The `json_table` SQL/JSON function projects specific JSON data to columns of various SQL data types. You can use the `json_table` function to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

See Create View on JSON Data for more information on creating views over JSON Data.

Use Web Services with Oracle APEX

You can interact with both SOAP and RESTful style web services from Oracle APEX in your Autonomous Database instance.
Web services enable applications to interact with one another over the web in a platform-neutral, language independent environment. In a typical web services scenario, a business application sends a request to a service at a given URL by using the HTTP protocol. The service receives the request, processes it, and returns a response. Web services are typically based on Simple Object Access Protocol (SOAP) or Representational State Transfer (REST) architectures.

Using REST Data Sources, APEX developers can declaratively access data services from a variety of REST endpoints, allowing both read and write operations. In addition to supporting smart caching rules for remote REST data, Oracle APEX also offers the unique ability to directly manipulate the results of REST data sources using industry standard SQL.

The `APEX_WEB_SERVICE` package enables you to integrate other systems with APEX by allowing you to interact with web services anywhere you can use PL/SQL in your application. The package contains procedures and functions to call both SOAP and RESTful style web services, and to simplify implementation of OAuth 2.0 flows.

- Submit an HTTP Request to a Private Host with Oracle APEX
  There are several requirements to submit an HTTP request to a private host from Oracle APEX in your Autonomous Database instance.
- Make External Calls Using a Customer-Managed Wallet with Oracle APEX
  Oracle APEX on Autonomous Database is preconfigured with an Oracle Wallet that will work with most HTTPS endpoints. If you want to consume REST APIs from servers that use less common or self-signed SSL certificates, you can configure a customer-managed wallet.

- Make External Calls Using a Web Proxy with Oracle APEX
  Your Oracle APEX instance does not require an outbound web proxy to make external REST APIs calls. Autonomous Databases configured with a private endpoint can use a web proxy deployed in your VCN if desired.
- Notes for Using Web Services with Oracle APEX
  Provides notes for working with web services in Oracle APEX from an Autonomous Database instance.

Submit an HTTP Request to a Private Host with Oracle APEX

There are several requirements to submit an HTTP request to a private host from Oracle APEX in your Autonomous Database instance.

To submit a request to a target host on a private endpoint or behind on-premises firewalls, the target host must be accessible from the source database's Oracle Cloud Infrastructure VCN:

1. Ensure the endpoint meets the prerequisites to submit an HTTP request, as described here: Submit an HTTP Request to a Private Host with UTL_HTTP.
2. Add the following access control list for the desired host as ADMIN (note the `private_target` parameter):

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host => 'www.example.com',
    ace => XS$ACE_TYPE(
      privilege_list => XS$NAME_LIST('http'),
      principal_name => APEX_APPLICATION.g_flow_schema_owner,
      principal_type => XS_ACL.ptype_db),
    private_target => true);
END;
/
```

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` database property to `PRIVATE_ENDPOINT`, you do not need to define access control lists for individual hosts in order to access them from APEX. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

Make External Calls Using a Customer-Managed Wallet with Oracle APEX

Oracle APEX on Autonomous Database is preconfigured with an Oracle Wallet that will work with most HTTPS endpoints. If you want to consume REST APIs from servers that use less common or self-signed SSL certificates, you can configure a customer-managed wallet.

Oracle APEX on Autonomous Database is preconfigured with an Oracle Wallet that contains more than 90 of the most common trusted root and intermediate SSL certificates. The `APEX_WEB_SERVICE` package automatically takes advantage of this Oracle Wallet without additional configuration from application developers.

If you want to consume REST APIs from servers that use less common or self-signed SSL certificates, you can configure a customer-managed wallet. First, follow configuration and deployment instructions in Prerequisites to Use a Customer-Managed Wallet with External

Calls. After the wallet is deployed to your Autonomous Database, grant `READ` on the directory object containing the wallet to the APEX platform schema as `ADMIN`:

```
BEGIN
  execute immediate 'grant READ on directory WALLET_DIR to ' ||
    APEX_APPLICATION.g_flow_schema_owner;
END;
```

Next, when you reference the wallet in `APEX_WEB_SERVICE` API calls, make sure to use the `DIR:` prefix instead of the usual `FILE:` prefix. For example:

```
l_resp := APEX_WEB_SERVICE.MAKE_REST_REQUEST(
  p_url         => 'https://www.example.com/',
  p_http_method => 'GET',
  p_wallet_path => 'DIR:WALLET_DIR'
);
```

You can also configure this wallet as the default for the entire Oracle APEX instance in **APEX Administration Services** by selecting Manage Instance → Instance Settings → Wallet → Wallet Path, or by setting the `WALLET_PATH` instance parameter.

To switch back to the preconfigured wallet, set `WALLET_PATH` to an empty value.

See Access Oracle APEX Administration Services for more information.

Make External Calls Using a Web Proxy with Oracle APEX

Your Oracle APEX instance does not require an outbound web proxy to make external REST APIs calls. Autonomous Databases configured with a private endpoint can use a web proxy deployed in your VCN if desired.

To use a web proxy define the following access control list as `ADMIN`:

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host           => 'www-proxy.example.com',
    lower_port     => 80,
    ace => XS$ACE_TYPE(
      privilege_list => XS$NAME_LIST('HTTP_PROXY'),
      principal_name => APEX_APPLICATION.g_flow_schema_owner,
      principal_type => XS_ACL.ptype_db),
    private_target => true);
END;
/
```

Then, you can use the web proxy in `APEX_WEB_SERVICE` API calls:

```
l_resp := APEX_WEB_SERVICE.MAKE_REST_REQUEST(
  p_url            => 'https://www.example.com/',
  p_http_method    => 'GET',
  p_proxy_override => 'www-proxy.example.com:80'
);
```

You can also configure a web proxy at the application level by setting Proxy Server property on Shared Components → Application Definition → Properties page, or at the instance level in **APEX Administration Services** from Manage Instance → Security → Instance Proxy.

If you attempt to use a web proxy when your Autonomous Database is configured with a public endpoint, an error is returned:

```
ORA-01031: insufficient privileges
```

See Submit an HTTP Request to a Private Host with UTL_HTTP for more information on proxies when using `UTL_HTTP` API.

See Access Oracle APEX Administration Services for more information.

Notes for Using Web Services with Oracle APEX

Provides notes for working with web services in Oracle APEX from an Autonomous Database instance.

Note the following when working with web services in Oracle APEX:

- All web services must be secured. Only HTTPS services are supported on the default port (443). Connections through IP addresses are not allowed.
- Each Autonomous Database instance is preconfigured with a network access control list (ACL) to permit outbound web service calls from Oracle APEX to public endpoints.
- `APEX_WEB_SERVICE` requests do not honor the custom wallet you set with `UTL_HTTP.SET_WALLET` API calls.
- There is a default limit of 1,000 outbound web service requests per APEX workspace in a rolling 24-hour period (this applies for new databases, some older databases may have a larger limit). If the limit of outbound web service calls is reached, the following SQL exception is raised on the subsequent request and the request is blocked:

  ```
  ORA-20001: You have exceeded the maximum number of web service requests per
  workspace. Please contact your administrator.
  ```

  You can raise or remove the default limit of outbound web service requests by setting a value for the `MAX_WEBSERVICE_REQUESTS` instance parameter or by updating the Maximum Web Service Requests attribute in APEX Administration Services. For example, to change the limit to 250,000, connect to your database as ADMIN using a SQL client and execute the following:

  ```
  BEGIN
    APEX_INSTANCE_ADMIN.SET_PARAMETER('MAX_WEBSERVICE_REQUESTS', '250000');
    COMMIT;
  END;
  /
  ```

To learn more, see:

- APEX_WEB_SERVICE in *Oracle APEX API Reference*
- Managing REST Data Sources in *Oracle APEX App Builder User's Guide*

Send Email from Oracle APEX

You can use the `APEX_MAIL` package to send email from Oracle APEX applications deployed in Autonomous Database.

Before you use `APEX_MAIL` you must configure an SMTP server that will deliver email from Oracle APEX. Oracle APEX on Autonomous Database supports Oracle Cloud Infrastructure Email Delivery service as well as third party email providers.

- Configure OCI Email Delivery
  Your Oracle APEX instance can utilize OCI Email Delivery service to send email from APEX applications.
- Configure Third Party Email Provider
  Your Oracle APEX instance can utilize third party email providers to send email from APEX applications.
- Validate Email Configuration
  Shows the steps to confirm your email provider is ready to use with `APEX_MAIL`.
- Notes for Sending Email from Oracle APEX
  Provides notes for working with email providers in Oracle APEX from an Autonomous Database instance.

Configure OCI Email Delivery

Your Oracle APEX instance can utilize OCI Email Delivery service to send email from APEX applications.

To configure `APEX_MAIL` functionality to use OCI Email Delivery service:

1. Identify the SMTP connection endpoint for Email Delivery. You configure the endpoint as the SMTP Host in your APEX instance in Step 4. You may need to subscribe to additional Oracle Cloud Infrastructure regions if Email Delivery is not available in your current region. See Configure SMTP Connection for more information.
2. Generate SMTP credentials for Email Delivery. Your APEX instance uses credentials to authenticate with Email Delivery servers when you send email. See Creating SMTP Credentials for more information.
3. Create an approved sender for Email Delivery. You need to complete this step for all email addresses you use as the "From" with `APEX_MAIL.SEND` calls, as the Application Email "From" address in your apps, or in the `SMTP_FROM` instance parameter. See Managing Approved Senders for more information.
4. Connect to your Autonomous Database as ADMIN user using a SQL client and configure the following SMTP parameters using `APEX_INSTANCE_ADMIN.SET_PARAMETER`:
   - `SMTP_HOST_ADDRESS`: Specifies the SMTP connection endpoint from Step 1
   - `SMTP_USERNAME`: Specifies the SMTP credential user name from Step 2
   - `SMTP_PASSWORD`: Specifies the SMTP credential password from Step 2
   - `SMTP_HOST_PORT`: Keep the default value for this parameter (587)
   - `SMTP_TLS_MODE`: Keep the default value for this parameter (`STARTTLS`)

For example:

```
BEGIN
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_ADDRESS', 'smtp.email.us-
phoenix-1.oci.oraclecloud.com');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_USERNAME',
'ocid1.user.oc1.username');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_PASSWORD', 'password');
  COMMIT;
END;
/
```

See APEX_INSTANCE_ADMIN for more information.

See Overview of Email Delivery for more information.

Configure Third Party Email Provider

Your Oracle APEX instance can utilize third party email providers to send email from APEX applications.

Before configuring a third party email provider in APEX, ensure the following prerequisites are met:

- Your Autonomous Database must be configured to use a Private Endpoint.
- The email provider's SMTP endpoint (port 25 or 587) must be accessible from the Virtual Cloud Network (VCN) and subnet where your Autonomous Database is provisioned.

See Configure Network Access with Private Endpoints for more information.

After the above prerequisites are met:

1. Add the following access control list for the SMTP endpoint as ADMIN (note the `private_target` parameter):

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host => 'smtp.example.com',
    ace => XS$ACE_TYPE(
      privilege_list => XS$NAME_LIST('SMTP'),
      principal_name => APEX_APPLICATION.g_flow_schema_owner,
      principal_type => XS_ACL.ptype_db),
    private_target => true);
END;
/
```

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` database property to `PRIVATE_ENDPOINT`, you do not need to define access control lists for individual SMTP endpoints in order to access them from APEX. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

2. Connect to your Autonomous Database as ADMIN user using a SQL client and configure the following SMTP parameters using `APEX_INSTANCE_ADMIN.SET_PARAMETER`. If your third

party email provider does not require authentication, skip the `SMTP_USERNAME` and `SMTP_PASSWORD` parameters.

- `SMTP_HOST_ADDRESS`: Specifies the SMTP connection endpoint from Step 1
- The valid values for `SMTP_HOST_PORT` parameter are 25 or 587
- Set the value for the `SMTP_TLS_MODE` parameter to `Y`

For example:

```
BEGIN
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_ADDRESS',
'smtp.example.com');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_PORT', '587');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_TLS_MODE', 'Y');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_USERNAME', 'username');
  APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_PASSWORD', 'password');
  COMMIT;
END;
/
```

See APEX_INSTANCE_ADMIN for more information.

Validate Email Configuration

Shows the steps to confirm your email provider is ready to use with `APEX_MAIL`.

1. Validate the email configuration settings using a SQL client as ADMIN:

   ```
   BEGIN
     APEX_INSTANCE_ADMIN.VALIDATE_EMAIL_CONFIG;
   END;
   /
   ```

   If any errors are reported (for example, "`ORA-29279: SMTP permanent error: 535 Authentication credentials invalid`"), adjust the SMTP parameters or Virtual Cloud Network (VCN) configuration and repeat the validation step.

   See APEX_INSTANCE_ADMIN for more information.

2. Send a test email using APEX SQL Workshop, If you are using OCI Email Delivery, ensure the `p_from` parameter matches one of the approved senders. For example:

   ```
   BEGIN
     APEX_MAIL.SEND(
       p_from => 'alice@example.com',
       p_to   => 'bob@example.com',
       p_subj => 'Email from Oracle Autonomous Database',
       p_body => 'Sent using APEX_MAIL');
   END;
   /
   ```

   See APEX_MAIL for more information.

3. To monitor email delivery in your APEX instance:

a. Sign in to APEX Administration Services.

b. Open the Manage Instance page.

c. Click the Mail Queue link in the Manage Meta Data section.

Alternatively, query `APEX_MAIL_QUEUE` and `APEX_MAIL_LOG` views using a SQL client.

Notes for Sending Email from Oracle APEX

Provides notes for working with email providers in Oracle APEX from an Autonomous Database instance.

Note the following when working with email providers in Oracle APEX:

- There is a default limit of 1,000 emails per workspace in a 24-hour period. You can update or remove this limit in Oracle APEX Administration Services or by setting the `WORKSPACE_EMAIL_MAXIMUM` instance parameter. If you are using OCI Email Delivery service, the service may impose additional limitations.
- When using OCI Email Delivery service, an approved sender must be set up for all possible “From” addresses or mail will be rejected. See Managing Approved Senders for more information.

Control Oracle APEX Upgrades

Oracle automatically maintains Oracle APEX in your Autonomous Database including the deployment of patches and upgrades. When a new Oracle APEX release becomes available in your region, for example, APEX 24.2.0, you have a choice when to apply this upgrade within the 45-day upgrade window. You can optionally extend this window to 90 days.

> **Note:**
>
> The latest Oracle APEX Patch Set Bundles are automatically applied on Autonomous Database and cannot be deferred.

- Defer Oracle APEX Upgrades
  Describes the steps to defer Oracle APEX upgrades.
- Apply Oracle APEX Upgrades
  When you have deferred upgrades and an upgrade is available, you have the option to apply the upgrade at any time before the specified upgrade date.

Defer Oracle APEX Upgrades

Describes the steps to defer Oracle APEX upgrades.

Deferring Oracle APEX upgrades allows you to do the following:

- Control when Oracle APEX is upgraded on your Autonomous Database. While there should be minimal disruption on a live system, you can still choose to upgrade at a time or on a day with less activity, for example on a weekend day.
- Validate your applications against the new version of Oracle APEX before you upgrade your production system.

  To validate and test before you upgrade your production system, do the following:

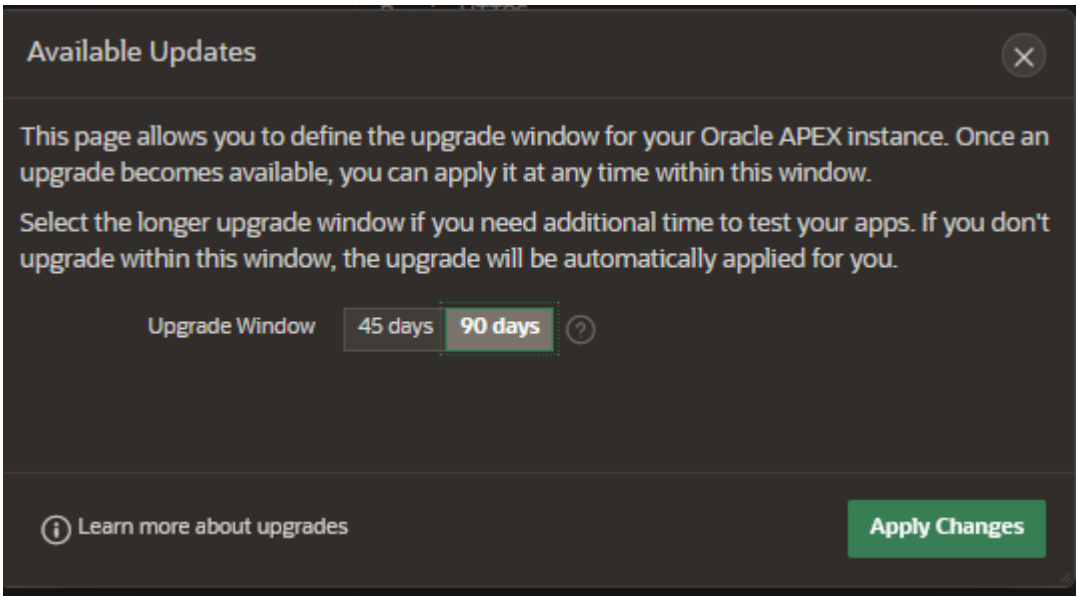
- Clone your production or test environment. See Clone an Autonomous Database Instance for more information.
- Upgrade Oracle APEX on the clone as specified in Apply Oracle APEX Upgrades.
- Perform your testing and validation on the clone in a non-production environment.

To defer Oracle APEX upgrades:

1. Open Oracle APEX Administration Services.

   See Access Oracle APEX Administration Services for more information.
2. Click **APEX** to open the Administration Services page.
3. Open the Available Updates dialog by clicking the next to **Available Updates**.

   This shows the Available Updates dialog.
4. In the Available Updates dialog select an **Upgrade Window**.



5. Click **Apply Changes**.

Notes for deferred Oracle APEX upgrades:

- If an Upgrade Window is selected and updates are available, then on the date indicated in the Available Updates dialog, Oracle APEX updates are automatically applied to your Autonomous Database instance. You cannot postpone the updates beyond the listed date.
- If an upgrade window is set and updates are available, you cannot schedule the Oracle APEX upgrades for a specific date and time. When you are ready to upgrade, access Oracle APEX Administration Services and click **Upgrade Now**. See Apply Oracle APEX Upgrades for details.
- If your Autonomous Database is stopped at the time when a new Oracle APEX release becomes available in your region, the update is automatically applied the next time you start your database, regardless of the Upgrade Window setting. For example, if the Autonomous Database is stopped when a new Oracle APEX release becomes available, based on the Auto Start/Stop Schedule, the update is automatically applied the next time the database starts.

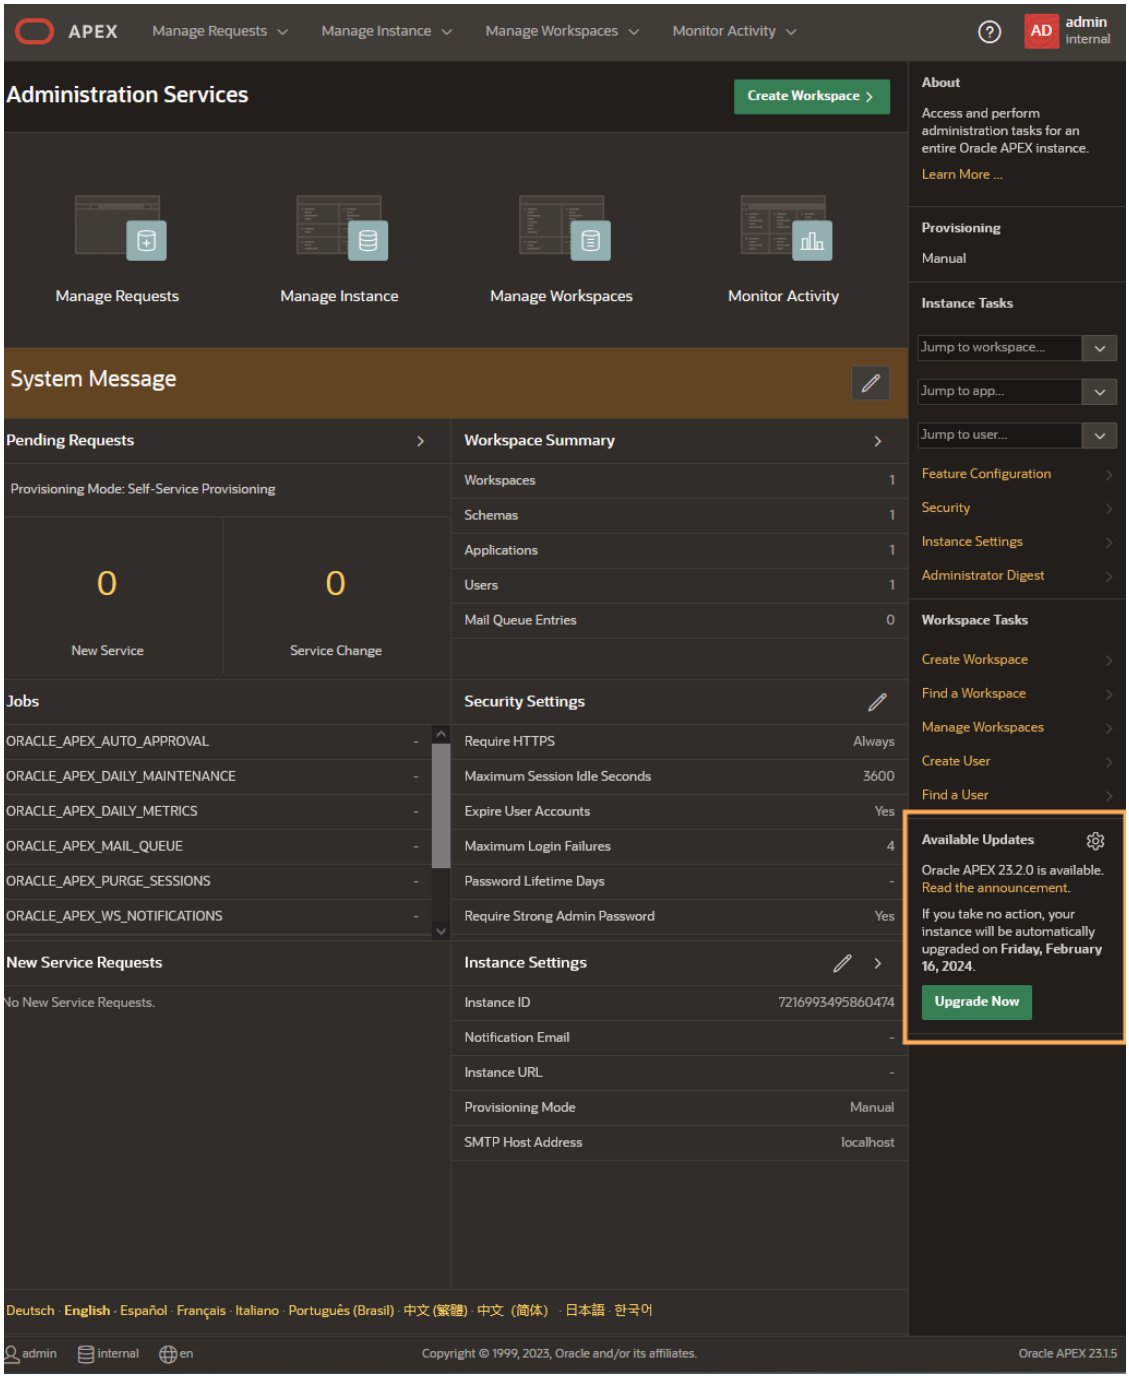
- When you change the Upgrade Window setting, the change applies to future upgrades and does not impact an Oracle APEX upgrade that is already available to your Autonomous Database.
- If your database did not have Oracle APEX activity in the past 6 months, the next Oracle APEX upgrade will be automatically applied regardless of the Upgrade Window setting.

Apply Oracle APEX Upgrades

When you have deferred upgrades and an upgrade is available, you have the option to apply the upgrade at any time before the specified upgrade date.

When Oracle APEX upgrades are not available the Available Updates area shows **System is up-to-date**.

When the Defer Upgrade setting specifies an Upgrade Window, if an Oracle APEX upgrade is available and you take no action, the upgrade is applied automatically on the date specified in the Available Updates area.



If you previously deferred upgrades by specifying an upgrade window, as specified in Defer Oracle APEX Upgrades, then you can upgrade at any time, as follows:

1. Open Oracle APEX Administration Services.
2. Click **APEX** to open the Administration Services page.
3. Open the Available Updates dialog by clicking the next to **Available Updates**.
4. On the Available Updates dialog click **Upgrade Now**.

This starts the Oracle APEX upgrade process in the background. You can continue using Administration Services and App Builder as well as running apps during most of the upgrade process.

Access Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL

By default you access Oracle APEX apps, REST endpoints, and developer tools on Autonomous Database using the `oraclecloudapps.com` domain name. You can optionally configure a vanity URL or custom domain name that is easy to remember to help promote your brand identity.

After you acquire a desired domain name and matching SSL certificate from a vendor of your choice, deploy an Oracle Cloud Infrastructure Load Balancer in your Virtual Cloud Network (VCN) using your Autonomous Database as the backend. Your Autonomous Database instance must be configured with a private endpoint in the same VCN. See Configuring Network Access with Private Endpoints for more information.

To learn more, see the following:

- Introducing Vanity URLs for APEX and ORDS on Oracle Autonomous Database
- Automate Vanity URL Configuration Using Terraform

Oracle APEX Limitations on Autonomous Database

This section summarizes restrictions and limitations of Oracle APEX included in Oracle Autonomous Database and APEX Service.

> **Tip:**
>
> This section does not apply to co-managed databases (for example, OCI Base Database Service) and Oracle Autonomous Database on Dedicated Exadata Infrastructure.

In a fully managed environment (such as Oracle Autonomous Database Serverless), certain limitations are required to protect the security and performance of your Oracle APEX environment.

- Administration Services - The following Oracle APEX Administration Services configuration options are disabled, or have been predefined by Oracle and cannot be altered.
  - Manage Instance, Feature Configuration:
    - Monitoring - Web Service Activity Logging, Enable Application Tracing
  - Manage Instance, Security, Security Settings:
    - Security - Unhandled Errors
    - Authentication Control:
      - HTTP Protocol - Require Outbound HTTPS
      - General - Single Sign-On Logout URL
  - Manage Instance, Manage Logs and Files:
    - SQL Workshop Log
    - Page View Activity Log
    - Developer Activity Log

        - External Click Counting Log
        - Login Access Log
        - Web Service Activity Log
        - REST Synchronization Log
        - Automation Log
    - Manage Instance, Instance Settings - Storage - All tablespace settings
    - Manage Instance, Workspace Purge Settings
    - Manage Workspaces, Existing Workspaces, Edit Workspace Information:
        - Login Control
        - Session Timeout
        - Workspace Isolation
- Only the following `APEX_INSTANCE_ADMIN` procedures and functions are supported:
    - `ADD_AUTHORIZED_URL`
    - `ADD_SCHEMA`
    - `ADD_WORKSPACE`
    - `CREATE_CLOUD_CREDENTIAL`
    - `CREATE_OR_UPDATE_ADMIN_USER`
    - `DISABLE_WORKSPACE`
    - `ENABLE_WORKSPACE`
    - `FREE_WORKSPACE_APP_IDS`
    - `GET_AUTHORIZED_URLS`
    - `GET_PARAMETER`
    - `GET_SCHEMAS`
    - `GRANT_EXTENSION_WORKSPACE`
    - `REMOVE_APPLICATION`
    - `REMOVE_AUTHORIZED_URL`
    - `REMOVE_SAVED_REPORTS`
    - `REMOVE_SAVED_REPORT`
    - `REMOVE_SCHEMA`
    - `REMOVE_SUBSCRIPTION`
    - `REMOVE_WORKSPACE`
    - `RESERVE_WORKSPACE_APP_IDS`
    - `REVOKE_EXTENSION_WORKSPACE`
    - `SET_LOG_SWITCH_INTERVAL`
    - `SET_PARAMETER`
    - `UNLOCK_USER`

  - `VALIDATE_EMAIL_CONFIG`

  See APEX_INSTANCE_ADMIN in *Oracle APEX API Reference*.

- The following application authentication schemes are supported with limitations:
  - HTTP Header Variable: Only after configuring a vanity URL.

    See Access Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL for more information.
  - LDAP Directory, including `APEX_LDAP` API: With the same restrictions that apply to the `DBMS_LDAP` package.

    See PL/SQL Package Notes for Autonomous Database for more information.
  - SAML Sign-In: Only when using a customer managed ORDS.

    See About Customer Managed Oracle REST Data Services on Autonomous Database for more information.
- Disabled options in SQL Workshop:

  The ability to create and manage database links in Object Browser is disabled. To create a database link, use the `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` PL/SQL API.

  See Use Database Links with Autonomous Database for more information.
- Runtime environment:

  Oracle APEX is only available as a Full Development environment. Converting into a Runtime environment, which minimizes the installed software footprint and removes UI components such as App Builder and Administration Services, is not supported.

  See About the Differences Between Runtime and Full Development Environments in *Oracle APEX App Builder User's Guide* to learn more.

Using JSON Documents with Autonomous Database

Autonomous Database has full support for data represented as JSON documents. In Autonomous Databases, JSON documents can coexist with relational data.

You can access and manage JSON documents as follows:

- Using Simple Oracle Document Access (SODA) APIs for NoSQL-style access to document collections.
- Using SQL and PL/SQL to access JSON documents in tables.
- Work with Simple Oracle Document Access (SODA) in Autonomous Database
  Simple Oracle Document Access (SODA) is a set of NoSQL-style APIs that let you use collections of JSON documents in Autonomous Database, retrieve them, and query them, without needing to know Structured Query Language (SQL) or how the documents are stored in the database.
- Work with JSON Documents Using SQL and PL/SQL APIs on Autonomous Database
  Autonomous Database supports JavaScript Object Notation (JSON) data natively in the database.
- Load JSON Documents with Autonomous Database
  You can use the PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` to load JSON documents into SODA collections or use `DBMS_CLOUD.COPY_DATA` to load JSON documents into an existing table in Autonomous Database.

- Import SODA Collection Data Using Oracle Data Pump Version 19.6 or Later
  Shows the steps to import SODA collections into Autonomous Database with Oracle Data Pump.

Work with Simple Oracle Document Access (SODA) in Autonomous Database

Simple Oracle Document Access (SODA) is a set of NoSQL-style APIs that let you use collections of JSON documents in Autonomous Database, retrieve them, and query them, without needing to know Structured Query Language (SQL) or how the documents are stored in the database.

Autonomous Database supports storing and querying JSON documents natively. SODA document collections are backed by ordinary database tables and views; you can take advantage of database features for use with the content of SODA documents.

SODA drivers are available for several languages and frameworks including: Java, Node.js, Python, C (using Oracle Call Interface), and PL/SQL, and SODA for REST. SODA for REST maps SODA operations to Uniform Resource Locator (URL) patterns, so it can be used with most programming languages.

To get started with SODA, see the following:

- Overview of SODA

Depending on the SODA API you want to work with, see the following:

> **Note:**
>
> If you are using Always Free Autonomous Database with Oracle Database 23ai, then to avoid compatibility problems of SODA drivers, Oracle recommends the following:
>
> - Use the driver versions that are needed for working with `JSON` type as specified in SODA Drivers. See SODA Drivers for more information.
> - For projects that were started using a database release prior to Oracle Database 21c, explicitly specify the metadata for the default collection as specified in the example in SODA Drivers. For projects started using release Oracle Database 21c or later, just use the default metadata. See SODA Drivers for more information.

SODA API	Download and Installation	More Information
SODA for Java	Download SODA for Java SODA for Java Prerequisites **Versions:** SODA for Java, using the latest version is recommended. The minimum supported version is: 1.1.4. Use SODA for Java in conjunction with `ojdbc8.jar` (available at Oracle Database JDBC driver and Companion Jars Downloads, or on Maven Central). Autonomous Database does not support Metadata builder. To customize collection metadata pass collection metadata strings directly to the createCollection method. See SODA Collection Metadata on Autonomous Database for more information.	SODA for Java
SODA for REST	Access RESTful Services and SODA for REST	Use SODA for REST with Autonomous Database
SODA for C	Oracle Instant Client Downloads **Versions:** For SODA for C, Oracle Client libraries must be 19.6 and above. You can obtain Oracle Instant Client from Oracle Instant Client Downloads.	SODA for C
SODA for PL/SQL	No need to download. This is included with Autonomous Database.	SODA for PL/SQL
SODA for Node.js	Multiple downloads described in install instructions: Quick Start node-oracledb Installation **Versions:** SODA support was introduced in version 3.0. Using the latest version is recommended, the minimum recommended version is 4.0. Oracle Client libraries must be 19.6 and above. You can obtain Oracle Instant Client from Oracle Instant Client Downloads.	Node-oracledb SODA Requirements
SODA for Python	Multiple downloads described in install instructions: cx_Oracle 7 Installation **Versions:** SODA support was introduced in version 7.0. Using the latest version is recommended, the minimum recommended version is 7.1. Oracle Client libraries must be 19.6 and above. You can obtain Oracle Instant Client from Oracle Instant Client Downloads.	Introduction to cx_Oracle

- SODA Notes
  When you use SODA with Autonomous Database the following restrictions apply:

SODA Notes

When you use SODA with Autonomous Database the following restrictions apply:

- Automatic indexing is not supported for SQL and PL/SQL code that uses the SQL/JSON function `json_exists`. See SQL/JSON Condition JSON_EXISTS for more information.
- Automatic indexing is not supported for SODA query-by-example (QBE).

Work with JSON Documents Using SQL and PL/SQL APIs on Autonomous Database

Autonomous Database supports JavaScript Object Notation (JSON) data natively in the database.

When you use Autonomous Database to store JSON data you can take advantage of all the features available in your database. You can combine your JSON data with non-JSON data; then, using Autonomous Database features such as Oracle Machine Learning Notebooks, you can analyze your data and create reports. You can access JSON data stored in the database the same way you access other database data, including using Oracle Call Interface (OCI), Microsoft .NET Framework, and Java Database Connectivity (JDBC).

See JSON in Oracle Database to get started.

Load JSON Documents with Autonomous Database

You can use the PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` to load JSON documents into SODA collections or use `DBMS_CLOUD.COPY_DATA` to load JSON documents into an existing table in Autonomous Database.

Topics

- About Loading JSON Documents
- Load a JSON File of Line-Delimited Documents into a Collection
- Load an Array of JSON Documents into a Collection
- Monitor and Troubleshoot COPY_COLLECTION Loads
- Create Credentials and Copy JSON Data into an Existing Table

Import SODA Collection Data Using Oracle Data Pump Version 19.6 or Later

Shows the steps to import SODA collections into Autonomous Database with Oracle Data Pump.

You can export and import SODA collections using Oracle Data Pump Utilities starting with version 19.6. Oracle recommends using the latest Oracle Data Pump version for importing data from Data Pump files into your database.
Download the latest version of Oracle Instant Client, which includes Oracle Data Pump, for your platform from Oracle Instant Client Downloads. See the installation instructions on the platform install download page for the installation steps required after you download Oracle Instant Client.

In Oracle Data Pump, if your source files reside on Oracle Cloud Infrastructure Object Storage you can use Oracle Cloud Infrastructure native URIs, Swift URIs, or pre-authenticated URIs. See DBMS_CLOUD Package File URI Formats for details on these file URI formats.

If you are using an Oracle Cloud Infrastructure pre-authenticated URI, you still need to supply a `credential` parameter. However, credentials for a pre-authenticated URL are ignored (and the supplied credentials do not need to be valid). See DBMS_CLOUD Package File URI Formats for information on Oracle Cloud Infrastructure pre-authenticated URIs.

This example shows how to create the SODA collection metadata and import a SODA collection with Data Pump.

1. On the source database, export the SODA collection using the Oracle Data Pump `expdp` command.

   See Export Your Existing Oracle Database to Import into Autonomous Database for more information.

2. Upload the dump file set from Step 1 to Cloud Object Storage.

3. Create a SODA collection with the required SODA collection metadata on your Autonomous Database.

   For example, if you export a collection named *MyCollectionName* from the source database with the following metadata:

   - The content column is a `BLOB` type.
   - The version column uses the `SHA256` method.

   Then on the Autonomous Database where you import the collection, create a new collection:

   - By default on Autonomous Database for a new collection the content column is set to `BLOB` with the `jsonFormat` specified as `OSON`.
   - By default on Autonomous Database for a new collection the `versionColumn.method` is set to `UUID`.

   See SODA Default Collection Metadata on Autonomous Database for details.

   For example:

