.

#### Caution:
Backups that were configured using the Console may become unusable if you make changes using these commands. For backups configured using the Console, use these commands with support guidance only.

#### Note:
Instead of using `dbcli`, you can use the Console or the API to manage backing up your bare metal or virtual machine DB system databases to Object Storage. For information about managed backups, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage on page 1435.

After a database is associated with a backup configuration, you can use the `dbcli create-backup` command in a cron job to run backups automatically. You can use a cron utility such as CronMaker to help build expressions. For more information, see [http://www.cronmaker.com](http://www.cronmaker.com).

The following commands are available to manage backup configurations:

- `dbcli create-backupconfig`
- `dbcli list-backupconfigs`
- `dbcli describe-backupconfig`
- dbcli update-backupconfig
- dbcli delete-backupconfig

**dbcli create-backupconfig**

Use the `dbcli create-backupconfig` command to create a backup configuration that defines the backup destination and recovery windows.

**Syntax**

```bash
dbcli create-backupconfig -d {DISK|OBJECTSTORE|NONE} -c <bucket> -o <object_store_swift_id> -on <object_store_swift_name> -w <n> -n <name> [-cr|-no-cr] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--container</td>
<td>The name of an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets on page 3398. You must also specify --backupdestination objectstore and the --objectstoreswiftId parameter.</td>
</tr>
<tr>
<td>-cr</td>
<td>--crosscheck</td>
<td>(Optional) Indicates whether to enable the crosscheck operation. This operation determines if the files on the disk or in the media management catalog correspond to data in the RMAN repository. If omitted, the default setting is used (crosscheck is enabled by default).</td>
</tr>
<tr>
<td>-no-cr</td>
<td>--no-crosscheck</td>
<td></td>
</tr>
<tr>
<td>-d</td>
<td>--backupdestination</td>
<td>The backup destination as one of the following (these values are <strong>not</strong> case sensitive): DISK - The local Fast Recovery Area. OBJECTSTORE - The Oracle Cloud Infrastructure Object Storage service. You must also specify the --container and --objectstoreswiftId parameters. NONE - Disables the backup.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--name</td>
<td>The name of the backup configuration.</td>
</tr>
<tr>
<td>-o</td>
<td>--objectstoreswiftId</td>
<td>The ID of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the <code>dbcli list-objectstoreswifts</code> command to get the object store ID. Use the <code>dbcli create-objectstoreswift</code> command to create an object store. You must also specify <code>--backupdestination objectstore</code> and the <code>--container</code> parameter.</td>
</tr>
<tr>
<td>-on</td>
<td>--objectstoreswiftName</td>
<td>The name of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the <code>dbcli list-objectstoreswifts</code> command to get the object store ID. Use the <code>dbcli create-objectstoreswift</code> command to create an object store. You must also specify <code>--backupdestination objectstore</code> and the <code>--container</code> parameter.</td>
</tr>
<tr>
<td>-w</td>
<td>--recoverywindow</td>
<td>The number of days for which backups and archived redo logs are maintained. The interval always ends with the current time and extends back in time for the number of days specified. For a DISK backup destination, specify 1 to 14 days. For an OBJECTSTORE backup destination, specify 1 to 30 days.</td>
</tr>
</tbody>
</table>
Example

The following command creates a backup configuration named dbbkcfg1:

```
[root@dbsys ~]# dbcli create-backupconfig -d Disk -w 7 -n dbbkcfg1
{
   "jobId" : "4e0e6011-db53-4142-82ef-eb561658a0a9",
   "status" : "Success",
   "message" : null,
   "reports" : [ {
      "taskId" : "TaskParallel_919",
      "taskName" : "persisting backup config metadata",
      "taskResult" : "Success",
      "startTime" : "November 18, 2016 20:21:25 PM UTC",
      "endTime" : "November 18, 2016 20:21:25 PM UTC",
      "status" : "Success",
      "taskDescription" : null,
      "parentTaskId" : "TaskSequential_915",
      "jobId" : "4e0e6011-db53-4142-82ef-eb561658a0a9",
      "tags" : [ ],
      "reportLevel" : "Info",
      "updatedTime" : "November 18, 2016 20:21:25 PM UTC"
   } ],
   "createTimestamp" : "November 18, 2016 20:21:25 PM UTC",
   "description" : "create backup config:dbbkcfg1",
   "updatedTime" : "November 18, 2016 20:21:25 PM UTC"
}
```

dbcli list-backupconfigs

Use the `dbcli list-backupconfigs` command to list all the backup configurations in the DB system.

Syntax

```
dbcli list-backupconfigs [-h] [-j]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

Example

The following command lists a backup configuration:

```
[root@dbsys ~]# dbcli list-backupconfigs

ID                                       Name                 RecoveryWindow
---------------------------------------- -------------------- -----------------------------
------------------ ----------------- -----------------------------
ccdd56fe-a40b-4e82-b38d-5f76c265282d     dbbkcfg1             7
Disk              July 10, 2016 12:24:08 PM UTC
```

**dbcli describe-backupconfig**

Use the `dbcli describe-backupconfig` command to show details about a specific backup configuration.

**Syntax**

```
dbcli describe-backupconfig -i <id> -in <name> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--backupconfigid</td>
<td>The backup configuration ID. Use the <code>dbcli list-backupconfigs</code> command to get the ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--backupconfigname</td>
<td>The backup configuration name. Use the <code>dbcli list-backupconfigs</code> command to get the name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays details about a backup configuration:

```
[root@dbsys ~]# dbcli describe-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d
Backup Config details
------------------------------------------
   ID: ccdd56fe-a40b-4e82-b38d-5f76c265282d
   Name: dbbkcfg1
   RecoveryWindow: 7
   BackupDestination: Disk
   CreatedTime: July 10, 2016 12:24:08 PM UTC
   UpdatedTime: July 10, 2016 12:24:08 PM UTC
```

**dbcli update-backupconfig**

Use the `dbcli update-backupconfig` command to update an existing backup configuration.

**Syntax**

```
dbcli update-backupconfig -i <id> -in <name> -w <n>
```

- `d {DISK|OBJECTSTORE|NONE}`
- `c <bucket> -o <object_store swift_id> -on <object_store swift_name> [-cr|no-cr] [-h] [-j]`
## Database Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--container</td>
<td>The name of an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets on page 3398. You must also specify --backupdestination objectstore and the --objectstoreswiftId parameter.</td>
</tr>
<tr>
<td>-cr</td>
<td>--crosscheck</td>
<td>(Optional) Indicates whether to enable the crosscheck operation. This operation determines if the files on the disk on in the media management catalog correspond to data in the RMAN repository. If omitted, the default setting is used (crosscheck is enabled by default).</td>
</tr>
<tr>
<td>-no-cr</td>
<td>--no-crosscheck</td>
<td></td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--backupconfigid</td>
<td>The ID of the backup configuration to update. Use the dbcli list-backupconfigs command to get the ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--backupconfigname</td>
<td>The name of the backup configuration to update. Use the dbcli list-backupconfigs command to get the name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-o</td>
<td>--objectstoreswiftId</td>
<td>The ID of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the dbcli list-objectstoreswifts command to get the object store ID. Use the dbcli create-objectstoreswift command to create an object store. You must also specify --backupdestination objectstore and the --container parameter.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-on</td>
<td>--objectstoreswiftname</td>
<td>The name of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the <code>dbcli list-objectstoreswifts</code> command to get the object store ID. Use the <code>dbcli create-objectstoreswift</code> command to create an object store. You must also specify <code>--backupdestination objectstore</code> and the <code>--container</code> parameter.</td>
</tr>
<tr>
<td>-w</td>
<td>--recoverywindow</td>
<td>The new disk recovery window. For a DISK backup destination, specify 1 to 14 days. For an OBJECTSTORE backup destination, specify 1 to 30 days.</td>
</tr>
</tbody>
</table>

**Example**

The following command updates the recovery window for a backup configuration:

```
[root@dbsys ~]# dbcli update-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d -w 5
{
    "jobId" : "0e849291-e1e1-4c7a-8dd2-62b522b9b807",
    "status" : "Created",
    "message" : null,
    "reports" : [ ],
    "createTimestamp" : 1468153731699,
    "description" : "update backup config: dbbkcfg1",
    "updatedTime" : 1468153731700
}
```

**dbcli delete-backupconfig**

Use the `dbcli delete-backupconfig` command to delete a backup configuration.

**Syntax**

```
dbcli delete-backupconfig -i <id> -in <name> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>
### Parameter | Full Name | Description
--- | --- | ---
-i | --id | The backup configuration ID to delete. Use the `dbcli list-backupconfigs` command to get the ID.
-in | --backupconfigname | The name of the backup configuration to delete. Use the `dbcli list-backupconfigs` command to get the name.
-j | --json | (Optional) Displays JSON output.

### Example
The following command deletes the specified backup configuration:

```
[root@dbsys ~]# dbcli delete-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d
```

### Bmccredential Commands
The following commands are available to manage credentials configurations, which are required for downloading DB system patches from the Oracle Cloud Infrastructure Object Storage service. For more information, see Patching a DB System on page 1407.

- `dbcli create-bmccredential`
- `dbcli list-bmccredentials`
- `dbcli describe-bmccredential`
- `dbcli delete-bmccredential`
- `dbcli update-bmccredential`

### Note:
The `bmccredential` commands are not available on 2-node RAC DB systems.

### dbcli create-bmccredential
Use the `dbcli create-bmccredential` command to create a credentials configuration.

### Prerequisites
Before you can create a credentials configuration, you'll need these items:

- An RSA key pair in **PEM format** (minimum 2048 bits). See How to Generate an API Signing Key on page 4180.
- The fingerprint of the public key. See How to Get the Key's Fingerprint on page 4183.
- Your tenancy's **OCID** and user name's OCID. See Where to Get the Tenancy's OCID and User's OCID on page 4184.

Then you'll need to upload the public key in the Console. See How to Upload the Public Key on page 4184.

### Syntax
```
dbcli create-bmccredential -c [backup|patching|other] -t <tenant_ocid> -u <user_ocid> -f <fingerprint> -k <private_key_path> -p|-hp <passphrase> [-n <credentials_name>] [-e <object_store_url>] [-h] [-j]
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--credentialsType</td>
<td>The type of Object Storage credentials configuration to create (these values are <strong>not</strong> case sensitive):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>BACKUP - Reserved for the future use.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PATCHING - For downloading patches from the service.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OTHER - Reserved for the future use.</td>
</tr>
<tr>
<td>-e</td>
<td>--objectStoreUrl</td>
<td>(Optional) The Object Storage endpoint URL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Omit this parameter when --credentialsType PATCHING is specified. The following URL is assumed:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="https://objectstorage">https://objectstorage</a>.&lt;region_name&gt;.oraclecloud.com</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See <a href="https://docs.oracle.com/en-us/iaas/Content/Home.htm">Regions and Availability Domains</a> for region name strings.</td>
</tr>
<tr>
<td>-f</td>
<td>--fingerPrint</td>
<td>The public key fingerprint. You can find the fingerprint in the Console by clicking your user name in the upper right corner and then clicking User Settings. The fingerprint looks something like this:</td>
</tr>
<tr>
<td>-k</td>
<td>--privateKey</td>
<td>The path to the private key file in PEM format, for example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>-k /root/.ssh/privkey</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--name</td>
<td>(Optional) The name for the new credentials configuration. The name is useful for tracking the configuration.</td>
</tr>
</tbody>
</table>
## Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-p</td>
<td>--passPhrase</td>
<td>The passphrase for the public/private key pair, if you specified one when creating the key pair. Specify <code>-p</code> (with no passphrase) to be prompted. Specify <code>-hp &lt;passphrase&gt;</code> to provide the passphrase in the command.</td>
</tr>
<tr>
<td>-hp</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-t</td>
<td>--tenantOcid</td>
<td>Your tenancy OCID. See Where to Find Your Tenancy’s OCID on page 198. The tenancy OCID looks something like this: ocid1.tenancy.oc1..&lt;unique_ID&gt;</td>
</tr>
<tr>
<td>-u</td>
<td>--userOcid</td>
<td>The user name OCID for your Oracle Cloud Infrastructure user account. You can find the OCID in the Console: Open the Profile menu (👤) and click User Settings. The user name OCID looks something like this: ocid1.user.oc1..&lt;unique_ID&gt;</td>
</tr>
</tbody>
</table>

### Example

The following command creates a credentials configuration:

```
[root@dbsys ~]# dbcli create-bmccredential -c patching -hp mypass -t ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsdfsq -u ocid1.user.oc1..aaaaaaalhdxviuxqi7xevqsksccl6edokgldvuf6raskcioq4x2z7watsfa-f 60:9e:56:26:4b:dd:46:dc:8c:a8:05:6d:9f:0a:30:d2 -k /root/.ssh/privkey

{
  "jobId" : "f8c80510-b717-4ee2-a47e-cd380480b28b",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "December 26, 2016 22:46:38 PM PST",
  "resourceList" : [ ],
  "description" : "BMC Credentials Creation",
  "updatedTime" : "December 26, 2016 22:46:38 PM PST"
}
```

### dbcli list-bmccredentials

Use the `dbcli list-bmccredentials` command to list the credentials configurations on the DB system.

Oracle Cloud Infrastructure User Guide 1500
Syntax

dbcli list-bmccredentials [-h] [-j]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

Example

The following command lists the credentials configurations on the DB system:

```
[root@dbsys ~]# dbcli list-bmccredentials
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Type</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>f19d7c8b-d0d5-4jhf-852b-eb2a81cb7ce5</td>
<td>patch1</td>
<td>Patching</td>
<td></td>
</tr>
<tr>
<td><a href="https://objectstorage.us-phoenix-1.oraclecloud.com">https://objectstorage.us-phoenix-1.oraclecloud.com</a></td>
<td></td>
<td>Configured</td>
<td></td>
</tr>
<tr>
<td>f1a8741c-b0c4-4jhf-239b-ab2a81jhfd64</td>
<td>patch2</td>
<td>Patching</td>
<td></td>
</tr>
<tr>
<td><a href="https://objectstorage.us-phoenix-1.oraclecloud.com">https://objectstorage.us-phoenix-1.oraclecloud.com</a></td>
<td></td>
<td>Configured</td>
<td></td>
</tr>
</tbody>
</table>

**dbcli describe-bmccredential**

Use the dbcli describe-bmccredential command to display details about a credentials configuration.

Syntax

```
dbcli describe-bmccredential -i <credentials_id> [-h] [-j]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
<td>The ID for the credentials configuration. Use the dbcli list-bmccredentials on page 1500 command to get the ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

Example

The following command displays details about the specified credentials configuration:

```
[root@dbsys ~]# dbcli describe-bmccredential -i 09f9988e-ee5d-4dfe-8814-890828d1c763
```

BMC Credentials details

```
```

Oracle Cloud Infrastructure User Guide 1501

**dbcli delete-bmccredential**

Use the `dbcli delete-bmccredential` command to delete a credentials configuration.

**Syntax**

```
dbcli delete-bmccredential -i <credentials_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
<td>The ID for the credentials configuration. Use the <code>dbcli list-bmccredentials</code> command to get the ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command deletes the specified credentials configuration:

```
[root@dbsys ~]# dbcli delete-bmccredential -i f19d7c8b-d0d5-4jhf-852b-eb2a81cb7ce5
```

**dbcli update-bmccredential**

Use the `dbcli update-bmccredential` command to update a credentials configuration.

**Syntax**

```
dbcli update-bmccredential -i <credentials_id> -n <credentials_name> -c [backup|patching|other] -p|-hp <passphrase> -f <fingerprint> -k <private_key_path> [-h] [-j]
```
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--credentialsType</td>
<td>The type of Object Storage credentials configuration (these values are <strong>not</strong> case sensitive): BACKUP - Reserved for the future use. PATCHING - For downloading patches from the service. OTHER - Reserved for the future use.</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
<td>The ID for the credentials configuration. Use the <code>dbcli list-bmccredentials</code> command to get the ID.</td>
</tr>
<tr>
<td>-f</td>
<td>--fingerPrint</td>
<td>The public key fingerprint, for example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><img src="example.png" alt="Example" /></td>
</tr>
<tr>
<td>-k</td>
<td>--privateKey</td>
<td>The path to the private key file in PEM format, for example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><img src="example.png" alt="Example" /></td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--name</td>
<td>(Optional) The name for the credentials configuration. Use the <code>dbcli list-bmccredentials</code> command to get the name.</td>
</tr>
<tr>
<td>-p</td>
<td>--passPhrase</td>
<td>The passphrase for the public/private key pair, if you specified one when creating the key pair. Specify <code>-p</code> (with no passphrase) to be prompted. Specify <code>-hp &lt;passphrase&gt;</code> to provide the passphrase in the command.</td>
</tr>
<tr>
<td></td>
<td>-hp</td>
<td></td>
</tr>
</tbody>
</table>
Example

The following command updates a credentials configuration:

```
[root@dbsys ~]# dbcli update-bmccredential -c OTHER -i 6f921b29-61b6-56f4-889a-ce9270621956
{
    "jobId" : "6e95a69e-cf73-4e51-a444-c7e4b9631c27",
    "status" : "Created",
    "message" : null,
    "reports" : [ ],
    "createTimestamp" : "January 19, 2017 12:01:10 PM PST",
    "resourceList" : [ ],
    "description" : "Update BMC Credentials of object 6f921b29-61b6-48f4-889a-ce9270621945",
    "updatedTime" : "January 19, 2017 12:01:10 PM PST"
}
```

Component Command

dbcli describe-component

<table>
<thead>
<tr>
<th>Tip:</th>
<th>Your DB system might not include this newer command. If you have trouble running the command, use the CLI Update Command on page 1483 command to update the database CLI and then retry the command.</th>
</tr>
</thead>
</table>

Note: The dbcli describe-component command is not available on 2-node RAC DB systems. Patching 2-node systems from Object Storage is not supported.

Use the dbcli describe-component command to show the installed and available patch versions for the server, storage, and/or database home components in the DB system.

This command requires a valid Object Storage credentials configuration. Use the Bmccredential Commands on page 1498 command to create the configuration if you haven’t already done so. If the configuration is missing or invalid, the command fails with the error: Failed to connect to the object store. Please provide valid details.

For more information about updating the CLI, creating the credentials configuration, and applying patches, see Patching a DB System on page 1407.

Syntax

dbcli describe-component [-s <server_group>] [-d <db_group>] [-h] [-j]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td>--dbhomes</td>
<td>(Optional) Lists the installed and available patch versions for only the database home components.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-s</td>
<td>--server</td>
<td>(Optional) Lists the installed and available patch versions for only the server components.</td>
</tr>
</tbody>
</table>

**Example**

The following command to show the current component versions and the available patch versions in the object store:

```
[root@dbsys ~]# dbcli describe-component
```

```
System Version
--------------
12.1.2.10.0

Component                                Installed Version    Available
Version ---------------------------------------- -------------------
----------------------
OAK                                      12.1.2.10.0          up-to-date
GI                                       12.1.0.2.161018      up-to-date
ORADB12102_HOME1                         12.1.0.2.161018      up-to-date
ORADB12102_HOME2, ORADB12102_HOME3       12.1.0.2.160719
  12.1.0.2.161018
```

**Database Commands**

The following commands are available to manage databases:

- `dbcli clone-database`
- `dbcli create-database`
- `dbcli delete-database`
- `dbcli describe-database`
- `dbcli list-databases`
- `dbcli modify-database`
- `dbcli recover-database`
- `dbcli register-database`
- `dbcli update-database`

**dbcli clone-database**

Use the `dbcli clone-database` command to clone a database.

**Syntax**

```
dbcli clone-database -f <name> -u <name> -n <name> [-s <shape>] [-t <type>] [m <sys_password>] [-p <tde_password>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>--sourcedbname</td>
<td>Source database name.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>-m</td>
<td>--syspassword</td>
<td>(Optional) Password for SYS.</td>
</tr>
<tr>
<td>-n</td>
<td>--dbname</td>
<td>Database name.</td>
</tr>
<tr>
<td>-p</td>
<td>--tdepassword</td>
<td>(Optional) Password for source TDE wallet.</td>
</tr>
<tr>
<td>-s</td>
<td>--dbshape</td>
<td>(Optional) Database shape.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Examples: odb1, odb2.</td>
</tr>
<tr>
<td>-t</td>
<td>--dbtype</td>
<td>(Optional) Database Type: SI</td>
</tr>
<tr>
<td>-u</td>
<td>--databaseUniqueName</td>
<td>Database unique name.</td>
</tr>
</tbody>
</table>

**dbcli create-database**

Use the `dbcli create-database` command to create a new database. You can create a database with a new or existing Oracle Database home, however each database home can have only one database.

It takes a few minutes to create the database. After you run the `dbcli create-database` command, you can use the `dbcli list-jobs` command to check the status of the database creation job.

**Tip:**

Wait for the database creation job to complete before you attempt to create another database. Running multiple `dbcli create-database` commands at the same time can result in some of the creation jobs not completing.

Once the database is created, you can use the `dbcli list-databases -j` command to see additional information about the database.

**Note:**

The `dbcli create-database` command is available on bare metal DB systems only.

You must create and activate a master encryption key for any PDBs that you create. After creating or plugging in a new PDB on a 1- or 2-node RAC DB System, use the `dbcli update-tdekey` command to create and activate a master encryption key for the PDB. Otherwise, you might encounter the error `ORA-28374: typed master key not found in wallet` when attempting to create tablespaces in the PDB. In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers. For more information, see "Overview of Managing a Multitenant Environment" in the Oracle Database Administrator’s Guide.

**Syntax**

```
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bi</td>
<td>--backupconfigid</td>
<td>Defines the backup configuration identifier for future use. Use the dbcli list-backupconfigs command to get the ID.</td>
</tr>
<tr>
<td>-bn</td>
<td>--backupconfigname</td>
<td>Defines the backup configuration name for future use. Use the dbcli list-backupconfigs command to get the name.</td>
</tr>
<tr>
<td>-c</td>
<td>--cdb</td>
<td>(Optional) Indicates whether to create a Container Database. If omitted, a Container Database is not created.</td>
</tr>
<tr>
<td>-no-c</td>
<td>--no-cdb</td>
<td></td>
</tr>
<tr>
<td>-cs</td>
<td>--characterset</td>
<td>(Optional) Defines the character set for the database. The default is AL32UTF8.</td>
</tr>
<tr>
<td>-cl</td>
<td>--dbclass</td>
<td>Defines the database class. The options are OLTP, DSS, or IMDB. The default is OLTP. For Enterprise Editions, all three classes are supported. For Standard Edition, only OLTP is supported.</td>
</tr>
<tr>
<td>-co</td>
<td>--dbconsole</td>
<td>(Optional) Indicates whether the Database Console is enabled. If omitted, the console is not enabled. This parameter is not available for a version 11.2.0.4 database on a 2-node RAC DB system. For more information, see To enable the console for a version 11.2.0.4 database on a multi-node DB system on page 1432.</td>
</tr>
<tr>
<td>-no-co</td>
<td>--no-dbconsole</td>
<td></td>
</tr>
<tr>
<td>-d</td>
<td>--pdbadmin</td>
<td>Defines the name of the Pluggable Database (PDB) Admin User. The default value is pdbadmin.</td>
</tr>
<tr>
<td>-dn</td>
<td>--dbdomainname</td>
<td>(Optional) Database domain name (indicates the logical location of the database within the network structure).</td>
</tr>
<tr>
<td>-dt</td>
<td>--dbterritory</td>
<td>(Optional) Defines the territory for the database. The default is AMERICA.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-dh</td>
<td>--dbhomeid</td>
<td>Identifies the database home in which to create the database. The database home must be empty because each database home can have only one database. You can use the dbcli list dbhomes command to get the DB home ID. If this parameter is omitted, the database is created with a new Oracle home.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-l</td>
<td>--dblanguage</td>
<td>(Optional) Defines the language for the database. The default is AMERICAN.</td>
</tr>
<tr>
<td>-m</td>
<td>--adminpassword</td>
<td>A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word &quot;oracle&quot; either in forward or reversed order and regardless of casing. Specify -m (with no password) to be prompted for the password.</td>
</tr>
<tr>
<td>-n</td>
<td>--dbname</td>
<td>Defines the name given to the new database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.</td>
</tr>
<tr>
<td>-ns</td>
<td>--nationalscharacterset</td>
<td>(Optional) Defines the national character set for the database. The default is AL16UTF16.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-p</td>
<td>--pdbname</td>
<td>(Optional) Defines a unique name for the PDB. The PDB name must begin with an alphabetic character and can contain a maximum of 30 alphanumeric characters. The only special character permitted is the underscore (_). The default value is pdb1. PDB names must be unique within a CDB and within the listener to which they are registered. Make sure the PDB name is unique on the system. To ensure uniqueness, do not use the default name value (pdb1).</td>
</tr>
<tr>
<td>-r</td>
<td>--dbstorage</td>
<td>Defines the database storage, either ACFS or ASM. The default value is ASM. See Usage Notes on page 1510 for more information.</td>
</tr>
<tr>
<td>-s</td>
<td>--dbshape</td>
<td>Identifies the database sizing template to use for the database. For example, odb1, odb2, or odb3. The default is odb1. For more information, see Database Sizing Templates on page 1552.</td>
</tr>
<tr>
<td>-u</td>
<td>--databaseUniqueName</td>
<td>Defines a unique name for the database to ensure uniqueness within an Oracle Data Guard group (a primary database and its standby databases). The unique name can contain only alphanumeric and underscore (_) characters. The unique name cannot be changed. The unique name defaults to the name specified in the --dbname parameter.</td>
</tr>
</tbody>
</table>
| -v        | --version | Defines the database version as one of the following:  
  - 18.1.0.0  
  - 12.2.0.1  
  - 12.1.0.2 (the default)  
  - 11.2.0.4 |
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-y</td>
<td>--dbtype</td>
<td>Defines the database type. Specify SI for a 1-node instance, RAC for a 2-node cluster, or RACOne for 1-node instance with a second node in cold standby mode. The default value is RAC. These values are not case sensitive.</td>
</tr>
</tbody>
</table>

#### Usage Notes

- You cannot mix Oracle Database Standard Edition and Enterprise Edition databases on the same DB system. (You can mix supported database versions on the DB system, but not editions.)
- When `--dbhomeid` is not provided, the `dbcli create-database` command will create a new Oracle Database home.

**Note:**

Bare metal DB systems allow only one database per database home.

- When `--dbhomeid` is provided, the `dbcli create-database` command creates the database using the Oracle home specified. Use the `dbcli list-dbhomes` command to get the `dbhomeid`. The database home you specify must be empty.
- Oracle Database 12.1 or later databases are supported on both Oracle Automatic Storage Management (ASM) and Oracle ASM Cluster file system (ACFS). The default is Oracle ACFS.
- Oracle Database 11.2 is supported on Oracle ACFS.
- Each database is configured with its own Oracle ACFS file system for the datafiles and uses the following naming convention: `/u02/app/db user/oradata/db name`. The default size of this mount point is 100G.
- Online logs are stored in the `/u03/app/db user/redo/` directory.
- The Oracle Fast Recovery Area (FRA) is located in the `/u03/app/db user/fast_recovery_area` directory.

#### Examples

To create a database and be prompted for the password interactively:

```
[root@dbsys ~]# dbcli create-database -n hrdb -c -m -cl OLTP -s odb2 -p pdb1
Password for SYS, SYSTEM and PDB Admin:
```

```
{
   "jobId" : "f12485f2-dcbe-4ddf-ae01-de24d37037b6",
   "status" : "Created",
   "message" : null,
   "reports" : [ ],
   "createTimestamp" : "August 08, 2016 03:54:03 AM EDT",
   "description" : "Database service creation with db name: hrdb",
   "updatedTime" : "August 08, 2016 03:54:03 AM EDT"
}
```

To create a database non-interactively, providing the password on the command line:

```
[root@dbsys ~]# dbcli create-database -n crmdb -hm <password> -cl OLTP -s odb2
```

```
{
   "jobId" : "30b5e2a6-493b-4461-98b8-78e9a5f8cdd",
   "status" : "Created",
   "message" : null,
```
dbcli delete-database

Use the `dbcli delete-database` command to delete a database.

**Note:**
The `dbcli create-database` command is available on bare metal DB systems only.

**Syntax**

```
dbcli delete-database -i <db_id> -in <db_name> [-fd] [-j] [-h]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-fd</td>
<td>--force</td>
<td>(Optional) Forces the delete operation.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>The ID of the database to delete. Use the <code>dbcli list-databases</code> command to get the database ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>The name of the database to delete. Use the <code>dbcli list-databases</code> command to get the database name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**
The following command deletes the database named 625d9b8a-baea-4994-94e7-4c4a857a17f9:

```
[root@dbsys ~]# dbcli delete-database -i 625d9b8a-baea-4994-94e7-4c4a857a17f9
```

**dbcli describe-database**

Use the `dbcli describe-database` command to display database details.

**Syntax**

```
dbcli describe-database -i <db_id> -in <db_name> [-h] [-j]
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>The ID of the database to display. Use the <code>dbcli list-databases</code> command to get the database ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>The name of the database to display. Use the <code>dbcli list-databases</code> command to get the database name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

### Example

The following command displays information for a database named b727bf80-c99e-4846-ac1f-28a81a725df6:

```
[root@dbsys ~]# dbcli describe-dbhome -i b727bf80-c99e-4846-ac1f-28a81a725df6
```

DB Home details

```
ID: b727bf80-c99e-4846-ac1f-28a81a725df6
Name: OraDB12102_home1
Version: 12.1.0.2
Home Location: /u01/app/orauser/product/12.1.0.2/dbhome_1
Created: Jun 2, 2016 10:19:23 AM
```

### dbcli list-databases

Use the `dbcli list-databases` command to list all databases on the DB system.

**Syntax**

```
dbcli list-databases [-h] [-j]
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

### Example

The following command displays a list of databases:

```
[root@dbsys ~]# dbcli list-databases
```

```
ID            DB Name    DB Version           CDB
Class Shape   Storage     Status
------ ------ -------- ---------  -------
```
Database

The following command displays the JSON output for a database:

```
[root@dbsys ~]# dbcli list-databases -j
{
  "id" : "80ad855a-5145-4f8f-a08f-406c5e4684ff",
  "name" : "dbtst",
  "dbName" : "dbtat",
  "databaseUniqueName" : "dbtst_phx1cs",
  "dbVersion" : "12.1.0.2",
  "dbHomeId" : "2efe7af7-0b70-4e9b-ba8b-71f11c6fe287",
  "instanceOnly" : false,
  "registerOnly" : false,
  "dbId" : "167525515",
  "isCdb" : true,
  "pdbBName" : "pdb1",
  "pdbAdminUserName" : "pdbuser",
  "enableTDE" : true,
  "dbType" : "SI",
  "dbTargetNodeNumber" : "0",
  "dbClass" : "OLTP",
  "dbShape" : "odb2",
  "dbStorage" : "ACFS",
  "dbCharacterSet" : {
    "characterSet" : "US7ASCII",
    "nlsCharacterset" : "AL16UTF16",
    "dbTerritory" : "AMERICA",
    "dbLanguage" : "AMERICAN"
  },
  "dbConsoleEnable" : false,
  "backupConfigId" : null,
  "backupDestination" : "NONE",
  "cloudStorageContainer" : null,
  "state" : {
    "status" : "CONFIGURED"
  },
  "createTime" : "November 09, 2016 17:23:05 PM UTC",
  "updatedTime" : "November 09, 2016 18:00:47 PM UTC"
}
```

dbcli modify-database

Use the `dbcli modify-database` command to modify a database.

**Syntax**

```
dbcli modify-database -i <db_id> -dh <destination_db_home_id> [-h] [-j]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dh</td>
<td>--destdbhomeid</td>
<td>Destination database home ID.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--databaseid</td>
<td>Database ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**(dbcli recover-database)**

Use the `dbcli recover-database` command to recover a database.

**Syntax**

```
bdcli recover-database [-br <json>] [-in <db_name>] [-i <db_id>] [-r <time>]
[-t {Latest|PITR|SCN}] [-s] [-l <location>] [-tp <tde_password>] [-h] [-j]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-br</td>
<td>--backupReport</td>
<td>(Optional) JSON input for backup report.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>(Optional) Database resource ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>(Optional) Database name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-l</td>
<td>--tdeWalletLocation</td>
<td>(Optional) TDE wallet backup location. TDE wallet should be backed up in tar.gz format.</td>
</tr>
<tr>
<td>-r</td>
<td>--recoveryTimeStamp</td>
<td>(Required when recovery type is PITR) Recovery timestamp in the format mm/dd/yyyy hh:mm:ss. Default: [ ]</td>
</tr>
<tr>
<td>-s</td>
<td>--scn</td>
<td>(Required when recovery type is SCN) SCN.</td>
</tr>
<tr>
<td>-t</td>
<td>--recoverytype</td>
<td>(Required when backup report is provided) Recovery type. Possible values are Latest, PITR, and SCN.</td>
</tr>
<tr>
<td>-tp</td>
<td>--tdeWalletPassword</td>
<td>(Optional) TDE wallet password.</td>
</tr>
</tbody>
</table>

**(dbcli register-database)**

Use the `dbcli register-database` command to register a database that has been migrated to Oracle Cloud Infrastructure. The command registers the database to the dcs-agent so it can be managed by the dcs-agent stack.
**Note:**

The dbcli register-database command is not available on 2-node RAC DB systems.

**Syntax**

```bash
dbcli register-database -bi <bkup_config_id> -c {OLTP|DSS|IMDB} [-co|-no-co] -s (odb1|odb2|...) -t SI [-o <db_host_name>] [-tp <password>] -sn <service_name> -p [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bi</td>
<td>--backupconfigid</td>
<td>Defines the backup configuration ID. Use the dbcli list-backupconfigs command to get the ID.</td>
</tr>
<tr>
<td>-c</td>
<td>--dbcclass</td>
<td>Defines the database class. The options are OLTP, DSS, or IMDB. The default is OLTP. For Enterprise Editions, all three classes are supported. For Standard Edition, only OLTP is supported.</td>
</tr>
<tr>
<td>-co</td>
<td>--dbconsole</td>
<td>(Optional) Indicates whether the Database Console is enabled or not. If omitted, the console is not enabled.</td>
</tr>
<tr>
<td>-no-co</td>
<td>--no-dbconsole</td>
<td></td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-o</td>
<td>--hostname</td>
<td>(Optional) Defines the database host name. The default is Local host name.</td>
</tr>
<tr>
<td>-p</td>
<td>--syspassword</td>
<td>Defines a strong password for SYS. Specify -p with no password. You will be prompted for the password. If you must provide the password in the command, for example in a script, use -hp &lt;password&gt; instead of -p.</td>
</tr>
<tr>
<td>-s</td>
<td>--dbshape</td>
<td>Defines the database sizing template to use for the database. For example, odb1, odb2, and odb3. For more information, see Database Sizing Templates on page 1552.</td>
</tr>
</tbody>
</table>
### Parameter
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-sn</td>
<td>--servicename</td>
<td>Defines the database service name used to build the EZCONNECT string for connecting to the database. The connect string format is hostname:port/servicename.</td>
</tr>
<tr>
<td>-t</td>
<td>--dbtype</td>
<td>(Optional) Defines the Database Type as single node (SI). The default value is SI.</td>
</tr>
<tr>
<td>-tp</td>
<td>--tdeWalletPassword</td>
<td>(Optional) Password for TDE wallet. Required if TDE is enabled on the migrated database.</td>
</tr>
</tbody>
</table>

### Example
The following command registers the database with the specified database class, service name, and database sizing template.

```
[root@dbsys ~]# dbcli register-database -c OLTP -s odb1 -sn crmdb.example.com -p
```

Password for SYS:
```
{
   "jobId": "317b430f-ad5f-42ae-bb07-13f053d266e2",
   "status": "Created",
   "message": null,
   "reports": [
   ],
   "createTimestamp": "August 08, 2016 05:55:49 AM EDT",
   "description": "Database service registration with db service name: crmdb.example.com",
   "updatedTime": "August 08, 2016 05:55:49 AM EDT"
}
```

### dbcli update-database
Use the `dbcli update-database` command to associate a backup configuration with a database.

### Syntax
```
dbcli update-database -i <db_id> -bi <bkup_config_id> -b <bkup_config_name> [-id <id>] [-in <name>] [-no-ab] [-h] [-j]
```

### Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bi</td>
<td>--backupconfigid</td>
<td>Defines the backup configuration ID. Use the <code>dbcli list-backupconfigs</code> command to get the ID.</td>
</tr>
<tr>
<td>-bin</td>
<td>--backupconfigname</td>
<td>Defines the backup configuration name for future use. Use the <code>dbcli list-backupconfigs</code> command to get the name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-id</td>
<td>--databaseid</td>
<td>(Optional.) Specifies the DBID, which is a unique 32-bit identification number computed when the database is created. RMAN displays the DBID upon connection to the target database. You can obtain the DBID by querying the V$DATABASE view or the RC_DATABASE and RC_DATABASE_INCARNATION recovery catalog views.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>Defines the database name to be updated. Use the <code>dbcli list-databases</code> command to get the database name.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>Defines the database ID to be updated. Use the <code>dbcli list-databases</code> command to get the database ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-no-ab</td>
<td>--noautobackup</td>
<td>(Optional) Disables automatic backups for the specified database.</td>
</tr>
</tbody>
</table>

**Note:**
Once disabled, automatic backup cannot be re-enabled using the CLI. To re-enable automatic backup, use the Console.