```
DECLARE
   collection_create SODA_COLLECTION_T;
BEGIN
   collection_create := DBMS_SODA.CREATE_COLLECTION('MyCollectionName');
END;
/
COMMIT;
```

   You can use the PL/SQL function `DBMS_SODA.LIST_COLLECTION_NAMES` to discover existing collections. See LIST_COLLECTION_NAMES Function for more information.

   You can view the metadata for the SODA collections by querying the view `USER_SODA_COLLECTIONS`. See USER_SODA_COLLECTIONS for more information.

4. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example, to create Oracle Cloud Infrastructure Auth Token credentials:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
```

```
    password => 'password'
  );
END;
/
```

For more information on Oracle Cloud Infrastructure Auth Token authentication see CREATE_CREDENTIAL Procedure.

For example, to create Oracle Cloud Infrastructure Signing Key based credentials:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       user_ocid       =>
'ocid1.user.oc1..aaaaaaaauq54mi7zdyfhw33ozkwuontjceel7fok5nq3bf2vwetkpqsoa'
,
       tenancy_ocid    =>
'ocid1.tenancy.oc1..aabbbbbbaafcue47pqmrf4vigneebgbcmmoy5r7xvoypicjqqge32ew
nrcyx2a',
       private_key     =>
'MIIEogIBAAKCAQEAtUnxbmrekwgVac6FdWeRzoXvIpA9+0r1.....wtnNpESQQQ0QLGPD8NM//
JEBg=',
       fingerprint     =>
'f2:db:f9:18:a4:aa:fc:94:f4:f6:6c:39:96:16:aa:27');
END;
/
```

For more information on Oracle Cloud Infrastructure Signing Key based credentials see CREATE_CREDENTIAL Procedure.

Supported credential types:

- Data Pump Import supports Oracle Cloud Infrastructure Auth Token based credentials and Oracle Cloud Infrastructure Signing Key based credentials.

  For more information on Oracle Cloud Infrastructure Signing Key based credentials see CREATE_CREDENTIAL Procedure.

- Data Pump supports using an Oracle Cloud Infrastructure Object Storage pre-authenticated URL for the `dumpfile` parameter. When you use a pre-authenticated URL, providing the `credential` parameter is required and the `credential` value can be `NULL`. See Using Pre-Authenticated Requests for more information.

5. Run Data Pump Import with the *dumpfile* parameter set to the list of file URLs on your Cloud Object Storage and the *credential* parameter set to the name of the credential you created in the previous step.

> **Note:**
>
> Import the collection data using the option `CONTENT=DATA_ONLY`.

Specify the collection you want to import using the `INCLUDE` parameter. This is useful if a data file set contains the entire schema and the SODA collection you need to import is included as part of the dump file set.

Use `REMAP_DATA` to change any of the columns during import. This example shows using `REMAP_DATA` to change the version column method from `SHA256` to `UUID`.

```
impdp admin/password@db2022adb_high \
     directory=data_pump_dir \
     credential=def_cred_name \
     dumpfile= https://namespace-string.objectstorage.us-ashburn-1.oci.customer-
oci.com/n/namespace-string/b/bucketname/o/export%l.dmp \

     encryption_pwd_prompt=yes \
     SCHEMA=my_schema \
     INCLUDE=TABLE:\"= \'MyCollectionName\'\"  \
     CONTENT=DATA_ONLY \
     REMAP_DATA=my_schema.'\"MyCollectionName\"'.VERSION:SYS.DBMS_SODA.TO_UUID
```

Notes for Data Pump parameters:

- If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

  Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.

In Oracle Data Pump version 19.6 and later, the *credential* argument authenticates Oracle Data Pump to the Cloud Object Storage service you are using for your source files. The `credential` parameter cannot be an Azure service principal, Amazon Resource Name (ARN), or a Google service account. See Accessing Cloud Resources by Configuring Policies and Roles for more information on resource principal based authentication.

The *dumpfile* argument is a comma delimited list of URLs for your Data Pump files.

For the best import performance use the `HIGH` database service for your import connection and set the `parallel` parameter to one quarter the number of ECPUs (.25 x **ECPU count**). If you are using OCPU compute model, set the parallel parameter to the number of OCPUs (1 x **OCPU count**).

For information on which database service name to connect to run Data Pump Import, see Manage Concurrency and Priorities on Autonomous Database.

For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD Package File URI Formats.

> **Note:**
>
> To perform a full import or to import objects that are owned by other users, you need the `DATAPUMP_CLOUD_IMP` role.

For information on disallowed objects in Autonomous Database, see SQL Commands.

In this import example, the specification for the `REMAP_DATA` parameter uses the function `DBMS_SODA.TO_UUID` to generate UUID values. By default, for on-premise databases, the version column of a SODA collection is computed using SHA-256 hash of the document's content. On Autonomous Database the version column uses UUID generated values, which are independent of the document's content.

In this example the `REMAP_DATA` parameter uses the `DBMS_SODA.TO_UUID` function to replace the source collection version type with UUID versioning. If in the export dump file set that you are importing the `versionColumn.method` is already set to UUID, then the `REMAP_DATA` for this field is not required.

For detailed information on Oracle Data Pump Import parameters see *Oracle Database Utilities*.

The log files for Data Pump Import operations are stored in the directory you specify with the Data Pump Import `DIRECTORY` parameter. See Accessing the Log File for Data Pump Import for more information.

Developing RESTful Services in Autonomous Database

You can develop and deploy RESTful Services with native Oracle REST Data Services (ORDS) support on Autonomous Databases. Simple Oracle Document Access (SODA) for REST lets you use a database as a simple JSON document store.

- About Oracle REST Data Services in Autonomous Database
- Access RESTful Services and SODA for REST
  Each Autonomous Database includes Oracle REST Data Services (ORDS) that provides HTTPS interfaces for working with the contents of your Oracle Database in REST enabled schemas.
- Develop with Oracle REST Data Services on Autonomous Database
  Autonomous Database supports Oracle REST Data Services (ORDS).
- Use SODA for REST with Autonomous Database
  Autonomous Database supports Simple Oracle Document Access (SODA) for REST.
- Access Oracle REST Data Services, Oracle APEX, and Developer Tools Using a Vanity URL
- About Customer Managed Oracle REST Data Services on Autonomous Database

About Oracle REST Data Services in Autonomous Database

Oracle REST Data Services (ORDS) makes it easy to develop REST interfaces for relational data in a database.

ORDS is a mid-tier Java application that maps HTTP(S) verbs, such as GET, POST, PUT, DELETE, and so on, to database transactions, and returns any results as JSON data.

> **Note:**
>
> The Oracle REST Data Services (ORDS) application in Autonomous Database is preconfigured and fully managed. ORDS connects to the database using the `low` predefined database service with a fixed maximum number of connections (the number of connections for ORDS does not change based on the number of ECPUs (OCPUs if your database uses OCPUs). It is not possible to change the default ORDS configuration.
> See About Customer Managed Oracle REST Data Services on Autonomous Database for information on using an additional alternative ORDS deployment that enables flexible configuration options.

See Oracle REST Data Services for information on using Oracle REST Data Services.

See Database Service Names for Autonomous Database for information on the `low` database service.

Access RESTful Services and SODA for REST

Each Autonomous Database includes Oracle REST Data Services (ORDS) that provides HTTPS interfaces for working with the contents of your Oracle Database in REST enabled schemas.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To use Oracle REST Data Services and SODA for REST:

1. From the Autonomous Database details page select **Database Actions** and in the list click **View all database actions**.
2. On the Database Actions launchpad, under **Related Services**, click the **RESTful Services and SODA** card to see the base URL.
3. Click **Copy** to copy the URL.

If you are using Always Free Autonomous Database with Oracle Database 23ai Oracle recommends the following:

- For projects that were started using a database release prior to Oracle Database 21c, explicitly specify the metadata for the default collection as specified in the example in the section SODA Drivers.
- For projects started using release Oracle Database 21c or later, just use the default metadata.

See SODA Drivers for more information.

Develop with Oracle REST Data Services on Autonomous Database

Autonomous Database supports Oracle REST Data Services (ORDS).

Developing RESTful services is easy with the following development interfaces:

- Database Actions (SQL Developer Web): Use Database Actions on Autonomous Database to REST enable users. See Manage Users and User Roles on Autonomous Database - Connecting with Database Actions for more information.
- SQL Developer (desktop): With SQL Developer on your desktop, you can connect to your database and enable REST services access to tables and views, or develop custom RESTful Services based on your SQL and PL/SQL code. See Connect Oracle SQL Developer with a Wallet (mTLS) for more information.
- Oracle APEX: With APEX you can use the RESTful Services development pages to build and maintain your services and REST enabled objects. You can use the APEX SQL Workshop to access your Oracle RESTful Services and REST enabled objects. See How to Access RESTful Services for more information.

The Autonomous Database `ADMIN` account is REST Enabled. This allows for REST Services to be published in the ADMIN schemas and allows you to access Database Actions using the ADMIN database user account. Oracle recommends you create an application schema account for your RESTful Services and REST enabled objects. Services are secured using Database Authentication and your REST enabled schema.

The authenticated database user is only permitted access if the schema is REST enabled and the URL mapping for the request points to their own schema. A user is not authenticated when a request points to any other database schema. For example, the following request authenticated as the REST enabled schema `HR` is accessible:

```
GET /ords/hr/module/service/
```

However, when authenticated as the REST enabled schema `SCOTT`, the same request:

```
GET /ords/hr/module/service/
```

results in an error:

```
401 HTTP Unauthorized response/error
```

Any database user whose credentials are correct and meets these rules is authenticated and granted the ORDS, mid-tier, role: `SQL Developer`. The `SQL Developer` role enables the user to access any endpoint that requires the `SQL Developer` role.

See REST-Enable a Database Table in *Quick Start Guide* for information on how to enable a table for REST access.

Use SODA for REST with Autonomous Database

Autonomous Database supports Simple Oracle Document Access (SODA) for REST.

- Overview of Using SODA for REST

- Load Purchase-Order Sample Data Using SODA for REST
  Oracle provides a substantial set of JSON purchase-order documents, in plain-text file `POList.json`, as a JSON array of objects, where each such object represents a document.
- Use SODA for REST with OAuth Client Credentials
  You can access SODA for REST on Autonomous Database using OAuth authentication. Depending on your application, accessing SODA for REST with OAuth authentication can improve performance and security.

Overview of Using SODA for REST

SODA for REST is a predeployed REST service that can be used to store JSON documents in your database.

SODA enables flexible, NoSQL-style application development without having to use SQL. With SODA, JSON documents are stored in named collections and managed using simple CRUD operations (create, read, update and delete). And while SQL isn't required, JSON stored in SODA collections is still fully accessible from SQL when needed. For example, an operational application may be fully built using SODA (without SQL) but then the data may be later analyzed using SQL from outside of the application. Autonomous Database SODA gives application developers the best of the NoSQL and SQL worlds - fast, flexible, and scalable application development without losing the ability to leverage SQL for analytics and reporting.

SODA for REST is deployed in ORDS under the following URL pattern, where *schema* corresponds to a REST-enabled database schema.

```
/ords/schema/soda/latest/*
```

The following examples use the cURL command line tool (http://curl.haxx.se/) to submit REST requests to the database. However, other 3rd party REST clients and libraries should work as well. The examples use database schema `ADMIN`, which is REST-enabled. You can SODA for REST with cURL commands from the Oracle Cloud Shell.

This command creates a new collection named "fruit" in the `ADMIN` schema:

```
> curl -X PUT -u 'ADMIN:<password>' \
"https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/latest/fruit"
```

These commands insert three JSON documents into the fruit collection:

```
> curl -X POST -u 'ADMIN:<password>' \
 -H "Content-Type: application/json" --data '{"name":"orange", "count":42}' \
 "https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/latest/fruit"

{"items":[{"id":"6F7E5C60197E4C8A83AC7D7654F2E375"...

> curl -X POST -u 'ADMIN:<password>' \
 -H "Content-Type: application/json" --data '{"name":"pear", "count":5}' \
 "https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/latest/fruit"

{"items":[{"id":"83714B1E2BBA41F7BA4FA93B109E1E85"...

> curl -X POST -u 'ADMIN:<password>' \
 -H "Content-Type: application/json" \
 --data '{"name":"apple", "count":12, "color":"red"}' \
 "https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/latest/fruit"
```

```
{"items":[{"id":"BAD7EFA9A2AB49359B8F5251F0B28549"...
```

This example retrieves a stored JSON document from the collection:

```
> curl -X POST -u 'ADMIN:<password>' \
 -H "Content-Type: application/json" --data '{"name":"orange"}' \
 "https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/latest/fruit?
action=query"

{
  "items": [
    {
      "id":"6F7E5C60197E4C8A83AC7D7654F2E375",
      "etag":"57215643953D7C858A7CB28E14BB48549178BE307D1247860AFAB2A958400E16",
      "lastModified":"2019-07-12T19:00:28.199666Z",
      "created":"2019-07-12T19:00:28.199666Z",
      "value":{"name":"orange", "count":42}
    }
  ],
  "hasMore":false,
  "count":1
}
```

This SQL query accesses the fruit collection:

```
SELECT
     f.json_document.name,
     f.json_document.count,
     f.json_document.color
FROM fruit f;
```

The query returns these three rows:

```
name      count     color
--------- --------- -------
orange    42        null
pear      5         null
apple     12        red
```

> **Note:**
>
> If you are using Always Free Autonomous Database with Oracle Database 23ai, Oracle recommends the following:
> For projects that were started using a database release prior to Oracle Database 21c, explicitly specify the metadata for the default collection as specified in the example in the section SODA Drivers. For projects started using release Oracle Database 21c or later, just use the default metadata. See SODA Drivers for more information.

These examples show a subset of the SODA and SQL/JSON features. See the following for more information:

- SODA for REST for complete information on Simple Oracle Document Access (SODA)
- SODA for REST HTTP Operations for information on the SODA for REST HTTP operations

Load Purchase-Order Sample Data Using SODA for REST

Oracle provides a substantial set of JSON purchase-order documents, in plain-text file `POList.json`, as a JSON array of objects, where each such object represents a document.

The following examples use the cURL command line tool (http://curl.haxx.se/) to submit REST requests to the database. However, other 3rd party REST clients and libraries should work as well. The examples use database schema `ADMIN`, which is REST-enabled. You can use SODA for REST with cURL commands from the Oracle Cloud Shell.

You can load this sample purchase-order data set into a collection `purchaseorder` on your Autonomous Database with SODA for REST, using these curl commands:

```
curl -X GET "https://raw.githubusercontent.com/oracle/db-sample-schemas/
master/order_entry/POList.json" -o POList.json

curl -X PUT -u 'ADMIN:password' \
"https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/
latest/purchaseorder"

curl -X POST -H -u 'ADMIN:password' 'Content-type: application/json' -d
@POList.json \
"https://example-db.adb.us-phoenix-1.oraclecloudapps.com/ords/admin/soda/
latest/purchaseorder?action=insert"
```

You can then use this purchase-order data to try out examples in *Oracle Database JSON Developer's Guide*.

For example, the following query selects both the `id` of a JSON document and values from the JSON purchase-order collection stored in column `json_document` of table `purchaseorder`. The values selected are from fields `PONumber`, `Reference`, and `Requestor` of JSON column `json_document`, which are projected from the document as virtual columns (see SQL NESTED Clause Instead of JSON_TABLE for more information).

```
SELECT id, t.*
  FROM purchaseorder
    NESTED json_document COLUMNS(PONumber, Reference, Requestor) t;
```

See the following for more information:

- SODA for REST for complete information on Simple Oracle Document Access (SODA)
- SODA for REST HTTP Operations for information on the SODA for REST HTTP operations

Use SODA for REST with OAuth Client Credentials

You can access SODA for REST on Autonomous Database using OAuth authentication. Depending on your application, accessing SODA for REST with OAuth authentication can improve performance and security.

Perform the following steps to use OAuth authentication to provide limited access to SODA for REST on Autonomous Database:

1. As the ADMIN user, access Database Actions and create a user with the required privileges.
   a. Access Database Actions as ADMIN.

      See Access Database Actions as ADMIN for more information.

   b. In Database Actions, click ☰ to show the available actions.
   c. In Database Actions, under **Administration** select **Database Users**.
   d. Click **Create User**.
   e. In the **Create User** area, on the **User** tab enter **User Name** and a **Password** and confirm the password.
   f. Select **Web Access**.
   g. In the **Create User** area, select the **Granted Roles** tab and grant `DWROLE` to the user.
   h. Click **Create User**.

   See Manage Users and User Roles on Autonomous Database - Connecting with Database Actions for more information.
2. Use a SQL worksheet in Database Actions to grant user privileges required to load data.
   a. Access Database Actions as ADMIN.

      See Access Database Actions as ADMIN for more information.

   b. In Database Actions, click ☰ to show the available actions.
   c. In Database Actions, under **Development** click **SQL** to open a SQL worksheet.
   d. Grant user privileges required to load data to the user from Step 1.

      ```
      GRANT UNLIMITED TABLESPACE TO user_name;
      ```

   See Manage User Privileges on Autonomous Database - Connecting with a Client Tool for more information.
3. Sign out as the ADMIN user.
4. Sign in to Database Actions as the user that is setting up to use OAuth authentication.
5. In Database Actions, use a SQL worksheet to register the OAuth client.
   a. Register the OAuth client.

      For example, enter the following commands into the SQL worksheet, where you supply the appropriate values for your user and your client application.

      ```
      BEGIN
        OAUTH.create_client(
          p_name            => 'my_client',
      ```

```
    p_grant_type      => 'client_credentials',
    p_owner           => 'Example Company',
    p_description     => 'A client for my SODA REST resources',
    p_support_email   => 'user_name@example.com',
    p_privilege_names => 'my_priv'
  );

  OAUTH.grant_client_role(
    p_client_name => 'my_client',
    p_role_name   => 'SQL Developer'
  );

  OAUTH.grant_client_role(
    p_client_name => 'my_client',
    p_role_name   => 'SODA Developer'
  );
  COMMIT;
END;
/
```

b. In the SQL worksheet, click **Run Script** to run the command.

See OAUTH PL/SQL Package Reference for more information.

This registers a client named `my_client` to access the `my_priv` privilege using OAuth client credentials.

6. Obtain the `client_id` and `client_secret` required to generate the access token.

For example, in the SQL worksheet run the following command:

```
SELECT id, name, client_id, client_secret FROM user_ords_clients;
```

7. Obtain the access token. To get an access token you send a `REST GET` request to *`database_ORDS_urluser_name`*`/oauth/token`.

The *`database_ORDS_url`* is available from Database Actions, under **Related Services**, on the **RESTful Services and Soda** card. See Access RESTful Services and SODA for REST for more information.

In the following command, use the `client_id` and the `client_secret` you obtained in Step 6.

The following example uses the `cURL` command line tool (http://curl.haxx.se/) to submit REST requests to Autonomous Database. However, other 3rd party REST clients and libraries should work as well.
You can use the `cURL` command line tool to submit the `REST GET` request. For example:

```
> curl -i -k --user SBA-iO9Xe12cdZHYfryBGQ..:vvUQ1AagTqAqdA2oN7afSg.. --
data "grant_type=client_credentials"https://mqssyowmqvgac1y-
doc.adb.region.oraclecloudapps.com/ords/user_name/oauth/token
HTTP/1.1 200 OK
Date: Mon, 22 Jun 2020 15:17:11 GMT
Content-Type: application/jsonTransfer-Encoding: chunked
Connection: keep-alive
X-Frame-Options: SAMEORIGIN
```

```
{"access_token":"JbOKtAuDgEh2DXx0QhvPGg","token_type":"bearer","expires_in"
:3600}
```

To specify both the `client_id` and the `client_secret` with the curl `--user` argument, enter a colon to separate the `client_id` and the `client_secret`. If you only specify the user name, `client_id`, curl prompts for a password and you can enter the `client_secret` at the prompt.

8. Use the access token to access the protected resource.

   The token obtained in the previous step is passed in the Authorization header. For example:

```
> curl -i -H "Authorization: Bearer JbOKtAuDgEh2DXx0QhvPGg" -X GET https://
database_id.adb.region.oraclecloudapps.com/ords/user_name/soda/latest
HTTP/1.1 200 OK
Date: Mon, 22 Jun 2020 15:20:58 GMT
Content-Type: application/json
Content-Length: 28
Connection: keep-alive
X-Frame-Options: SAMEORIGIN
Cache-Control: private,must-revalidate,max-age=0