**Example**
The following command associates a backup configuration file with a database:

```
[root@dbsys ~]# dbcli update-database -bi 78a2a5f0-72b1-448f-bd86-cf41b30b64ee -i 71ec8335-113a-46e3-b81f-235f4d1b6fde
{
    "jobId" : "2b104028-a0a4-4855-b32a-b97a37f5f9c5",
    "status" : "Created",
    "message" : null,
    "reports" : [ ],
    "createTimestamp" : 1467775842977,
    "description" : "update database id:71ec8335-113a-46e3-b81f-235f4d1b6fde",
    "updatedTime" : 1467775842978
}
```
Dbhome Commands

The following commands are available to manage database homes:

- `dbcli create-dbhome`
- `dbcli describe-dbhome`
- `dbcli delete-dbhome`
- `dbcli list-dbhomes`
- `dbcli update-dbhome`

`dbcli create-dbhome`

Use the `dbcli create-dbhome` command to create an Oracle Database Home.

**Syntax**

```
dbcli create-dbhome -v <version> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
| -v        | --version | Defines the Database Home version. Specify one of the supported versions:  
            - 18.1.0.0  
            - 12.2.0.1  
            - 12.1.0.2  
            - 11.2.0.4 |

**Example**

The following command creates an Oracle Database Home version 12.1.0.2:

```
[root@dbsys ~]# dbcli create-dbhome -v 12.1.0.2
```

`dbcli describe-dbhome`

Use the `dbcli describe-dbhome` command to display Oracle Database Home details.

**Syntax**

```
dbcli describe-dbhome -i <db_home_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>
Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i</td>
<td>--dbhomeid</td>
<td>Identifies the database home ID. Use the <code>dbcli list-dbhomes</code> command to get the ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following output is an example of using the display Oracle Database Home details command.

```
[root@dbsys ~]# dbcli describe-dbhome -i 52850389-228d-4397-bbe6-102fda65922b
DB Home details
----------------------------------------------------------------
ID: 52850389-228d-4397-bbe6-102fda65922b
Name: OraDB12102_home1
Version: 12.1.0.2
Home Location: /u01/app/oracle/product/12.1.0.2/dbhome_1
Created: June 29, 2016 4:36:31 AM UTC
```

**dbcli delete-dbhome**

Use the `dbcli delete-dbhome` command to delete a database home from the DB system.

**Syntax**

```
dbcli delete-dbhome -i <db_home_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbhomeid</td>
<td>Identifies the database home ID to be deleted. Use the <code>dbcli list-dbhomes</code> command to get the ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**dbcli list-dbhomes**

Use the `dbcli list-dbhomes` command to display a list of Oracle Home directories.

**Syntax**

```
dbcli list-dbhomes [-h] [-j]
```

**Parameter**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>
Database

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays a list of Oracle Home directories.

```
[root@dbsys ~]# dbcli list-dbhomes
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>DB Version</th>
<th>Home</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------------------</td>
<td>--------------------</td>
<td>------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>b727bf80-c99e-4846-ac1f-28a81a725df6 OraDB12102_home1</td>
<td>12.1.0.2 /u01/app/orauser/product/12.1.0.2/dbhome_1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**dbcli update-dbhome**

**Tip:**

Your DB system might not include this newer command. If you have trouble running the command, use the CLI Update Command on page 1483 command to update the database CLI and then retry the command.

Use the `dbcli update-dbhome` command to apply the DBBP bundle patch to a database home. For more information about applying patches, see Patching a DB System on page 1407.

**Syntax**

```
dbcli update-dbhome -i <db_home_id> -n <node> [--local] [--precheck] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbhomeid</td>
<td>The ID of the database home. Use the <code>dbcli list-dbhomes</code> command to get the ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--node</td>
<td>(Optional) Node number to be updated. Use the <code>dbcli list-nodes</code> command to get the node number.</td>
</tr>
<tr>
<td></td>
<td>--local</td>
<td>(Optional) Performs the operation on the local node of a multi-node high availability (HA) system. This parameter is not needed to perform the operation on a single-node system.</td>
</tr>
</tbody>
</table>
Example

The following commands update the database home and show the output from the update job:

```bash
[root@dbsys ~]# dbcli update-dbhome -i e1877dac-a69a-40a1-b65a-d5e190e671e6 
{  
    "jobId" : "493e703b-46ef-4a3f-909d-bbd123469bea",  
    "status" : "Created",  
    "message" : null,  
    "reports" : [ ],  
    "createTimestamp" : "January 19, 2017 10:03:21 AM PST",  
    "resourceList" : [ ],  
    "description" : "DB Home Patching: Home Id is e1877dac-a69a-40a1-b65a-d5e190e671e6",  
    "updatedTime" : "January 19, 2017 10:03:21 AM PST"
}

# dbcli describe-job -i 493e703b-46ef-4a3f-909d-bbd123469bea

Job details

ID: 493e703b-46ef-4a3f-909d-bbd123469bea
Description: DB Home Patching: Home Id is e1877dac-a69a-40a1-b65a-d5e190e671e6
Status: Running
Created: January 19, 2017 10:03:21 AM PST

DbstORAGE Commands

The following commands are available to manage database storage:

- dbcli list-dbstorages
- dbcli describe-dbstorage
- dbcli create-dbstorage
- dbcli delete-dbstorage
**dbcli list-dbstorages**

Use the `dbcli list-dbstorages` command to list the database storage in the DB system.

**Syntax**

```
dbcli list-dbstorages [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays details about database storage:

```
[root@dbsys ~]# dbcli list-dbstorages
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Type</th>
<th>DBUnique Name</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>_________________________</td>
<td></td>
<td>____________________</td>
<td>______</td>
</tr>
<tr>
<td>afb4a1ce-d54d-4993-a149-0f28c9fb33a4</td>
<td>Acfs</td>
<td>db1_2e56b3a9b815</td>
<td>Configured</td>
</tr>
<tr>
<td>d81e8013-4551-4d10-880b-d1a796bca1bc</td>
<td>Acfs</td>
<td>db11xp</td>
<td>Configured</td>
</tr>
</tbody>
</table>

**dbcli describe-dbstorage**

Use the `dbcli describe-dbstorage` command to show detailed information about a specific database storage resource.

**Syntax**

```
dbcli describe-dbstorage -i <db_storage_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
<td>Defines the database storage ID. Use the <code>dbcli list-dbstorages</code> command to get the database storage ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
Example

The following command displays the database storage details for 105a2db2-625a-45ba-8bdd-ee46da0fd83a:

[root@dbsys ~]# dbcli describe-dbstorage -i 105a2db2-625a-45ba-8bdd-ee46da0fd83a

DBStorage details
----------------------------------------------------------------
ID: 105a2db2-625a-45ba-8bdd-ee46da0fd83a
DB Name: db1
DBUnique Name: db1
DB Resource ID: 439e7bd7-f717-447a-8046-08b5f6493df0
Storage Type: DATA Location: /u02/app/oracle/oradata/db1
RECO Location: /u03/app/oracle/fast_recovery_area/
REDO Location: /u03/app/oracle/redo/
State: ResourceState(status=Configured)
Created: July 3, 2016 4:19:21 AM UTC
UpdatedTime: July 3, 2016 4:41:29 AM UTC

dbcli create-dbstorage

Use the dbcli create-dbstorage command to create the database storage layout without creating the complete database. This is useful for database migration and standby database creation.

Syntax

dbcli create-dbstorage -n <db_name> [-u <db_unique_name>] [-r {ACFS|ASM}] [-s <datasize>] [-h] [-j]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--dbname</td>
<td>Defines the database name. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.</td>
</tr>
<tr>
<td>-r</td>
<td>--dbstorage</td>
<td>(Optional) Defines the type of database storage as ACFS or ASM. The default value is ASM.</td>
</tr>
<tr>
<td>-s</td>
<td>--dataSize</td>
<td>(Optional) Defines the data size in GBs. The minimum size is 10GB. The default size is 100GB.</td>
</tr>
<tr>
<td>-u</td>
<td>--databaseUniqueName</td>
<td>(Optional) Defines the unique name for the database. The default is the database name specified in --dbname.</td>
</tr>
</tbody>
</table>
Example
The following command creates database storage with a storage type of ACFS:

```
[root@dbsys ~]# dbcli create-dbstorage -r ACFS -n testdb -u testdbname
{
   "jobId" : "5884a77a-0577-414f-8c36-1e9d8ae9cee",
   "status" : "Created",
   "message" : null,
   "reports" : [ ],
   "createTimestamp" : 1467952215102,
   "description" : "Database storage service creation with db name: testdb",
   "updatedTime" : 1467952215103
}
```

dbcli delete-dbstorage

Use the `dbcli delete-dbstorage` command to delete database storage that is not being used by the database. A error occurs if the resource is in use.

Syntax

```
dbcli delete-dbstorage -i <dbstorageID> [-h] [-j]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
</tr>
</tbody>
</table>

Example

The following command deletes the specified database storage:

```
[root@dbsys ~]# dbcli delete-dbstorage -i f444dd87-86c9-4969-a72c-fb2026e7384b
{
   "jobId" : "467c9388-18c6-4e1a-8655-2fd3603856ef",
   "status" : "Running",
   "message" : null,
   "reports" : [ ],
   "createTimestamp" : 1467952336843,
   "description" : "Database storage service deletion with id: f444dd87-86c9-4969-a72c-fb2026e7384b",
   "updatedTime" : 1467952336856
}
```
Dgconfig Commands

**dbcli list-dgconfigs**

Use the `dbcli list-dgconfigs` command to list DG configurations.

**Syntax**

```
dbcli list-dgconfigs [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

Featuretracking Commands

**dbcli list-featuretracking**

Use the `dbcli list-featuretracking` command to list tracked features.

**Syntax**

```
dbcli list-featuretracking [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

Job Commands

The following commands are available to manage jobs:

- `dbcli describe-job`
- `dbcli list-jobs`

**dbcli describe-job**

Use the `dbcli describe-job` command to display details about a specific job.

**Syntax**

```
dbcli describe-job -i <job_id> [-h] [-j]
```
**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--jobid</td>
<td>Identifies the job. Use the <code>dbcli list-jobs</code> command to get the jobid.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays details about the specified job ID:

```
[root@dbsys ~]# dbcli describe-job -i 74731897-fb6b-4379-9a37-246912025c17
```

Job details

```
<table>
<thead>
<tr>
<th>Task Name</th>
<th>Start Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backup Validations</td>
<td>November 18, 2016 8:33:04 PM UTC</td>
</tr>
<tr>
<td>validate recovery window</td>
<td>November 18, 2016 8:33:13 PM UTC</td>
</tr>
<tr>
<td>Db cross check</td>
<td>November 18, 2016 8:33:17 PM UTC</td>
</tr>
<tr>
<td>Database Backup</td>
<td>November 18, 2016 8:33:23 PM UTC</td>
</tr>
<tr>
<td>Backup metadata</td>
<td>November 18, 2016 8:34:22 PM UTC</td>
</tr>
</tbody>
</table>
```

**dbcli list-jobs**

Use the `dbcli list-jobs` command to display a list of jobs, including the job IDs, status, and the job created date and time stamp.

**Syntax**

```
dbcli list-jobs [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
Example

The following command displays a list of jobs:

```
[root@dbsys ~]# dbcli list-jobs
ID                                       Description                                              Status
Created
----------------------------------------
---------------------------------------------------------------------------

```

Latestpatch Command

dbcli describe-latestpatch

Tip:
Your DB system might not include this newer command. If you have trouble running the command, use the CLI Update Command on page 1483 command to update the database CLI and then retry the command.

Note:
The dbcli describe-latestpatch command is not available on 2-node RAC DB systems. Patching 2-node systems from Object Storage is not supported.

Use the dbcli describe-latestpatch command show the latest patches applicable to the DB system and available in Oracle Cloud Infrastructure Object Storage.

This command requires a valid Object Storage credentials configuration. Use the Bmccredential Commands on page 1498 command to create the configuration if you haven't already done so. If the configuration is missing or invalid, the command fails with the error: Failed to connect to the object store. Please provide valid details.

For more information about updating the CLI, creating the credentials configuration, and applying patches, see Patching a DB System on page 1407.

Syntax

dbcli describe-latestpatch [-h] [-j]
**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays patches available in the object store:

```
[root@dbsys ~]# dbcli describe-latestpatch
```

<table>
<thead>
<tr>
<th>componentType</th>
<th>availableVersion</th>
</tr>
</thead>
<tbody>
<tr>
<td>gi</td>
<td>12.1.0.2.161018</td>
</tr>
<tr>
<td>db</td>
<td>11.2.0.4.161018</td>
</tr>
<tr>
<td>db</td>
<td>12.1.0.2.161018</td>
</tr>
<tr>
<td>oak</td>
<td>12.1.2.10.0</td>
</tr>
</tbody>
</table>

**LogcleanJob Commands**

The following commands are available to manage log cleaning jobs:

- `dbcli create-logCleanJob`
- `dbcli describe-logCleanJob`
- `dbcli list-logCleanJobs`

**dbcli create-logCleanJob**

Use the `dbcli create-logCleanJob` command to create a log cleaning job.

**Syntax**

```
dbcli create-logCleanJob [-c {gi|database|dcs}] [-o <number>] [u {Day|Hour|Minute}] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--components</td>
<td>(Optional) Components. Possible values are gi, database, and dcs. Separate multiple values by commas.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-o</td>
<td>--olderThan</td>
<td>(Optional) Quantity portion of time interval. Default: 30. Cleans logs older than the specified time interval (−o and −u).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-u</td>
<td>--unit</td>
<td>(Optional) Unit portion of time interval. Possible values: Day, Hour, or Minute. Default: Day. Cleans logs older than the specified time interval (-c and -u).</td>
</tr>
</tbody>
</table>

**dbcli describe-logCleanJob**

Use the `dbcli describe-logCleanJob` command to display the summary for a log cleaning job.

**Syntax**

```
dbcli describe-logCleanJob -i <job_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--jobid</td>
<td>ID of log cleaning job for which to display the summary.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**dbcli list-logCleanJobs**

Use the `dbcli list-logCleanJobs` command to list log cleaning jobs.

**Syntax**

```
dbcli list-logCleanJobs [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Logspaceusage Command**

**dbcli list-logSpaceUsage**

Use the `dbcli list-logSpaceUsage` command to list log space usage.

**Syntax**

```
dbcli list-logSpaceUsage [-c {gi|database|dcs}] [-h] [-j]
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--components</td>
<td>(Optional) Components. Possible values: gi, database, and dcs. Separate multiple values by commas.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

### Netsecurity Commands

The following commands are available to manage network encryption on the DB system:

- `dbcli describe-netsecurity`
- `dbcli update-netsecurity`

**dbcli describe-netsecurity**

Use the `dbcli describe-netsecurity` command to display the current network encryption setting for a database home.

**Syntax**

```
dbcli describe-netsecurity -H <db_home_id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-H</td>
<td>--dbHomeId</td>
<td>Defines the database home ID. Use the <code>dbcli list-dbhomes</code> command to get the dbhomeid.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays the encryption setting for specified database home:

```
[root@dbsys ~]# dbcli describe-netsecurity -H 16c96a9c-f579-4a4c-a645-8d4d22d6889d
```

**NetSecurity Rules**

```
DatabaseHomeID: 16c96a9c-f579-4a4c-a645-8d4d22d6889d

Role: Server
  EncryptionAlgorithms: AES256 AES192 AES128
  IntegrityAlgorithms: SHA1
  ConnectionType: Required

Role: Client
  EncryptionAlgorithms: AES256 AES192 AES128
  IntegrityAlgorithms: SHA1
```
Use the `dbcli update-netsecurity` command to update the Oracle Net security configuration on the DB system.