{"items":[],"hasMore":false}
```

See Configuring Secure Access to RESTful Services for complete information on secure access to RESTful Services.

Access Oracle REST Data Services, Oracle APEX, and Developer Tools Using a Vanity URL

By default you access Oracle REST Data Services (ORDS) endpoints, Oracle APEX apps, and developer tools on Autonomous Database using the `oraclecloudapps.com` domain name.

To access Oracle REST Data Services (ORDS) endpoints, you can optionally configure a vanity URL or custom domain name that is easy to remember to help promote your brand identity.

After you acquire a desired domain name and matching SSL certificate from a vendor of your choice, deploy an Oracle Cloud Infrastructure Load Balancer in your Virtual Cloud Network (VCN) using your Autonomous Database as the backend. Your Autonomous Database instance must be configured with a private endpoint in the same VCN. See Configuring Network Access with Private Endpoints for more information.

To learn more, see the following:

- Introducing Vanity URLs for APEX and ORDS on Oracle Autonomous Database
- Automate Vanity URL Configuration Using Terraform

About Customer Managed Oracle REST Data Services on Autonomous Database

Optionally, you can configure Autonomous Database to use Oracle REST Data Services (ORDS) running in a customer managed environment.

When you provision an Autonomous Database instance, by default Oracle REST Data Services (ORDS) is preconfigured and available for the instance. With the default Oracle REST Data Services, Oracle performs any required configuration, patching, and maintenance. When you use the default ORDS on Autonomous Database, you cannot modify any of the ORDS configuration options.

Use a customer managed environment if you want manual control of the configuration and management of Oracle REST Data Services. For example, use this option when your applications require larger connection pools or if you need more control over the ORDS configuration options.

When ORDS runs in a customer managed environment, you are responsible for configuration, patching, and maintenance of ORDS. After you configure Autonomous Database to use your customer managed ORDS in addition to the existing autonomously managed ORDS, you can route ORDS HTTPS traffic through your environment. The default Autonomous Database web server and ORDS are still running and ORDS traffic goes to the ORDS running in the customer managed environment. This provides an additional and alternative HTTPS solution for Autonomous Database.

Installing and configuring a customer managed environment for ORDS allows you to run ORDS with configuration options that are not possible using the default Oracle managed ORDS available with Autonomous Database.

See Installing and Configuring Customer Managed ORDS on Autonomous Database for more information.

Installing and configuring a customer managed environment for ORDS is only supported with Autonomous Database Serverless. Your Autonomous Database must be configured for one of the following workload types: Data Warehouse, Transaction Processing, or JSON Database.

> **Note:**
>
> Oracle REST Data Services 19.4.6 or higher is required to use a customer managed environment for ORDS with Autonomous Database. Customer managed environment for ORDS is not supported if your database is configured for APEX workload type.

Using Oracle Database API for MongoDB

Oracle Database API for MongoDB makes it possible to connect to Oracle Autonomous Database using MongoDB language drivers and tools.

Oracle Database API for MongoDB leverages the converged database capabilities of an Autonomous Database to manage multiple data types, including JSON data, within a single database. For example, these converged database capabilities allow you to use SQL to query or update JSON data.

> **Note:**
>
> MongoDB requires that you configure network access to use ACLs or that you define a private endpoint for the Autonomous Database instance.

See Oracle Database API for MongoDB for more information.

See About Autonomous JSON Database for more information.

See About Autonomous Database Workload Types for more information.

  Connecting your MongoDB application to Autonomous Database includes several steps, depending upon your requirements.

Configure Access for MongoDB and Enable MongoDB

Oracle Database API for MongoDB enables you to use an Oracle Autonomous Database as the data store.

To use the MongoDB API you can create and configure a new Autonomous Database or modify the configuration of an existing Autonomous Database.

> **Note:**
>
> MongoDB requires that you configure network access to use ACLs or that you define a private endpoint for the Autonomous Database instance. In addition to configuring the network access, you must enable MongoDB API on the Autonomous Database instance.

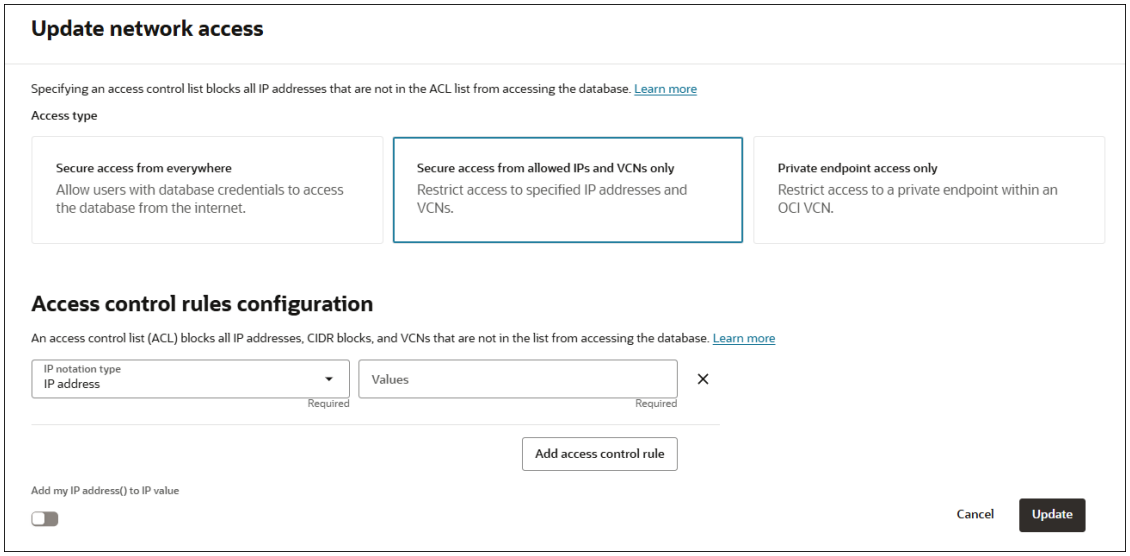
- Configure Access for MongoDB
  To use the MongoDB API, you can create and configure a new Autonomous Database or modify the configuration of an existing Autonomous Database by configuring ACLs or by defining a private endpoint.
- Enable MongoDB API on Autonomous Database
  After you configure the network access for the Autonomous Database instance, enable the MongDB API.

Configure Access for MongoDB

To use the MongoDB API, you can create and configure a new Autonomous Database or modify the configuration of an existing Autonomous Database by configuring ACLs or by defining a private endpoint.

Configure a New Autonomous Database for MongoDB

Follow the steps in Provision or Clone an Autonomous Database, up to the point where you select your Network Access Type.



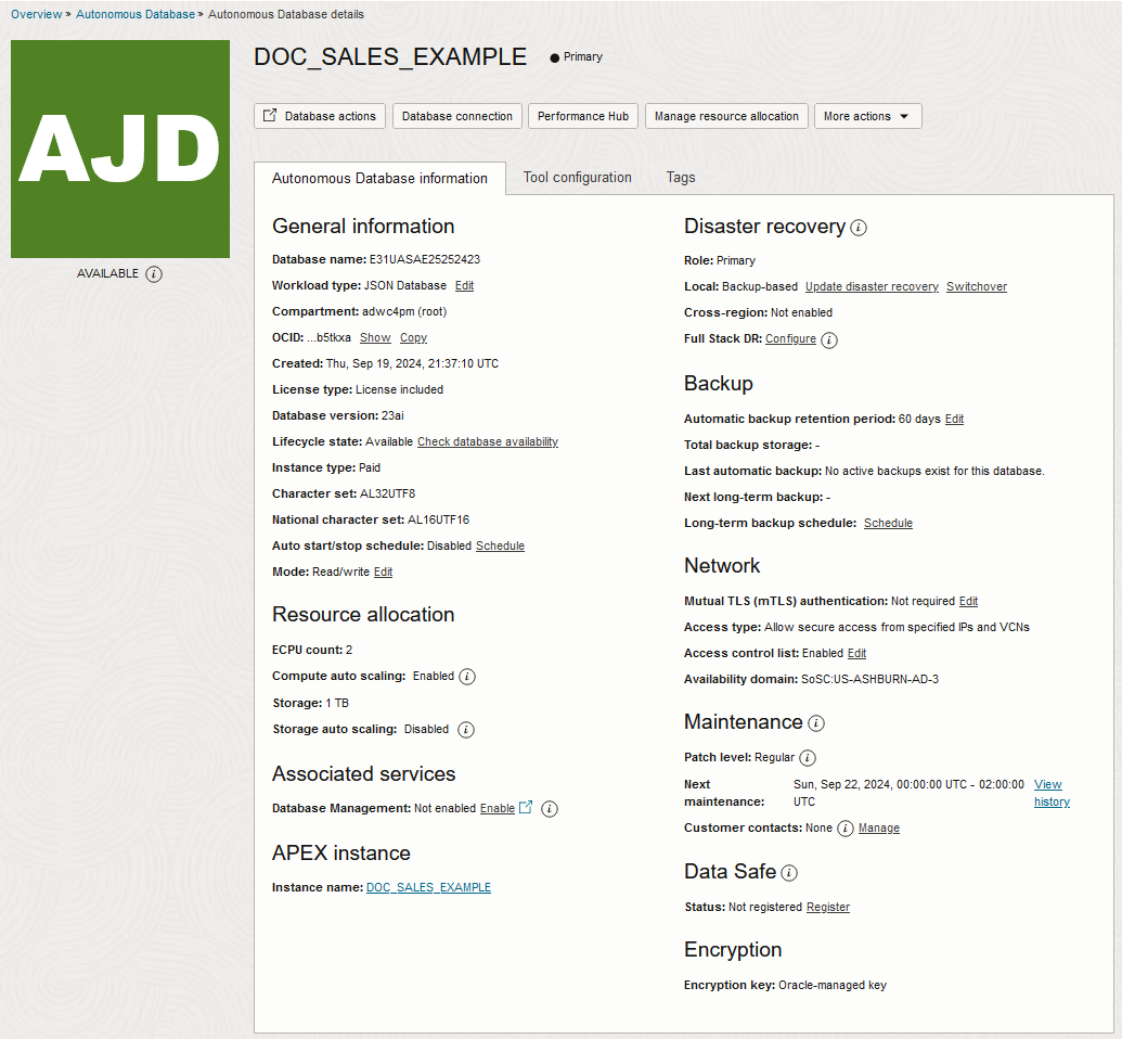
At this point, to use Oracle Database API for MongoDB configure secure access by selecting and configuring one of these network access types:

- **Secure access from allowed IPs and VCNs only**
- **Private endpoint access only**

  See Configure Network Access with Private Endpoints for information on configuring an Autonomous Database instance with a private endpoint.

Configure an Existing Autonomous Database for MongoDB

Open the Oracle Cloud Infrastructure Console for your Autonomous Database instance.



> **Note:**
>
> To use Oracle Database API for MongoDB the Network must be configured and the **Access type** must be either: **Secure access from allowed IPs and VCNs only** or **Private endpoint access only**.

Access Control List (ACL) Setup

See Configure Access Control Lists for an Existing Autonomous Database Instance for more information.

To configure your ACL for an IP address, you will need to obtain the public IP address. There are several ways to show your public IP address:

- In the choose network access area, click **Add my IP address**. This copies your IP address into the **Values** field.
- After disabling any VPN, use the WhatIsMyIP website.
- After disabling any VPN, use the curl command: `curl -s https://ifconfig.me`.

> **Note:**
>
> Public IP addresses may change. Any change to your public IP address will require a change in the ACL. If you are unable to access your database, your ACL should be something you check.

ACLs Types and Use Cases

ACL Type	Use Case	Comment
IP Address	Local development laptops sharing the same public IP address	Easiest way to get started. Any laptop connected on this LAN will have access to the database with the database credentials.
CIDR Block	Local development laptop	Using IPv4/32 notation
IP Addresses separated by commas	Small number of local development laptops connected on distinct LANs (having distinct public IP addresses)	Can be tedious to manage with 10+ laptops.
CIDR Block	Local development laptops connected on the same subnet exposed to Internet (each laptop has its own public IP Address)	Rely on CIDR Block notation. See calculator here for more information. Example: `89.84.109.0/24` gives 256 possible IP addresses from `89.84.109.0` to `89.84.109.255`
VCN with CIDR Block	For testing, production, or CI/CD pipeline hosted on OCI having their own VCN and Compute instances	Assign OCI compartment per environment type.
Mixing IP Address and VCN with CIDR Block	Local development laptop accessing a test Autonomous Database with connections from the testing environment or CI/CD pipeline	A common configuration option for on-going development work.

Enable MongoDB API on Autonomous Database

After you configure the network access for the Autonomous Database instance, enable the MongDB API.

To enable the MongoDB API for an existing instance:

1. On the Autonomous Database details page, select the **Tool configuration** tab.
2. Click **Edit tool configuration**.
3. In the MongoDB API row, select in the **Enable tool** column to show **Enabled**.
4. Click **Apply**.

The **Lifecycle state** changes to updating until MongoDB is enabled.

You can also enable the MongoDB API when you provision or clone an instance by selecting **Show advanced options** and selecting the **Tools** tab.

See Manage Autonomous Database Built-in Tools for more information.

User Management for MongoDB

Oracle Database API for MongoDB enables you to use an Oracle Autonomous Database as the data store. If you want or need to use an existing Autonomous Database for this purpose, here is the workflow.

Oracle Database API for MongoDB enables the mapping of Autonomous Database objects to MongoDB objects as follows:

MongoDB Object	Oracle Autonomous Database Object
database	schema
collection	table
document	document (in a column)

For example, you could create a collection using the Oracle Database API for MongoDB as follows:

```
use scott;
db.createCollection('fruit');
```

A table named **FRUIT** is created in the schema **SCOTT**.

When you connect to the Oracle Database API for MongoDB, you authenticate using an Autonomous Database username and password. This authenticated connection then accesses collections within the corresponding schema. This user must meet the following requirements:

- The user's schema must be ORDS-enabled, which is sometimes referred to as enabled for Web Access. See Basic Setup to Enable ORDS Database API for more information.
- The user must have the following roles and privileges: `SODA_APP`, `CREATE TABLE`, and `CREATE SESSION`. See Manage User Roles and Privileges on Autonomous Database for more information.
- The user has a quota on tablespace **DATA**. See Create Users on Autonomous Database for more information.

> **Note:**
>
> The role `DWROLE` in the Autonomous Database contains these roles, among others.

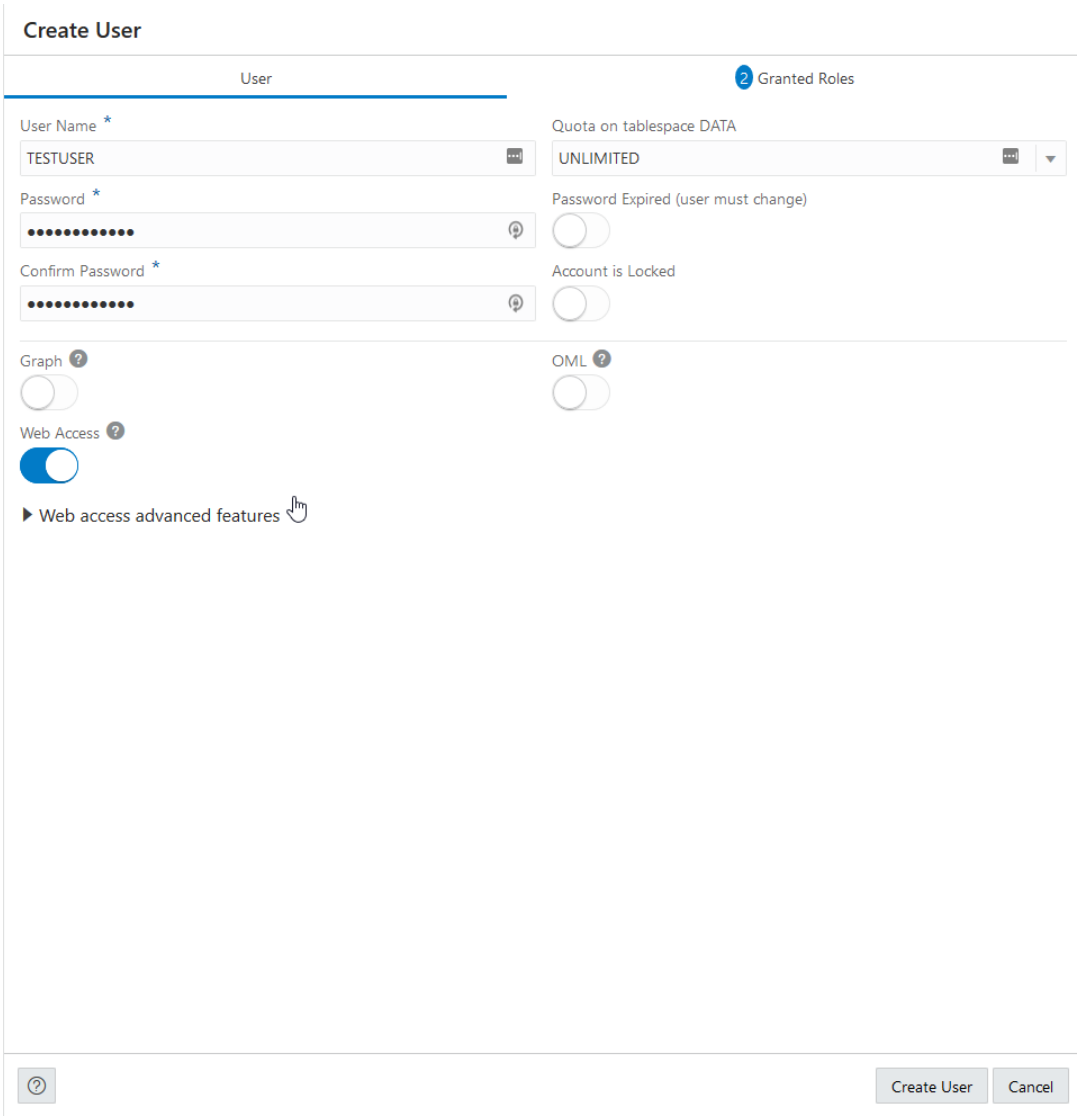
Access to schemas not granted to the user is prohibited. For example, the user **SCOTT** can only access collections in the schema **SCOTT**. There is one exception. If the authenticated user has the Autonomous Database privileges `CREATE USER`, `ALTER USER` and `DROP USER`, that user can access any ORDS-enabled schema.

Additionally, a user with these privileges can implicitly create schemas. That is, when the user creates a collection in a database that does not exist, the schema will be created automatically. See Oracle Database API for MongoDB for more information.

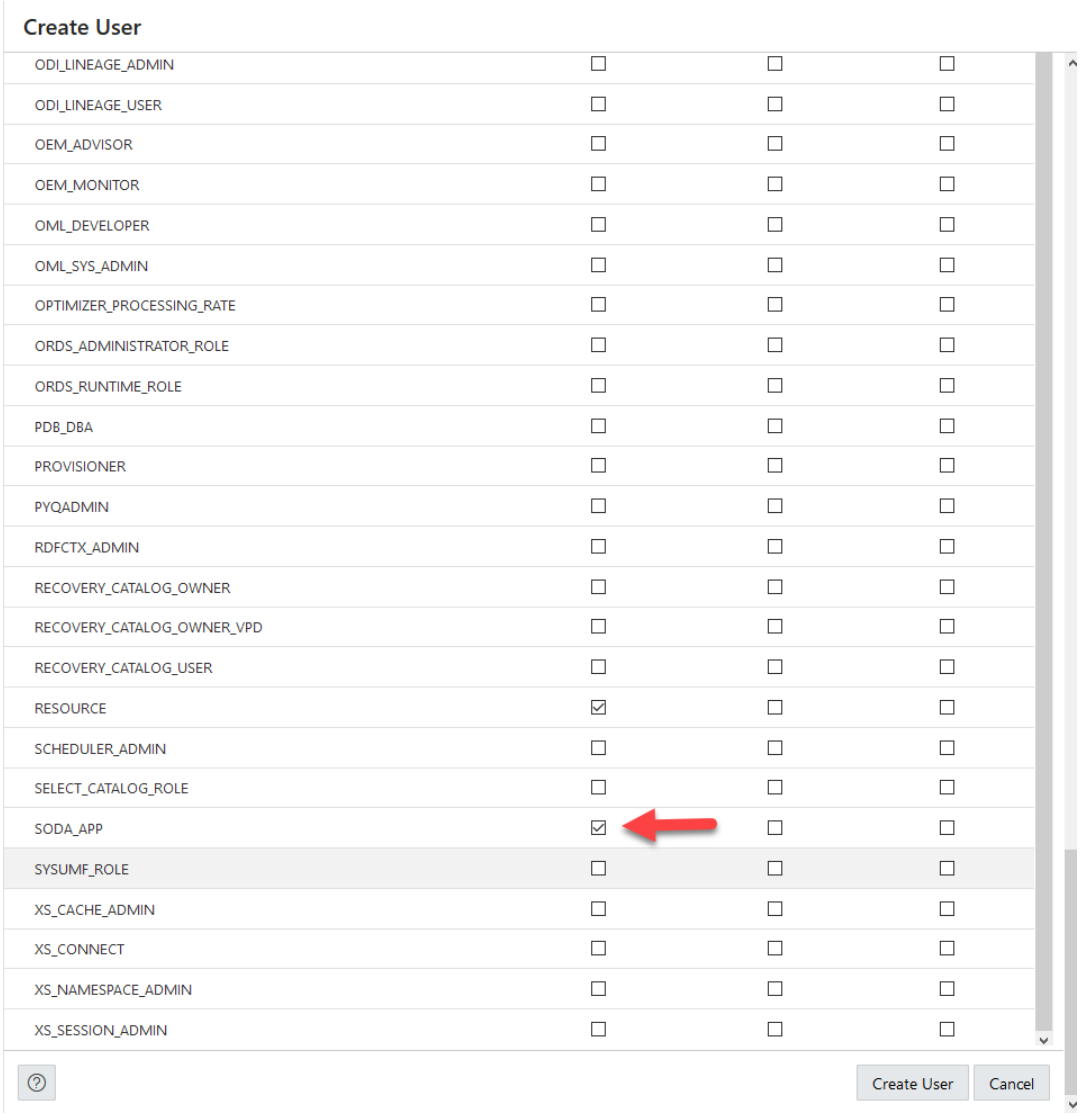
Create a Test Autonomous Database User for MongoDB

The steps that follow use Database Actions to create a test user with the proper roles. You can also use Database Actions SQL or other SQL command line utilities to execute the SQL statements directly. See Create Users on Autonomous Database - Connecting with a Client Tool for more information.

1. Open the Oracle Cloud Infrastructure Console for your Autonomous Database.
2. Select **Database Actions**.
3. From the Database Actions Launchpad, select **Administration** > **Database Users**.
4. Select **+ Create User** on the Database Users page.
5. Enter a **User Name** and **Password** for your test user. Select **Web Access**, and set the **Quota on tablespace DATA**.



6. Select the **Granted Roles** tab.
7. In addition to the default roles, select and add the `SODA_APP` role for the user.



8. Select the **Create User** button.

You can user this user, or a similarly authenticated user, for testing purposes. See Test Connection Using the Command Line for more information.

Connect MongoDB Applications to Autonomous Database

Connecting your MongoDB application to Autonomous Database includes several steps, depending upon your requirements.

Topics

- Retrieve the Autonomous Database Connection String from Database Actions
- Test Connection Using the Command Line
- Test Connection Using a Node.js Application
- Retrieve the Autonomous Database MongoDB Connection String
- Test Connection Using the Command Line
- Test Connection Using a Node.js Application

Retrieve the Autonomous Database MongoDB Connection String

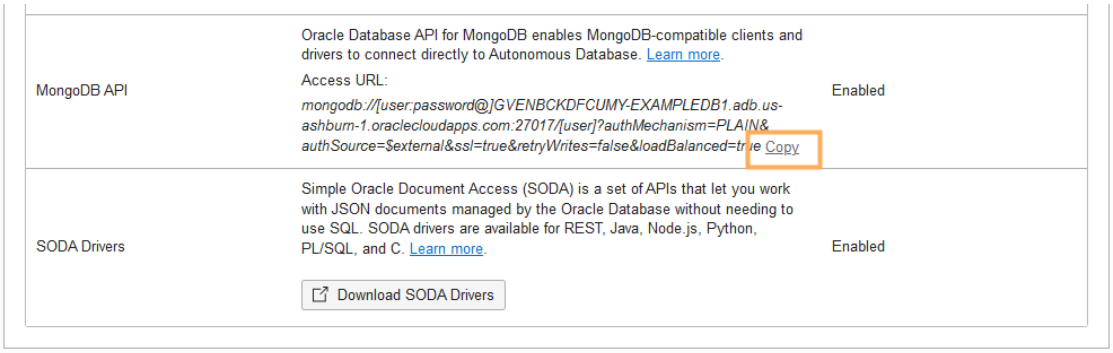
You can retrieve the MongoDB API connection string from the Oracle Cloud Infrastructure Console.

After you obtain the MongoDB API connection string you can use the MongoDB Shell, which is a command-line utility, to connect and query your data.

First you must configure network access and enable the MongoDB API. See Configure Access for MongoDB for more information.

To retrieve the MongoDB API connection string:

1. On the Autonomous Database details page, select the **Tool configuration** tab.
2. In the MongoDB API row, under Access URL click **Copy**.



- Retrieve the Autonomous Database Connection String from Database Actions

Retrieve the Autonomous Database Connection String from Database Actions

Use the MongoDB Shell which is a command-line utility used to connect and query your data.

1. You can retrieve the connection string for your Autonomous Database instance with Database Actions.

   See Access Database Actions as ADMIN for more information.
2. On the Database Actions Launchpad, under **Related Services**, click **Oracle Database API for MongoDB**.
3. On the **Oracle Database API for MongoDB** page click **Copy**.

Test Connection Using the Command Line

1. Login as the test user. See Create a Test Autonomous Database User for MongoDB for more information.

```
$ mongosh --tls --tlsAllowInvalidCertificates 'mongodb://
TESTUSER:<PASSWORD>@<database URL>.
<OCI region>.oraclecloudapps.com:27017/admin?
authMechanism=PLAIN&authSource=$external&ssl=true&loadBalanced=false'
Current Mongosh Log ID: 614c9e2a01e3575c8c0b2ec7
Connecting to:          mongodb://TESTUSER:<PASSWORD>@<database
URL>.<OCIregion>.oraclecloudapps.com:27017/admin?
authMechanism=PLAIN&authSource=$external&tls=true&loadBalanced=false
```

```
Using MongoDB:                  3.6.2
Using Mongosh:                  1.0.7
For mongosh info see: https://docs.mongodb.com/mongodb-shell/admin
> show dbs
testuser    0 B
>
```

Note:

Use URI percent-encoding to replace any reserved characters in your connection-string URI — in particular, characters in your username and password. These are the reserved characters and their percent encodings:

!	#	$	%	&	'	(	)	*	+
%21	%23	%24	%25	%26	%27	%28	%29	%2A	%2B

,	/	:	;	=	?	@	[	]
%2C	%2F	%3A	%3B	%3D	%3F	%40	%5B	%5D

For example, if your username is `RUTH` and your password is `@least1/2#?` then your MongoDB connection string to server *<server>* might look like this:

```
'mongodb://RUTH:%40least1%2F2%23%3F@<server>:27017/ruth/ ...'
```

Depending on the tools or drivers you use, you might be able to provide a username and password as separate parameters, instead of as part of a URI connection string. In that case you likely won't need to encode any reserved characters they contain.

See also:

- Percent Encoding - Reserved Characters
- Uniform Resource Identifier (URI): Generic Syntax

2. Create a collection and insert documents into your collection.

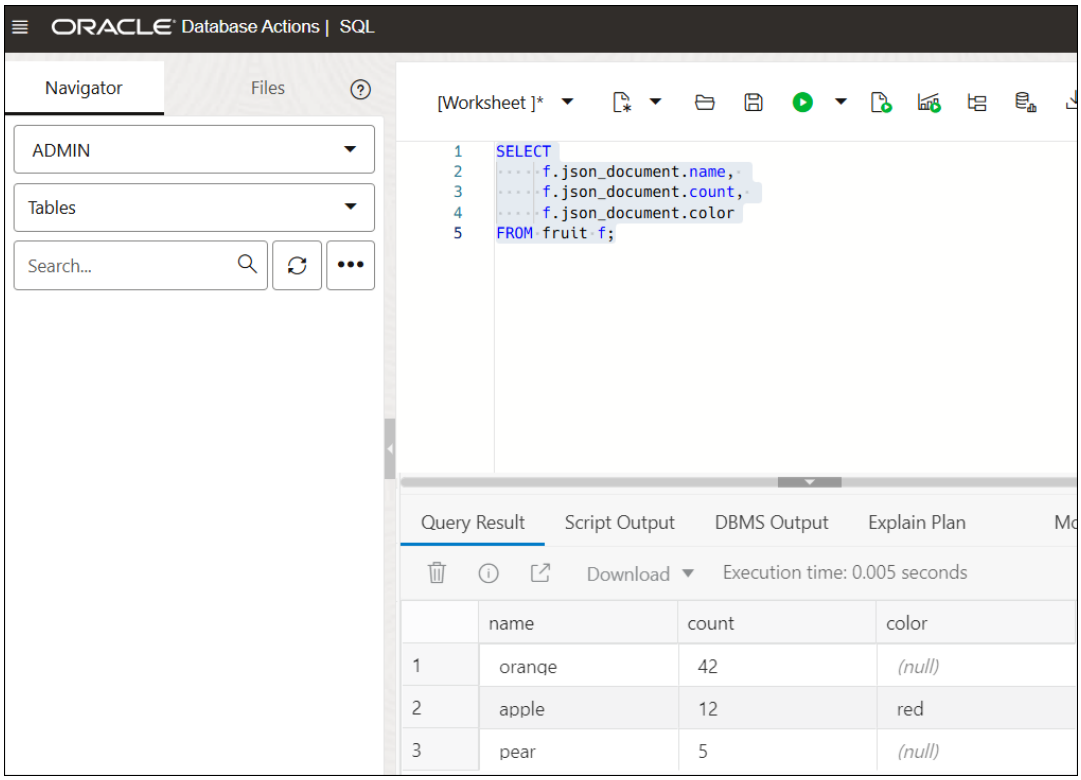
```
testuser> show collections

testuser> db.createCollection( 'fruit' )
{ ok: 1 }
testuser> show collections
fruit
testuser> db.fruit.insertOne( {name:"orange", count:42} )
{
  acknowledged: true,
  insertedId: ObjectId("614ca31fdab254f63e4c6b47")
}
testuser> db.fruit.insertOne( {name:"apple", count:12, color: "red"} )
{
  acknowledged: true,
  insertedId: ObjectId("614ca340dab254f63e4c6b48")
```

```
}
testuser> db.fruit.insertOne( {name:"pear", count:5} )
{
  acknowledged: true,
  insertedId: ObjectId("614ca351dab254f63e4c6b49")
}
testuser>
```

3. Query the collection using a SQL client such as Database Actions.

```
SELECT
     f.json_document.name,
     f.json_document.count,
     f.json_document.color
FROM fruit f;
```



Test Connection Using a Node.js Application

1. Download Node.js. If you have already downloaded or installed Node.js for your environment, you can skip this step.

```
$ wget https://nodejs.org/dist/latest-v14.x/node-v14.17.5-linux-x64.tar.xz
```

2. Extract the contents of the Node,js archive. If you have already downloaded or installed Node.js for your environment, you can skip this step.

```
$ tar -xf node-v14.17.5-linux-x64.tar.xz
```

3. Configure the `PATH` environment variable. If you have already downloaded or installed Node.js for your environment, you can skip this step.

```
$ export PATH="`pwd`"/node-v14.17.5-linux-x64/bin:$PATH
```

4. Test your connection with a Javascript example.

   a. Create a new directory.

```
$ mkdir autonomous_mongodb
$ cd autonomous_mongodb
$ npm init -y
```

   b. Install mongodb dependency.

```
$ npm install mongodb
```

   c. Create a JavaScript application named `connect.js`.

```
const { MongoClient } = require("mongodb");
const uri =
   "mongodb://TESTUSER:<PASSWORD>@<Database URI>.<OCI
region>.oraclecloudapps.com:27017/admin?
authMechanism=PLAIN&authSource=$external&ssl=true&loadBalanced=false";

const client = new MongoClient(uri);

async function run() {
  try {
        await client.connect();

        const database = client.db('admin');
        const movies = database.collection('movies');

        // Insert a movie
        const doc = { title: 'Back to the Future',
                      year: 1985, genres: ['Adventure', 'Comedy', 'Sci-
Fi'] }
        const result = await movies.insertOne(doc);

        // Query for a movie that has the title 'Back to the Future' :)
        const query = { title: 'Back to the Future' };
        const movie = await movies.findOne(query);

        console.log(movie);
  } finally {
     // Ensures that the client will close when you finish/error
     await client.close();
  }
}
run().catch(console.dir);
```

> **Note:**
>
> Use URI percent-encoding to replace any reserved characters in your connection-string URI — in particular, characters in your username and password. These are the reserved characters and their percent encodings:
>
> | ! | # | $ | % | & | ' | (|) | * | + |
> |---|---|---|---|---|---|---|---|---|---|
> | %21 | %23 | %24 | %25 | %26 | %27 | %28 | %29 | %2A | %2B |
>
> | , | / | : | ; | = | ? | @ | [|] |
> |---|---|---|---|---|---|---|---|---|
> | %2C | %2F | %3A | %3B | %3D | %3F | %40 | %5B | %5D |
>
> For example, if your username is `RUTH` and your password is `@least1/2#?` then your MongoDB connection string to server *<server>* might look like this:
>
> ```
> 'mongodb://RUTH:%40least1%2F2%23%3F@<server>:27017/ruth/ ...'
> ```
>
> Depending on the tools or drivers you use, you might be able to provide a username and password as separate parameters, instead of as part of a URI connection string. In that case you likely won't need to encode any reserved characters they contain.
>
> See also:
>
> - Percent Encoding - Reserved Characters
> - Uniform Resource Identifier (URI): Generic Syntax

d. Run the example. The output should look similar to the following.

```
$ node connect
{
  _id: new ObjectId("611e3266005202371acf27c1"),
  title: 'Back to the Future',
  year: 1985,
  genres: [ 'Adventure', 'Comedy', 'Sci-Fi' ]
}
```

Send Email and Notifications on Autonomous Database

There are a number of options for sending email on Autonomous Database. You can also send notifications to a Slack channel, to MSTeams, or to an OCI Notifications topic.

- Send Email on Autonomous Database
  There are a number of options for sending email on Autonomous Database. You can also send text messages or the output of an SQL query to a Slack or MSTeams channel.
- Send Slack Notifications from Autonomous Database
  Describes how to configure Slack so that you can send messages, alerts, or output of a query from Autonomous Database to a Slack Channel. Also describes the procedures you use to send Slack notifications.

- Send Messages to OCI Notifications Service from Autonomous Database
  Describes how to send messages from Autonomous Database to an OCI Notifications service topic.
- Send Microsoft Teams Notifications from Autonomous Database
  Describes how to configure Microsoft Teams so that you can send messages, alerts, or output of a query from Autonomous Database to a Microsoft Teams Channel. Also describes the procedures you use to send Microsoft Teams notifications.

Send Email on Autonomous Database

There are a number of options for sending email on Autonomous Database. You can also send text messages or the output of an SQL query to a Slack or MSTeams channel.

- Send Email with Email Delivery Service on Autonomous Database
  Describes the steps to send email using `UTL_SMTP` on Autonomous Database.
- Send Email with an Email Provider on a Private Endpoint
  Describes the steps to send email with an email provider that is on Private Endpoint.
- Use Credential Objects to set SMTP Authentication
  Describes how to pass a credential objects to `UTL_SMTP.SET_CREDENTIAL` APIs.
- Send Email from Autonomous Database Using DBMS_CLOUD_NOTIFICATION
  Use the `DBMS_CLOUD_NOTIFICATION` package to send messages and query results as email.

Send Email with Email Delivery Service on Autonomous Database

Describes the steps to send email using `UTL_SMTP` on Autonomous Database.

To send email with Oracle Cloud Infrastructure Email Delivery Service:

1. Identify your SMTP connection endpoint for Email Delivery. You may need to subscribe to additional Oracle Cloud Infrastructure regions if Email Delivery is not available in your current region.

   For example, select one of the following for the SMTP connection endpoint:

   - smtp.us-phoenix-1.oraclecloud.com
   - smtp.us-ashburn-1.oraclecloud.com
   - smtp.email.uk-london-1.oci.oraclecloud.com
   - smtp.email.eu-frankfurt-1.oci.oraclecloud.com

   > **Note:**
   >
   > If the SMTP connection endpoint is in a different region from your Autonomous Database, then you must create a request at Oracle Cloud Support to have Cloud Operations enable that region's Email Delivery service for your Autonomous Database.

   See Configure SMTP Connection for more information.

2. Generate SMTP credentials for Email Delivery. `UTL_SMTP` uses credentials to authenticate with Email Delivery servers when you send email.

   See Generate SMTP Credentials for a User for more information.

3. Create an approved sender for Email Delivery. Complete this step for all email addresses you use as the "`From`" with `UTL_SMTP.MAIL`.

   See Managing Approved Senders for more information.

4. Allow SMTP access for ADMIN user by appending an Access Control Entry (ACE).

   For example:

```
BEGIN
  -- Allow SMTP access for user ADMIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host => 'www.us.example.com',
    lower_port => 587,
    upper_port => 587,
    ace => xs$ace_type(privilege_list => xs$name_list('SMTP'),
                       principal_name => 'ADMIN',
                       principal_type => xs_acl.ptype_db));
END;
/
```

5. Create a PL/SQL procedure to send email.

   For example, see the sample code shown in SMTP Send Email Sample Code.

6. Send a test email using the PL/SQL procedure you created in step 5.

   For example:

```
execute send_mail('taylor@example.com', 'Email from Oracle Autonomous
Database', 'Sent using UTL_SMTP');
```

See UTL_SMTP for information on `UTL_SMTP`.

See PL/SQL Package Notes for Autonomous Database for `UTL_SMTP` restrictions with Autonomous Database.

- SMTP Send Email Sample Code
  Shows sample code for sending email with `UTL_SMTP` on Autonomous Database.

SMTP Send Email Sample Code

Shows sample code for sending email with `UTL_SMTP` on Autonomous Database.

```
CREATE OR REPLACE PROCEDURE SEND_MAIL (
  msg_to varchar2,
  msg_subject varchar2,
  msg_text varchar2 )
IS

  mail_conn utl_smtp.connection;
  username varchar2(1000):= 'ocid1.user.oc1.username';
  passwd varchar2(50):= 'password';
  msg_from varchar2(50) := 'adam@example.com';
  mailhost VARCHAR2(50) := 'smtp.us-ashburn-1.oraclecloud.com';

BEGIN
  mail_conn := UTL_smtp.open_connection(mailhost, 587);
  utl_smtp.starttls(mail_conn);
```

```
  UTL_SMTP.AUTH(mail_conn, username, passwd, schemes => 'PLAIN');

  utl_smtp.mail(mail_conn, msg_from);
  utl_smtp.rcpt(mail_conn, msg_to);

  UTL_smtp.open_data(mail_conn);

  UTL_SMTP.write_data(mail_conn, 'Date: ' || TO_CHAR(SYSDATE, 'DD-MON-YYYY
HH24:MI:SS') || UTL_TCP.crlf);
  UTL_SMTP.write_data(mail_conn, 'To: ' || msg_to || UTL_TCP.crlf);
  UTL_SMTP.write_data(mail_conn, 'From: ' || msg_from || UTL_TCP.crlf);
  UTL_SMTP.write_data(mail_conn, 'Subject: ' || msg_subject || UTL_TCP.crlf);
  UTL_SMTP.write_data(mail_conn, 'Reply-To: ' || msg_to || UTL_TCP.crlf ||
UTL_TCP.crlf);
  UTL_SMTP.write_data(mail_conn, msg_text || UTL_TCP.crlf || UTL_TCP.crlf);

  UTL_smtp.close_data(mail_conn);
  UTL_smtp.quit(mail_conn);

EXCEPTION
  WHEN UTL_smtp.transient_error OR UTL_smtp.permanent_error THEN
    UTL_smtp.quit(mail_conn);
    dbms_output.put_line(sqlerrm);
  WHEN OTHERS THEN
    UTL_smtp.quit(mail_conn);
    dbms_output.put_line(sqlerrm);
END;
/
```

Where:

- *mailhost*: specifies the SMTP Connection Endpoint from Step 1 in Send Email with Email Delivery Service on Autonomous Database.
- *username*: specifies the SMTP credential username from Step 2 in Send Email with Email Delivery Service on Autonomous Database.
- *passwd*: specifies the SMTP credential password from Step 2 in Send Email with Email Delivery Service on Autonomous Database.
- *msg_from*: specifies one of the approved senders from Step 3 in Send Email with Email Delivery Service on Autonomous Database.

Send Email with an Email Provider on a Private Endpoint

Describes the steps to send email with an email provider that is on Private Endpoint.

To send email from Autonomous Database using a email provider on a private endpoint, the email provider must be accessible from the Oracle Cloud Infrastructure VCN (the Autonomous Database instance's private endpoint). For example, you can access an email provider when:

- Both the source Autonomous Database instance and the email provider are in the same Oracle Cloud Infrastructure VCN.
- The source Autonomous Database instance and the email provider are in different Oracle Cloud Infrastructure VCNs that are paired.

- The email provider is on an on-premises network that is connected to the source Autonomous Database instance's Oracle Cloud Infrastructure VCN using FastConnect or VPN.

As a prerequisite, to send email using an email provider, define the following ingress and egress rules:

- Define an egress rule in the source database's subnet security list or network security group such that the traffic to the target host is allowed on port 587 or port 25 (depending on which port you are using).
- Define an ingress rule in the target host's subnet security list or network security group such that the traffic from the source Autonomous Database instance's IP address to port 587 or port 25 is allowed (depending on which port you are using).

To send email from an email provider on private endpoint:

1. Allow SMTP access for ADMIN user by appending an Access Control Entry (ACE).

   For example:

```
-- Create an Access Control List for the host
BEGIN
   DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'www.example.com',
         lower_port => 587,
         upper_port => 587,
         ace => xs$ace_type(privilege_list => xs$name_list('SMTP'),
                            principal_name => 'ADMIN',
                            principal_type => xs_acl.ptype_db),
         private_target => TRUE);
END;
/
```

> **Note:**
>
> `DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE` only supports a single hostname for the `host` parameter (on a private endpoint, using an IP address, a SCAN IP, or a SCAN hostname is not supported).

   If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

2. Create a PL/SQL procedure to send email.
3. Send a test email using the PL/SQL procedure you created in step 2.

   For example:

```
execute send_mail('taylor@example.com', 'Email from Oracle Autonomous
Database', 'Sent using private email provider');
```

Use Credential Objects to set SMTP Authentication

Describes how to pass a credential objects to `UTL_SMTP.SET_CREDENTIAL` APIs.

The `SET_CREDENTIAL` subprogram sends the AUTH command to authenticate to the SMTP server.

The `UTL_SMTP.SET_CREDENTIAL` subprogram enables you to pass credential objects to set SMTP authentication. Credential objects are schema objects, hence they can be accessed only by privileged users and enable you to configure schema-level privileges to access control the credentials. Passing credential objects is a appropriate and secure way to store and manage username/password/keys for authentication.

The `UTL_SMTP.SET_CREDENTIAL` subprogram is a secure and convenient alternative to `UTL_SMTP.AUTH` subprogram.

Example

```
...
UTL_SMTP.AUTH (l_mail_conn, 'ocid1.user.oc1.username', 'xxxxxxxxxxxx',
schemes => 'PLAIN');
...
```

As shown in the example above, when you invoke `AUTH` subprogram, you must pass the username/password in clear text as part of PL/SQL formal parameters. You might need to embed the username/password into various PL/SQL automation or cron scripts. Passing clear text passwords is a compliance issue that is addressed in `UTL_SMTP.SET_CREDENTIAL` subprogram.

See AUTH Function and Procedure for more information.

`UTL_SMTP.SET_CREDENTIAL` Syntax

```
PROCEDURE UTL_SMTP.SET_CREDENTIAL (
    c          IN OUT NOCOPY connection,
    credential IN            VARCHAR2,
    schemes    IN            VARCHAR2 DEFAULT NON_CLEARTEXT_PASSWORD_SCHEMES
);

FUNCTION UTL_SMTP.SET_CREDENTIAL (
    c          IN OUT NOCOPY connection,
    credential IN            VARCHAR2,
    schemes    IN            VARCHAR2 DEFAULT NON_CLEARTEXT_PASSWORD_SCHEMES)
    RETURN reply;
```

Example

- Create a credential object:

  ```
  BEGIN DBMS_CLOUD.CREATE_CREDENTIAL (
      credential_name => 'HTTP_CRED',
      username        => 'web_app_user',
      password        => '<password>' );
  END;
  ```

  This creates a credential object which creates a stored username/password pair.

  See CREATE_CREDENTIAL Procedure for more information.

  See Specifying Scheduler Job Credentials for more information.

- Execute `UTL_SMTP.SET_CREDENTIAL` procedure:

```
DECLARE
      l_mail_conn UTL_SMTP.CONNECTION;
    BEGIN
      l_mail_conn := UTL_SMTP.OPEN_CONNECTION('smtp.example.com', 587);
      UTL_SMTP.SET_CREDENTIAL(l_mail_conn, 'SMTP_CRED', SCHEMES =>
'PLAIN');
      ...
END;
```

  This example sends the command to authenticate to the SMTP server. The Web server needs this information to authorize the request. The value `l_mail_conn` is the SMTP connection, `SMTP_CRED` is the credentials name and `PLAIN` is the SMTP authentication scheme.

See UTL_SMTP for more information.

See PL/SQL Package Notes for Autonomous Database for information on restrictions for `UTL_SMTP` on Autonomous Database.

Send Email from Autonomous Database Using DBMS_CLOUD_NOTIFICATION

Use the `DBMS_CLOUD_NOTIFICATION` package to send messages and query results as email.

- Send Messages as Email from Autonomous Database
- Send Query Results as Email from Autonomous Database

Send Messages as Email from Autonomous Database

You can use the `DBMS_CLOUD_NOTIFICATION` to send messages as an email.

1. Identify your SMTP connection endpoint for Email Delivery. You may need to subscribe to additional Oracle Cloud Infrastructure regions if Email Delivery is not available in your current region.

   For example, select one of the following for the SMTP connection endpoint:

   - smtp.us-phoenix-1.oraclecloud.com
   - smtp.us-ashburn-1.oraclecloud.com
   - smtp.email.uk-london-1.oci.oraclecloud.com
   - smtp.email.eu-frankfurt-1.oci.oraclecloud.com

   See Configure SMTP Connection for more information.

2. Generate SMTP credentials for Email Delivery. `UTL_SMTP` uses credentials to authenticate with Email Delivery servers when you send email.

   See Generate SMTP Credentials for a User for more information.

3. Create an approved sender for Email Delivery. Complete this step for all email addresses you use as the "`From`" with `UTL_SMTP.MAIL`.

   See Managing Approved Senders for more information.

4. Allow SMTP access for ADMIN user by appending an Access Control Entry (ACE).

For example:

```
BEGIN
  -- Allow SMTP access for user ADMIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host => 'www.us.example.com',
    lower_port => 587,
    upper_port => 587,
    ace => xs$ace_type(privilege_list => xs$name_list('SMTP'),
                       principal_name => 'ADMIN',
                       principal_type => xs_acl.ptype_db));
END;
/
```

5. Create a credential object and use `DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE` to send a message as an email.

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'EMAIL_CRED',
        username        => 'username',
        password        => 'password'
   );
   END;
/
BEGIN
   DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE(
        provider        => 'email',
        credential_name => 'EMAIL_CRED',
        message         => 'Subject content',
        params          => json_object('recipient' value
'mark@example.com, suresh@example.com',
                                       'to_cc'  value 'nicole@example.com,
jordan@example.com',
                                       'to_bcc' value
'manisha@example.com',
                                       'subject' value 'Test subject',
                                       'smtp_host' value
'smtp.email.example.com',
                                       'sender'    value
'approver_sender@example.com' )
   );
   END;
/
```

Use the `params` parameter to specify the sender, smtp_host, subject, recipient, and recipients of a CC or BCC in `string` values.

- *sender*: specifies the Email ID of the approved sender from Step 3.
- *smtp_host*: specifies the SMTP host name from step 2.
- *subject*: specifies the subject of the email.
- *recipient*: specifies the email IDs of recipients. Use a comma between email IDs when there are multiple recipients.

- *to_cc*: specifies the email IDs that are receiving a CC of the email. Use a comma between email IDs when there are multiple CC recipients.
- *to_bcc*: specifies the email IDs that are receiving a BCC of the email. Use a comma between email IDs when there are multiple BCC recipients.

See SEND_MESSAGE Procedure for more information.

Send Query Results as Email from Autonomous Database

You can use the `DBMS_CLOUD_NOTIFICATION` package to send the results of a query as an email.

To use `DBMS_CLOUD_NOTIFICATION` to send mail:

1. Identify your SMTP connection endpoint for Email Delivery. You may need to subscribe to additional Oracle Cloud Infrastructure regions if Email Delivery is not available in your current region.

   For example, select one of the following for the SMTP connection endpoint:

   - smtp.us-phoenix-1.oraclecloud.com
   - smtp.us-ashburn-1.oraclecloud.com
   - smtp.email.uk-london-1.oci.oraclecloud.com
   - smtp.email.eu-frankfurt-1.oci.oraclecloud.com

   See Configure SMTP Connection for more information.

2. Generate SMTP credentials for Email Delivery. `UTL_SMTP` uses credentials to authenticate with Email Delivery servers when you send email.

   See Generate SMTP Credentials for a User for more information.

3. Create an approved sender for Email Delivery. Complete this step for all email addresses you use as the "`From`" with `UTL_SMTP.MAIL`.

   See Managing Approved Senders for more information.

4. Allow SMTP access for ADMIN user by appending an Access Control Entry (ACE).

   For example:

   ```
   BEGIN
     -- Allow SMTP access for user ADMIN
     DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
       host => 'www.us.example.com',
       lower_port => 587,
       upper_port => 587,
       ace => xs$ace_type(privilege_list => xs$name_list('SMTP'),
                          principal_name => 'ADMIN',
                          principal_type => xs_acl.ptype_db));
   END;
   /
   ```

5. Create a credential object and use `DBMS_CLOUD_NOTIFICATION.SEND_DATA` to send the output of a query as an email.

   ```
   BEGIN
      DBMS_CLOUD.CREATE_CREDENTIAL(
           credential_name => 'EMAIL_CRED',
   ```

```
        username        => 'username',
        password        => 'password'
   );
   END;
/
BEGIN
   DBMS_CLOUD_NOTIFICATION.SEND_DATA(
        provider        => 'email',
        credential_name => 'EMAIL_CRED',
        query           => 'SELECT tablespace_name FROM dba_tablespaces',
        params          => json_object('recipient' value
'mark@example.com, suresh@example.com',
                                       'to_cc'  value
'nicole@example.com1, jordan@example.com',
                                       'to_bcc' value
'manisha@example.com',
                                       'subject' value 'Test subject',
                                       'type' value 'json',
                                       'title' value 'mytitle',
                                       'message' value 'This is the
message',
                                       'smtp_host' value
'smtp.email.example.com',
                                       'sender'    value
'approver_sender@example.com' )
   );
   END;
/
```

Use the `params` parameter to specify the sender, smtp_host, subject, recipient, recipients of a CC or BCC, the message, data type, and the title in `String` values.

- *sender*: specifies the Email ID of the approved sender from Step 3.
- *smtp_host*: specifies the SMTP host name from step 2.
- *subject*: specifies the subject of the email. The maximum size is 100 characters.
- *recipient*: This specifies the email IDs of recipients. Use a comma between email IDs when there are multiple recipients.
- *to_cc*: specifies the email IDs that are receiving a CC of the email. Use a comma between email IDs when there are multiple CC recipients.
- *to_bcc*: specifies the email IDs that are receiving a BCC of the email. Use a comma between email IDs when there are multiple BCC recipients.
- *message*: specifies the message text.
- *type*: specifies the output format as either CSV or JSON.
- *title*: specifies the title of the attachment of SQL output. The title should only contain letters, digits, underscores, hyphens, or dots as characters in its value due to it being used to generate a file name.

The maximum message size for use with `DBMS_CLOUD_NOTIFICATION.SEND_DATA` for mail notification is 32k bytes.

See SEND_DATA Procedure for more information.

Send Slack Notifications from Autonomous Database

Describes how to configure Slack so that you can send messages, alerts, or output of a query from Autonomous Database to a Slack Channel. Also describes the procedures you use to send Slack notifications.

- Prepare to Send Slack Notifications from Autonomous Database
  To send Slack notifications, you must configure your Slack application to receive messages from Autonomous Database. Next, create a credential to use with the `DBMS_CLOUD_NOTIFICATION` procedures to send Slack notifications from Autonomous Database.
- Send Messages to a Slack Channel
- Send Query Results to a Slack Channel

Prepare to Send Slack Notifications from Autonomous Database

To send Slack notifications, you must configure your Slack application to receive messages from Autonomous Database. Next, create a credential to use with the `DBMS_CLOUD_NOTIFICATION` procedures to send Slack notifications from Autonomous Database.

To use Slack with `DBMS_CLOUD_NOTIFICATION` procedures:

1. Create your Slack app.

   The Slack app is installed in a Slack Workspace, which in turn has Channels where messages can be sent. The bot token of the Slack app must have the following permission scopes defined:

   ```
   channels:read
   chat:write
   files:write
   ```

   See Creating an app for information on setting up a Slack app.
2. Have your Slack admin add the Slack app to the channels to which `DBMS_CLOUD_NOTIFICATION` can send message through the "Integrations" option in the channel.

   See Basic app setup for more information.
3. Locate the app's bot token available in the Slack app specific page, under `https://app.slack.com`.

   See Basic app setup for more information.
4. Create a credential object to access the Slack app from Autonomous Database.

   > **Tip:**
   >
   > If you can not use the `CREATE_CREDENTIAL` procedure successfully, consult with the ADMIN user to grant execute access on `DBMS_CLOUD` packages.

   The credential's username is `SLACK_TOKEN` and the password is the bot token.

For example:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL(
     credential_name => 'SLACK_CRED',
     username    => 'SLACK_TOKEN',
     password    => 'xoxb-34....96-34....52-zW....cy');
END;
/
```

See CREATE_CREDENTIAL Procedure for more information.

5. Configure access control to allow user access to external network services (Slack).

```
BEGIN
 DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE (
  host         => 'slack.com',
  lower_port   => 443,
  upper_port   => 443,
  ace          => xs$ace_type(
      privilege_list => xs$name_list('http'),
      principal_name => example_invoking_user,
      principal_type => xs_acl.ptype_db));
END;
```

See Configuring Access Control for External Network Services for more information.

6. If you are sending SQL, configure access control to allow sending of output with `DBMS_CLOUD_NOTIFICATION.SEND_DATA`.