**Syntax**

```
dbcli update-netsecurity { -c | -s } -t {REJECTED | ACCEPTED | REQUESTED | REQUIRED } -H db_home_id > -e {AES256 | AES192 | AES128 } -i {SHA1 | SHA512 | SHA384 | SHA256 } [-h ] [-j ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>--client</td>
<td>Indicates that the specified data encryption or data integrity configuration is for the client. (--client and --server are mutually exclusive.)</td>
</tr>
<tr>
<td>-e</td>
<td>--encryptionAlgorithms</td>
<td>Defines the algorithm to be used for encryption. Specify either AES256, AES192, or AES128.</td>
</tr>
<tr>
<td>-H</td>
<td>--dbHomeId</td>
<td>Defines the database home ID. Use the <code>dbcli list-dbhomes</code> command to get the dbHomeId.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--integrityAlgorithms</td>
<td>Defines the algorithm to be used for integrity. Specify either SHA1, SHA512, SHA384, or SHA256. For Oracle Database 11g, the only accepted value is SHA1.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-s</td>
<td>--server</td>
<td>Indicates that the specified data encryption or data integrity configuration is for the server. (--client and --server are mutually exclusive.)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -t        | --connectionType | Specifies how Oracle Net Services data encryption or data integrity is negotiated with clients. The following values are listed in the order of increasing security:  
REJECTED - Do not enable data encryption or data integrity, even if required by the client.  
ACCEPTED - Enable data encryption or data integrity if required or requested by the client.  
REQUESTED - Enable data encryption or data integrity if the client permits it.  
REQUIRED - Enable data encryption or data integrity or preclude the connection.  
For detailed information about network data encryption and integrity, see https://docs.oracle.com/database/121/DBSEG/asoconfg.htm#DBSEG1047. |

**Example**

The following command updates the connection type to ACCEPTED:

```
[root@dbsys ~]# dbcli update-netsecurity -H a2ffbb07-c9c0-4467-a458-bce4d3b76cd5 -t ACCEPTED
```

**Node Command**

**dbcli list-nodes**

Use the `dbcli list-nodes` command to display a list of nodes, including the node numbers.

**Syntax**

```
dbcli list-nodes [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>
Example

The following command displays a list of nodes:

```
[root@dbsys ~]# dbcli list-nodes
node Number node Name          ilom Name            IP Address       Subnet Mask Gateway
---------- ---------------------------------------- -------------------- ------------------ ------------------
0      rac21          N/A     N/A        N/A  N/A        N/A
1      rac22          N/A     N/A        N/A   N/A
```

Objectstoreswift Commands

You can back up a database to an existing bucket in the Oracle Cloud Infrastructure Object Storage service by using the `dbcli create-backup` on page 1488 command, but first you'll need to:

1. Create an object store on the DB system, which contains the endpoint and credentials to access Object Storage, by using the `dbcli create-objectstoreswift` command.
2. Create a backup configuration that refers to the object store ID and the bucket name by using the `dbcli create-backupconfig` on page 1492 command.
3. Associate the backup configuration with the database by using the `dbcli update-database` on page 1516 command.

The following commands are available to manage object stores.

- `dbcli create-objectstoreswift`
- `dbcli describe-objectstoreswift`
- `dbcli list-objectstoreswifts`

**dbcli create-objectstoreswift**

Use the `dbcli create-objectstoreswift` command to create an object store.

**Syntax**

```
dbcli create-objectstoreswift -n <object_store_name>
  -t <object_storage_namespace> -u <user_name> --endpointurl
  https://swiftobjectstorage.<region_name>.oraclecloud.com/v1 -p [-h] [-j]
```

where `<object_storage_namespace>` is your tenancy's Object Storage namespace.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-e</td>
<td>--endpointurl</td>
<td>The following endpoint URL. <a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1. See Regions and Availability Domains for region name strings.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--name</td>
<td>The name for the object store to be created.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Full Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-p</td>
<td>--swiftpassword</td>
<td>The auth token that you generated by using the Console or IAM API. For information about generating an auth token for use with Swift, see Managing User Credentials on page 2456. This is not the password for the Oracle Cloud Infrastructure user. Specify <code>-p</code> (with no password) to be prompted. Specify <code>-hp &quot;&lt;password&gt;&quot;</code> in quotes to provide the password (auth token) in the command.</td>
</tr>
<tr>
<td>-t</td>
<td>--tenantname</td>
<td>The Object Storage namespace. of your tenancy.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>The user name for the Oracle Cloud Infrastructure user account, for example: <code>-u djones@example.com</code> This is the user name you use to sign in to the Console. The user name must have tenancy-level access to the Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access to all of the cloud services. Instead, an administrator can create a policy that allows tenancy-level access to just Object Storage. The following is an example of such a policy. Allow group DBAdmins to manage buckets in tenancy Allow group DBAdmins to manage objects in tenancy For more information about adding a user to a group, see Managing Groups on page 2419. For more information about policies, see Getting Started with Policies on page 2135.</td>
</tr>
</tbody>
</table>
**Example**

The following command creates an object store and prompts for the Swift password:

```
[root@dbsys ~]# dbcli create-objectstoreswift -n r2swift
   -t MyObjectStorageNamespace -u djones@example.com -
   e https://swiftobjectstorage.<region_name>.oraclecloud.com/v1
Password for Swift:

{
   "jobId" : "c565bb71-f67b-4fab-9d6f-a34ee36feb7",
   "status" : "Created",
   "message" : "Create object store swift",
   "reports" : [ ],
   "createTimestamp" : "January 19, 2017 11:11:33 AM PST",
   "resourceList" : [ { 
      "resourceId" : "8a0fe039-f5d4-426a-8707-256c612b3a30",
      "resourceType" : "ObjectStoreSwift",
      "jobId" : "c565bb71-f67b-4fab-9d6f-a34ee36feb7",
      "updatedTime" : "January 19, 2017 11:11:33 AM PST"
   } ],
   "description" : "create object store:biyanr2swift",
   "updatedTime" : "January 19, 2017 11:11:33 AM PST"
}
```

**dbcli describe-objectstoreswift**

Use the `dbcli describe-objectstoreswift` command to display details about an object store.

**Syntax**

```
dbcli describe-objectstoreswift -i <object_store_swift_id> -
in <object_store_swift_name> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--objectstoreswiftid</td>
<td>The object store ID. Use the <code>dbcli list-objectstoreswifts</code> command to get the ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--objectstoreswiftName</td>
<td>The object store name. Use the <code>dbcli list-objectstoreswifts</code> command to get the name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command displays details about an object store:

```
[root@dbsys ~]# dbcli describe-objectstoreswift -i 910e9e2d-25b4-49b4-b88e-
   ff0332f7df87
Object Store details
----------------------------------------------------------------
ID: 910e9e2d-25b4-49b4-b88e-ff0332f7df87
```
dbcli list-objectstoreswifts

Use the `dbcli list-objectstoreswifts` command to list the object stores on a DB system.

**Syntax**

```
dbcli list-objectstoreswifts [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command lists the object stores on the DB system:

```
[root@dbsys ~]# dbcli list-objectstoreswifts
```

<table>
<thead>
<tr>
<th>ID</th>
<th>TenantName</th>
<th>Name</th>
<th>UserName</th>
<th>Url</th>
<th>createTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>2915bc6a-6866-436a-a38c-32302c7c4d8b</td>
<td>LargeComputers</td>
<td>swiftobjstr1</td>
<td><a href="mailto:djones@example.com">djones@example.com</a></td>
<td><a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1</td>
<td>November 10, 2016 8:42:18 PM UTC</td>
</tr>
<tr>
<td>910e9e2d-25b4-49b4-b88e-ff0332f7df87</td>
<td>LargeComputers</td>
<td>objstrswift15</td>
<td><a href="mailto:djones@example.com">djones@example.com</a></td>
<td><a href="https://swiftobjectstorage">https://swiftobjectstorage</a>.&lt;region_name&gt;.oraclecloud.com/v1</td>
<td>November 16, 2016 11:25:34 PM UTC</td>
</tr>
</tbody>
</table>

**Pendingjob Command**

**dbcli list-pendingjobs**

Use the `dbcli list-pendingjobs` command to display a list of pending jobs.

**Syntax**

```
dbcli list-pendingjobs [-h] [-j]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Rmanbackupreport Commands**

The following commands are available to manage RMAN backup reports:

- `dbcli create-rmanbackupreport`
- `dbcli delete-rmanbackupreport`
- `dbcli describe-rmanbackupreport`
- `dbcli list-rmanbackupreports`

**dbcli create-rmanbackupreport**

Use the `dbcli create-rmanbackupreport` command to create an RMAN backup report.

**Syntax**

```
dbcli create-rmanbackupreport -w {summary|detailed} -rn <name> [-i <db_id>] [-in <db_name>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>(Optional) Database resource ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbname</td>
<td>(Optional) Database resource name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-rn</td>
<td>--rptname</td>
<td>RMAN backup report name. Maximum number of characters: 30. Wrap name in single quotes when special characters are used.</td>
</tr>
<tr>
<td>-w</td>
<td>--reporttype</td>
<td>RMAN backup report type. Possible values: summary or detailed.</td>
</tr>
</tbody>
</table>

**dbcli delete-rmanbackupreport**

Use the `dbcli delete-rmanbackupreport` command to delete an RMAN backup report.

**Syntax**

```
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td>--dbid</td>
<td>(Optional) Database resource ID.</td>
</tr>
<tr>
<td>-dn</td>
<td>--dbname</td>
<td>(Optional) Database resource name.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--reportid</td>
<td>(Optional) RMAN backup report ID</td>
</tr>
<tr>
<td>-in</td>
<td>--rptname</td>
<td>(Optional) RMAN backup report name</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-n</td>
<td>--numofday</td>
<td>(Optional) Number of days since created (provided with Database ID/Database Name)</td>
</tr>
</tbody>
</table>

**dbcli describe-rmanbackupreport**

Use the `dbcli describe-rmanbackupreport` command to

**Syntax**

```
dbcli describe-rmanbackupreport [-i <rpt_id>] [-in <rpt_name>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--id</td>
<td>(Optional) RMAN backup report ID</td>
</tr>
<tr>
<td>-in</td>
<td>--name</td>
<td>(Optional) RMAN backup report name</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**dbcli list-rmanbackupreports**

Use the `dbcli list-rmanbackupreports` command to

**Syntax**

```
dbcli list-rmanbackupreports [-i <db_id>] [-in <db_name>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbid</td>
<td>(Optional) Database resource ID.</td>
</tr>
</tbody>
</table>
Schedule Commands

The following commands are available to manage schedules:

- `dbcli describe-schedule`
- `dbcli list-schedules`
- `dbcli update-schedule`

**dbcli describe-schedule**

Use the `dbcli describe-schedule` command to describe a schedule.

**Syntax**

```
  dbcli describe-schedule -i <id> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--scheduleid</td>
<td>Schedule ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**dbcli list-schedules**

Use the `dbcli list-schedules` command to list schedules.

**Syntax**

```
  dbcli list-schedules [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**dbcli update-schedule**

Use the `dbcli update-schedule` command to update a schedule.

**Syntax**

```
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td>--disable</td>
<td>(Optional) Disables the schedule.</td>
</tr>
<tr>
<td>-e</td>
<td>--enable</td>
<td>(Optional) Enables the schedule.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--scheduleid</td>
<td>Schedule ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-t</td>
<td>--description</td>
<td>(Optional) Description</td>
</tr>
<tr>
<td>-x</td>
<td>--cronExpression</td>
<td>(Optional) Cron expression. Use cronmaker.com to generate a valid cron expression.</td>
</tr>
</tbody>
</table>

### Scheduled execution Command

**dbcli list-scheduledExecutions**

Use the `dbcli list-scheduledExecutions` command to list scheduled executions.

**Syntax**

```
dbcli list-scheduledExecutions [-e <execution_id>] [-i <schedule_id>] [-h] [-j]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-e</td>
<td>--executionid</td>
<td>(Optional) Execution ID.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--scheduleid</td>
<td>(Optional) Schedule ID.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

### Server Command

**dbcli update-server**

**Tip:**

Your DB system might not include this newer command. If you have trouble running the command, use the CLI Update Command on page 1483 command to update the database CLI and then retry the command.

Use the `dbcli update-server` command to apply patches to the server components in the DB system. For more information about applying patches, see Patching a DB System on page 1407.

**Syntax**

```
dbcli update-server [-n <number>] [--local] [--precheck] [-h] [-j]
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-l</td>
<td>--local</td>
<td>(Optional) Performs the operation on the local node of a multi-node high availability (HA) system. This parameter is not needed to perform the operation on a single-node system.</td>
</tr>
<tr>
<td>-n</td>
<td>--node</td>
<td>(Optional) Node number to be updated. Use the <code>dbcli list-nodes</code> command to get the node number.</td>
</tr>
<tr>
<td>-p</td>
<td>--precheck</td>
<td>(Optional) Runs precheck operations to check prerequisites.</td>
</tr>
</tbody>
</table>

### Examples

The following commands update the server and show the output from the update job:

```bash
[root@dbsys ~]# dbcli update-server
{
  "jobId" : "9a02d111-e902-4e94-bc6b-9b820ddf6ed8",
  "status" : "Created",
  "reports" : [ ],
  "createTimestamp" : "January 19, 2017 09:37:11 AM PST",
  "resourceList" : [ ],
  "description" : "Server Patching",
  "updatedTime" : "January 19, 2017 09:37:11 AM PST"
}
```

```bash
# dbcli describe-job -i 9a02d111-e902-4e94-bc6b-9b820ddf6ed8
```

Job details

<table>
<thead>
<tr>
<th>Task Name</th>
<th>Start Time</th>
<th>End Time</th>
<th>Status</th>
</tr>
</thead>
</table>
The following command updates node 0 of the server only, with precheck:

```
# dbcli update-server -n 0 -p
{
   "jobId" : "3e2a1e3c-83d3-4101-86b8-4d525f3f8c18",
   "status" : "Created",
   "message" : null,
   "reports" : [ ],
   "createTimestamp" : "April 26, 2019 06:07:27 AM UTC",
   "resourceList" : [ ],
   "description" : "Server Patching Prechecks",
   "updatedTime" : "April 26, 2019 06:07:27 AM UTC"
}
```

**System Command**

**dbcli describe-system**

Use the `dbcli describe-system` command to display details about the system. On a 2-node RAC DB system, the command provides information about the local node.

**Syntax**

```
dbcli describe-system [-b] [-d] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b</td>
<td>--bom</td>
<td>(Optional) Displays BOM information.</td>
</tr>
<tr>
<td>-d</td>
<td>--details</td>
<td>(Optional) Displays additional information about the DB system, including dcs CLI and agent version information.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**TDE Commands**

The following commands are available to manage TDE-related items (backup reports, keys, and wallets):

- `dbcli list-tdebackupreports`
- `dbcli update-tdekey`
- `dbcli recover-tdewallet`
**dbcli list-tdebackupreports**

Use the `dbcli list-tdebackupreports` command to list backup reports for TDE wallets.

**Syntax**

```
$ dbcli list-tdebackupreports [-i <db_id>] [-in <db_name>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-i</td>
<td>--dbResid</td>
<td>(Optional) Displays the TDE Wallet backup reports for the specified database resource ID. Use the <code>dbcli list-databases</code> command to get the database resource ID.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbResname</td>
<td>(Optional) Displays the TDE Wallet backup reports for the specified database resource name. Use the <code>dbcli list-databases</code> command to get the database resource name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command lists the backup reports for TDE wallets:

```
[root@dbsys ~]# dbcli list-tdebackupreports
DbResID     OraDbId   BackupLocation
--------------------------------------- ------------------------
538ca5b1-654d-4418-8ce1-f49b6c987a60  1257156075   https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/dbaasimage/backuptest/host724007/tdewallet/Testdb5/1257156075/2017-08-17/TDEWALLET_BMC60_2017-08-17_10-58-17.0990.tar.gz

```
**dbcli update-tdekey**

Use the `dbcli update-tdekey` command to update the TDE encryption key inside the TDE wallet. You can update the encryption key for Pluggable Databases (if -pdbNames are specified), and/or the Container Database (if -rootDatabase is specified).

**Syntax**

```
dbcli update-tdekey -i <db_id> -p [-all] -n <pdbname1,pdbname2> [-r|-no-r] -t <tag_name> [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-all</td>
<td>--allPdbNames</td>
<td>(Optional) Flag to rotate (update) all PDB names. To update all instead of specified PDB names, use this parameter instead of -n. Default: false.</td>
</tr>
<tr>
<td>-i</td>
<td>--databaseId</td>
<td>Defines the database ID for which to update the key.</td>
</tr>
<tr>
<td>-p</td>
<td>--password</td>
<td>Defines the TDE Admin wallet password. Specify -p with no password. You will be prompted for the password. If you must provide the password in the command, for example in a script, use -hp &lt;password&gt; instead of -p.</td>
</tr>
<tr>
<td>-n</td>
<td>--pdbNames</td>
<td>Defines the PDB names to be rotated (updated).</td>
</tr>
<tr>
<td>-r</td>
<td>--rootDatabase</td>
<td>Indicates whether to rotate the key for the root database if it is a container database.</td>
</tr>
<tr>
<td>-no-r</td>
<td>--no-rootDatabase</td>
<td></td>
</tr>
<tr>
<td>-t</td>
<td>-tagName</td>
<td>Defines the TagName used to backup the wallet. The default is OdaRotateKey.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
</tbody>
</table>

**Example**

The following command updates the key for pdb1 and pdb2 only:

```
[root@dbsys ~]# dbcli update-tdekey -dbid ee3eaab6-a45b-4e61-a218-c4ba665503d9 -p -n pdb1,pdb2

TDE Admin wallet password: {}
```
The following command updates pdb1, pdb2, and the container database:

```bash
[root@dbsys ~]# dbcli update-tdekey -dbid ee3eaab6-a45b-4e61-a218-c4ba665503d9 -p -n pdb1,pdb2 -r
```

TDE Admin wallet password:

```json
{
  "jobId" : "c72385f0-cd81-42df-a8e8-3a1e7cab1278",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467876433783,
  "description" : "TDE update",
  "updatedTime" : 1467876433783
}
```

dbcli recover-tdewallet

Use the `dbcli recover-tdewallet` command to recover a TDE wallet.

**Syntax**

```
dbcli recover-tdewallet -in <db_name> -tp <password> [-l <location>] [-h] [-j]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--help</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-in</td>
<td>--dbName</td>
<td>Database name.</td>
</tr>
<tr>
<td>-j</td>
<td>--json</td>
<td>(Optional) Displays JSON output.</td>
</tr>
<tr>
<td>-l</td>
<td>--tdeWalletBackupLocation</td>
<td>(Optional) TDE wallet backup location. TDE wallet should be backed up in tar.gz format.</td>
</tr>
<tr>
<td>-tp</td>
<td>--tdeWalletPassword</td>
<td>Defines the TDE Admin wallet password.</td>
</tr>
</tbody>
</table>

**Admin Commands**

The following commands are to perform administrative actions on the DB system:

- `dbadmcli manage diagcollect`
- `dbadmcli power`
- `dbadmcli power disk status`
- `dbadmcli show controller`
• `dbadmcli show disk`
• `dbadmcli show diskgroup`
• `dbadmcli show env.hw` (environment type and hardware version)
• `dbadmcli show env.hw` (environment type and hardware version)
• `dbadmcli show fs` (file system details)
• `dbadmcli show storage`
• `dbadmcli stordiag`

**dbadmcli manage diagcollect**

Use the `dbadmcli manage diagcollect` command to collect diagnostic information about a DB system for troubleshooting purposes, and for working with Oracle Support Services.

**Syntax**

```
  dbadmcli manage diagcollect --storage [-h]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>--storage</td>
<td>Collects all of the logs for any storage issues.</td>
</tr>
</tbody>
</table>

**Example**

```
[root@dbsys ~]# dbadmcli manage diagcollect --storage
Collecting storage log data. It will take a while, please wait...
Collecting oak data. It will take a while, please wait...
tar: Removing leading `/` from member names
tar: /opt/oracle/oak/onecmd/tmp/OakCli-Command-Output.log: file changed as we read it
Logs are collected to: /opt/oracle/oak/log/dbsys/oakdiag/oakStorage-dbsys-20161118_2101.tar.gz
```

**dbadmcli power**

Use the `dbadmcli power` command to power a disk on or off.

**Note:**

The `dbadmcli power` command is not available on 2-node RAC DB systems.

**Syntax**

```
  dbadmcli power {-on|-off} <name> [-h]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>name</td>
<td>Defines the disk resource name. The resource name format is pd_[0..3]. Use the <code>dbadmcli show disk</code> command to get the disk resource name.</td>
</tr>
<tr>
<td>-off</td>
<td>Powers off the disk.</td>
</tr>
<tr>
<td>-on</td>
<td>Powers on the disk.</td>
</tr>
</tbody>
</table>

**dbadmcli power disk status**

Use the `dbadmcli power disk status` command to display the current power status of a disk.

**Syntax**

```
dbamcli power disk status <name> [-h]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>name</td>
<td>Identifies a specific disk resource name. The resource name format is pd_[0..3]. For example, pd_01.</td>
</tr>
</tbody>
</table>

**Example**

```
[root@dbsys ~]# dbadmcli power disk status pd_00
The disk is powered ON
```

**dbadmcli show controller**

Use the `dbadmcli show controller` command to display details of the controller.

**Syntax**

```
dbamcli show controller <controller_id> [-h]
```

**Parameter**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controller_id</td>
<td>The ID number of the controller. Use the <code>dbadmcli show storage</code> command to get the ID.</td>
</tr>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>

**dbadmcli show disk**

Use the `dbadmcli show disk` command to display the status of a single disk or all disks on the DB system.
Database

Syntax

```
dbadmcli show disk [<name>] [-shared] [-all] [-getlog] [-h]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-all</td>
<td>(Optional) Displays detailed information for the named disk.</td>
</tr>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>-getlog</td>
<td>(Optional) Displays all the SMART log entries for an NVMe disk.</td>
</tr>
<tr>
<td>name</td>
<td>(Optional) Identifies a specific disk resource name. The resource name format is pd_[0..3]. If omitted, the command displays information about all disks on the system.</td>
</tr>
<tr>
<td>-shared</td>
<td>(Optional) Displays all the shared disks.</td>
</tr>
</tbody>
</table>

Examples

To display the status of all the disks on the system:

```
[root@dbsys ~]# dbadmcli show disk
NAME    PATH            TYPE            STATE            STATE_DETAILS
pd_00   /dev/nvme2n1    NVD             ONLINE          Good
pd_01   /dev/nvme3n1    NVD             ONLINE          Good
pd_02   /dev/nvme1n1    NVD             ONLINE          Good
pd_03   /dev/nvme0n1    NVD             ONLINE          Good
```

To display the status of a disk named pd_00:

```
[root@dbsys ~]# dbadmcli show disk pd_00
The Resource is : pd_00
ActionTimeout : 1500
ActivePath     : /dev/nvme2n1
AsmDiskList    : [data_00] [reco_00]

**VendorName** : Samsung
**gid** : 0
**mode** : 660
**uid** : 0

To display the SMART logs for an NVMe disk:

```bash
[root@dbsys ~]# dbadmcli show disk pd_00 -getlog
SMART / Health Information :
---------------------------
Critical Warning : Available Spare below Threshold : FALSE
Critical Warning : Temperature above Threshold : FALSE
Critical Warning : Reliability Degraded : FALSE
Critical Warning : Read-Only Mode : FALSE
Critical Warning : Volatile Memory Backup Device Failure : FALSE
Temperature : 32 degree Celsius
Available Spare : 100%
Available Spare Threshold : 10%
Device Life Used : 0%
Data Units Read (in 512k byte data unit) : 89493
Data Units Written (in 512k byte data unit) : 270387
Number of Host Read Commands : 4588381
Number of Host Write Commands : 6237344

Number of Power Cycles : 227
Number of Power On Hours : 1115
Number of Unsafe Shutdowns : 218
Number of Media Errors : 0
Number of Error Info Log Entries : 0
```

**dbadmcli show diskgroup**

Use the `dbadmcli show diskgroup` command to list configured diskgroups or display a specific diskgroup configuration.

**Syntax**

To list configured diskgroups:

```bash
dbamcli show diskgroup [-h]
```
To display DATA configurations:

```
dbadmcli show diskgroup [DATA] [-h]
```

To display RECO configurations:

```
dbadmcli show diskgroup [RECO] [-h]
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>(Optional) Displays the DATA diskgroup configurations.</td>
</tr>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
<tr>
<td>RECO</td>
<td>(Optional) Displays the RECO diskgroup configurations.</td>
</tr>
</tbody>
</table>

### Examples

To list all diskgroups:

```
[root@dbsys ~]# dbadmcli show diskgroup
DiskGroups
---------
DATA
RECO
```

To display DATA configurations:

```
[root@dbsys ~]# dbadmcli show diskgroup DATA
ASM_DISK  PATH            DISK  STATE  STATE_DETAILS
data_00  /dev/NVD_S00_S2LHNAAH101026p1  pd_00  ONLINE  Good
data_01  /dev/NVD_S01_S2LHNAAH101008p1  pd_01  ONLINE  Good
```

### dbadmcli show env_hw

Use the `dbadmcli show env_hw` command to display the environment type and hardware version of the current DB system.

**Syntax**

```
dbadmcli show env_hw [-h]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>

### dbadmcli show fs

Use the `dbadmcli show fs` command to display file system details.
**Syntax**

dbadmcli show fs [-h]

**Parameter**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>

**dbadmcli show storage**

Use the `dbadmcli show storage` command to show the storage controllers, expanders, and disks.

**Syntax**

dbadmcli show storage [-h]

To show storage errors:

`dbadmcli show storage -errors [-h]`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-errors</td>
<td>(Optional) Shows storage errors.</td>
</tr>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>

**Example**

To display storage devices:

```
[root@dbsys ~]# dbadmcli show storage
==== BEGIN STORAGE DUMP ========

dbadmcli stordiag

Use the dbadmcli stordiag command to collect detailed information for each disk or NVM Express (NVMe).

Syntax

dbadmcli stordiag <name> [-h]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Defines the disk resource name. The resource name format is pd_[0..3].</td>
</tr>
<tr>
<td>-h</td>
<td>(Optional) Displays help for using the command.</td>
</tr>
</tbody>
</table>

Example

To display detailed information for NVMe pd_00:

[root@dbsys ~]# dbadmcli stordiag pd_0

Database Sizing Templates

When you create a database using the dbcli create-database command, you can specify a database sizing template with the --dbshape parameter. The sizing templates are configured for different types of database workloads. Choose the template that best matches the most common workload your database performs:
- Use the OLTP templates if your database workload is primarily online transaction processing (OLTP).
- Use the DSS templates if your database workload is primarily decision support (DSS) or data warehousing.
- Use the in-memory (IMDB) templates if your database workload can fit in memory, and can benefit from in-memory performance capabilities.

The following tables describe the templates for each type of workload.

### OLTP Database Sizing Templates

<table>

Storage Scaling Considerations for Virtual Machine Databases Using Fast Provisioning

**Note:**
This topic applies only to 1-node virtual machine DB systems.

When you provision a virtual machine DB system using the fast provisioning option, the **Available storage** (GB) value you specify during provisioning determines the maximum total storage available through scaling.

The following table details the maximum storage value available through scaling for each setting offered in the provisioning workflow:

<table>
<thead>
<tr>
<th>Initial storage specified during provisioning (GB)</th>
<th>Maximum storage available through scaling (GB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>256</td>
<td>2560</td>
</tr>
<tr>
<td>512</td>
<td>2560</td>
</tr>
<tr>
<td>1024</td>
<td>5120</td>
</tr>
<tr>
<td>2048</td>
<td>10240</td>
</tr>
<tr>
<td>4096</td>
<td>20480</td>
</tr>
<tr>
<td>8192</td>
<td>40960</td>
</tr>
</tbody>
</table>

For more information on creating a virtual machine DB system, see [Creating Bare Metal and Virtual Machine DB Systems](#) on page 1370.

**Security Technical Implementation Guide (STIG) Tool for Virtual Machine DB systems**

This topic describes a python script, referred to as the STIG tool, for Oracle Cloud Infrastructure virtual machine DB systems provisioned using Oracle Linux 7. The STIG tool is used to ensure security compliance with DISA's Oracle Linux 7 STIG. The script does the following:

- Makes the base image of the virtual machine DB system compliant with the Oracle Linux 7 STIG
- Embeds certain STIG rules into the system that can be activated after provisioning when required to meet security compliance standards
- Categorizes the embedded rules, allowing you to view and monitor the rules in the following categories:
  - **Static**: Rules included in the base image
  - **DoD**: Rules optionally activated after provisioning when needed to meet U.S. Department of Defense compliance standards
  - **Runtime**: Rules activated after provisioning when needed. Intended for use by all users needing to harden security for virtual machine DB systems (including users outside of the U.S. Department of Defense).
- Provides a rollback capability, allowing you to roll back a DB system to a state with no configuration modifications made by the script
- Provides a compliance check capability, allowing you to see how many of the scripts rules are successfully passed by the DB system

**Acquiring the STIG Tool**

The STIG tool is provided for all newly-provisioned virtual machine DB systems. The STIG tool is provided in the following OS directory location on virtual machine DB system nodes:

```
/opt/oracle/dcs/bin/dbcsstig
```

Updated versions of the STIG tool will be available for download from the [Oracle Technology Network (OTN)](http://www.oracle.com/technology). Updated versions of the STIG tool are also provided as available when you update the DB system agent.
Using the STIG Tool

Use the following syntax for the STIG tool:

```
dbcsstig --<operation> <category>
```

For example:

```
dbcsstig --fix dod
```

Command Reference

Operations

<table>
<thead>
<tr>
<th>Operation Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>--check, -c</td>
<td>Checks for compliance with rules included in specified category</td>
</tr>
<tr>
<td>--fix, -f</td>
<td>Applies fixes for rules included in specified category</td>
</tr>
<tr>
<td>--rollback, -rb</td>
<td>Rolls back system configuration changes implemented by the STIG tool</td>
</tr>
<tr>
<td>--version, -v</td>
<td>Provides version information for the STIG tool script</td>
</tr>
<tr>
<td>--help, -h</td>
<td>Provides command line help information</td>
</tr>
</tbody>
</table>

Rule Categories

<table>

</tbody>
</table>

Enabling FIPS, SE Linux, and STIG on Bare Metal or Virtual Machine DB System Components

This topic describes how to add FIPS security enhancements to a bare metal or virtual machine DB system in Oracle Cloud Infrastructure (OCI). The procedure is performed on each system node, and enables the following:

- Federal Information Processing Standards (FIPS)
- Security Enhanced (SE) Linux
- Security Technical Implementation Guide (STIG) standards

To enable FIPS, SE Linux, and STIG

1. Open an SSH session to the DB system node and switch to the root user, then navigate to `/opt/oracle/dcs/bin`:

```
# sudo -s
# cd /opt/oracle/dcs/bin
```
2. Run the following command to enable FIPS:

```
# dbcli secure-dbsystem -se -sd -fo -fd
```

The system provide details on the enable job:

```
Job details
ID: <job_ID_number>
Description: Secure DB System
Status: Created
Created: November 8, 2020 4:12:29 PM UTC
Progress: 0%
Message:

Task Name Start Time End Time Status
```

3. Verify the job details as follows:

```
# dbcli describe-job -i <job_ID_number>
```

The system provides information on the progress, status, and details of the enable job. For example:

```
Job details
ID: <job_ID_number>
Description: Secure DB System
Status: Success
Created: November 8, 2020 4:12:29 PM UTC
Progress: 100%
Message:

Task Name Start Time End Time Status
```

4. Once the Job details output shows the Status "Success", you must restart your DB system node using the OCI Console. This is required because enabling FIPS and SE Linux updates OS kernel. See To start, stop, or reboot a database system on page 1383 for instructions.

To check a DB system node for FIPS and SE Linux configurations

To confirm that FIPS and SE Linux are enabled on your DB system node, use the following dbcli command:

```
# dbcli get-dbsystemsecurestatus
```
The system returns details as shown in the following example:

```json
{
    "isSELinuxEnabledForOS" : true,
    "isFipsEnabledForOS" : true,
    "fipsStatusForDBs" : [ {
        "databaseResId" : "<DB_ID_number>",
        "status" : true
    } ]
}
```

### External Database Service

You can manage and monitor Oracle Databases that are located outside of Oracle Cloud Infrastructure (OCI) using OCI's External Database service. External Database allows you use cloud-based tools such as Database Management with your external databases.

### About the Database Management Service

As a Database Administrator, you can use the Oracle Cloud Infrastructure Database Management service to monitor and manage your Oracle Databases. Database Management supports Oracle Database versions 11.2.0.4 and later. Using Database Management you can:

- Monitor the key performance and configuration metrics of your fleet of Oracle Databases. You can also compare and analyze database metrics over a selected period of time.
- Group your critical Oracle Databases, which reside across compartments into a Database Group, and monitor them.
- Create SQL jobs to perform administrative operations on a single Oracle Database or a Database Group.

For complete documentation on the Database Management service, see Database Management. The rest of the External Database section of the documentation covers only the creation and management of external database "handles" and the OCI external database connection resource that allows you connect your external database to a handle in OCI.

### How the External Database Service Works

To manage an external database using OCI's External Database service, you create an OCI resource known as a "handle" that represents the external database within your tenancy. After creating a handle for your database, you create a second resource called a database connection. The connection stores the information required for your OCI tenancy to connect to the external database. After creating the connection resource and connecting the OCI handle to your external database instance, you can enable the Database Management service to monitor the health and performance of your database.

### The OCI External Database Handle

You can create an OCI external database handle for the following types of external databases:

- External container databases
- External pluggable databases
- External non-container databases

The handle stores a few pieces of metadata that allow you to manage your database instance within OCI. This metadata includes the following information related to managing the handle in OCI:

- An OCID, which allows the external database instance to be identified and managed within OCI.
- An OCI display name
- Compartments assignment information (optional)
- Tags (optional)
In addition to the OCI-related metadata, the handle stores metadata derived from the database instance. This includes the database unique name, the Oracle Database software edition and version, and other details. All of this information stored by the handle can be viewed in the OCI Console or retrieved using the API. Metadata derived from the external database instance (such as database unique name) is only populated in the handle after a database connection is established between the handle and the instance.

**Scanning an External Container Database to Discover Pluggable Databases**

After you create and connect an external container database handle, you can use the handle to scan the external container database and discover pluggable databases that have not been connected to OCI. If any pluggable databases are discovered that are not connected to Oracle Cloud Infrastructure, the connection details for these databases are listed in the work request generated by the scan operation. See To scan an external container database for pluggable databases on page 1562 for more information.

**The OCI Database Connection Resource**

The OCI database connection resource stores details about how a specific handle connects to an external Oracle Database instance. These details include the following:

- Connection strings details (DNS hostname, port, service name, network protocol)
- Connection type and OCI agent ID
- User credentials and role

**Prerequisites**

To use the External Database service, you will need the following:

- An Oracle Cloud Infrastructure (OCI) tenancy. See Setting Up Your Tenancy on page 122 for information if you do not currently use OCI.
- One or more external databases located outside of OCI. The External Database service supports container databases, pluggable databases, and non-container databases that use the following Oracle Database software versions: 11gR2, 12cR1, 12cR2, 18c, and 19c. You can use the External Database service with database clones and with high-availability / disaster recovery databases standby databases.
- A Management Agent Cloud Service agent with source credentials. See the Management Agent documentation for details on creating this resource in OCI.