```
BEGIN
 DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE (
  host         => 'files.slack.com',
  lower_port   => 443,
  upper_port   => 443,
  ace          => xs$ace_type(
      privilege_list => xs$name_list('http'),
      principal_name => example_invoking_user,
      principal_type => xs_acl.ptype_db));
END;
```

See Configuring Access Control for External Network Services for more information.

Send Messages to a Slack Channel

After creating the Slack credential object as described in Prepare to Send Slack Notifications from Autonomous Database, you can use the `DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE` procedure to send a message to a Slack channel.

Example:

```
BEGIN
   DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE(
      provider          => 'slack',
      credential_name   => 'SLACK_CRED',
```

```
      message           => 'Alert from Autonomous Database...',
      params            => json_object('channel' value 'C0....08'));
END;
/
```

Use the `params` parameter to specify the Slack channel.

- `channel`: Specifies the Channel ID.

  The Channel ID is a unique ID for a channel and is different from the channel name. In Slack, when you view channel details you can find the Channel ID on the “About” tab. See How to Find your Slack Team ID and Slack Channel ID for more information.

See SEND_MESSAGE Procedure for more information.

Send Query Results to a Slack Channel

After creating the Slack credential object as described in Prepare to Send Slack Notifications from Autonomous Database, you can use the `DBMS_CLOUD_NOTIFICATION.SEND_DATA` procedure to send the output of a query to a Slack channel.

Example:

```
BEGIN
  DBMS_CLOUD_NOTIFICATION.SEND_DATA(
      provider => 'slack',
      credential_name => 'SLACK_CRED',
      query => 'SELECT username, account_status, expiry_date FROM USER_USERS
WHERE rownum < 5',
      params => json_object('channel' value 'C0....08',
                            'type' value 'csv'));
END;
/
```

Use the `params` parameter to specify the Slack channel and the data type:

- `channel`: Specifies the Channel ID.

  The Channel ID is a unique ID for a channel and is different from the channel name. In Slack, when you view channel details you can find the Channel ID on the “About” tab. See How to Find your Slack Team ID and Slack Channel ID for more information.

- `type`: Specifies the output type. Valid values are: '`csv`' or '`json`'.

See SEND_DATA Procedure for more information.

Related Topics

- SEND_DATA Procedure
  The `SEND_DATA` procedure sends the results of the specified query to a provider.

Send Messages to OCI Notifications Service from Autonomous Database

Describes how to send messages from Autonomous Database to an OCI Notifications service topic.

The subscriptions you configure with the OCI Notifications service determine endpoints for a topic. Published messages are sent to each subscription for a topic. There are a number of

supported subscription protocols, including: email, function, and Slack. See Overview of Notifications for more information.

When you use the OCI Notifications service with `DBMS_CLOUD_NOTIFICATION` package, only the `DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE` procedure is supported (the `DBMS_CLOUD_NOTIFICATION.SEND_DATA` procedure is not supported).

- Prepare to Send OCI Notifications from Autonomous Database
  To send notifications to topics in OCI Notifications service, first create topics and subscriptions in OCI Notifications.
- Send Messages to an OCI Notifications Topic
  Describes the steps to send messages to an OCI Notifications service topic.
- Limitations for Notifications with OCI Notifications Service
  There are limitations when you use `DBMS_CLOUD_NOTIFICATION` to send messages and you use the `oci` provider (OCI Notifications service).

Prepare to Send OCI Notifications from Autonomous Database

To send notifications to topics in OCI Notifications service, first create topics and subscriptions in OCI Notifications.

As a prerequisite, before you send messages with OCI Notifications, do the following:

1. Create an OCI Notifications topic.

   See Creating a Topic for details on creating a topic.
2. Create OCI Notifications subscriptions.

   See Creating a Subscription for details on creating a subscription.

   The subscriptions you configure determine endpoints for a topic. Published messages are sent to each subscription for a topic. There are a number of supported subscription protocols, including: email, function, and Slack.

   See Overview of Notifications for more information.
3. After you create the OCI Notifications subscriptions, confirm the subscriptions.

   You can only publish messages to confirmed subscriptions. See Confirming a Subscription for details on confirming subscriptions.

Send Messages to an OCI Notifications Topic

Describes the steps to send messages to an OCI Notifications service topic.

1. Create a topic and create subscriptions.

   See Prepare to Send OCI Notifications from Autonomous Database for details.
2. Create a credential object to access OCI Notifications service from Autonomous Database.

   You can use either Oracle Cloud Infrastructure signing key credentials or resource principal credentials.

   - Create Oracle Cloud Infrastructure signing key credentials. For example:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'OCI_KEY_CRED',
       user_ocid       =>
'ocid1.user.oc1..aaaaaaaauq54mi7zdyfhw33ozkwuontjceel7fok5nq3bf2vwetkpqs
```

```
oa',
       tenancy_ocid    =>
'ocid1.tenancy.oc1..aabbbbbbaafcue47pqmrf4vigneebgbcmmoy5r7xvoypicjqqge3
2ewnrcyx2a',
       private_key     =>
'MIIEogIBAAKCAQEAtUnxbmrekwgVac6FdWeRzoXvIpA9+0r1.....wtnNpESQQQ0QLGPD8N
M//JEBg=',
       fingerprint     =>
'f2:db:f9:18:a4:aa:fc:94:f4:f6:6c:39:96:16:aa:27');
END;
/
```

See CREATE_CREDENTIAL Procedure for more information.

- Create resource principal credentials and policies.

  See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Send a message.

   - Send a message using Oracle Cloud Infrastructure signing key credentials:

     ```
     BEGIN
         DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE(
             provider         => 'oci',
             credential_name  => 'OCI_KEY_CRED',
             message          => 'Text message',
             params           => json_object('topic_ocid' value
     'oci********pa',
                                             'title'value 'Title for
     message'));
     END;
     /
     ```

   - Send a message with resource principal credentials:

     ```
     BEGIN
         DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE(
             provider         => 'oci',
             credential_name  => 'OCI$RESOURCE_PRINCIPAL',
             message          => 'Text message',
             params           => json_object('topic_ocid' value
     'oci********pa',
                                             'title'      value 'Title for
     message'));
     END;
     /
     ```

   With the `oci` provider there are different possible endpoints for a message, based on the subscriptions. The `title` parameter is treated differently for different subscription protocols:

   - email: The `title` specifies the subject line of the message.
   - Slack: The `title` value is not used. If it is included the value is ignored.

See SEND_MESSAGE Procedure for more information.

Limitations for Notifications with OCI Notifications Service

There are limitations when you use `DBMS_CLOUD_NOTIFICATION` to send messages and you use the `oci` provider (OCI Notifications service).

Note the following limitations:

- Message Size Limit: The message size limit per request is 64KB. Messages exceeding this size cannot be sent or processed within a single request.
- Message Delivery Rate Limit: There are different message delivery rate limits depending on the protocol used.
  - `email` protocol: the limit is 10 messages per minute per endpoint.

  This restriction may impact the speed at which messages can be transmitted and received.
- Transactions Per Minute (TPM) per-tenancy Limit: There is a TPM limit of 60 per topic for this operation. This limit represents the maximum number of messages per minute that can be processed or handled for a given topic. Exceeding this limit may result in messages not being processed or processed at a slower rate.
- The the Autonomous Database instance, the credential, if you are using user credentials, and the subscription topic must all be located in the same region.

See Overview of Notifications for more information on OCI Notifications.

Send Microsoft Teams Notifications from Autonomous Database

Describes how to configure Microsoft Teams so that you can send messages, alerts, or output of a query from Autonomous Database to a Microsoft Teams Channel. Also describes the procedures you use to send Microsoft Teams notifications.

- Prepare to Send Microsoft Teams Notifications from Autonomous Database
  Get started by configuring a bot in your Microsoft Teams app. Next, create a credential to use with the `DBMS_CLOUD_NOTIFICATION` procedures to send Microsoft Teams notifications from Autonomous Database.
- Send Messages to a Microsoft Teams Channel
- Send Query Results to a Microsoft Teams Channel

Prepare to Send Microsoft Teams Notifications from Autonomous Database

Get started by configuring a bot in your Microsoft Teams app. Next, create a credential to use with the `DBMS_CLOUD_NOTIFICATION` procedures to send Microsoft Teams notifications from Autonomous Database.

To configure Microsoft Teams notifications:

1. Create your Microsoft Teams app and add a bot in it. See Developer Portal for Teams for information on setting up an app.
2. From the **Bot Management** section, ensure that the bot has a secret key, scope set to *Team* and permission to send notifications.
3. Publish the app to your org to make it available to the people in your org.
4. After your IT admin approves the app from the admin center, install the app from the **Apps** section in Teams.

5. Request the `Files.ReadWrite.All` and `ChannelSettings.Read.All` permissions to the app for Graph API from the Azure Portal using the following instructions:
   a. Log into your Azure Portal, navigate to **Azure Active Directory** using the left panel, and select the **Application** option.
   b. The Application page displays the apps that you own along with the bots added to those apps. Click the bot to view its details.
   c. Copy the *directory/tenant id* from the bot overview page for later use.
   d. Then, go to **API permissions** in the left panel. Under **API permissions**, click **Add permission**, select **Microsoft graph** and then **Application permission**.
   e. Search for `Files.ReadWrite.All` and `ChannelSettings.Read.All` permissions and add them.
6. Have your IT admin approve the above-requested permissions from the Azure portal by following the steps below:
   a. Log into your Azure Portal, navigate to **Azure Active Directory** using the left panel, and select the **Application** option.
   b. Select **All applications** from the **Application** page.
   c. Search the *application/bot* by its name, go to **API permissions**, and grant the ADMIN consent for the requested permissions: `Files.ReadWrite.All` and `ChannelSettings.Read.All`.

> **Tip:**
>
> After your app is approved by the IT Admin, you can provide the bot id and secret key to other users to install the app within Teams in the org.

7. After the app is approved by the IT admin and the above requested permissions are granted, you can use the app's bot ID and secret key are used to create the credential object and generate a bot token.
8. To send a query result to a Microsoft Teams channel, obtain the `team id` and the `tenant id`.

> **Tip:**
>
> The `team id` is located in the team link between /team/ and /conversations. The `tenant id` is located after "tenantId=" at the end of the team link. This link is found by clicking the three dots next to the team name and selecting **Get link to team**.

   For example:

   `https://teams.microsoft.com/l/team/`*`teamID`*`/conversations?groupId=`*`groupid`*`%tenantId=`*`tenantid`*

9. Obtain the `channelID`.

> **Tip:**
>
> `channelID` is located in the channel link between /team/ and the channel name. This link is found by clicking the three dots next to the channel name and selecting **Get link to channel**.

For example:

```
https://teams.microsoft.com/l/channel/channelID/channel_name?
groupId=groupid&tenantId=tenantid
```

10. Create a credential object to access the Microsoft Teams app from Autonomous Database.

> **Tip:**
>
> If you can not use the `CREATE_CREDENTIAL` procedure successfully, consult with the ADMIN user to grant execute access on `DBMS_CLOUD` packages.

The credential's username is the bot_id and the password is the bot key.

For example:

```
BEGIN
    DBMS_CLOUD.CREATE_CREDENTIAL(credential_name => 'TEAMS_CRED',
        username        => 'bot_id',
        password        => 'bot_secret');
END;
/
```

See CREATE_CREDENTIAL Procedure for more information.

Send Messages to a Microsoft Teams Channel

After creating the Microsoft Teams credential object as described in Prepare to Send Microsoft Teams Notifications from Autonomous Database, you can use the `DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE` procedure to send a message to a Microsoft Teams channel.

Example:

```
BEGIN
     DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE(
        provider        => 'msteams',
        credential_name => 'TEAMS_CRED',
        message         => 'text from new teams api',
        params          => json_object('channel' value 'channelID'));
END;
/
```

Use the `params` parameter to specify the channel.

- *channel*: specifies the Channel ID obtained from Step 10 in Prepare to Send Microsoft Teams Notifications from Autonomous Database.

See SEND_MESSAGE Procedure for more information.

Send Query Results to a Microsoft Teams Channel

After creating the Microsoft Teams credential object as described in Prepare to Send Microsoft Teams Notifications from Autonomous Database, you can use the `DBMS_CLOUD_NOTIFICATION.SEND_DATA` procedure to send the output of a query to a Microsoft Teams channel.
Example:

```
BEGIN
     DBMS_CLOUD_NOTIFICATION.SEND_DATA(provider => 'msteams',
        credential_name => 'TEAMS_CRED',
        query           => 'SELECT tablespace_name FROM dba_tablespaces',
        params          => json_object('tenant'value '5b743bc******c0286',
                                       'team'value '0ae401*********5d2bd',
                                       'channel'value
'19%3a94be023*****%40thread.tacv2',
                                       'title'value 'today',
                                       'type'value 'csv'));
END;
/
```

Use the `params` parameter to specify the tenant, team, channel, title, and data type in `string` values.

- *tenant*: specifies the tenant ID obtained from Step 8 in Prepare to Send Microsoft Teams Notifications from Autonomous Database.
- *team*: specifies the team ID obtained from Step 8 in Prepare to Send Microsoft Teams Notifications from Autonomous Database.
- *channel*: specifies the channel ID obtained from Step 9 in Prepare to Send Microsoft Teams Notifications from Autonomous Database.
- *title*: specifies the title of the file. The title can only contain alphabets, digits, underscores, and hyphens. The file name that appears in Microsoft Teams will be a concatenation of the title parameter and the timestamp to ensure uniqueness. The maximum title size is 50 characters.

  For example: '*title*'_'*timestamp*'.'*format*'
- *type*: This specifies the output format. Valid values are CSV or JSON.

> **Note:**
>
> The maximum file size supported when using `DBMS_CLOUD_NOTIFICATION.SEND_DATA` for Microsoft Teams is 4MB.

See SEND_DATA Procedure for more information.

User Defined Notification Handler for Scheduler Jobs

Database Scheduler provides an email notification mechanism to track the status of periodically running or automated jobs. In addition to this, the Database Scheduler also supports user-defined PL/SQL Scheduler job notification handler procedure.

Adding a scheduler job notification handler procedure allows you to monitor scheduled or automated jobs running in your Autonomous Database.

- About User Defined Notification Handler for Scheduler Jobs
  The Database Scheduler supports job notification handler procedure that can make use of custom code to call HTTP or REST endpoints for improved monitoring of scheduler jobs in an Autonomous Database instance.
- Create a Job Notification Handler Procedure
  Provides steps to create a job notification handler.
- Register the Job Handler Notification Procedure
  Use `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE` procedure to set `JOB_NOTIFICATION_HANDLER` attribute value to register the job handler notification procedure.
- Trigger the Job Handler Notification Procedure
  You must call the `DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION` procedure to trigger the user defined job notification handler procedure.
- De-Register the Job Handler Notification Procedure
  Use `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE` to de-register the job handler notification procedure.

About User Defined Notification Handler for Scheduler Jobs

The Database Scheduler supports job notification handler procedure that can make use of custom code to call HTTP or REST endpoints for improved monitoring of scheduler jobs in an Autonomous Database instance.

The handler procedure receives all pertinent information regarding the job, such as the job owner's name, class name, event type, and timestamp in JSON format. Based on the information, the handler procedure then takes the required action.

See DBMS_SCHEDULER for more information on Oracle Scheduler.

Configuring user defined notification handler for scheduler jobs consists of these steps:

- Create a job notification handler procedure as described in: Create a Job Notification Handler Procedure.
- Register the job notification handler procedure for the database as described in: Register the Job Handler Notification Procedure.
- Trigger the job notification handler procedure as described in: Trigger the Job Handler Notification Procedure
- De-Register the job notification handler procedure for the database as described in: De-Register the Job Handler Notification Procedure.

Create a Job Notification Handler Procedure

Provides steps to create a job notification handler.

1. Create a credential object.

   See CREATE_CREDENTIAL Procedure for more information.

   See Specifying Scheduler Job Credentials for more information.

2. Create a Job notification handler:

   Example to create a job notification handler procedure to send a message to a Slack channel:

```
CREATE OR REPLACE PROCEDURE ADMIN.SEND_NOTIFICATION(data_in CLOB) AS
BEGIN
  DBMS_CLOUD_NOTIFICATION.SEND_MESSAGE (
    provider          => 'slack',
    credential_name   => 'SLACK_CRED',
    message           => data_in,
    params            => JSON_OBJECT('channel' value 'adw-job-nfy');
end;
/
```

   This example creates the `SEND_NOTIFICATION` procedure.

   This user defined procedure sends the provided input data as a message to the specified Slack channel.

   See Send Slack Notifications from Autonomous Database for more information.

   See SEND_MESSAGE Procedure for more information.

   Example to create a job notification handler procedure to insert the message into a table:

```
CREATE TABLE ADMIN.JOB_STATUS(jnfy_data CLOB);

CREATE OR REPLACE PROCEDURE ADMIN.INSERT_JOB_STATUS(data_in CLOB) AS
  l_sessuser VARCHAR2(128) := SYS_CONTEXT('userenv','session_user');
BEGIN
  INSERT INTO ADMIN.JOB_STATUS (jnfy_data) VALUES (data_in || TO_CLOB(' :
Sent By Session User : ' || l_sessuser));
  COMMIT;
END;
/
```

   This example creates the `JOB_STATUS` table and `INSERT_JOB_STATUS` procedure to insert the session-specific values into the table.

   You must be logged in as the ADMIN user or have `CREATE ANY PROCEDURE` system privilege to create a job notification handler procedure.

> **Note:**
>
> An `ORA-27405` is returned when you specify an invalid owner or object name as the job notification handler procedure.

Existing `DBMS_SCHEDULER` procedures `ADD_JOB_EMAIL_NOTIFICATION` and `REMOVE_JOB_EMAIL_NOTIFICATION` are enhanced to support the job notification handler procedure.

See ADD_JOB_EMAIL_NOTIFICATION Procedure and REMOVE_JOB_EMAIL_NOTIFICATION Procedure for more information.

Use DBA_SCHEDULER_NOTIFICATIONS dictionary view to query the list of notifications for a scheduler job. See DBA_SCHEDULER_NOTIFICATIONS for more information.

Register the Job Handler Notification Procedure

Use DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE procedure to set JOB_NOTIFICATION_HANDLER attribute value to register the job handler notification procedure.

The JOB_NOTIFICATION_HANDLER attribute specifies the job handler notification procedure that you want to use.

To register the job handler notification procedure you must:

- Be logged in as the ADMIN user or have MANAGE SCHEDULER privilege.
- Have EXECUTE privilege on the handler procedure or EXECUTE ANY PROCEDURE system privilege.

The JOB_NOTIFICATION_HANDLER attribute and EMAIL_SERVER attribute are mutually exclusive. The ATTRIBUTE parameter of the SET_SCHEDULER_ATTRIBUTE procedure can have either the JOB_NOTIFICATION_HANDLER or the EMAIL_SERVER value at a time. You are allowed to either configure email notifications or create your notification handler for your scheduler jobs.

An ORA-27488 error is raised when you attempt to set both EMAIL_SERVER and JOB_NOTIFICATION_HANDLER global attributes.

Execute DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE procedure to register the job handler notification procedure:

```
BEGIN

DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE('job_notification_handler','ADMIN.SEND_
NOTIFICATION');
END;
/
```

This example registers the ADMIN.SEND_NOTIFICATION procedure as the job handler notification procedure for your database.

See SET_SCHEDULER_ATTRIBUTE Procedure for more information.

Execute this command to verify the job notification handler:

```
SELECT value FROM dba_scheduler_global_attribute WHERE
attribute_name='JOB_NOTIFICATION_HANDLER';

VALUE
---------------
"ADMIN"."SEND_NOTIFICATION"
```

See DBA_SCHEDULER_GLOBAL_ATTRIBUTE for more information.

You must assign `EXECUTE` privilege to allow other users to use the job notification handler. For example:

```
GRANT EXECUTE ON ADMIN.SEND_NOTIFICATION To DWUSER;
```

`ORA-27476 ("\"%s\".\"%s\" does not exist")` or `ORA-27486 ("insufficient privileges")` error is thrown if you do not have privilege on the job handler notification procedure.

Trigger the Job Handler Notification Procedure

You must call the `DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION` procedure to trigger the user defined job notification handler procedure.

The overloaded form of the `DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION` enables you to trigger the job notification handler procedure and send a notification. However, these notifications are not sent out in the form of an email when you have registered the job notification handler procedure. Hence, the parameters `SUBJECT`, and `BODY` are optional. The `RECIPIENT` parameter is still mandatory. Since this overloaded form of procedure is not sending email notifications so, you can provide any string value for the `RECIPIENT` parameter.

For example, the following steps create a scheduler job, add notification for the job, enable the job, verify the notification entries, show the data received by the job notification handler procedure, and remove notification for the job.

1. Create a scheduler job in the `DWUSER` schema:

```
BEGIN
 DBMS_SCHEDULER.CREATE_JOB(
   job_name   => 'DWUSER.MY_JOB',
   job_type   => 'PLSQL_BLOCK',
   job_action => 'BEGIN null; END;',
   enabled    => FALSE,
   auto_drop  => FALSE);
END;
/
```

   This creates a job `DWUSER.MY_JOB` with the specified attributes.

   See CREATE_JOB Procedure for more information.

2. Configure the job to send notifications at specified events.

```
BEGIN
  DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION(
    job_name   => 'DWUSER.MY_JOB',
    recipients => 'PLACEHOLDER_STRING',
    subject    => 'Job Notification-%job_owner%.%job_name%-%event_type%',
    body       => '%event_type% occurred at %event_timestamp%.
%error_message%',
    events     => 'job_started, job_succeeded, job_completed');
END;
/
```

This procedure adds notifications for the DWUSER.MY_JOB job. The notifications are sent whenever any of the specified job state events is raised.

See ADD_JOB_EMAIL_NOTIFICATION Procedure for more information.

3. Enable the scheduler job.

```
EXEC DBMS_SCHEDULER.ENABLE('DWUSER.MY_JOB');
```

See ENABLE Procedure for more information.

When you enable the DWUSER.MY_JOB job, the USER_SCHEDULER_NOTIFICATIONS view is populated with the job notification entries. To verify you can query the USER_SCHEDULER_NOTIFICATIONS view. For example:

```
SELECT  job_name, recipient, event, subject, body
FROM user_scheduler_notifications
ORDER BY notification_owner, owner, job_name;

JOB_NAME    RECIPIENT            EVENT          SUBJECT         BODY
-------    ------------------   -------------  ---------------
---------------
MY_JOB     placeholder_string   JOB_STARTED    Job Notificatio
%event_type% oc
                                               n-%job_owner%.% curred at
%even
                                               job_name%-%even
t_timestamp%. %
                                               t_type%
error_message%

MY_JOB     placeholder_string  JOB_SUCCEEDED    Job Notificatio
%event_type% oc
                                                n-%job_owner%.% curred at
%even
                                                job_name%-%even
t_timestamp%. %
                                                t_type%
error_message%

MY_JOB    placeholder_string  JOB_COMPLETED    Job Notificatio
%event_type% oc
                                               n-%job_owner%.% curred at
%even
                                               job_name%-%even
t_timestamp%. %
                                               t_type%
error_message%
```

See USER_SCHEDULER_NOTIFICATIONS View for more information.

When the job DWUSER.MY_JOB is executed and any of the specified job state events is raised, the job notification handler procedure is triggered and receives the specified

information as input. For example, the `ADMIN.SEND_NOTIFICATION` job notification handler procedure receives the following:

```
{"job_owner":"DWUSER","job_name":"MY_JOB","job_class_name":"DEFAULT_JOB_CLA
SS","event_type":"JOB_STARTED","event_timestamp":"12-JAN-23 08.13.46.193306
 PM UTC","error_code":0,"error_msg":null,"sender":null,"recipient":"data_lo
ad_pipeline","subject":"Job Notification-DWUSER.MY_JOB-JOB_STARTED","msg_te
xt":"JOB_STARTED occurred at 12-JAN-23 08.13.46.193306 PM UTC. ","comments"
:"User defined job notification handler"}

{"job_owner":"DWUSER","job_name":"MY_JOB","job_class_name":"DEFAULT_JOB_CLA
SS","event_type":"JOB_SUCCEEDED","event_timestamp":"12-JAN-23 08.13.46.2863
44 PM UTC","error_code":0,"error_msg":null,"sender":null,"recipient":"data_
load_pipeline","subject":"Job Notification-DWUSER.MY_JOB-JOB_SUCCEEDED","ms
g_text":"JOB_SUCCEEDED occurred at 12-JAN-23 08.13.46.286344 PM UTC. ","com
ments":"User defined job notification handler"}
```

4. Remove the job notification. For example:

```
EXEC DBMS_SCHEDULER.REMOVE_JOB_EMAIL_NOTIFICATION('DWUSER.MY_JOB');
```

See REMOVE_JOB_EMAIL_NOTIFICATION Procedure for more information.

De-Register the Job Handler Notification Procedure

Use `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE` to de-register the job handler notification procedure.

To de-register the job handler notification procedure you must be logged in as the ADMIN user or have `MANAGE SCHEDULER` privilege.

Example to de-register the job handler notification procedure:

```
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE ('job_notification_handler','');
END;
/
```

Oracle Extensions for IDEs

Oracle extensions let developers connect to, browse, and manage Autonomous Databases directly from common IDEs.

- Use Oracle Cloud Infrastructure Toolkit for Eclipse
  Oracle Cloud Infrastructure Toolkit for Eclipse is a plugin that enables Java developers to easily connect to Oracle Autonomous Database through their IDE. The plugin is free and is available for Linux, UNIX, Microsoft Windows, and Apple Mac OS.
- Use Oracle Developer Tools for Visual Studio
  Oracle Developer Tools for Visual Studio is a tightly integrated extension for Microsoft Visual Studio and Oracle Autonomous Database. The extension is free and supports Visual Studio 2019 and Visual Studio 2017 on Microsoft Windows.

- Use Oracle Developer Tools for VS Code
  Oracle Developer Tools for VS Code is a tightly integrated extension for Microsoft Visual Studio Code (VS Code) and Oracle Autonomous Database. The extension is free and is available for Linux, Microsoft Windows, and Apple Mac OS.

Use Oracle Cloud Infrastructure Toolkit for Eclipse

Oracle Cloud Infrastructure Toolkit for Eclipse is a plugin that enables Java developers to easily connect to Oracle Autonomous Database through their IDE. The plugin is free and is available for Linux, UNIX, Microsoft Windows, and Apple Mac OS.

You can use the plugin to perform cloud and database operations right from Eclipse, such as creating Autonomous Databases, stopping and starting, scaling up and down, and so on. You can also use the plugin to easily connect to the databases to browse the schema, access tables, execute SQL statements, and perform other development tasks.

Users with permissions to manage the databases can perform a number of actions, including those listed below. For detailed information about permissions, see Toolkit for Eclipse in the Oracle Cloud Infrastructure documentation. You can:

- Create Autonomous Databases
- Start, stop, terminate, clone, and restore Autonomous Databases
- Scale up and down
- Download the client credentials zip file (database wallet)
- Connect to Autonomous Databases
- Browse the schema
- Choose compartments and regions
- Change the administrator password, and so on

Download the latest version of the plugin from GitHub (`com.oracle.oci.eclipse-`*`version`*`.zip`, where *`version`* is the latest version, for instance `1.2.0`):

`https://github.com/oracle/oci-toolkit-eclipse/releases`

Then follow the installation instructions and details about how to get started in this step-by-step walkthrough:

New Eclipse Plugin for Accessing Autonomous Database (ATP/ADW)

Use Oracle Developer Tools for Visual Studio

Oracle Developer Tools for Visual Studio is a tightly integrated extension for Microsoft Visual Studio and Oracle Autonomous Database. The extension is free and supports Visual Studio 2019 and Visual Studio 2017 on Microsoft Windows.

You can use the extension to perform database management operations right from Visual Studio, such as creating Autonomous Databases, stopping and starting, scaling up and down, and so on. You can also use the extension to easily connect to the databases and perform development tasks, such as browsing your Oracle schema and launching integrated Oracle designers and wizards to create and alter schema objects.

Users with permissions to manage the databases can perform a number of actions, including the following:

- Sign up for Oracle Cloud

- Connect to a cloud account using a simple auto-generated config file and key file
- Create new or clone existing Always Free Autonomous Database, Autonomous Database Dedicated, and Autonomous Database Serverless databases
- Automatically download credentials files (including wallets) and quickly connect, browse, and operate on Autonomous Database schemas
- Change compartments and regions without reconnecting
- Start, stop, or terminate Autonomous Database
- Scale up/down Autonomous Database resources
- Restore from backup
- Update instance credentials
- Rotate wallets
- Convert Always Free Autonomous Database to paid:

> **Note:**
>
> Promotion of Always Free to a paid Autonomous Database is supported only if the database version for the Always Free Autonomous Database is Oracle Database 19c or Oracle Database 23ai.

Download the extension from Visual Studio Marketplace:

- Oracle Developer Tools for Visual Studio 2019
- Oracle Developer Tools for Visual Studio 2017

You'll find lots of information about the extension on those Marketplace pages.

Then follow the installation instructions and details about how to get started in this step-by-step walkthrough:

New Release: Visual Studio Integration with Oracle Autonomous Database

For detailed information about how to use the extension, see the online documentation that's optionally installed with Oracle Developer Tools for Visual Studio. Press the F1 key to display the context-sensitive help for each dialog.

Use Oracle Developer Tools for VS Code

Oracle Developer Tools for VS Code is a tightly integrated extension for Microsoft Visual Studio Code (VS Code) and Oracle Autonomous Database. The extension is free and is available for Linux, Microsoft Windows, and Apple Mac OS.

You can use the extension to connect to Autonomous Databases right from Visual Studio Code and easily explore database schema, view table data, and edit and execute SQL and PL/SQL.

Download the extension from Visual Studio Marketplace:

Oracle Developer Tools for VS Code

Installation instructions and information about how to get started can be found in this quick start guide:

Getting Started Using Oracle Developer Tools for VS Code

Use Oracle Java on Autonomous Database

Autonomous Database supports Oracle JVM. Oracle JVM is a standard, Java-compatible environment that runs any pure Java application.

Oracle JVM is compatible with the standard JLS and the JVM specifications. It supports the standard Java binary format and the standard Java APIs. In addition, Oracle Database adheres to standard Java language semantics, including dynamic class loading at run time.

See About Using Java in Oracle Database for information on Oracle Java.

- Enable Oracle Java
  Use `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` to enable Oracle Java on Autonomous Database.
- Check Oracle Java Version
  You can check the Oracle Java version and the component registry for information on Oracle Java in the Autonomous Database instance.
- Load Java classes and JAR Files into Autonomous Database
  You can use the client-side `loadjava` option to load Java classes and JAR files into Oracle JVM on an Autonomous Database instance.
- Notes for Oracle Java on Autonomous Database
  Provides notes for using Oracle Java on Autonomous Database.