**Creating External Database Handles**

This topic provides information on creating OCI external database handles using the OCI Console and API. See External Database Service on page 1558 for an overview of the External Database service.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud external database resources on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more information about writing policies for databases, see Details for the Database Service on page 2240.

**Using the Console**
To create an OCI external pluggable database resource

This procedure describes the steps you take to create an OCI external pluggable database resource, also called a "handle". The handle functions as a representation within OCI of an Oracle Database instance located outside of the Oracle's cloud. **Note:** This procedure is not used to create an Oracle Database instance outside of Oracle's Cloud.

1. Open the . Under , click .
2. Choose your Compartment.
4. Click Create External Pluggable Database.

The Create an external pluggable database dialog opens.

5. Choose a compartment for the external pluggable database.
6. Enter a database display name. The display name is a user-friendly name to help you easily identify the resource.
7. Select an external container database to house the pluggable database.
8. Click Show Advanced Options to specify the following options for the database:

   **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

9. Click Create External Pluggable Database.

WHAT NEXT?

- After creating the OCI external pluggable database resource (the handle), you can configure the handle's connection to the external pluggable database instance. See To create a connection for an OCI external pluggable database resource on page 1564 for more information.
- After connecting the handle to an external pluggable database instance, you can enable Database Management for your external pluggable database. See the Database Management documentation for more information.

To create an OCI external container database

This procedure describes the steps you take to create an OCI external container database resource, also called a "handle". The handle functions as a representation within OCI of an Oracle Database instance located outside of the Oracle's cloud. **Note:** This procedure is not used to create an Oracle Database instance outside of Oracle's Cloud.

1. Open the . Under , click .
2. Choose your Compartment.
4. Click Create External Container Database.

The Create an external container database dialog opens.

5. Choose a compartment for the external pluggable database.
6. Enter a container database display name. The display name is a user-friendly name to help you easily identify the resource.
7. Click Show Advanced Options to specify the following options for the database:

   **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

8. Click Create External Container Database.

WHAT NEXT?

- After creating the OCI external container database resource (the handle), you can configure the resource's connection to a container database located outside of OCI. See To create a connection for an OCI external pluggable database resource on page 1564 for more information.
After connecting the handle to an external container database, you can perform a scan of the external container database to discover pluggable databases. See To scan an external container database for pluggable databases on page 1562 for more information.

After connecting the handle to an external container database, you can enable Database Management for your external container database. See the Database Management documentation for more information.

To create an OCI external non-pluggable database

This procedure describes the steps you take to create an OCI external non-container database resource, also called a "handle". The handle functions as a representation within OCI of an Oracle Database instance located outside of the Oracle's cloud. Note: This procedure is not used to create an Oracle Database instance outside of Oracle's Cloud.

1. Open the . Under , click .
2. Choose your Compartment.
4. Click Create External Non-Container Database.
   The Create an external non-container database dialog opens.
5. Choose a compartment for the external non-container database.
6. Enter a non-container database display name. The display name is a user-friendly name to help you easily identify the resource.
7. Click Show Advanced Options to specify the following options for the database:
   Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
8. Click Create External Non-Container Database.

WHAT NEXT?

After creating the OCI external non-container database resource (the handle), you can configure the handle’s connection to the external database instance. See To create a connection for an OCI external non-container database resource on page 1565 for more information.

After connecting the handle to an external database instance, you can enable Database Management for the external database. See the Database Management documentation for more information.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create OCI external database handles:

- CreateExternalContainerDatabase
- CreateExternalPluggableDatabase
- CreateExternalNonContainerDatabase

Managing External Database Handles

This topic provides information on managing Oracle Cloud Infrastructure (OCI) external database handles using the OCI Console and API. See External Database Service on page 1558 for an overview of the External Database service.

Note:

See the Database Management documentation for instructions on enabling Database Management for an external database handle in the OCI Console.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* you should work in.

For administrators: The policy in *Let database admins manage Oracle Cloud external database resources* on page 2150 lets the specified group do everything with databases and related Database resources.

If you’re new to policies, see *Getting Started with Policies* on page 2135 and *Common Policies* on page 2142. For more information about writing policies for databases, see *Details for the Database Service* on page 2240.

**Using the Console**

*To move an OCI external database handle to another compartment*

1. Open the . Under , click .
2. Choose your *Compartment*.
3. Under *External Databases*, click either *Pluggable Database*, *Container Databases*, or *Non-Container Databases*, depending on the type of external database handle you are managing.
4. In the list of external database handles, click on the name of the handle you want to move.
5. On the external database details page, click the *Move Resource* button.
6. In the *Move Resource to a Different Compartment* dialog, choose a new compartment using the drop-down selector.
7. Click *Move Resource*.

*To delete an OCI external database handle*

This topic describes how to delete the following OCI resources:

- External pluggable database handle
- External container database handle
- External non-container database handle

1. Open the . Under , click .
2. Choose your *Compartment*.
3. Under *External Databases*, click either *Pluggable Database*, *Container Databases*, or *Non-Container Databases*, depending on the type of external database handle you are deleting.
4. In the list of external database handles, click on the name of the handle you want to delete.
5. On the external database details page, click the *Delete* button.

*To scan an external container database for pluggable databases*

1. Open the . Under , click .
2. Choose your *Compartment*.
3. Under *External Databases*, click *Container Databases*.
4. In the list of external container database handles, click on the name of the handle that is connected to the container database you want to scan.

5. On the external container database details page, click **Scan for Pluggable Databases**.

   If any pluggable databases are discovered that are not connected to Oracle Cloud Infrastructure, the connection details for these databases are listed in the **work request** generated by the scan operation.

Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 4368 and [Security Credentials](#) on page 179. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 4225.

Use these API operations to manage external container database resources:

- ListExternalContainerDatabases
- GetExternalContainerDatabase
- ChangeExternalContainerDatabaseCompartment
- ScanExternalContainerDatabasePluggableDatabases
- EnableExternalContainerDatabaseDatabaseManagement
- DisableExternalContainerDatabaseDatabaseManagement
- UpdateExternalContainerDatabase
- DeleteExternalContainerDatabase

Use these API operations to manage external pluggable database resources:

- ListExternalPluggableDatabases
- GetExternalPluggableDatabase
- ChangeExternalPluggableDatabaseCompartment
- EnableExternalPluggableDatabaseDatabaseManagement
- DisableExternalPluggableDatabaseDatabaseManagement
- UpdateExternalPluggableDatabase
- DeleteExternalPluggableDatabase

Use these API operations to manage external non-container database resources:

- ListExternalNonContainerDatabases
- GetExternalNonContainerDatabase
- ChangeExternalNonContainerDatabaseCompartment
- EnableExternalNonContainerDatabaseDatabaseManagement
- DisableExternalNonContainerDatabaseDatabaseManagement
- UpdateExternalNonContainerDatabase
- DeleteExternalNonContainerDatabase

Creating and Managing an External Database Connection

This topic provides information on managing Oracle Cloud Infrastructure (OCI) external database connections using the OCI Console and API. The external database connection resource allows you to connect an OCI external database handle to an Oracle Database instance located outside of OCI. See [External Database Service](#) on page 1558 for more information about the External Database service and the database connection resource.

**Note:**

Currently the External Database service supports only Management Agent Cloud Service (MACS) agents for creating a connection to your external databases. Enterprise Manager Cloud Control Agents are not supported at this time.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment you should work in.

For administrators: The policy in Let database admins manage Oracle Cloud external database resources on page 2150 lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies on page 2135 and Common Policies on page 2142. For more information about writing policies for databases, see Details for the Database Service on page 2240.

Using the Console

To create a connection for an OCI external pluggable database resource

1. Open the . Under , click .
2. Choose your Compartment.
4. In the list of OCI external pluggable database resources (also called "handles"), click the display name of the handle you want to create a connection for.
5. Click Connect to External Pluggable Database.

   The Connect to an external pluggable database dialog opens.
6. Enter a connection display name. This is a user-friendly name to help you easily identify the resource.
7. Enter the DNS hostname for the database on your premises that you are connecting to Oracle Cloud.
8. Enter the port being used by the database outside of Oracle Cloud Infrastructure for database connections.
9. Enter the service name for the database outside of Oracle Cloud Infrastructure that will be used by the connection.
10. Enter the connection agent ID. See Management Agent for more information about this Oracle Cloud Infrastructure feature.
11. Enter the Username for the database credentials that will be used by this connection.
12. Enter the Password for the database credentials that will be used by this connection.
13. Enter a Credential name prefix. This string is the first part of the full credential name. Your prefix is prepended to a system-generated Credential name prefix to create the full credential name.
14. Enter the Role for the database credentials that will be used by this connection.
15. Click Show Advanced Options to specify the following options for the database:

   Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.
16. Click Connect to External Pluggable Database.

To create a connection for an OCI external container database resource

1. Open the . Under , click .
2. Choose your Compartment.
4. In the list of OCI external container database resources (also called "handles"), click the display name of the handle you want to create a connection for.
5. Click Connect to External Pluggable Database.

   The Connect to an external pluggable database dialog opens.
6. Enter a connection display name. This is a user-friendly name to help you easily identify the resource.
7. Enter the DNS hostname for the database on your premises that you are connecting to Oracle Cloud Infrastructure.
8. Enter the port being used by the database outside of Oracle Cloud Infrastructure for database connections.
9. Enter the service name for the database outside of Oracle Cloud Infrastructure that will be used by the connection.
10. Enter the connection agent ID. See Management Agent for more information about this Oracle Cloud Infrastructure feature.
11. Enter the Username for the database credentials that will be used by this connection.
12. Enter the Password for the database credentials that will be used by this connection.
13. Enter a Credential name prefix. This string is the first part of the full credential name. Your prefix is prepended to a system-generated Credential name prefix to create the full credential name.
14. Enter the Role for the database credentials that will be used by this connection.
15. Click Show Advanced Options to specify the following options for the database:

   Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

16. Click Connect to External Pluggable Database.

To create a connection for an OCI external non-container database resource

1. Open the . Under , click .
2. Choose your Compartment.
4. In the list of OCI external non-container database resources (also called "handles"), click the display name of the handle you want to create a connection for.
5. Click Connect to External Non-Container Database.

   The Connect to an Connect to an external non-container database dialog opens.

6. Enter a connection display name. This is a user-friendly name to help you easily identify the resource.
7. Enter the DNS hostname for the database on your premises that you are connecting to Oracle Cloud.
8. Enter the port being used by the database outside of Oracle Cloud Infrastructure for database connections.
9. Enter the service name for the database outside of Oracle Cloud Infrastructure that will be used by the connection.
10. Enter the connection agent ID. See Management Agent for more information about this Oracle Cloud Infrastructure feature.
11. Enter the Username for the database credentials that will be used by this connection.
12. Enter the Password for the database credentials that will be used by this connection.
13. Enter a Credential name prefix. This string is the first part of the full credential name. Your prefix is prepended to a system-generated Credential name prefix to create the full credential name.
14. Enter the Role for the database credentials that will be used by this connection.
15. Click Show Advanced Options to specify the following options for the database:

   Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, then skip this option (you can apply tags later) or ask your administrator.

16. Click Connect to External Non-Container Database.

To check the connection status of an external database connection

1. Open the . Under , click .
2. Choose your Compartment.
3. Under External Databases, click either Pluggable Database, Container Databases, or Non-Container Databases, depending on the type of external database you are using.
4. In the list of external database handles, click the name of the handle you want to check the connection status of.
5. On the Database Details page, under Resources, click Connections.
6. In the list of database connections, click the name of the connection you want to check the status of.
7. Click Check Connection Status. A "Check Connection Status" work request is created. Click on the work request name to see details of the connection status.
To update the connection credentials of an external database handle

1. Open the . Under , click .
2. Choose your **Compartment**.
3. Under **External Databases**, click either **Pluggable Database**, **Container Databases**, or **Non-Container Databases**, depending on the type of external database handle connection you are updating.
4. In the list of external database handles, click on the name of the handle associated with the connection you want to update.
5. On the external database details page, under **Resources**, click **Connections**.
6. In the list of connections, click the name of the connection you want to update.
7. On the External Connection Details page, click **Update Connection Credentials**.
8. In the **Update credentials** dialog, enter the following information:
   - Username
   - Password
   - Role
9. Click **Update Credentials**.

To update the connection strings of an external database handle

1. Open the . Under , click .
2. Choose your **Compartment**.
3. Under **External Databases**, click either **Pluggable Database**, **Container Databases**, or **Non-Container Databases**, depending on the type of external database handle connection you are updating.
4. In the list of external database handles, click on the name of the handle associated with the connection you want to update.
5. On the external database details page, under **Resources**, click **Connections**.
6. In the list of connections, click the name of the connection you want to update.
7. On the External Connection Details page, click **Update Connection Strings**.
8. In the **Update connection strings** dialog, enter the following information:
   - DNS hostname
   - Port
   - Service
9. Click **Update Connection Strings**.

To delete an external database connection

1. Open the . Under , click .
2. Choose your **Compartment**.
3. Under **External Databases**, click either **Pluggable Database**, **Container Databases**, or **Non-Container Databases**, depending on the type of external database handle you are deleting.
4. In the list of external database handles, click on the name of the handle associated with the connection you want to delete.
5. On the external database details page, under **Resources**, click **Connections**.
6. In the list of connections, click the name of the connection you want to delete.
7. On the External Connection Details page, click **Delete**.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to create and manage external database connections:

- CreateExternalDatabaseConnector
- ListExternalDatabaseConnectors
- GetExternalDatabaseConnector
Oracle Database Software Images

This topic provides an overview of the database software image resource type, which you can use to create databases and Oracle Database Homes, and to patch databases. Database software images give you the ability to create a customized Oracle Database software configuration that includes your chosen updates (PSU, RU or RUR), and optionally, a list of one-off (or interim) patches or an Oracle Home inventory file. This reduces the time required to provision and configure your databases, and makes it easy for your organization to create an approved "gold image" for developers and database administrators.

Using Database Software Images in Oracle Cloud Infrastructure

Creation and Storage of Database Software Images

Database software images are resources within your tenancy that you create prior to provisioning or patching a DB system, Exadata Cloud Service instance, Database Home, or database. There is no limit on the number of database software images you can create in your tenancy, and you can create your images with any Oracle Database software version and update supported in Oracle Cloud Infrastructure.

Database software images are automatically stored in Oracle-managed Object Storage and can be viewed and managed in the Oracle Cloud Infrastructure Console. Note that database software images incur Object Storage usage costs. Database software image are regional-level resources and can be accessed from any availability domain within their region.

See To create a database software image on page 1568 for information on creating an image.

Using a Database Software Image with a Bare Metal or Virtual Machine DB System

Provisioning: After you create a database software image, you can use it to provision the initial database in a new bare metal or virtual machine DB system, or to provision a new database in an existing bare metal DB system. For more information, see the following topics:

• To create a DB system on page 1372
• To create a new database in an existing DB system on page 1415

Patching: You can use a database software image to update the database software of an existing virtual machine or bare metal database in Oracle Cloud Infrastructure. This is sometimes referred to as in-place patching. See To patch a database on page 1422 for information on using a custom database software image to patch a database in a bare metal or virtual machine DB system. To determine if a database has been patched with a particular database software image, follow the instructions in To view the patch history of a database on page 1422. For Oracle Data Guard associations, you can use a custom database software image for in-place patching on both the primary and standby database instances to ensure that both databases have the same patches.

Using a Database Software Image with an Exadata Cloud Service Instance

Provisioning: After you create a database software image, you can use it to create an Oracle Database Home in an Exadata Cloud Service instance. For more information, see To create a new Database Home in an existing Exadata Cloud Service instance on page 1330.

Patching: To patch a database in an Exadata Cloud Service instance using a custom database software image, create the Database Home using the image, and then move the database to that Database Home. For more information, see Patching Individual Oracle Databases in an Exadata Cloud Service Instance on page 1287.

Setting up Data Guard: When creating an Oracle Data Guard association, you can use a custom database software image to create a new Database Home for the new standby database. For more information, see To enable Oracle Data Guard on an Exadata Cloud Service instance on page 1342.
Using the Console

To create a database software image

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
3. Click Create Database Software Image.
4. In the Display name field, provide a display name for your image. Avoid entering confidential information.
5. Choose your Compartment.
6. Choose a Shape family. A custom database software images is compatible with only one shape family. Available shape families are the following:
   - Bare metal and virtual machine DB systems
   - Exadata Cloud Service instances
7. Choose the Database version for your image.
8. Choose the patch set update, proactive bundle patch, or release update. For information on Oracle Database patching models, see Release Update Introduction and FAQ (Doc ID 2285040.1).
9. Optionally, you can enter a comma-separated list of one-off (interim) patch numbers.
10. Optionally, you can upload an Oracle Home inventory file from an existing Oracle Database.
11. Click Show Advanced Options to add tags to your database software image. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 211. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
12. Click Create Database Software Image.

To view the patch information of a database software image

To view the Oracle Database version, update information (PSU/BP/RU level) and included one-off (interim) patches of a database software image, use the following instructions:

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
3. In the list of database software images, find the image you want to view and click on the display name of the image.
4. On Database Software Image Details page for your selected image, details about the image are displayed:
   - The Oracle Database version is displayed in the General Information section. For example: 19.0.0.0
   - The PSU/BP/RU field of the Patch Information section displays update level for the image. For example: 19.5.0.0
   - The One-Off Patches field displays the number of one-off patches included in the image, if any. The count includes all patches specified when creating the image (excluding patches listed in Isinventory). To view the included patches (if any are included), click the Copy All link and paste the list of included patches into a text editor. The copied list of patch numbers is comma-separated and can be used to create additional database software images.