Enable Oracle Java

Use `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` to enable Oracle Java on Autonomous Database.

1. Run `DBMS_CLOUD_ADMIN.ENABLE_FEATURE`.

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
          feature_name => 'JAVAVM' );
   END;
   /
   ```

   This initiates the request to install Oracle Java on the Autonomous Database instance.

   See ENABLE_FEATURE Procedure for more information.

2. Restart the Autonomous Database instance.

   See Restart Autonomous Database for more information.

After you restart the Autonomous Database instance, the Java installation proceeds for some time after the database starts. See Check Oracle Java Version to verify that Oracle JVM is enabled and the installation is complete.

Check Oracle Java Version

You can check the Oracle Java version and the component registry for information on Oracle Java in the Autonomous Database instance.

1. Check the component registry status and version for Oracle Java.

   ```
   SELECT status, version FROM DBA_REGISTRY
      WHERE comp_id = 'JAVAVM';
   ```

```
STATUS VERSION
------ ----------
VALID  19.0.0.0.0
```

If Oracle Java is not installed, this query shows no rows.

If Oracle Java is loading this query shows status `LOADING`. For example:

```
STATUS  VERSION
------- -------
LOADING null
```

2. Check the Oracle Java JDK version.

```
SELECT dbms_java.get_jdk_version FROM DUAL;

GET_JDK_VERSION
---------------
1.8.0_411
```

If Oracle Java is not installed, this query shows an error message.

Load Java classes and JAR Files into Autonomous Database

You can use the client-side `loadjava` option to load Java classes and JAR files into Oracle JVM on an Autonomous Database instance.

The client-side `loadjava` option is supported as follows:

1. The JDK opens the JAR file.
2. The client-side opens a communication channel with the Autonomous Database.
3. The Java code is submitted to the Oracle JVM running on the Autonomous Database for loading.

This process is similar to creating a dynamic Java stored procedure from SQL code, where no file access is involved, but the code gets created.

Note the following:

- The Java code you load cannot invoke any operating system or network calls.
- Use of server-side `loadjava`, that is calls to the procedure `dbms_java.loadjava` is not supported. The procedure `dbms_java.loadjava` accesses the file system of the database server where the Oracle JVM runs. This is not allowed on Autonomous Database and calls to the procedure `dbms_java.loadjava` from within your Java application are not supported.

Notes for Oracle Java on Autonomous Database

Provides notes for using Oracle Java on Autonomous Database.

- You cannot disable Oracle Java after it is enabled on the Autonomous Database instance.
- Autonomous Database performs Oracle Java patching, as required, during the regular Autonomous Database maintenance window.

During Oracle Java patching, Java is not available and users could get an error similar to the following:

```
ERROR at line 1:
ORA-29548: Java system class reported: release of Java system classes in
the
database (19.0.0.0.220118 1.8) does not match that of the oracle executable
(19.0.0.0.220419 1.8).
```

During the maintenance window, when the Java patching phase is active there is no response for Java session calls or you see the `ORA-29548` error. After the maintenance window completes, Java usage is restored.

You can use the events `NewMaintenanceSchedule` and `ScheduledMaintenanceWarning` to be notified of Oracle Java patching. See Information Events on Autonomous Database for more information.

See About Scheduled Maintenance and Patching for more information.

Test Workloads with Oracle Real Application Testing

Oracle Real Application Testing is an extremely cost-effective and easy-to-use proactive performance management solution that enables you to fully assess the outcome of a system change in test or production.

- About Oracle Real Application Testing
  You can use Oracle Real Application Testing to capture a workload on a production system and replay it on a test system with the exact timing, concurrency, and transaction characteristics of the original workload.
- Capture-Replay Workloads between Autonomous Databases
  You can Capture and Replay from an Autonomous Database instance into another Autonomous Database instance.
- Capture-Replay Workloads between non-Autonomous and Autonomous Databases
  You can Capture and Replay from a non-Autonomous Database instance into an Autonomous Database.
- Test Workloads Against an Upcoming Patch
  Using the workload auto replay feature you can automatically capture a workload from a production database that is on the regular patch level and replay the workload on a target refreshable clone that is on the early patch level.

About Oracle Real Application Testing

You can use Oracle Real Application Testing to capture a workload on a production system and replay it on a test system with the exact timing, concurrency, and transaction characteristics of the original workload.

Oracle Real Application Testing provides an accurate method to test the impact of a variety of system changes and enables you to perform the following tasks:

- You can test the effects of a system change on a workload without affecting the production system.
- You can capture a workload on a production system and simulate the same workload on a test system.

You can use Oracle Database Replay to capture a workload from either an Autonomous Database instance or an on-premises database or any other cloud service database, and replay the workload on Autonomous Database. This enables you to compare how a workload runs on an Autonomous Database with another Autonomous Database, an on-premises database, or some other cloud service database.

Real Application Testing enables you to do any of the following Capture-Replay actions:

Capture Replay Option	Description
Capture-Replay Workloads between Autonomous Databases.	See Capture-Replay Workloads between Autonomous Databases for more information.
Capture Workload from Autonomous Database Oracle Database 19c and Replay on Autonomous Database with Oracle Database 23ai	This Capture-Replay allows you to capture a workload on an Autonomous Database with Oracle Database 19c and replay on an Autonomous Database with Oracle Database 23ai. See Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay for more information.
Capture a Workload from a non-Autonomous Database and Replay on Autonomous Database.	See Capture-Replay Workloads between non-Autonomous and Autonomous Databases for more information.
Capture a workload from a production Autonomous Database and replay it on a target Autonomous Database at a different patch level (after a patch is applied to the target Autonomous Database).	See Test Workloads Against an Upcoming Patch for more information.

Capture-Replay Workloads between Autonomous Databases

You can Capture and Replay from an Autonomous Database instance into another Autonomous Database instance.

This enables you to compare workloads across different Autonomous Database instances. These Autonomous Database instances may vary at patch levels, database versions, or regions.

The Capture-Replay workflow between Autonomous Databases consists of the following steps (you either cancel or finish a workload capture, not both):

- (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details
  Subscribe to `com.oraclecloud.databaseservice.autonomous.database.information` Information events to be notified at the start and completion of a capture and replay.
- Capture a Workload on an Autonomous Database Instance
  The first step in using Database Replay is to capture a production workload.
- Cancel a Workload Capture on an Autonomous Database Instance
  Run `DBMS_CLOUD_ADMIN.CANCEL_WORKLOAD_CAPTURE` to cancel the current workload capture on your Autonomous Database instance.
- Finish a Workload Capture on Autonomous Database Instance
  Run `DBMS_CLOUD_ADMIN.FINISH_WORKLOAD_CAPTURE` to complete a workload capture on your Autonomous Database instance.
- Prepare a Refreshable Clone for Workload Replay
  Provides steps to prepare a refreshable clone for a workload replay.

- Replay a Workload on an Autonomous Database Instance
  After you complete a workload capture you can replay it on a test system. Oracle replays the actions recorded during workload capture with the same timing, concurrency, and transaction dependencies of the production system.
- Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay
  You can use Oracle Real Application Testing to capture a workload from Autonomous Database on Oracle Database 19c and replay on a refreshable clone on Oracle Database 23ai.

(Optional) Subscribe to Information Events to be Notified of Capture and Replay Details

Subscribe to `com.oraclecloud.databaseservice.autonomous.database.information` Information events to be notified at the start and completion of a capture and replay.

> **Note:**
>
> This step is optional. You can also find status and historical information for a workload capture in the `DBA_CAPTURE_REPLAY_STATUS` and `DBA_CAPTURE_REPLAY_HISTORY` views.
> See DBA_CAPTURE_REPLAY_STATUS View and DBA_CAPTURE_REPLAY_HISTORY View for more information.

Information events provide notifications about begin and end times of capture and replay and contain a PAR URL to access the capture and replay reports.

Autonomous Database Information events include the following:

- `WorkloadCaptureBegin`: This event is triggered when a workload capture is initiated.
- `WorkloadCaptureEnd`: This event is triggered when a workload capture completes successfully and generates a pre-authenticated (PAR) URL to download the capture file.
- `WorkloadReplayBegin`: This event is triggered when a workload replay is initiated.
- `WorkloadReplayEnd`: This event is triggered when a workload replay completes successfully and generates a pre-authenticated (PAR) URL to download the replay reports.

See Information Events on Autonomous Database for more information.

Capture a Workload on an Autonomous Database Instance

The first step in using Database Replay is to capture a production workload.

> **Note:**
>
> You can capture a workload in an Autonomous Database instance and replay it in another Autonomous Database instance. You can replay the captured workload on a full clone or on a refreshable clone. The capture and replay targets must be in a consistent logical state. So, you must provision a refreshable clone or a full clone of the Autonomous Database instance on which you want to capture the workload.
> See Clone, Move, or Upgrade an Autonomous Database Instance for more information.

When you begin workload capture on a production system, all requests from external clients directed to Oracle Database are tracked and stored in binary files called capture files.

A workload capture results in the creation of two subdirectories, `cap` and `capfiles`, which contain the capture files. The capture files provide all pertinent information about the client request, including transaction details, bind values, and SQL text. These capture files are platform independent and can be transported to another system.

Run `DBMS_CLOUD_ADMIN.START_WORKLOAD_CAPTURE` to initiate workload capture on an Autonomous Database instance.

See Clone, Move, or Upgrade an Autonomous Database Instance for more information.

To initiate a workload capture on your Autonomous Database instance you must be logged in as the `ADMIN` user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

Example to initiate a workload capture:

```
BEGIN
   DBMS_CLOUD_ADMIN.START_WORKLOAD_CAPTURE(
        capture_name => 'test',
        duration     => 60);
   END;
/
```

This starts the workload capture on your Autonomous Database instance.

The parameters are:

- `capture_name`: is the name of the workload capture.
- `duration`: is the duration (in minutes) for which you need to capture the workload. This parameter is optional.

See START_WORKLOAD_CAPTURE Procedure for more information.

Workload Capture Events

You can subscribe to the Information event `com.oraclecloud.databaseservice.autonomous.database.information` to be notified at the start of `START_WORKLOAD_CAPTURE`. See (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details for more information.

Workload Capture and Replay Views

You can find information about workload capture and replay in the `DBA_CAPTURE_REPLAY_STATUS` and `DBA_CAPTURE_REPLAY_HISTORY` views. See DBA_CAPTURE_REPLAY_STATUS View and DBA_CAPTURE_REPLAY_HISTORY View for more information.

Cancel a Workload Capture on an Autonomous Database Instance

Run `DBMS_CLOUD_ADMIN.CANCEL_WORKLOAD_CAPTURE` to cancel the current workload capture on your Autonomous Database instance.

To cancel a workload capture, you must be logged in as the `ADMIN` user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

Example:

```
BEGIN
    DBMS_CLOUD_ADMIN.CANCEL_WORKLOAD_CAPTURE;
END;
/
```

This cancels the current workload capture and performs a refresh on the refreshable clone.

You can query the `DBA_CAPTURE_REPLAY_STATUS` view to check the cancel workload status.

See DBA_CAPTURE_REPLAY_STATUS View for more information.

See CANCEL_WORKLOAD_CAPTURE Procedure for more information.

Finish a Workload Capture on Autonomous Database Instance

Run `DBMS_CLOUD_ADMIN.FINISH_WORKLOAD_CAPTURE` to complete a workload capture on your Autonomous Database instance.

Example to finish a workload capture on your Autonomous Database instance:

```
BEGIN
    DBMS_CLOUD_ADMIN.FINISH_WORKLOAD_CAPTURE;
END;
/
```

To run this procedure you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`. When you run this procedure a workload capture file is uploaded to Object Store as a zip file.

See FINISH_WORKLOAD_CAPTURE Procedure for more information.

Workload Capture Events

You can subscribe to the Information event `com.oraclecloud.databaseservice.autonomous.database.information` to be notified about a workload capture, that includes:

- The completion of `FINISH_WORKLOAD_CAPTURE`.
- The `captureDownloadURL` field that contains the PAR URL to access the capture and reports in Object Store. The capture and reports are valid for seven (7) days from the date when the PAR URL is generated.

See (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details for more information.

Workload Capture and Replay Views

You can query the `DBA_CAPTURE_REPLAY_STATUS` view to check the status of a completed workload capture. See DBA_CAPTURE_REPLAY_STATUS View for more information.

You can find information about workload capture and replay in the `DBA_CAPTURE_REPLAY_HISTORY` view. See DBA_CAPTURE_REPLAY_HISTORY View for more information.

You can query the `ID`, `NAME`, `START_TIME`, and `END_TIME` columns of the `DBA_WORKLOAD_CAPTURES` view to retrieve the details of your workload capture. See DBA_WORKLOAD_CAPTURES for more information.

Prepare a Refreshable Clone for Workload Replay

Provides steps to prepare a refreshable clone for a workload replay.

> **Note:**
>
> This step is not applicable when you are replaying a workload on a full clone.

You have two options to prepare a refreshable clone to replay a workload capture. You can run `DBMS_CLOUD_ADMIN.PREPARE_REPLAY` to automatically prepare a refreshable clone for a workload replay. This procedure refreshes the refreshable clone to the start time of the capture and disconnects the refreshable clone. You also have the option to manually prepare a refreshable clone to replay a workload capture.

Automatically Prepare a Refreshable Clone for Workload Replay

Example to automatically prepare a refreshable clone for a workload replay:

```
BEGIN
 DBMS_CLOUD_ADMIN.PREPARE_REPLAY (
    capture_name    'test'
END;
/
```

To run this procedure you must be logged in as the `ADMIN` user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

`DBMS_CLOUD_ADMIN.PREPARE_REPLAY` does the following:

- Refreshes the refreshable clone to the capture start timestamp.
- Disconnects the refreshable clone.

Optionally, at this point before you replay a capture, you can make changes to the a refreshable clone. For example, changing parameter values and turning certain features on/off to see the impact on the replay.

Manually Prepare a Refreshable Clone for Workload Replay

These manual refreshable clone steps are not required when you automatically prepare a refreshable clone by running `DBMS_CLOUD_ADMIN.PREPARE_REPLAY`.

Perform the following steps to manually prepare for a workload replay:

1. Find the capture start timestamp by querying the `DBA_WORKLOAD_CAPTURES` view. See DBA_WORKLOAD_CAPTURES for more information.
2. Refresh the refreshable clone to the capture start timestamp. See Refresh a Refreshable Clone on Autonomous Database for more information.
3. Manually disconnect the refreshable clone. See Disconnect a Refreshable Clone from the Source Database for more information.

4. Optionally, before you replay a capture, you can make changes to the refreshable clone. For example, changing parameter values, turning certain features on/off to see the impact on the replay.

Replay a Workload on an Autonomous Database Instance

After you complete a workload capture you can replay it on a test system. Oracle replays the actions recorded during workload capture with the same timing, concurrency, and transaction dependencies of the production system.

Run the procedure `DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD` to initiate workload replay on your database. You must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN` to run `DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD`.

You can replay a captured workload on a refreshable clone or on a full clone of the Autonomous Database instance from which the workload was captured. The capture and replay targets must be in a consistent logical state.

Replay Workload On a Refreshable Clone

The following example downloads the capture files from Object Storage, replays the captured workload, and uploads a replay report to Object Storage.

```
BEGIN
  DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD(
      capture_name => 'CAP_TEST1');
END;
/
```

The `CAPTURE_NAME` parameter specifies the name of the workload capture. This parameter is mandatory.

Replay Workload On a Full Clone

This following example downloads capture files from the Object Storage, replays the captured workload on the clone, and uploads a replay report to Object Storage.

```
BEGIN
  DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD(
       capture_name                => 'CAP_TEST1',
       capture_source_tenancy_ocid => 'OCID1.TENANCY.REGION1..ID1',
       capture_source_db_name      => 'ADWFINANCE');
END;
/
```

> **Note:**
>
> If there are multiple captures with the same capture name, the `REPLAY_WORKLOAD` procedure uses the latest capture. Oracle recommends that you use a unique capture name for each capture to prevent confusion on which capture you are replaying.

The `CAPTURE_NAME` parameter specifies the name of the workload capture. This parameter is mandatory.

The `CAPTURE_SOURCE_TENANCY_OCID` parameter specifies the source tenancy OCID of the workload capture. This parameter is mandatory when running the workload capture in a full clone.

The `CAPTURE_SOURCE_DB_NAME` parameter specifies the source database name of the workload capture. This parameter is mandatory when running the workload capture in a full clone.

See REPLAY_WORKLOAD Procedure for more information.

Workload Replay Events

Subscribe to the Information event `com.oraclecloud.databaseservice.autonomous.database.information` to be notified about the following

- The start and completion of a `REPLAY_WORKLOAD`.
- The Object Store link to download replay reports. The event provides a PAR URL to access the reports in the `replayDownloadURL` field. The reports are valid for seven (7) days from the date when the PAR URL is generated.

See Information Events on Autonomous Database for more information.

Workload Capture and Replay Views

You can query the `DBA_CAPTURE_REPLAY_STATUS` view to check the workload replay status.

See DBA_CAPTURE_REPLAY_STATUS View for more information.

You can find information about workload capture and replay in the `DBA_CAPTURE_REPLAY_HISTORY` view. See DBA_CAPTURE_REPLAY_HISTORY View for more information.

Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay

You can use Oracle Real Application Testing to capture a workload from Autonomous Database on Oracle Database 19c and replay on a refreshable clone on Oracle Database 23ai.

This Capture-Replay option is especially useful when you want test your workloads running on Oracle Database 19c before you upgrade to Oracle Database 23ai.

Follow these steps to replay your workloads on a different database version:

1. (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details
2. Capture your workloads on an Autonomous Database with Oracle Database 19c. See Capture a Workload on an Autonomous Database Instance for more information.
3. Run `DBMS_CLOUD_ADMIN.FINISH_WORKLOAD_CAPTURE` to complete the workload capture on your Oracle Database 19c sourceAutonomous Database instance.
4. Prepare your target Oracle Database 23ai Refreshable Clone. See Prepare a Refreshable Clone for Workload Replay for more information.
5. After you complete the workload capture and prepare the Oracle Database 23ai target Refreshable Clone, replay the workload on the target. See Replay a Workload on an Autonomous Database Instance for more information.

Capture-Replay Workloads between non-Autonomous and Autonomous Databases

You can Capture and Replay from a non-Autonomous Database instance into an Autonomous Database.

This enables you to compare workloads between an on-prem database or other cloud service database and an Autonomous Database instance.

Topics

- Capture a Workload
  The first step in using Database Replay is to capture the production workload.
- Replay a Workload on an Autonomous Database Instance
  After you complete a workload capture, you can replay it on a test system. Oracle replays on the test system the actions recorded during workload capture, with the same timing , concurrency, and transaction dependencies of the production system.

Capture a Workload

The first step in using Database Replay is to capture the production workload.

When you begin workload capture on the production system, all requests from external clients directed to Oracle Database are tracked and stored in binary files called capture files.

A workload capture results in the creation of two subdirectories, `cap` and `capfiles`, which contain the capture files.

The capture files provide all pertinent information about the client request, including transaction details, bind values, and SQL text.

These capture files are platform independent and can be transported to another system.

See Workload Capture to capture a workload on an on-premises database.

Replay a Workload on an Autonomous Database Instance

After you complete a workload capture, you can replay it on a test system. Oracle replays on the test system the actions recorded during workload capture, with the same timing , concurrency, and transaction dependencies of the production system.

Run `DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD` to initiate workload replay on your database. You must be logged in as the `ADMIN` user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN` to run `REPLAY_WORKLOAD`.

Example to replay on an Autonomous Database instance a workload captured from an on-premises database:

```
BEGIN
   DBMS_CLOUD_ADMIN.REPLAY_WORKLOAD(
      location_uri    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
      credential_name => 'CRED_TEST',
      synchronization => TRUE,
      process_capture => TRUE);
END;
/
```

This downloads the capture files contained in the Object Storage location specified in the `location_uri` parameter, and replays the workload capture from the capture files. The replay generates and uploads the replay and Automatic Workload Repository reports to the Object Storage location specified in the `location_uri` parameter.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

See Upload Files to Your Oracle Cloud Infrastructure Object Store Bucket for more information on uploading files to Object Storage.

See Navigate to Oracle Cloud Infrastructure Object Storage and Create Bucket for more information on Object Storage.

The `credential_name` parameter specifies the credential to access the object storage bucket. The credential that you supply must have the write privileges to write into the Object Storage bucket. The write privileges are required to upload the replay report to the bucket.

If you do not specify a `credential_name` value, then `DEFAULT_CREDENTIAL` is used.

You don't need to create a credential to access Oracle Cloud Infrastructure Object Store if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

The `synchronization` parameter specifies the synchronization method used during workload replay. A `TRUE` value indicates that the synchronization is SCN based.

The `process_capture` specifies whether you need to specify `process_capture` value or not. A `TRUE` value indicates that the replay includes `process_capture`.

> **Note:**
>
> You must maintain the same logical state of the capture and replay databases at the start of the capture time.

See REPLAY_WORKLOAD Procedure for more information.

Workload Replay Events

You can subscribe to the Information event `com.oraclecloud.databaseservice.autonomous.database.information` to be notified about the `WorkloadReplayBegin` and `WorkloadReplayEnd` events. These events provide information about:

- Start and completion of the `REPLAY_WORKLOAD`.
- The `replayDownloadURL` field that contains the PAR URL to access the reports in Object Store. The PAR URL is valid for 7 days from the date of generation.

See Information Events on Autonomous Database for more information.

Workload Capture and Replay Views

You can query the `DBA_CAPTURE_REPLAY_STATUS` and `DBA_CAPTURE_REPLAY_HISTORY` views to check the workload replay status.

See DBA_CAPTURE_REPLAY_STATUS View and DBA_CAPTURE_REPLAY_HISTORY View for more information.

Test Workloads Against an Upcoming Patch

Using the workload auto replay feature you can automatically capture a workload from a production database that is on the regular patch level and replay the workload on a target refreshable clone that is on the early patch level.

This feature allows you to test an upcoming patch by running an existing workload that is in production against a patch, before the patch reaches production.

- About Testing Workloads Against an Upcoming Patch
  Using the workload auto replay feature you can automate the process of capture-replay to capture a workload that runs on a production database and automatically replay the workload on a target refreshable clone after an upcoming patch is applied on the target.
- Enable Workload Auto Replay
  The `WORKLOAD_AUTO_REPLAY` feature allows you run a workload from your production database and monitor for any divergence on an instance that is patched one week in advance. This feature allows you to test an upcoming patch by running an existing workload that is in production against a patch before the patch reaches production.
- Disable Workload Auto Replay
  Run `DBMS_CLOUD_ADMIN.DISABLE_FEATURE` to disable `WORKLOAD_AUTO_REPLAY`.

About Testing Workloads Against an Upcoming Patch

Using the workload auto replay feature you can automate the process of capture-replay to capture a workload that runs on a production database and automatically replay the workload on a target refreshable clone after an upcoming patch is applied on the target.

Autonomous Database provides the ability to provision an instance or create a refreshable clone with the **Early** patch level option. On instances running at the **Early** patch level, Autonomous Database applies upcoming maintenance patches a week before the patches are applied to production databases (databases that are provisioned at the **Regular** patch level). Using the `WORKLOAD_AUTO_REPLAY` feature you can assure that an upcoming patch is tested against your workload before the patch goes to production. This allows you to verify that the patch either fixes a known issue or does not introduce an issue that affects your workload.

To find information about captures and replays, subscribe to Information events. Information events provide notification for workload capture and reply events and include a PAR URL where you can download the capture file and replay report. See (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details for more information.

When `WORKLOAD_AUTO_REPLAY` is enabled the source database captures a workload by running for a specified number of minutes. By default the workload capture starts when you enable `WORKLOAD_AUTO_REPLAY` (optionally you can use parameters to set the capture start day and time). Next, Autonomous Database checks the target database to verify the patching status. After the upcoming weekly patch is applied, Autonomous Database replays the workload on the target database. This capture-replay cycle continues automatically each week with Autonomous Database capturing the workload on the source database, waiting for the upcoming patch to be applied, and replaying the workload on the refreshable clone.

Note the following for enabling `WORKLOAD_AUTO_REPLAY`:

- The source database must use the **Regular** patch level.
- The target database must use the **Early** patch level.

- The target database must be a refreshable clone of the source database, and must be created before you enable `WORKLOAD_AUTO_REPLAY`.
- A source database can enable `WORKLOAD_AUTO_REPLAY` for no more than one refreshable clone (you can enable this feature for a maximum of one refreshable clone, even if you create multiple refreshable clones from the same source database).
- After you enable `WORKLOAD_AUTO_REPLAY`, the capture-replay cycle continues every week. Autonomous Database runs a capture on the source database and then replays the workload on the target database, until you disable `WORKLOAD_AUTO_REPLAY`.

You can find information about workload captures and replays in the `DBA_CAPTURE_REPLAY_HISTORY` view. See DBA_CAPTURE_REPLAY_HISTORY View for more information.

Autonomous Database automatically applies patches on your database. Oracle provides a service level objective of zero regressions in your production database due to these patches. See Zero-Regression Service Level Objective for more information.

Enable Workload Auto Replay

The `WORKLOAD_AUTO_REPLAY` feature allows you run a workload from your production database and monitor for any divergence on an instance that is patched one week in advance. This feature allows you to test an upcoming patch by running an existing workload that is in production against a patch before the patch reaches production.

To enable `WORKLOAD_AUTO_REPLAY`:

1. Create a refreshable clone of the production database.

   When you create the target refreshable clone, set the patch level to **Early**.

   See Set the Patch Level and Create a Refreshable Clone for an Autonomous Database Instance for more information.

2. Run `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` on the source database.

   For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
        feature_name => 'WORKLOAD_AUTO_REPLAY',
        params       => JSON_OBJECT(
                          'target_db_ocid' VALUE
'OCID1.autonomousdatabase.REGION..ID1',
                          'capture_duration' VALUE 120,
                          'capture_day' VALUE 'MONDAY',
                          'capture_time' VALUE '15:00'));
END;
/
```

   Where the parameters are:

   - `feature_name`: the value `WORKLOAD_AUTO_REPLAY` enables the workload auto replay feature.
   - `params`: is a JSON Object with the following value pairs:
     - `target_db_ocid`: accepts a `string` value. The value specifies the OCID of the target refreshable clone database on which the captured workload is replayed.

This parameter is mandatory.

- `capture_duration`: accepts a `number` value. The value specifies the duration in minutes for which the workload is captured on the production database. The value must be in the range between 1 and 720 minutes.

  This parameter is mandatory.

- `capture_day`: accepts a `string` value. The value specifies the day of the week the workload capture on the production database should begin.

  This parameter is optional.

- `capture_time`: accepts a value in the `HH24:MM` format. The value specifies the time of the day the workload capture on the production database should begin.

  This parameter is optional.

By default the workload capture starts when you enable `WORKLOAD_AUTO_REPLAY`. When the optional `capture_day` and `capture_time` are specified, the automatic workload capture and replay happen at the specified timestamp.

For example if `capture_day` is Monday and `capture_time` is 15:00, the first capture on the production database starts at 3PM on the next Monday. The same day of week and time are also used to schedule subsequent captures and replays.

See ENABLE_FEATURE Procedure for more information.

A an error value of `ORA-20000: Invalid argument for target_db_ocid` could indicate that the OCID you supplied is not a refreshable clone. In this case, you need to supply an OCID with a value for a refreshable clone.

3. Query the `DBA_CAPTURE_REPLAY_STATUS` view to check the workload replay status.

   See Replay a Workload on an Autonomous Database Instance and DBA_CAPTURE_REPLAY_STATUS View for more information.

This example enables `WORKLOAD_AUTO_REPLAY` on the source Autonomous Database and on the specified target refreshable clone database. With `WORKLOAD_AUTO_REPLAY` enabled, every week Autonomous Database runs a capture on the source database and replays the workload on the target database, until you disable `WORKLOAD_AUTO_REPLAY`.

To find information about captures and replays, subscribe to Information events. Information events provide notification for workload capture and reply events and include a PAR URL where you can download the capture file and replay report. See (Optional) Subscribe to Information Events to be Notified of Capture and Replay Details for more information.

You can find information about workload captures and replays in the `DBA_CAPTURE_REPLAY_HISTORY` view. See DBA_CAPTURE_REPLAY_HISTORY View for more information.

Disable Workload Auto Replay

Run `DBMS_CLOUD_ADMIN.DISABLE_FEATURE` to disable `WORKLOAD_AUTO_REPLAY`.

Run `DBMS_CLOUD_ADMIN.DISABLE_FEATURE` to disable workload auto replay. For example:

```
BEGIN
DBMS_CLOUD_ADMIN.DISABLE_FEATURE(
    feature_name => 'WORKLOAD_AUTO_REPLAY');
END;
/
```

You must be logged in as ADMIN or have DBMS_CLOUD_ADMIN privileges to run DBMS_CLOUD_ADMIN.DISABLE_FEATURE.

See DISABLE_FEATURE Procedure for more information.

Manage and Store Files in a Cloud Code Repository with Autonomous Database

Autonomous Database provides routines to manage and store files in Cloud Code (Git) Repositories. The supported Cloud Code Repositories are: GitHub, AWS CodeCommit, and Azure Repos.

- About Cloud Code Repositories with Autonomous Database
  The DBMS_CLOUD_REPO package provides a single interface for accessing a Cloud Code Repository from Autonomous Database.
- Initialize a Cloud Code Repository
  The DBMS_CLOUD_REPO initialization routines initialize a Cloud Code Repository. After you obtain a Cloud Code Repository handle, you use the handle to access the Cloud Code Repository.
- Create and Manage a Cloud Code Repository
  The DBMS_CLOUD_REPO management routines allow you to manage a Cloud Code Repository by creating, listing, updating, or deleting a repository.
- Create and Manage Branches in a Cloud Code Repository
  The DBMS_CLOUD_REPO management routines allow you to manage Cloud Code Repository branches by creating, listing, merging, or deleting branches in a repository.
- Export Schema Objects to the Cloud Code Repository Branch
  The DBMS_CLOUD_REPO management routine allows you to export metadata of the objects in a schema to the Cloud Code Repository branch. You can filter your list based on the object names or object types.
- Use File Operations with a Cloud Code Repository
  The DBMS_CLOUD_REPO file operations allow you to create, get, list, update, or delete files in a Cloud Code Repository.
- Use SQL Install Operations with a Cloud Code Repository
  The DBMS_CLOUD_REPO SQL Install operations allow you to store and download SQL scripts from a Cloud Code Repository.

About Cloud Code Repositories with Autonomous Database

The DBMS_CLOUD_REPO package provides a single interface for accessing a Cloud Code Repository from Autonomous Database.

The supported Cloud Code Repositories provide the following features:

- Git Version Control System: Git is software for tracking changes in any set of files, usually used for coordinating work among programmers collaboratively developing source code during software development. Its goals include speed, data integrity, and support for distributed, non-linear workflows.
- Git Repository: A Git repository is a virtual storage of your project. It allows you to save versions of your code, which you can access when needed.

The DBMS_CLOUD_REPO APIs use a repository handle (REPO object). The repository handle is an opaque JSON object that represents a Cloud Code Repository of a specific cloud provider. A

REPO object can be passed to different DBMS_CLOUD_REPO APIs. This opaque object ensures that DBMS_CLOUD_REPO procedures and functions are multicloud compatible; you do not have to change your code when you migrate from one Cloud Code Repository provider to another Cloud Code Repository.

Autonomous Database provides the following to help you work with Cloud Code Repositories:

- Repository initialization operations to allow you to initialize a repository.

  See Initialize a Cloud Code Repository for more information.
- Repository management operations that let you create, list, update or delete a repository.

  See Create and Manage a Cloud Code Repository for more information.
- Repository branch management operations that let you create, list, merge or delete branches in a repository.

  See Create and Manage Branches in a Cloud Code Repository for more information.
- Export the metadata DDL of all objects in a schema to a repository.

  See Export Schema Objects to the Cloud Code Repository Branch for more information.
- Repository file management operations to upload, download, update, and delete files.

  See Use File Operations with a Cloud Code Repository for more information.
- SQL install operations that let you export database object metadata DDL to a repository and install SQL statements into the database from a Cloud Code Repository.

  See Use SQL Install Operations with a Cloud Code Repository for more information.

Initialize a Cloud Code Repository

The DBMS_CLOUD_REPO initialization routines initialize a Cloud Code Repository. After you obtain a Cloud Code Repository handle, you use the handle to access the Cloud Code Repository.

To initialize a Cloud Code Repository:

1. Create a credential to access the Cloud Code Repository.

   See CREATE_CREDENTIAL Procedure for information on creating credentials.
2. Depending on the repository, GitHub, Azure Repos, or AWS CodeCommit, call DBMS_CLOUD_REPO.INIT_REPO with the parameters for the particular repository to obtain a repository handle.

   The following examples provide samples for each supported Cloud Code Repository.

   - **GitHub Initialization:**

```
DEFINE repo_name='test_repo';
DEFINE cred_name='GITHUB_CRED';
VAR repo clob
BEGIN
  :repo := DBMS_CLOUD_REPO.INIT_REPO(
               params => JSON_OBJECT('provider' value 'github',
                                     'repo_name' value '&repo_name',
                                     'credential_name' value
'&cred_name',
                                     'owner'           value
'<myuser>')
          );
```

```
END;
/
```

- **Azure Repos Initialization:**

```
DEFINE repo_name='test_repo';
DEFINE cred_name='AZURE_REPO_CRED';
VAR repo clob
BEGIN
  :repo := DBMS_CLOUD_REPO.INIT_REPO(
               params => JSON_OBJECT('provider' value 'azure',
                                     'repo_name' value '&repo_name',
                                     'credential_name' value
'&cred_name',
                                     'organization' value '<myorg>',
                                     'project' value '<myproject>')
          );
END;
/
```

- **AWS CodeCommit Initialization:**

```
DEFINE repo_name='test_repo';
DEFINE cred_name='AWS_REPO_CRED';
VAR repo clob
BEGIN
  :repo := DBMS_CLOUD_REPO.INIT_REPO(
               params => JSON_OBJECT('provider' value 'aws',
                                     'repo_name' value '&repo_name',
                                     'credential_name' value
'&cred_name',
                                     'region' value 'us-east-1')
          );
END;
/
```

See DBMS_CLOUD_REPO Initialization Operations for details on the initialization functions.

Create and Manage a Cloud Code Repository

The `DBMS_CLOUD_REPO` management routines allow you to manage a Cloud Code Repository by creating, listing, updating, or deleting a repository.

First, obtain a Cloud Code Repository handle to provide access a repository. See Initialize a Cloud Code Repository for details.

1. To create a repository:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.CREATE_REPOSITORY(
        repo => :repo,
        description => 'test repo'
  );
```

```
END;
/
```

2. To update a repository:

```
VAR repo clob
DEFINE repo_name='test_repo';
BEGIN
  DBMS_CLOUD_REPO.UPDATE_REPOSITORY(
        repo => :repo,
        new_name => '&repo_name' || '_new'
  );
END;
/
```

3. To list repositories:

```
col id format a30
col name format a10
col description format a15
select id, name, bytes, private, description from
  DBMS_CLOUD_REPO.LIST_REPOSITORIES(:repo);
```

4. To delete a repository:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.DELETE_REPOSITORY(
        repo => :repo
  );
END;
/
```

See DBMS_CLOUD_REPO Repository Management Operations for more information.

Create and Manage Branches in a Cloud Code Repository

The `DBMS_CLOUD_REPO` management routines allow you to manage Cloud Code Repository branches by creating, listing, merging, or deleting branches in a repository.

To perform Cloud Code Repository branch management operations you must first:

- Create a credential.

  See CREATE_CREDENTIAL Procedure for details.
- Obtain a handle.

  See Initialize a Cloud Code Repository for details.
- Create a repository.

  See Create and Manage a Cloud Code Repository for details.
- Log in as the ADMIN user or have `EXECUTE` privilege on `DBMS_CLOUD_REPO`.

1. To create a branch in a Cloud Code Repository:

```
BEGIN
  DBMS_CLOUD_REPO.CREATE_BRANCH (
    repo            => l_repo,
    branch_name     => 'test_branch',
    parent_branch   => 'main'
    );
END;
/
```

2. To delete a branch in a Cloud Code Repository:

```
BEGIN
  DBMS_CLOUD_REPO.DELETE_BRANCH (
      repo        => l_repo,
      branch_name => 'test_branch'
  );
END;
/
```

3. To merge a branch into another branch in a Cloud Code Repository:

```
BEGIN
  DBMS_CLOUD_REPO.MERGE_BRANCH (
    repo               => l_repo,
    branch_name        => 'test_branch',
    target_branch_name => 'main'
    );
END;
/
```

4. To list branches in a Cloud Code Repository:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_BRANCHES (repo => l_repo);
```

5. You can list commits in a branch in Cloud Code Repository based on the following;
   - Repository
   - Branch
   - The file path of the branch
   - SHA/commit_id

> **Note:**
>
> SHA is a checksum 40-character string composed of hexadecimal characters (0–9 and a–f).

To list commits based on the repository:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_COMMITS (
    repo => :repo);
```

To list commits based on the repository, commit_id and file path of the branch:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_COMMITS (
    repo        => l_repo,
    commit_id   => '66dd2b23b74cd0afabd11af66c6aa9c550540ba6',
    file_path   => 'sub_dir/test11.sql'
```

To list commits based on the repository, and file path of the branch:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_COMMITS (
    repo        => :repo,
    branch_name => 'branch1');
```

To list commits based on the repository, branch_name and file path of the branch:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_COMMITS (
    repo         => :repo,
    branch_name  => 'branch1',
    file_path    => 'sub_dir/test11.sql');
```

To list commits based on the repository and commit_id of the branch:

```
SELECT * FROM DBMS_CLOUD_REPO.LIST_COMMITS (
    repo => :repo,
    commit_id =>'66dd2b23b74cd0afabd11af66c6aa9c550540ba6');
```

See DBMS_CLOUD_REPO Repository Branch Management Operations for more information.

Export Schema Objects to the Cloud Code Repository Branch

The `DBMS_CLOUD_REPO` management routine allows you to export metadata of the objects in a schema to the Cloud Code Repository branch. You can filter your list based on the object names or object types.

To export schema metadata you must first:

- Create a credential.

  See CREATE_CREDENTIAL Procedure for details.
- Obtain a handle.

  See Initialize a Cloud Code Repository for details.
- Create a repository.

  See Create and Manage a Cloud Code Repository for details.
- Log in as the ADMIN user or have `EXECUTE` privilege on `DBMS_CLOUD_REPO`.

Use the `EXPORT_SCHEMA` procedure to export metadata of the objects in your schema to a Cloud Code Repository branch:

```
BEGIN
  DBMS_CLOUD_REPO.EXPORT_SCHEMA(
    repo          => l_repo,
    schema_name   => 'USER1',
    file_path     => 'myschema_ddl.sql'
    filter_list   =>
        to_clob('[
             { "match_type":"equal",
                 "type":"table"
             },
             { "match_type":"not_equal",
                 "type":"view"
             },
             { "match_type":"in",
                 "type":"table",
                 "name": " ''EMPLOYEE_SALARY'',''EMPLOYEE_ADDRESS'' "
             },
             { "match_type":"equal",
                 "type":"sequence",
                 "name": "EMPLOYEE_RECORD_SEQ"
             },
             { "match_type":"like",
                 "type":"table",
                 "name": "%OFFICE%"
             }
        ]'
     );
  );
END;
/
```

This example exports the metadata of the `USER1` schema into the `l_repo` repository. The export includes the metadata of the tables `EMPLOYEE_SALARY` and `EMPLOYEE_ADDRESS`, and any table name that contains `OFFICE`. It also exports the `EMPLOYEE_RECORD_SEQ` sequence and excludes the views in the schema.

See EXPORT_SCHEMA Procedure for more information.

Use File Operations with a Cloud Code Repository

The `DBMS_CLOUD_REPO` file operations allow you to create, get, list, update, or delete files in a Cloud Code Repository.

Obtain a Cloud Code Repository handle before using the file operations. See Initialize a Cloud Code Repository for details.

You also need to create a repository before you work with files. See Create and Manage a Cloud Code Repository for details.

1. To get a file:

```
SELECT DBMS_CLOUD_REPO.GET_FILE(repo => :repo, file_path => 'test1.sql')
```

2. To create a file:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.PUT_FILE(
        repo => :repo,
        file_path => 'test1.sql',
        contents => UTL_RAW.cast_to_raw('create table t1 (x varchar2(30))'
|| CHR(10) || '/')
  );
END;
/
```

3. To update a file:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.PUT_FILE(
        repo => :repo,
        file_path => 'test1.sql',
        contents => UTL_RAW.cast_to_raw('create table t2 (x varchar2(30))'
|| CHR(10) || '/')
  );
END;
/
```

4. To list files:

```
SELECT id, name, bytes, url FROM DBMS_CLOUD_REPO.LIST_FILES(repo => :repo);
```

5. To delete a file:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.DELETE_FILE(
        repo => :repo,
        file_path => 'test1.sql'
  );
END;
/
```

See DBMS_CLOUD_REPO File Operations for more information.

Use SQL Install Operations with a Cloud Code Repository

The `DBMS_CLOUD_REPO` SQL Install operations allow you to store and download SQL scripts from a Cloud Code Repository.

Obtain a Cloud Code Repository handle before using the SQL Install operations. See Initialize a Cloud Code Repository for details.

You also need to create a repository before you work with SQL Install operations. See Create and Manage a Cloud Code Repository for details.

The scripts are intended as schema install scripts and not as generic SQL scripts:

- Scripts cannot contain SQL*Plus client specific commands.
- Scripts cannot contain bind variables or parameterized scripts.
- SQL statements must be terminated with a slash on a new line (/).
- Scripts can contain DDL, DML PLSQL statements, but direct `SELECT` statements are not supported. Using SELECT within a PL/SQL block is supported.

Any SQL statement that can be run using `EXECUTE IMMEDIATE` will work if it does not contain bind variables or defines.

1. To upload DDL metadata to a Cloud Code Repository:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.EXPORT_OBJECT(
        repo => :repo,
        object_type => 'PACKAGE',
        object_name => 'MYPACK',
        file_path   => 'mypack.sql'
  );
END;
/
```

2. To install SQL statements from a file:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.INSTALL_FILE(
        repo => :repo,
        file_path     => 'test3.sql',
        stop_on_error => FALSE
  );
END;
/
```

3. To install SQL statements from a buffer:

```
VAR repo clob
BEGIN
  DBMS_CLOUD_REPO.INSTALL_SQL(
        repo => :repo,
        content   => 'create table t1 (x varchar2(30))' || CHR(10) || '/',
        stop_on_error => FALSE
  );
END;
/
```

See DBMS_CLOUD_REPO SQL Install Operations for more information.

Invoke User Defined Functions

You can invoke external functions such as OCI, AWS Lambda, Google Cloud Run functions and Azure remote functions in your Autonomous Database as SQL functions.

- About User Defined Functions
  User defined functions enable you to invoke externally available functions from PL/SQL or SQL code within your database.
- Steps to Invoke OCI Cloud Functions as SQL Functions
  Shows the steps to invoke OCI remote functions as SQL functions in your database.
- Steps to Invoke AWS Lambda as SQL Functions
  Shows the steps to invoke AWS remote functions as SQL functions in your database.
- Steps to Invoke Azure Functions as SQL Functions
  Shows the steps to invoke Azure remote functions as SQL functions in your database using HTTP trigger.
- Steps to Invoke Google Cloud Run Functions as SQL Functions
  Shows the steps to invoke Google Cloud Run functions as SQL functions in your database.
- Invoke External Procedures as SQL Functions
  Shows the steps to invoke external procedures using PL/SQL within your database.

About User Defined Functions

User defined functions enable you to invoke externally available functions from PL/SQL or SQL code within your database.

You can invoke the following external functions using user defined functions:

- **Oracle Cloud Infrastructure Functions**: Oracle Cloud Infrastructure Functions are fully managed, multi-tenant, highly scalable, on-demand, Functions-as-a-Service platform. Oracle Cloud Infrastructure Functions are built on enterprise-grade Oracle Cloud Infrastructure and powered by the Fn Project open-source engine. Use Oracle Cloud Infrastructure Functions also referred to as OCI Functions, to focus on developing code to meet the business requirements.

  See Overview of Functions for more information.
- **AWS Lambda**: AWS Lambda is a serverless, event-driven compute service that lets you run code for virtually any application or backend service without provisioning or managing servers.

  See AWS Lambda for more information.
- **Azure Function**: Azure Function is a serverless compute service that enables users to run event-triggered code without provisioning or managing infrastructure.

  See Azure Functions overview and Create your first function in the Azure portal for more information.
- **External Procedures**: External procedures are functions written in a third-generation language (C, for example) and callable from within PL/SQL or SQL as if they were a PL/SQL routine or function.

  See What Is an External Procedure? for more information.
- **Google Cloud Run Function**: Google Cloud Run function is a serverless compute service that enables user to run event-triggered code without having to provision or manage infrastructure.

See Google Cloud Run functions for more information.

Steps to Invoke OCI Cloud Functions as SQL Functions

Shows the steps to invoke OCI remote functions as SQL functions in your database.

To invoke cloud functions in OCI as SQL functions, we will be creating a catalog of SQL wrapper functions that reference and call their respective cloud function via their API endpoints. Before you create this catalog, it is assumed here that you have created the necessary cloud functions to be referenced by this catalog.

See Creating and Deploying Functions for more information on the creation and deployment of Oracle Cloud Infrastructure Functions and Application (ie a group of OCI Functions).

1. Create credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. The credential object that you are creating must be of type private key.

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'OCI_CRED',
       user_ocid       => 'user_ocid',
       tenancy_ocid    => 'tenancy_ocid',
       private_key     => 'private_key',
       fingerprint     => 'fingerprint'
  );
END;
/

PL/SQL procedure successfully completed.
```

   This creates the `OCI_CRED` credential.

   See CREATE_CREDENTIAL Procedure for more information.

   > **Note:**
   >
   > If you are using a Resource Principal for authentication, the necessary policies required for OCI Function access must be configured. See Details for Functions for more information.

2. Create a catalog.

   A catalog is a collection of wrapper functions that reference and call their respective cloud functions via their API endpoints.

   Example to create a catalog for Oracle Cloud Infrastructure Functions.

```
BEGIN
DBMS_CLOUD_FUNCTION.CREATE_CATALOG (
    credential_name  => 'OCI_CRED',
    catalog_name     => 'OCI_DEMO_CATALOG',
    service_provider => 'OCI',
    cloud_params     => '{"region_id":"phx",
      "compartment_id":"compartment_id"}'
);
```

```
END;
/

PL/SQL procedure successfully completed.
```

This creates the `OCI_DEMO_CATALOG` catalog.

See CREATE_CATALOG Procedure for more information. You can query DBA_CLOUD_FUNCTION_CATALOG View and USER_CLOUD_FUNCTION_CATALOG View views to retrieve the list of all the catalogs in your database.

3. You can list the functions in a catalog.

   Following is the example to list Oracle Cloud Infrastructure Functions:

```
VAR function_list CLOB;

BEGIN
    DBMS_CLOUD_FUNCTION.LIST_FUNCTIONS (
      credential_name  => 'OCI_CRED',
      catalog_name     => 'OCI_DEMO_CATALOG',
      function_list    => :function_list
 );
END;
/

PL/SQL procedure successfully completed.

SELECT JSON_QUERY (:function_list, '$' RETURNING VARCHAR2(32676) pretty)
AS search_results FROM dual;
SEARCH_RESULTS                          --This is a sample output
--------------------------------------------------------------------------------
--------------------
[
  {
    "functionName"   : "create_par",
    "functionId"     : "ocid.funfc.oc1.phx.aaaa_example",
    "invokeEndpoint" : "https://dw.us.func.oci.oraclecloud_example.com"
  },
  {
    "functionName"   : "fintech",
    "functionId"     : "ocid.funfc.oc1.phx.bbbb_example"
SEARCH_RESULTS
--------------------------------------------------------------------------------
--------------------
4ayosyosv4sthmya2lyza",
    "invokeEndpoint" : "https://dw.us.func.oci.oraclecloud.com_example"
  },
  {
    "functionName"   : "jwt_codec",
    "functionId"     : "ocid.funfc.oc1.phx.jwt_code_example",
    "invokeEndpoint" : "https://dw.us.func.oci.oraclecloud_example.com"
  },
SEARCH_RESULTS
--------------------------------------------------------------------------------
--------------------
  {
```

```
    "functionName"   : "oci-objectstorage-create-par-python",
    "functionId"     : "ocid.funfc.oc1.phx.aaaaaaaas_example",
    "invokeEndpoint" : "https://dw.us.func.oci.oraclecloud_example.com"
  },
  {
    "functionName"   : "run_dbt",
    "functionId"     : "ocid.funfc.oc1.phx.aaaaaaaav_example",

SEARCH_RESULTS
------------------------------------------------------------------------------
----------------------
    "invokeEndpoint" : "https://dw.us.func.oci.oraclecloud_example.com"
  }
]
```

See LIST_FUNCTIONS Procedure for more information.

4. Run the `DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS` to create wrapper SQL functions. You can use one of the following methods to create the wrapper SQL functions in the catalog, that call their respective cloud functions:

   - **SYNC_FUNCTIONS**: `SYNC_FUNCTIONS` is the quickest and simplest method, which automatically syncs (creates or deletes) wrapper functions in the catalog with the complete list of cloud functions defined in the region, compartment, and tenancy with which the catalog was created. For example:

```
BEGIN
 DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS (
        catalog_name => 'OCI_DEMO_CATALOG'
 );
END;
/
PL/SQL procedure successfully completed.
```

This creates a PL/SQL wrapper for adding new functions to the catalog and removing wrappers for functions that have been deleted from the catalog.

Run the following query to verify the sync.

```
SELECT object_name FROM sys.all_objects WHERE owner='TEST_USER' AND
object_type='FUNCTION';

OBJECT_NAME
------------------------------------------------------------------------------
-----
CREATE_PAR
FINTECH
JWT_CODEC
OCI-OBJECTSTORAGE-CREATE-PAR-PYTHON
RUN_DBT
```

> **Note:**
>
> Keep a note of the current user in order to run this command.

See SYNC_FUNCTIONS Procedure for more information.

- You can manually create a `SQL` Function in your catalog that calls its respective cloud function using `DBMS_CLOUD.CREATE_FUNCTION`. For example:

Example to create a function in the `OCI_DEMO_CATALOG` catalog.

```
VAR function_args CLOB;
EXEC :function_args := TO_CLOB('{"command": "VARCHAR2", "value":
"VARCHAR2"}');
BEGIN
    DBMS_CLOUD_FUNCTION.CREATE_FUNCTION (
        credential_name  => 'OCI_CRED',
        catalog_name     => 'OCI_DEMO_CATALOG',
        function_name    => 'fintech_fun',
        function_id      => 'ocid1.fnfunc.oc1.phx.aaabbbcccc_example',
        input_args       => :function_args
 );
END;
/

PL/SQL procedure successfully completed.
```

This creates the `FINTECH_FUN` function in the `OCI_DEMO_CATALOG` catalog.

The `FINTECH_FUN` function in the catalog is a reference to the respective cloud function whose endpoint is referenced by the `FUNCTION_ID` parameter. Invoking the function in the catalog along with its arguments runs the corresponding cloud function and provides the output returned by the cloud function.

Manually creating a function in the catalog also allows you to create custom return types and response handlers. For example:

```
CREATE OR REPLACE TYPE fintech_rt AS OBJECT (
    STATUS  VARCHAR2(1000),
    OUTPUT  CLOB
);
/

Type created.

CREATE OR REPLACE FUNCTION fintech_response_handler(function_response in
CLOB)
RETURN fintech_rt
IS
l_comp   fintech_rt;
l_json_obj  JSON_OBJECT_T;
status  VARCHAR2(1000);
output  CLOB;
BEGIN
```

```
      l_json_obj := JSON_OBJECT_T.parse(function_response);
      status     := l_json_obj.get('STATUS').to_string;
      output     := l_json_obj.get('RESPONSE_BODY').to_string;
      l_comp     := fintech_rt(status,output);
      RETURN l_comp;
END;
/
Function created.

VAR input_param clob;
VAR  l_return_type varchar2(100);
VAR  l_response_handler varchar2(1000);

exec :input_param       := TO_CLOB('{"command": "VARCHAR2", "value":
"VARCHAR2"}');
exec :l_return_type     := 'fintech_rt';
exec :l_response_handler := 'fintech_response_handler';

PL/SQL procedure successfully completed.

PL/SQL procedure successfully completed.

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_FUNCTION.CREATE_FUNCTION (CREDENTIAL_NAME => 'OCI_CRED',
FUNCTION_NAME => 'fintech_fun', CATALOG_NAME => 'OCI_DEMO_CATALOG',
FUNCTION_ID => 'ocid1.funfn.oci.phx.aaaaaa_example', INPUT_ARGS
=> :input_param, RETURN_TYPE => :l_return_type ,RESPONSE_HANDLER
=>:l_response_handler);

PL/SQL procedure successfully completed.
```

You can query DBA_CLOUD_FUNCTION View and USER_CLOUD_FUNCTION View views to retrieve the list of all the functions in your database.

See CREATE_FUNCTION Procedure for more information.

5. After the function is created you can `DESCRIBE` and invoke it.

```
DESC fintech_fun
COLUMN STATUS format a30
COLUMN OUTPUT format a30

DECLARE
l_comp fintech_rt;
BEGIN
l_comp := fintech_fun(command=>'tokenize',value => 'PHI_INFORMATION');
DBMS_OUTPUT.put_line ('Status of the function   =  '|| l_comp.status);
DBMS_OUTPUT.put_line ('Response of the function =  '|| l_comp.output);
END;
/

PL/SQL procedure successfully completed.
```

This invokes the `fintech_fun` cloud function by calling the function reference `oocid1.funfn.oci.phx.aaaaaa_example` in the `OCI_DEMO_CATALOG` catalog.

6. You can drop an existing function using `DROP_FUNCTION` procedure. For example:

```
EXEC DBMS_CLOUD_FUNCTION.DROP_FUNCTION (CATALOG_NAME =>
'OCI_DEMO_CATALOG', FUNCTION_NAME => 'fintech_fun');

PL/SQL procedure successfully completed.
```

This drops the `FINTECH_FUN` function from the `OCI_DEMO_CATALOG` catalog.

See DROP_FUNCTION Procedure for more information.

7. You can drop an existing catalog using `DROP_CATALOG` procedure. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.DROP_CATALOG (
      catalog_name     => 'OCI_DEMO_CATALOG'
  );
END;
/

PL/SQL procedure successfully completed.
```

This drops the `OCI_DEMO_CATALOG` from your database.

See DROP_CATALOG Procedure for more information.

Steps to Invoke AWS Lambda as SQL Functions

Shows the steps to invoke AWS remote functions as SQL functions in your database.

To invoke AWS Lambda as SQL functions, we will be creating a catalog of SQL wrapper functions that reference and call their respective cloud function via their API endpoints. Before you create this catalog, it is assumed here that you have created the necessary cloud functions to be referenced by this catalog.

> **Note:**
>
> To access AWS lambda functions you need to configure the necessary policies. See Creating an IAM policy to access AWS Lambda resources and Using resource-based policies for Lambda for more information.

1. Create a credential using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. The credential object that you are creating must be of type secret key.

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL (
    credential_name => 'AWS_CRED',
    username        => 'access_key_ID',
    password        => 'secret_access_key'
  );
```

```
END;
/
```

This creates the `AWS_CRED` credential.

See CREATE_CREDENTIAL Procedure for more information.

2. Create a catalog.

   A catalog is a collection of wrapper functions that reference and call their respective cloud functions via their API endpoints.

   Example to create a catalog for AWS functions.

```
BEGIN
    DBMS_CLOUD_FUNCTION.CREATE_CATALOG (
        credential_name  => 'AWS_CRED',
        catalog_name     => 'AWS_DEMO_CATALOG',
        service_provider => 'AWS',
        cloud_params     => '{"region_id":"ap-northeast-1"}'
 );
END;
/

PL/SQL procedure successfully completed.
```

   This creates the `AWS_DEMO_CATALOG` catalog.

   See CREATE_CATALOG Procedure for more information. You can query DBA_CLOUD_FUNCTION_CATALOG View and USER_CLOUD_FUNCTION_CATALOG View views to retrieve the list of all the catalogs in your database.

3. You can list the functions in a catalog.

   Following is the example to list AWS Lambda functions:

```
VAR function_list CLOB;

BEGIN
 DBMS_CLOUD_FUNCTION.LIST_FUNCTIONS (
    credential_name  => 'AWS_CRED',
    catalog_name     => 'AWS_DEMO_CATALOG',
    function_list    => :function_list
);
END;
/

PL/SQL procedure successfully completed.