To delete a database software image

1. Open the navigation menu. Under Oracle Database, click Bare Metal, VM, and Exadata.
3. In the list of database software images, find the image you want to delete and click the action icon (three dots) at the end of the row.
4. Click Delete.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use these API operations to manage database software images:
• CreateDatabaseSoftwareImage
• ListDatabaseSoftwareImages
• GetDatabaseSoftwareImage
• DeleteDatabaseSoftwareImage
• ChangeDatabaseSoftwareImageCompartment

Oracle Maximum Availability Architecture in Oracle Cloud Infrastructure

Oracle Maximum Availability Architecture is a set of best practices developed by Oracle engineers over many years for the integrated use of Oracle High Availability technologies.

Oracle Maximum Availability Architecture and Autonomous Database Cloud

High availability is suitable for all development, test, and production databases that have high uptime requirements and low data loss tolerance. By default, Autonomous Databases are highly available, incorporating a multi-node configuration to protect against localized hardware failures that do not require fast disaster recovery. Each Autonomous Database application service resides in at least one Oracle Real Application Clusters (Oracle RAC) instance with the option to fail over to another available Oracle RAC instance using Autonomous Data Guard for unplanned outages or planned maintenance activities, resulting in zero or near-zero downtime. Autonomous Database's automatic backups are stored in Oracle Cloud Infrastructure Object Storage and replicated to another availability domain, and can be restored in the event of a disaster. Major database upgrades, however, require downtime.

The uptime service-level objective per month is 99.95% (a maximum of 22 minutes of downtime per month), but when you use Maximum Availability Architecture best practices for continuous service, most months would effectively have zero downtime. The uptime service-level objective does not include downtime due to customer-initiated high availability tests, disaster recovery (such as an availability domain or regional outage), database corruptions, or downtime due to planned maintenance that cannot be done online or through an Oracle RAC rolling update solution, such as major database upgrades from one release to another.

The following table describes the recovery-time objectives and recovery-point objectives (data loss tolerance) for service-level objectives.

<table>
<thead>
<tr>
<th>Failure and Maintenance Events</th>
<th>Database Downtime</th>
<th>Service-Level Downtime (RTO)</th>
<th>Potential Service-Level Data Loss (RPO)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Localized events, including:</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Exadata cluster network topology failures</td>
<td>Zero</td>
<td>Near-zero</td>
<td>Zero</td>
</tr>
<tr>
<td>• Storage (disk and flash) failures</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Database instance failures</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Database server failures</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Periodic software and hardware maintenance updates</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Database Downtime (RTO)

- **Database Downtime (RTO)**: Minutes to hours
- **Service-Level Downtime (RTO)**: Minutes to hours
- **Potential Service-Level Data Loss (RPO)**: 15 minutes

<table>
<thead>
<tr>
<th>Failure and Maintenance Events</th>
<th>Database Downtime</th>
<th>Service-Level Downtime (RTO)</th>
<th>Potential Service-Level Data Loss (RPO)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Events requiring restoring from backup because standby database does not exist:</td>
<td>Minutes to hours</td>
<td>Minutes to hours</td>
<td>15 minutes</td>
</tr>
<tr>
<td>• Data corruptions</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Full database failures</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Complete storage failures</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Availability domain or region failures</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the preceding table, the amount of downtime for events requiring restoring from a backup varies due to the nature of the failure. In the most optimistic case, a physical block corruption is detected and the block is repaired with block media recovery in minutes. In this case, only a small portion of the database is affected with zero data loss.

In a more pessimistic case, an availability domain or data region fails, and a new cluster must be provisioned and restored with the latest database backup, including all archives, and a complete database recovery must be run. Data loss is limited by the last successful archive log backup, the frequency of which is every 15 minutes, by default, and includes a log switch and subsequent archive log backup of any redo that has not been backed up to Oracle Cloud Infrastructure Object Storage. Data loss can be seconds or, at worst, around 15 minutes.

**Autonomous Data Guard for Autonomous Databases on Dedicated Exadata Infrastructure**

Enable Autonomous Data Guard for mission-critical production databases that have more strict uptime requirements than databases with the default high-availability configuration and limited data-loss tolerance considering a wider range of potential problems, such as data corruption and database and regional site failures. Enabling Autonomous Data Guard adds one symmetric standby database with Oracle Data Guard to an Exadata rack that is located in another availability domain or in another region.

The primary and standby database systems are configured symmetrically to ensure that performance service levels are maintained after Data Guard role transitions. Oracle Data Guard features asynchronous redo transport (maximum performance mode) within the same region across availability domains, or across regions, by default. If zero data loss is required, then you can change to synchronous redo transport (maximum availability mode).

As with databases that are not Data Guard-enabled, each Autonomous Database application service resides in at least one Oracle RAC instance and will automatically fail over to another available Oracle RAC instance, as previously described. The standby database provides expanded application services to offload reporting, queries, and some updates. The Database Backup Cloud Service schedules automated backups, which are stored in Oracle Cloud Infrastructure Object Storage and replicated to another availability domain. Those backups can be used to restore databases in the event of a double disaster where both primary and standby databases are lost.

Local and remote virtual cloud network peering provides a secure, high-bandwidth network across availability domains and regions for any traffic between primary and standby servers.

The uptime service-level objective per month is 99.995% (maximum 132 seconds of downtime per month) and recovery-time objectives (downtime) and recovery-point objectives (data loss) are low, as described in the subsequent table, when a manual failover is initiated. When you use Maximum Availability Architecture best practices for continuous service, most months would have an effective downtime of zero. The uptime service-level objective does not include downtime as a result of user-initiated high availability tests, user-initiated Data Guard switchover tests, or the time it takes to initiate a manual Data Guard failover.

Users can choose whether their database failover site is located in a different availability domain within the same region or in a different region, contingent upon application or business requirements, and data center availability.
**Autonomous Data Guard Recovery Time (RTO) and Recovery Point (RPO) Service-level Objectives**

<table>
<thead>
<tr>
<th>Failure and Maintenance Events</th>
<th>Service-Level Downtime (RTO)</th>
<th>Potential Service-Level Data Loss (RPO)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Localized events, including:</td>
<td>Near zero</td>
<td>Zero</td>
</tr>
<tr>
<td>• Exadata cluster network fabric failures</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Storage (disk and flash) failures</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Database instance failures</td>
<td></td>
<td></td>
</tr>
<tr>

**Maintaining Application Uptime**

Ensure that network connectivity to Oracle Cloud Infrastructure is reliable so that you can access your tenancy's Autonomous Database resources.

Follow the guidelines in the [Continuous Availability: Best Practices for Applications Using Autonomous Database - Dedicated](#) and [Application Continuity: MAA Checklist for Preparation](#) white papers to experience application-level service uptime similar to that of the database uptime.

**Oracle Maximum Availability Architecture in Exadata DB Systems**

Oracle Maximum Availability Architecture in Oracle Cloud Infrastructure provides inherent high availability, data protection, and disaster recovery protection integrated with both cloud automation and lifecycle operations, enabling Oracle Cloud Infrastructure to be the best cloud solution for enterprise databases and applications.

**Oracle Maximum Availability Architecture Benefits in Oracle Cloud**

- **Deployment**: Oracle deploys Exadata in Oracle Cloud Infrastructure using Oracle Maximum Availability Architecture best practices, including configuration best practices for storage, network, operating system, Oracle Grid Infrastructure, and Oracle Database. Exadata is optimized to run enterprise Oracle Databases with extreme scalability and availability.

- **Oracle Maximum Availability Architecture database templates**: All cloud databases created with Oracle Cloud automation use Oracle Maximum Availability Architecture settings optimized for the Exadata in Oracle Cloud. Oracle does not recommend that you use custom scripts to create cloud databases.

- **Backup and restore automation**: When you configure automatic backup to Oracle Cloud Infrastructure Object Storage, backup copies exist across multiple availability domains for additional protection, and RMAN validates
cloud database backups for any physical corruptions. Database backups occur daily with a full backup occurring once per week and incremental backups occurring on all other days. Archive log backups occur frequently to reduce potential data loss in case of disaster.

- **Exadata inherent benefits**: Exadata is the best Oracle Maximum Availability Architecture platform that Oracle offers, engineered with hardware, software, database, and availability innovations to support the most mission-critical enterprise applications. Specifically, Exadata provides unique high availability, data protection, and quality-of-service capabilities that set Oracle apart from any other platforms or cloud vendor.

For a comprehensive list of Oracle Maximum Availability Architecture benefits for Exadata DB systems, see [Exadata Database Machine: Maximum Availability Architecture Best Practices](http://example.com) and [Deploying Oracle Maximum Availability Architecture with Exadata Database Machine](http://example.com). Examples of these benefits include:

- **High availability and low brownout**: Fully-redundant, fault-tolerant hardware exists in the storage, network, and database servers. Resilient, highly-available software, such as Oracle Real Application Clusters (Oracle RAC), Oracle Clusterware, Oracle Database, Oracle Automatic Storage Management, Oracle Linux, and Oracle Exadata Storage Server enable applications to maintain application service levels through unplanned outages and planned maintenance events. For example, Exadata has instant failure detection that can detect and repair database node, storage server, and network failures in less than two seconds, and resume application and database service uptime and performance. Other platforms can experience 30 seconds, or even minutes, of blackout and extended application brownouts for the same type of failures. Only the Exadata platform offers a wide range of unplanned outage and planned maintenance tests to evaluate end-to-end application and database brownouts and blackouts.

- **Data protection**: Exadata provides Oracle Database physical and logical block corruption prevention, detection, and, in some cases, automatic remediation. The Exadata Hardware Assisted Resilient Data (HARD) checks include support for server parameter files, control files, log files, Oracle data files, and Oracle Data Guard broker files when those files are stored in Exadata storage. This intelligent Exadata storage validation stops corrupted data from being written to disk when a HARD check fails, which eliminates a large class of failures that the database industry had previously been unable to prevent. Examples of the Exadata HARD checks include:

  - Redo and block checksum
  - Correct log sequence
  - Block type validation
  - Block number validation
  - Oracle data structures, such as block magic number, block size, sequence number, and block header and tail data structures

Exadata HARD checks initiate from Exadata storage software (cell services) and work transparently after enabling a database `DB_BLOCK_CHECKSUM` parameter, which is enabled by default in the cloud. Exadata is the only platform that currently supports the HARD initiative. Furthermore, Oracle Exadata Storage Server provides non-intrusive, automatic hard disk scrub and repair. This feature periodically inspects and repairs hard disks during idle time. If bad sectors are detected on a hard disk, then Oracle Exadata Storage Server automatically sends a request to Oracle Automatic Storage Management to repair the bad sectors by reading the data from another mirror copy. Finally, Exadata and Oracle Automatic Storage Management can detect corruptions as data blocks are read into the buffer cache and automatically repair data corruption with a good copy of the data block on a subsequent database write. This inherent intelligent data protection makes Exadata and Exadata Cloud the best data protection storage platform for Oracle Databases. For comprehensive data protection, a Maximum Availability Architecture best practice is to use a standby database on a separate Exadata to detect, prevent, and automatically repair corruptions that cannot be addressed by Exadata, alone. The standby database also minimizes downtime and data loss for disasters that result from site, cluster, and database failures.

- **Response time quality of service**: Only Exadata has end-to-end quality-of-service capabilities to ensure that response time remains low and optimum. Database server I/O capping and Exadata storage I/O latency capping ensures that read or write I/O can be redirected to partnered cells when response time exceeds a certain threshold. If storage becomes unreliable (but not failed) because of poor and unpredictable performance, then the disk or flash cache can be quarantined, offline, and later brought back online if heuristics show that I/O performance is back to acceptable levels. Resource management can help prioritize...
key database network or I/O functionality, so that your application and database perform at an optimized level. For example, database log writes get priority over backup requests on the Exadata network and storage. Furthermore, rapid response time is maintained during storage software updates by ensuring that partner flash cache is warmed so flash misses are minimized.

- **End-to-end testing and holistic health checks**: Because Oracle owns the entire Exadata Cloud infrastructure, end-to-end testing and optimizations benefit every Exadata customer around the world, whether hosted on premise or in the cloud. Validated optimizations and fixes required to run any mission-critical system are uniformly applied after rigorous testing. Health checks are designed to evaluate the entire stack. The Exadata health check utility **EXACHK** is Exadata cloud-aware and highlights any configuration and software alerts that may have occurred because of customer changes. No other cloud platform currently has this kind of end-to-end health check available. For Oracle Autonomous Database, **EXACHK** runs automatically to evaluate Maximum Availability Architecture compliance. For non-autonomous databases, Oracle recommends running **EXACHK** at least once a month, and before and after any software updates, to evaluate any new best practices and alerts.

- **Oracle Maximum Availability Architecture best practices paper**: Oracle Maximum Availability Architecture engineering collaborates with Oracle Cloud teams to integrate Oracle Maximum Availability Architecture practices that are optimized for Oracle Cloud Infrastructure and security. See **MAA Best Practices for the Oracle Cloud** for additional information about continuous availability, Oracle Data Guard, Hybrid Data Guard, Oracle GoldenGate, and other Maximum Availability Architecture-related topics.

The following table lists various software updates and the impacts associated with those updates on databases and applications.

### Achieving Continuous Availability for your Applications

As part of Exadata Cloud, all software updates (except for non-rolling database upgrades) can be done online or with Oracle RAC rolling updates to achieve continuous database uptime. Furthermore, any local failures of the storage, Exadata network, or Exadata database server are managed, automatically, and database uptime is maintained.

To achieve continuous application uptime during Oracle RAC switchover or failover events, follow these application-configuration best practices:

- Use non-default Oracle Clusterware-managed services to connect your application.
- Use recommended connection string with built-in timeouts, retries, and delays, so that incoming connections do not see errors during outages.
- Configure your connections with Fast Application Notification.
- Drain and relocate services prior to any planned maintenance outage on Exadata that requires restarting any of the Oracle RAC instances. Software updates to Exadata Dom0 or DomU are automatic. For Oracle Database and Oracle Grid Infrastructure software updates, Exadata Cloud-assisted tools and Autonomous Database drain and relocate services automatically.
- Leverage Application Continuity or Transparent Application Continuity to replay in-flight uncommitted transactions transparently after failures.

For more information, see [Continuous Availability: Best Practices for Applications Using Autonomous Database - Dedicated](#) and [Application Continuity: MAA Checklist for Preparation](#) white papers to experience application-level service uptime similar to that of the database uptime.

### Oracle Maximum Availability Architecture Reference Architectures in the Exadata Cloud

Exadata Cloud supports all four Oracle Maximum Availability Architecture reference architectures, providing support for all Oracle Databases, regardless of their specific high availability, data protection, and disaster recovery service-level agreements. See [MAA Best Practices for the Oracle Cloud](#) for more information about Oracle Maximum Availability Architecture in the Exadata Cloud.

### Security Zone Integration

This topic describes the Database service's support of security zones. Security zones are compartments in your tenancy created with a set of security policies called a security recipe. This topic concentrates on the Oracle-managed Maximum Security Recipe, which provides the highest level of protection for your Database resources. The policies of a particular security recipe are applied to any resource that is provisioned or moved into a security zone compartment that uses the recipe. Thus, the only way to apply security zone policies is to control the compartment assignments of your Oracle Cloud Infrastructure resources.

For a complete overview of security zones, see the Security Zone section of the Oracle Cloud Infrastructure user guide.

### Restrictions on Database Service Resources Located in Maximum Security Recipe Compartments

The Maximum Security Recipe includes all available security zone policies. For example, restrictions placed on a databases in a Maximum Security Recipe compartments include:
• The database cannot allow public network access
• The database must have automatic backups enabled
• The database cannot have Data Guard associations that aren’t located in security zone compartments

For a complete list of the Database restrictions implemented by the Maximum Security Recipe, see the Security Zone Policies topic.

Supported Database Service Resources

The following Database service resources can be provisioned and managed in security zones that use the Maximum Security Recipe:

• Autonomous Database: Databases using dedicated Exadata infrastructure and using shared Exadata infrastructure with private endpoint access
• Bare metal and virtual machine DB systems
• Exadata Cloud DB systems

Always Free Autonomous Databases, Autonomous Database configured with public endpoints, and the Exadata Cloud@Customer service are not compatible with Maximum Security Recipe compartments.

DB System Time Zone

The Time Zone field in the Console and in the API allows you to launch a bare metal, virtual machine, or Exadata DB system with a time zone other than UTC (the default). Although UTC is the recommended time zone to use, having a common time zone for your database clients and application hosts can simplify management and troubleshooting for the database administrator.

The time zone that you specify when you create the DB system applies to the host and to the Oracle Grid Infrastructure (if the system has Grid Infrastructure), and controls the time zone of the database log files. The time zone of the database itself is not affected, however, the database’s time zone affects only the timestamp datatype. You can change the database time zone manually but Oracle recommends that you keep it as UTC (the default) to avoid data conversion and improve performance when data is transferred among databases. This configuration is especially important for distributed databases, replication, and export and import operations.

Time Zone Options

Whether you use the Console or the API, the time zone options you can select from are represented in the named region format, for example, America/Los_Angeles. The Console allows you to select UTC, the time zone detected in your browser (if your browser supports time zone detection), or an alternate time zone.

To specify an alternate time zone (the Select another time zone option), you first select a value in the Region or country field to narrow the list of time zones to select from in the Time zone field. In the America/Los_Angeles example, America is the time region and Los_Angeles is the time zone. The options you see in these two fields roughly correlate with the time zones supported in both the Java.util.TimeZone class and on the Linux operating system. If you do not see the time zone you are looking for, try selecting "Miscellaneous" in the Region and country field.

Tip:

If you are using the API and would like to see a list of supported time zones, you can examine the time zone options in the Console. These options appear on the Create DB System page when you show advanced options after you select a DB system shape.

Changing Time Zones After Provisioning

Follow these steps if you need to change the time zone of the DB system host, Oracle Grid Infrastructure, or database, after you launch the DB system:
To change the time zone of the host on DB systems that use Grid Infrastructure

1. Log on to the host system as root.
2. Stop the CRS stack on all of the compute nodes.

   #Grid_Home/bin/crsct1 stop crs

3. Run the following commands to check the current time zone and to change it to the time zone you choose:

   $ cat /etc/sysconfig/clock
   ZONE="America/New_York"
   $ cp -p /etc/sysconfig/clock /etc/sysconfig/clock.20160629
   $ vi /etc/sysconfig/clock
   ZONE="Europe/Berlin"
   $ date
   Wed Jun 29 10:35:17 EDT 2016
   $ ln -sf /usr/share/zoneinfo/Europe/Berlin /etc/localtime
   $ date
   Wed Jun 29 16:35:27 CEST 2016

   In this example, the time zone was changed from America/New_York to Europe/Berlin.

   Tip:
   To see a list of valid time zones on the host, you can run the ls -l /usr/share/zoneinfo command.

4. (Optional) On an Exadata DB system, you can verify that /opt/oracle.cellos/cell.conf indicates the correct time zone. Using our example, the time zone entry in this file would be <Timezone>Europe/Berlin</Timezone>.
5. Restart the CRS stack on all of the compute nodes.

   #Grid_Home/bin/crsct1 start crs

To change the time zone of the host on DB systems that use Logical Volume Manager

Use this procedure for Fast Provisioned virtual machine DB systems, which use Logical Volume Manager instead of Grid Infrastructure for storage management.

1. Log on to the host system as root.
2. Stop the database and the listener on all of the compute nodes.

   #sqlplus / as sysdba
   SQL> shutdown immediate
   #lsnrctl stop

3. Stop all other running processes from the Oracle Database Home.
4. Run the following commands to check the current time zone and to change it to the time zone you choose:

   $ cat /etc/sysconfig/clock
   ZONE="America/New_York"
   $ cp -p /etc/sysconfig/clock /etc/sysconfig/clock.20160629
   $ vi /etc/sysconfig/clock
   ZONE="Europe/Berlin"
   $ date
   Wed Jun 29 10:35:17 EDT 2016
   $ ln -sf /usr/share/zoneinfo/Europe/Berlin /etc/localtime
In this example, the time zone was changed from *America/New_York* to *Europe/Berlin*.

Tip:

To see a list of valid time zones on the host, you can run the `ls -l /usr/share/zoneinfo` command.

5. As Oracle, restart the listener and the database on all of the compute nodes.

```
lsnrctl start
sqlplus / as sysdba
startup
```

**To change the time zone of the Oracle Grid Infrastructure**

The time zone of the Oracle Grid Infrastructure determines the time zone of the database log files.
You can change this time zone by updating the `TZ` property in the `GRID_HOME/crs/install/s_crsconfig_<node_name>_env.txt` configuration file.

Note:

This procedure does not apply to Fast Provisioned virtual machine DB systems, which use Logical Volume Manager instead of Grid Infrastructure for storage management.

1. Ensure that you are logged onto the host as `root` and that the CRS stack is stopped on all of the compute nodes. See To change the time zone of the host on DB systems that use Grid Infrastructure on page 1576.
2. Inspect the current time zone value in the `GRID_HOME/crs/install/s_crsconfig_<node_name>_env.txt` file.

```
$ cat /u01/app/19.0.0.0/grid/crs/install/s_crsconfig_node1_env.txt
#########################################################################
#This file can be used to set values for the NLS_LANG and TZ environment variables and to set resource limits for Oracle Clusterware and Database processes.
#1. The NLS_LANG environment variable determines the language and characterset used for messages. For example, a new value can be configured by setting NLS_LANG=JAPANESE_JAPAN.UTF8
#2. The Time zone setting can be changed by setting the TZ entry to the appropriate time zone name. For example, TZ=America/New_York
#3. Resource limits for stack size, open files and number of processes can be specified by modifying the appropriate entries.
#
#Do not modify this file except as documented above or under the direction of Oracle Support Services.
#########################################################################
TZ=UTC
NLS_LANG=AMERICAN_AMERICA.WE8ISO8859P1
CRS_LIMIT_STACK=2048
CRS_LIMIT_OPENFILE=65536
CRS_LIMIT_NPROC=16384
TNS_ADMIN=
```

In this example, the time zone is set to UTC.

3. Modify the time zone value, as applicable. Perform this task for all nodes in the cluster.
4. Restart the CRS stack on all of the compute nodes.

```
#Grid_Home/bin/crsctl start crs
```
For more information about changing the time zone of the Grid Infrastructure, see How To Change Timezone for Grid Infrastructure (Doc ID 1209444.1).

To change the time zone of a database

Use the `ALTER DATABASE SET TIME_ZONE` command to change the time zone of a database. This command takes either a named region such as America/Los_Angeles or an absolute offset from UTC.

This example sets the time zone to UTC:

```
ALTER DATABASE SET TIME_ZONE = '+00:00';
```

You must restart the database for the change to take effect. For more information, see Setting the Database Time Zone.

Database Metrics

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure Database service resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview on page 2660 and Notifications Overview on page 3350.

The Database service metrics help you measure useful quantitative data, such as CPU and storage utilization, the number of successful and failed database logon and connection attempts, database operations, SQL queries, and transactions, and so on. You can use metrics data to diagnose and troubleshoot problems with your Database Service resources.

See the following topics for information about currently available database metrics:

- Autonomous Database Metrics on page 1578
- External Database Metrics on page 1589

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Using the API

For information about using the API and signing requests, see REST APIs on page 4368 and Security Credentials on page 179. For information about SDKs, see Software Development Kits and Command Line Interface on page 4225.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Autonomous Database Metrics

This topic describes the metrics emitted by the Database service in the oci_autonomous_database namespace.

Resources: Autonomous Databases.

For a complete list of available metrics for Autonomous Databases, see Available Metrics: oci_autonomous_database on page 1579.

To view a default set of metrics charts in the Console, navigate to the Autonomous Database that you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.
Database

**Available Metrics: oci_autonomous_database**

The metrics listed in the following table are automatically available for any Autonomous Database that you create. You do not need to enable monitoring on the resource to get these metrics.

<table>
<thead>
<tr>
<th>Note:</th>
<th>Valid alarm intervals are 5 minutes or greater due to the frequency at which these metrics are emitted. See To create an alarm for details on creating alarms.</th>
</tr>
</thead>
</table>

Database service metrics for Autonomous Databases include the following *dimensions*:

**AUTONOMOUSDBTYPE**

The type of Autonomous Database, Autonomous Data Warehouse (ADW) or Autonomous Transaction Processing (ATP).

**deploymentType**

The Exadata infrastructure type, shared or dedicated. When using the Console to view default metric charts for multiple Autonomous Databases, you must specify this dimension.

**DISPLAYNAME**

The friendly name of the Autonomous Database.

**REGION**

The region in which the Autonomous Database resides.

**RESOURCEID**

The OCID of the Autonomous Database.

**RESOURCENAME**

The name of the Autonomous Database.

In the following table, metrics that are marked with an asterisk (*) can be viewed only on the Service Metrics page of the Oracle Cloud Infrastructure Console. All metrics can be filtered by the dimensions described in this topic. Note that some metrics are only available for Autonomous Databases using either shared Exadata infrastructure or dedicated Exadata infrastructure. This is indicated in the Applicable Exadata Infrastructure Type column.

**WaitTime**

**Metric**

**Wait Time**

**Unit**

seconds per second

**Description**

Average rate of accumulation of non-idle wait time by foreground sessions in the database over the time interval. The wait time component of Average Active Sessions.

**Applicable Exadata Infrastructure Type**

Dedicated only

---

**Using the Console**

**To view default metric charts for a single Autonomous Database**

1. Open the navigation menu. Under **Oracle Database**, click **Autonomous Data Warehouse**, **Autonomous JSON Database**, or **Autonomous Transaction Processing**.
2. Choose the **Compartment** that contains the Autonomous Database you want to view, and then click display name of the database to view its details.
3. Under **Resources**, click **Metrics**.

   The **Metrics** page displays a default set of charts for the current Autonomous Database. See **Available Metrics: oci_autonomous_database** on page 1579 for information about the default charts.

   For more information about monitoring metrics and using alarms, see **Monitoring Overview** on page 2660. For information about notifications for alarms, see **Notifications Overview** on page 3350.

**To view default metric charts for multiple Autonomous Databases**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the Autonomous Databases that you're interested in.
3. For **Metric Namespace**, select **oci_autonomous_database**.

   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

4. For **Dimensions**, specify an Exadata infrastructure deployment type (shared or dedicated). **Important**: If you do not specify a deployment type, no service metrics will display on the page.

   Optionally, you can specify other dimensions to filter your displayed metrics. See **To filter results** on page 2673 and **To select different resources** on page 2673 in the Monitoring documentation for more information.

   **Tip:**

   If there are multiple Autonomous Databases in the compartment, the charts default to show a separate line for each master encryption key. You can
instead show a single line aggregated across all Autonomous Databases in the compartment by selecting the Aggregate Metric Streams check box.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

## External Database Metrics

This topic describes the metrics emitted by the Database service in the `oracle_external_database` namespace.

Resources: External Databases.

To view a default set of metrics charts in the Console, navigate to the external database that you're interested in, and then click Metrics. You also can use the Monitoring service to create custom queries.

### Available Metrics: `oracle_external_database`

The metrics listed in the following table are automatically available for external databases.

<table>
<thead>
<tr>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Collection Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AllocatedStorageUtilizationByTablespace</strong></td>
<td>percent</td>
<td>Percentage of space used by tablespace out of allocated. <em>Not applicable to external container databases.</em></td>
<td>30 minutes</td>
</tr>
<tr>
<td><strong>BlockChanges</strong></td>
<td>changes per second</td>
<td>The average number of blocks changed per second.</td>
<td>5 minutes</td>
</tr>
</tbody>
</table>

Database service metrics for external databases include the following dimensions:

- **DISPLAYNAME**
  - The friendly name of the external database.

- **REGION**
  - The `region` in which the OCI external database resource resides.

- **RESOURCEID**
  - The `OCID` of the external database.

- **RESOURCENAME**
  - The name of the external database.

In the following table, metrics that are marked with an asterisk (*) can be viewed only on the Service Metrics page of the Oracle Cloud Infrastructure Console. All metrics can be filtered by the dimensions described in this topic.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Collection Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>CpuCount*</td>
<td>CPU Count</td>
<td>CPU</td>
<td>Container and non-container databases: The value of the cpu_count parameter, if set; otherwise, the value of num_cpus for the database host. Pluggable databases: The value of the cpu_count parameter if set. Otherwise the value of the cpu_count parameter of the associated container database (if set), or the num_cpus value of the database host if the cpu_count of the container database is not set.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>CpuTime*</td>
<td>CPU Time</td>
<td>seconds per second</td>
<td>Average rate of accumulation of CPU time by foreground sessions in the database over the time interval. The CPU time component of Average Active Sessions.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>CpuUtilization</td>
<td>CPU Utilization</td>
<td>percent</td>
<td>The CPU usage expressed as a percentage, aggregated across all consumer groups. The utilization percentage is reported with respect to the number of CPUs the database is allowed to use, which is two times the number of OCPUs.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>CurrentLogons</td>
<td>Current Logons</td>
<td>count</td>
<td>The number of successful logons during the selected interval.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Collection Frequency</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------</td>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>DBTime</td>
<td>DB Time</td>
<td>seconds per second</td>
<td>The amount of time database user sessions spend executing database code (CPU Time + WaitTime). DB Time is used to infer database call latency, because DB Time increases in direct proportion to both database call latency (response time) and call volume. It is calculated as the average rate of accumulation of database time by foreground sessions in the database over the time interval. Also known as Average Active Sessions.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>ExecuteCount</td>
<td>Execute Count</td>
<td>count</td>
<td>The number of user and recursive calls that executed SQL statements during the selected interval.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>IOPS*</td>
<td>IOPS</td>
<td>operations per second</td>
<td>The average number of I/O operations per second.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>IOThroughput*</td>
<td>IO Throughput</td>
<td>MB per second</td>
<td>The average throughput in MB per second.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>LogicalBlocksRead</td>
<td>Logical Reads</td>
<td>reads per second</td>
<td>The average number of logical block reads (&quot;db block gets&quot; plus &quot;consistent gets&quot;) per second. Includes buffered and direct I/O.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>MaxTablespaceSize</td>
<td>Max Tablespace Size</td>
<td>GB</td>
<td>Maximum possible tablespace size. Not applicable to external container databases.</td>
<td>30 minutes</td>
</tr>
<tr>
<td>Metric</td>
<td>Metric Display Name</td>
<td>Unit</td>
<td>Description</td>
<td>Collection Frequency</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------</td>
<td>-----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>MemoryUsage*</td>
<td>Memory Usage</td>
<td>MB</td>
<td>The total amount of memory used by the database during the collection interval. Not applicable to external pluggable databases.</td>
<td>15 minutes</td>
</tr>
<tr>
<td>MonitoringStatus</td>
<td>Monitoring Status</td>
<td>No unit; failed status is displayed when monitoring is interrupted.</td>
<td>5 minutes</td>
<td></td>
</tr>
<tr>
<td>ParseCount*</td>
<td>Parse Count (Total)</td>
<td>count</td>
<td>The number of hard and soft parses during the selected interval.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>ParsesByType*</td>
<td>Parses By Type</td>
<td>parses per second</td>
<td>The number of hard or soft parses per second.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>RedoSize*</td>
<td>Redo Generated</td>
<td>MB per second</td>
<td>The Average amount of redo generated in MB per second.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>StorageAllocated*</td>
<td>Storage Space Allocated</td>
<td>GB</td>
<td>Maximum amount of space allocated to the database during the interval.</td>
<td>30 minutes</td>
</tr>
<tr>
<td>StorageAllocatedByTablespace*</td>
<td>Storage Space By Tablespace</td>
<td>GB</td>
<td>Maximum amount of space allocated for each tablespace during the interval.</td>
<td>30 minutes</td>
</tr>
<tr>
<td>StorageUsed*</td>
<td>Storage Space Used</td>
<td>GB</td>
<td>Maximum amount of space used during the interval.</td>
<td>30 minutes</td>
</tr>
<tr>
<td>StorageUsedByTablespace*</td>
<td>Storage Space Used By Tablespace</td>
<td>GB</td>
<td>Maximum amount of space used by each tablespace during the interval.</td>
<td>30 minutes</td>
</tr>
<tr>
<td>StorageUtilization</td>
<td>Storage Utilization</td>
<td>percent</td>
<td>The percentage of provisioned storage capacity currently in use. Represents the total allocated space for all tablespaces.</td>
<td>30 minutes</td>
</tr>
</tbody>
</table>
### Metric Display Name

<table>
<thead>
<tr>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Collection Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>StorageUtilization</td>
<td>percent</td>
<td>The percentage of space utilized by each tablespace. <em>Not applicable to external container databases.</em></td>
<td>30 minutes</td>
</tr>
<tr>
<td>TransactionCount</td>
<td>count</td>
<td>The combined number of user commits and user rollbacks during the selected interval.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>TransactionsByStatus</td>
<td>transactions per second</td>
<td>The number of committed or rolled back transactions per second.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>UserCalls</td>
<td>count</td>
<td>The combined number of logons, parses, and execute calls during the selected interval.</td>
<td>5 minutes</td>
</tr>
<tr>
<td>WaitTime</td>
<td>seconds per second</td>
<td>Average rate of accumulation of non-idle wait time by foreground sessions in the database over the time interval. The wait time component of Average Active Sessions.</td>
<td>5 minutes</td>
</tr>
</tbody>
</table>

### Using the Console

**To view default metric charts for a single External Database**

1. Open the . Under , click .
2. Choose the **Compartment** that contains the External Database you want to view, and then click display name of the database to view its details.
3. Under **Resources**, click **Metrics**.

The **Metrics** page displays a default set of charts for the current External Database. See [Available Metrics: oracle_external_database](#) on page 1589 for information about the default charts.

For more information about monitoring metrics and using alarms, see [Monitoring Overview](#) on page 2660. For information about notifications for alarms, see [Notifications Overview](#) on page 3350.

**To create metrics queries for all available external database metrics using the Monitoring Service’s Metrics Explorer tool**

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Click **Metrics Explorer**. Note: external database metrics are not available in the **Service Metrics** tab. For information on building queries in the Metrics Explorer tab, see [Building Metric Queries](#) on page 2700.
3. Create a metrics query:
   - For **Compartment**, select the compartment that contains the external databases that you're interested in.
   - For **Metric Namespace**, select `oracle_external_database`.
   - Select a **Metric name**. See Available Metrics: `oracle_external_database` on page 1589 for definitions of each metric.
   - Select an **Interval**. See Available Metrics: `oracle_external_database` on page 1589 for information on the collection frequency of each external database metric.
   - Select the **Statistic** type. This is the aggregation function applied for converting a set of data points. Available functions include count, max, mean, rate, min, sum, and percentile.
   - Select a **Metric dimension**. Dimensions are used to filter metric data. For example, by choosing the "resourceID" dimension, you can specific a single external database by selecting the OCID of the OCI external database resource.

4. Click **Update Chart** after configuring your query.

For more information about monitoring metrics and using alarms, see Monitoring Overview on page 2660. For information about notifications for alarms, see Notifications Overview on page 3350.

Using the Oracle Database Service Overview to Manage Resources

This topic describes the **Overview** page in the Oracle Database section of the Oracle Cloud Infrastructure Console. The Overview page gives you a way to view and manage all of your tenancy's Oracle Database resources using a single dashboard tool. The Overview provides information on all of your work request activity, alarms, announcements and more, regardless of whether the databases use Autonomous Database, bare metal, virtual machine, Exadata Cloud, or Exadata Cloud@Customer infrastructure.

**Resource Summary Section**

The resource summary tiles provide you with details on how many Oracle Databases you have currently provisioned in your tenancy. The Autonomous Database tile provides total numbers of databases by workload type and infrastructure type.

![279 Autonomous Databases](image)

The Databases tile provides total numbers of bare metal, or virtual machine databases by database edition type, total numbers of Exadata databases by infrastructure type.