SELECT JSON_QUERY (:function_list, '$' RETURNING VARCHAR2(32676) pretty)
AS search_results FROM dual;

SEARCH_RESULTS                          --This is a sample output
--------------------------------------------------------------------------------
--------------------
[
  {
    "functionName"   : "test3_example",
```

```
    "functionArn"    : "arn:aws:lambda:ap-north-1:378:func:test3_example",
    "invokeEndpoint" : "https://swiy3.lambda-url.ap-
north-1.on.aws_example/"
  },
  {
    "functionName"   : "SumOfNum_example",
    "functionArn"    : "arn:aws:lambda:ap-
north-1:378:func:SumOfNum_example"

SEARCH_RESULTS
------------------------------------------------------------------------------
------------------------
    "invokeEndpoint" : "https://swiy3.lambda-url.ap-
north-1.on.aws_example/"
  },
  {
    "functionName"   : "testlambda_example",
    "functionArn"    : "arn:aws:lambda:ap-
north-1:378:func:testlambda_example",
    "invokeEndpoint" : "https://swiy3.lambda-url.ap-
north-1.on.aws_example/"
  },

SEARCH_RESULTS
------------------------------------------------------------------------------
------------------------
  {
    "functionName"   : "hellp-python_example",
    "functionArn"    : "arn:aws:lambda:ap-north-1:378:func:hellp-
python_example",
    "invokeEndpoint" : "https://swiy3.lambda-url.ap-
north-1.on.aws_example/"
  },
  {
    "functionName"   : "testlam_example",
    "functionArn"    : "arn:aws:lambda:ap-
north-1:378:func:testlam_example",

SEARCH_RESULTS
------------------------------------------------------------------------------
------------------------
    "invokeEndpoint" : "https://swiy3.lambda-url.ap-
north-1.on.aws_example/"
  }
]
```

See LIST_FUNCTIONS Procedure for more information.

4. Run the `DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS` to create wrapper SQL functions. You can use one of the following methods to create the wrapper SQL functions in the catalog, that call their respective cloud functions:

   - **SYNC_FUNCTIONS**: `SYNC_FUNCTIONS` is the quickest and simplest method, which automatically syncs (creates or deletes) wrapper functions in the catalog with the

complete list of cloud functions defined in the region, compartment, and tenancy with which the catalog was created. For example:

```
BEGIN
 DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS (
        catalog_name => 'AWS_DEMO_CATALOG'
 );
END;
/
PL/SQL procedure successfully completed.
```

This creates a PL/SQL wrapper for adding new functions to the catalog and removing wrappers for functions that have been deleted from the catalog.

Run the following query to verify the sync.

```
SELECT object_name FROM sys.all_objects WHERE owner='TEST_USER' AND
object_type='FUNCTION';

OBJECT_NAME
--------------------------------------------------------------------------------
-----
TESTLAMBDA
HELLP-PYTHON
TESTLAM
TEST3
SUMOFNUMBERS
```

> **Note:**
>
> Keep a note of the current user in order to run this command.

See SYNC_FUNCTIONS Procedure for more information.

- You can manually create a `SQL` Function in your catalog that calls its respective cloud function using `DBMS_CLOUD.CREATE_FUNCTION`.

Example to create a function in the `AWS_DEMO_CATALOG` catalog.

```
BEGIN
DBMS_CLOUD_FUNCTION.CREATE_FUNCTION (
  credential_name => 'AWS_CRED',
  catalog_name    => 'AWS_DEMO_CATALOG',
  function_name   => 'aws_testlambda',
  function_id     => 'arn:aws:lambda:ap-
northeast-1:378079562280:function:hellp-python'
);
END;
/
PL/SQL procedure successfully completed.
```

This creates the AWS_TESTLAMBDA function in the AWS_DEMO_CATALOG catalog.

The AWS_TESTLAMBDA function in the catalog is a reference to the respective cloud function whose endpoint is referenced by the FUNCTION_ID parameter. Invoking the function in the catalog along with its arguments runs the corresponding cloud function and provides the output returned by the cloud function.

You can query DBA_CLOUD_FUNCTION View and USER_CLOUD_FUNCTION View views to retrieve the list of all the functions in your database.

See CREATE_FUNCTION Procedure for more information.

5. After the function is created you can DESCRIBE and invoke it.

```
DESC AWS_TESTLAMBDA
COLUMN STATUS format a30
COLUMN OUTPUT format a30

SELECT AWS_TESTLAMBDA(NULL) FROM dual;

AWS_TESTLAMBDA(NULL)
----------------------------------------------------
{"STATUS":"200","RESPONSE_BODY":"Hello Python!!"}
```

This invokes the AWS_TESTLAMBDA function by calling the function reference arn:aws:lambda:ap-northeast-1:378079562280:function:hellp-python in the AWS_DEMO_CATALOG catalog.

6. You can drop an existing function using DROP_FUNCTION procedure. For example:

```
EXEC DBMS_CLOUD_FUNCTION.DROP_FUNCTION (CATALOG_NAME =>
'AWS_DEMO_CATALOG', FUNCTION_NAME => 'AWS_TESTLAMBDA');

PL/SQL procedure successfully completed.
```

This drops the AWS_TESTLAMBDA function from the AWS_DEMO_CATALOG catalog.

See DROP_FUNCTION Procedure for more information.

7. You can drop an existing catalog using DROP_CATALOG procedure. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.DROP_CATALOG (
      catalog_name     => 'AWS_DEMO_CATALOG'
  );
END;
/

PL/SQL procedure successfully completed.
```

This drops the AWS_DEMO_CATALOG from your database.

See DROP_CATALOG Procedure for more information.

Steps to Invoke Azure Functions as SQL Functions

Shows the steps to invoke Azure remote functions as SQL functions in your database using HTTP trigger.

To invoke Azure Function as SQL functions, create a catalog of SQL wrapper functions that reference and call their respective cloud function through their API endpoints. Before you create this catalog, it is assumed here that you have created the necessary Azure functions to be referenced by this catalog.

1. To access Azure functions you need to use Azure Service Principal with Autonomous Database. You must grant the **Website Contributor** role to the Azure Service Principal for the Azure function app under its **Access control** (IAM).

   See the following for more information:

   - Use Azure Service Principal to Access Azure Resources
   - Azure built-in roles
   - Assign Azure roles using the Azure portal

2. Create a catalog.

   A catalog is a collection of wrapper functions that reference and call their respective cloud functions via their API endpoints.

   Example to create a catalog for Azure functions.

   ```
   BEGIN
       DBMS_CLOUD_FUNCTION.CREATE_CATALOG (
           credential_name  => 'AZURE$PA',
           catalog_name     => 'AZURE_DEMO_CATALOG',
           service_provider => 'AZURE',
           cloud_params     =>
   '{"subscription_id":"XXXXXXXXXXXXXXXXXXXXXXXX_example"}'
    );
   END;
   /
   ```

   The `SUBSCRIPTION_ID` value in the `CLOUD_PARAMS` is the subscription_id of the Azure function app.

   This creates the `AZURE_DEMO_CATALOG` catalog and catalogs all the functions of the provided `SUBSCRIPTION_ID`.

   See CREATE_CATALOG Procedure for more information. You can query DBA_CLOUD_FUNCTION_CATALOG View and USER_CLOUD_FUNCTION_CATALOG View views to retrieve the list of all the catalogs in your database.

3. You can list the functions in a catalog.

   Following is the example to list Azure functions:

   ```
   VAR function_list CLOB;

   BEGIN
    DBMS_CLOUD_FUNCTION.LIST_FUNCTIONS (
       credential_name  => 'AZURE$PA',
       catalog_name     => 'AZURE_DEMO_CATALOG',
   ```

```
    function_list    => :function_list
);
END;
/

SELECT JSON_QUERY (:function_list, '$' RETURNING VARCHAR2(32676) pretty)
AS search_results FROM dual;
```

See LIST_FUNCTIONS Procedure for more information.

4. Run the `DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS` to create wrapper SQL functions. You can use one of the following methods to create the wrapper SQL functions in the catalog, that call their respective cloud functions:

   - **SYNC_FUNCTIONS**: `SYNC_FUNCTIONS` is the quickest and simplest method, which automatically syncs (creates or deletes) wrapper functions in the catalog with the complete list of Azure functions. For example:

```
BEGIN
 DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS (
        catalog_name => 'AZURE_DEMO_CATALOG'
 );
END;
/
```

This creates a PL/SQL wrapper for adding new functions to the catalog and removing wrappers for functions that have been deleted from the catalog.

> **Note:**
>
> When an Azure function is added, deleted, or disabled on the Azure function app, you must run the `SYNC_FUNCTIONS` to update the corresponding PL/SQL wrappers in the catalog.

Run the following query to verify the sync.

```
SELECT object_name FROM sys.all_objects WHERE owner='TEST_USER' AND
object_type='FUNCTION';
```

> **Note:**
>
> Keep a note of the current user in order to run this command.

See SYNC_FUNCTIONS Procedure for more information.

   - You can manually create a `SQL` Function in your catalog that calls its respective Azure function using `AZURE_DEMO_CATALOG`.

Example to create a function in the AZURE_DEMO_CATALOG catalog.

```
BEGIN
DBMS_CLOUD_FUNCTION.CREATE_FUNCTION (
  credential_name => 'AZURE$PA',
  catalog_name    => 'AZURE_DEMO_CATALOG',
  function_name   => 'azure_testfunc',
  function_id     => 'function_id_path',
  input_args      => :function_args
);
END;
/
```

> **Note:**
>
> The maximum length of the function name is limited to 100 characters.

This creates the AZURE_TESTFUNC function in the AZURE_DEMO_CATALOG catalog.

The AZURE_TESTFUNC function in the catalog is a reference to the respective Azure function whose subscription is referenced by the FUNCTION_ID parameter. Invoking the function in the catalog along with its arguments runs the corresponding Azure function and provides the output returned by the function.

You can query DBA_CLOUD_FUNCTION View and USER_CLOUD_FUNCTION View views to retrieve the list of all the functions in your database.

See CREATE_FUNCTION Procedure for more information.

See Azure Functions HTTP trigger for more information.

5. After the function is created you can DESCRIBE and invoke it.

```
DESC AZURE_TESTFUNC

SELECT AZURE_TESTFUNC(NULL) FROM dual;
```

This invokes the AZURE_TESTFUNC function by calling the function reference /subscriptions/44496e556-8ssp-4262-b389-0f15f685c879/resources/ADBStest/providers/Microsoft.Web/sites/AZUREADBS/functions/HttpTrigger_example in the AZURE_DEMO_CATALOG catalog.

6. You can drop an existing function using DROP_FUNCTION procedure. For example:

```
EXEC DBMS_CLOUD_FUNCTION.DROP_FUNCTION (CATALOG_NAME =>
'AZURE_DEMO_CATALOG', FUNCTION_NAME => 'AZURE_TESTFUNC');
```

This drops the AZURE_TESTFUNC function from the AZURE_DEMO_CATALOG catalog.

See DROP_FUNCTION Procedure for more information.

7. You can drop an existing catalog using `DROP_CATALOG` procedure. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.DROP_CATALOG (
      catalog_name     => 'AZURE_DEMO_CATALOG'
  );
END;
/
```

This drops the `AZURE_DEMO_CATALOG` from your database.

See DROP_CATALOG Procedure for more information.

Steps to Invoke Google Cloud Run Functions as SQL Functions

Shows the steps to invoke Google Cloud Run functions as SQL functions in your database.

To invoke Google Cloud Run functions as SQL functions, you create a library of SQL wrapper functions that reference and call their respective cloud functions. Before you create this catalog, it is assumed here that you have created the necessary cloud functions to be referenced by this catalog. See Create a Cloud Run function by using the Google Cloud console for more information.

1. To access Google Cloud Run functions from an Autonomous Database instance use your Google service account. You must grant the `cloudfunctions.functions.list` permission, and `Cloud Functions Invoker` and `Cloud Run Invoker` roles to the Google service account for the Google Cloud Platform (GCP) app.

   See the following for more information:

   - About Using a Google Service Account to Access Google Cloud Resources
   - Authorize access with IAM (1st gen)
   - Authorize access with IAM

2. Create a catalog. To create a catalog for Google Cloud Run functions with a user other than `ADMIN` you need to grant read privileges on the `CLOUD_INTEGRATIONS` view to that user.

   A catalog is a collection of wrapper functions that reference and call their respective cloud functions using their API endpoints.

```
BEGIN
    DBMS_CLOUD_FUNCTION.CREATE_CATALOG (
        credential_name  => 'GCP$PA',
        catalog_name     => 'GCP_DEMO_CATALOG',
        service_provider => 'GCP',
        cloud_params     => '{"project_id":"example_XXXXXX"}'
 );
END;
/
```

The `project_id` value in the `cloud_params` is the project ID of the Google Cloud Platform (GCP).

This creates the `GCP_DEMO_CATALOG` catalog and catalogs all the functions of the provided `project_id`.

See CREATE_CATALOG Procedure for more information. You can query DBA_CLOUD_FUNCTION_CATALOG View and USER_CLOUD_FUNCTION_CATALOG View views to retrieve the list of all the catalogs in your database.

3. List the functions in a catalog.

   Following is the example to list Google Cloud Run functions:

```
VAR function_list CLOB;

BEGIN
    DBMS_CLOUD_FUNCTION.LIST_FUNCTIONS (
        credential_name  => 'GCP$PA',
        catalog_name     => 'GCP_DEMO_CATALOG',
        function_list    => :function_list
 );
END;
/

SELECT JSON_QUERY (:function_list, '$' RETURNING VARCHAR2(32676) pretty)
AS search_results FROM dual;
```

   See LIST_FUNCTIONS Procedure for more information.

4. Run the `DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS` to create wrapper SQL functions. You can use one of the following methods to create the wrapper SQL functions in the catalog, that call their respective cloud functions:

   - **SYNC_FUNCTIONS**: `SYNC_FUNCTIONS` method to create wrapper SQL function is the quickest and simplest method, which automatically syncs (creates or deletes) wrapper functions in the catalog with the complete list of cloud functions defined in the region, compartment, and tenancy with which the catalog was created. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.SYNC_FUNCTIONS (
        catalog_name => 'GCP_DEMO_CATALOG'
 );
END;
/
```

   This creates a PL/SQL wrapper for adding new functions to the catalog and removing wrappers for functions that have been deleted from the catalog.

   Run the following query to verify the sync.

```
SELECT object_name FROM sys.all_objects WHERE owner='TEST_USER' AND
object_type='FUNCTION';
```

> **Note:**
>
> Keep a note of the current user in order to run this command.

See SYNC_FUNCTIONS Procedure for more information.

- You can manually create a SQL Function in your catalog that calls its respective cloud function using DBMS_CLOUD.CREATE_FUNCTION.

Example to create a function in the GCP_DEMO_CATALOG catalog.

```
EXEC :function_args  := TO_CLOB('{"name": "VARCHAR2"}');

BEGIN
    DBMS_CLOUD_FUNCTION.CREATE_FUNCTION (
        credential_name => 'GCP$PA',
        catalog_name    => 'GCP_DEMO_CATALOG',
        function_name   => 'gcp_testfunc',
        function_id     => 'function_id_path',
        input_args      => :function_args
 );
END;
/
```

This creates the GCP_TESTFUNC function in the GCP_DEMO_CATALOG catalog.

The GCP_TESTFUNC function in the catalog is a reference to the respective Google Cloud Run function whose project id is referenced by the FUNCTION_ID parameter. Invoking the function in the catalog along with its arguments runs the corresponding Google Cloud Run function and provides the output returned by the function.

You can query DBA_CLOUD_FUNCTION View and USER_CLOUD_FUNCTION View views to retrieve the list of all the functions in your database.

See CREATE_FUNCTION Procedure for more information.

5. After the function is created you can DESCRIBE and invoke it.

```
DESC GCP_TESTFUNC
COLUMN STATUS format a30
COLUMN OUTPUT format a30

SELECT GCP_TESTFUNC(NULL) FROM dual;
```

This invokes the GCP_TESTFUNC function by calling the function reference specified in the function_id parameter.

6. You can drop an existing function using DROP_FUNCTION procedure. For example:

```
EXEC DBMS_CLOUD_FUNCTION.DROP_FUNCTION (CATALOG_NAME =>
'GCP_DEMO_CATALOG', FUNCTION_NAME => 'GCP_TESTFUNC');
```

This drops the GCP_TESTFUNC function from the GCP_DEMO_CATALOG catalog.

See DROP_FUNCTION Procedure for more information.

7. You can drop an existing catalog using DROP_CATALOG procedure. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.DROP_CATALOG (
```

```
        catalog_name     => 'GCP_DEMO_CATALOG'
 );
END;
/
```

This drops the `GCP_DEMO_CATALOG` from your database.

See DROP_CATALOG Procedure for more information.

Invoke External Procedures as SQL Functions

Shows the steps to invoke external procedures using PL/SQL within your database.

- External Procedures Overview
  External procedures are functions written in a third-generation language and callable from within PL/SQL or SQL as if they were a PL/SQL routine or function.
- About Using External Procedures in Autonomous Database
  You can invoke and use external procedures in your Autonomous Database with user defined functions.
- Define the C Procedure
  Define the C procedure using one of these prototypes.
- Create a Shared Library (.so) File
  Create a shared object (`.so` file) library. The shared object library contains the C procedure (external procedure) which was defined in the previous step.
- Get the OCI Marketplace EXTPROC Stack Application
  Shows the steps to get the OCI Marketplace `EXTPROC` Stack Application.
- Launch EXTPROC Stack Application
  Launch the `EXTPROC` Stack Application from the EXTPROC Application Details page.
- Create Stack for EXTPROC Agent Application
  Shows the steps to create Stack for `EXTPROC` instance.
- Upload Wallet to Create Secure Connection to the EXTPROC Agent Instance
  A self-signed wallet is created as part of the `EXTPROC` agent application creation. This wallet allows you to access the `Extrpoc` agent instance.
- Steps to Invoke an External Procedure as a SQL Function
  Shows the steps to invoke an external Procedure as a SQL function.

External Procedures Overview

External procedures are functions written in a third-generation language and callable from within PL/SQL or SQL as if they were a PL/SQL routine or function.

External procedures promote reusability, efficiency, and modularity. Existing dynamic link libraries (DLLs) written in other languages can be called from PL/SQL programs. The DLLs are loaded only when needed and they can be enhanced without affecting the calling programs.

Using external procedures also enhances performance, because third-generation languages perform certain tasks more efficiently than PL/SQL, which is better suited for SQL transaction processing.

External procedures are useful when:

- Solving scientific and engineering problems

- Analyzing data
- Controlling real-time devices and processes

See What Is an External Procedure? for more information.

About Using External Procedures in Autonomous Database

You can invoke and use external procedures in your Autonomous Database with user defined functions.

You do not install external procedures on an Autonomous Database instance. To use an external procedure, the procedure is hosted remotely on a VM running in an Oracle Cloud Infrastructure Virtual Cloud Network (VCN).

External procedures are only supported when your Autonomous Database is on a private endpoint. The `EXTPROC` agent instance is hosted on a private subnet and the Autonomous Database access the `EXTPROC` agent through a Reverse Connection Endpoint (RCE).

> **Note:**
>
> Autonomous Database only supports C language external procedures.

External procedures are deployed by using:

- An Oracle provided container image with `EXTPROC` agent installed and configured as a part of the Oracle Cloud Infrastructure (OCI) Marketplace stack.

  The `EXTPROC` agent instance is hosted remotely on a VM running in an Oracle Cloud Infrastructure Virtual Cloud Network (VCN). The secure communication between your Autonomous Database and the `EXTPROC` agent instance is ensured by setting Network Security Group (NSG) rules such that the traffic is allowed from your Autonomous Database instance running on a private endpoint to the `EXTPROC` agent instance.

  The `EXTPROC` agent image is pre-configured to host and execute external procedures on port 16000.
- PL/SQL procedures to create a library and to register and invoke external functions and procedures.

  See DBMS_CLOUD_FUNCTION Package for more information.

Follow these steps to invoke an external procedure on Autonomous Database:

- Define the C procedure. See Define the C Procedure.
- Create a shared object (`.so` file) library. See Create a Shared Library (.so) File.
- Launch the Autonomous Database `EXTPROC` stack application. See Get the OCI Marketplace EXTPROC Stack Application.
- Provision and configure Oracle Autonomous Database `EXTPROC` agent. See Create Stack for EXTPROC Agent Application for more information.
- Configure your Autonomous Database to connect to the `EXTPROC` agent instance. See Upload Wallet to Create Secure Connection to the EXTPROC Agent Instance for more information.
- Create a remote library using `DBMS_CLOUD_FUNCTION.CREATE_CATALOG`. See Steps to Invoke an External Procedure as a SQL Function for more information.

- Use the user defined function you created in the previous step. See Steps to Invoke an External Procedure as a SQL Function for more information.

Define the C Procedure

Define the C procedure using one of these prototypes.

- Kernighan & Ritchie style prototypes. For example:

```
void UpdateSalary(x)
 float x;
...
```

- ISO/ANSI prototypes other than numeric data types that are less than full width (such as `float`, `short`, `char`). For example:

```
void UpdateSalary(double x)
...
```

- Other data types that do not change size under default argument promotions.

  This example changes size under default argument promotions:

```
void UpdateSalary(float x)
...
```

Create a Shared Library (.so) File

Create a shared object (`.so` file) library. The shared object library contains the C procedure (external procedure) which was defined in the previous step.

You generate a shared object library using the following command:

```
gcc -I/u01/app/oracle/extproc_libs/ -shared -fPIC -o extproc.so UpdateSalary.c
```

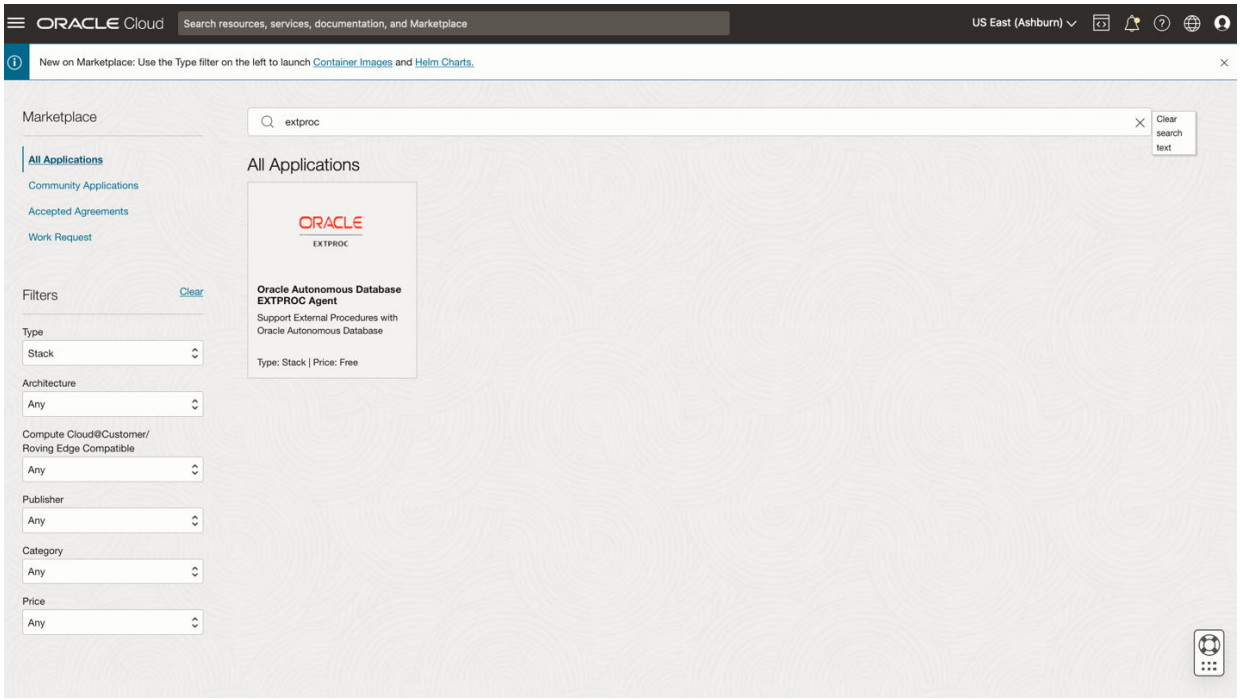
This creates the shared object (`.so`), `extproc.so` library. The `UpdateSalary` procedure, defined in the previous step, is contained in the `extproc.so` library. The shared object (`.so`) libraries are dynamically loaded at run time.

Get the OCI Marketplace EXTPROC Stack Application

Shows the steps to get the OCI Marketplace `EXTPROC` Stack Application.

Perform the following steps:

1. Sign in to the OCI Console at http://cloud.oracle.com. See Sign in to the Oracle Cloud Infrastructure Console for more information.
2. From the Oracle Cloud Infrastructure left navigation menu click **Marketplace** and then, under **Marketplace** click **All Applications**. This takes you to the Marketplace All Applications dashboard.
3. Enter `EXTPROC` in the search field and click **search**.
4. Click the `EXTPROC` widget of **Type: Stack**.



This takes you to the **Oracle Autonomous Database EXTPROC Agent** details page.

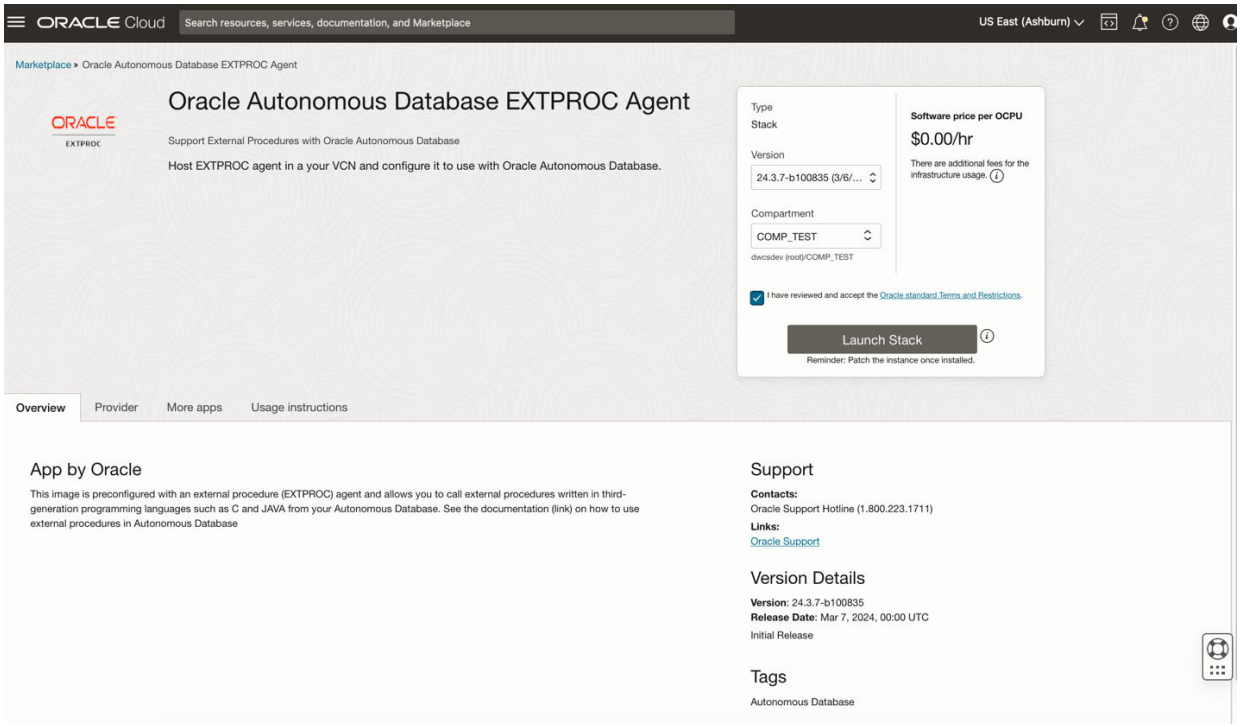
Launch EXTPROC Stack Application

Launch the `EXTPROC` Stack Application from the EXTPROC Application Details page.

1. On the Oracle Autonomous Database `EXTPROC` Agent page, under **Type Stack**, perform the following:
   - From the **Version** drop-down list, select the package version of the stack. By default, the menu displays the latest version.
   - From the **Compartment** drop-down list, select the name of the compartment where you want to launch the instance.

     > **Note:**
     >
     > If you don't have permission to launch the instance in the selected compartment, the instance is launched in the root compartment.

   - Select the **I have reviewed and accept the Oracle Standard Terms and Restrictions** checkbox.
2. Click **Launch Stack**.



This takes you to the **Create stack** page that allows you to create stack for the `EXTPROC` agent.

Create Stack for EXTPROC Agent Application

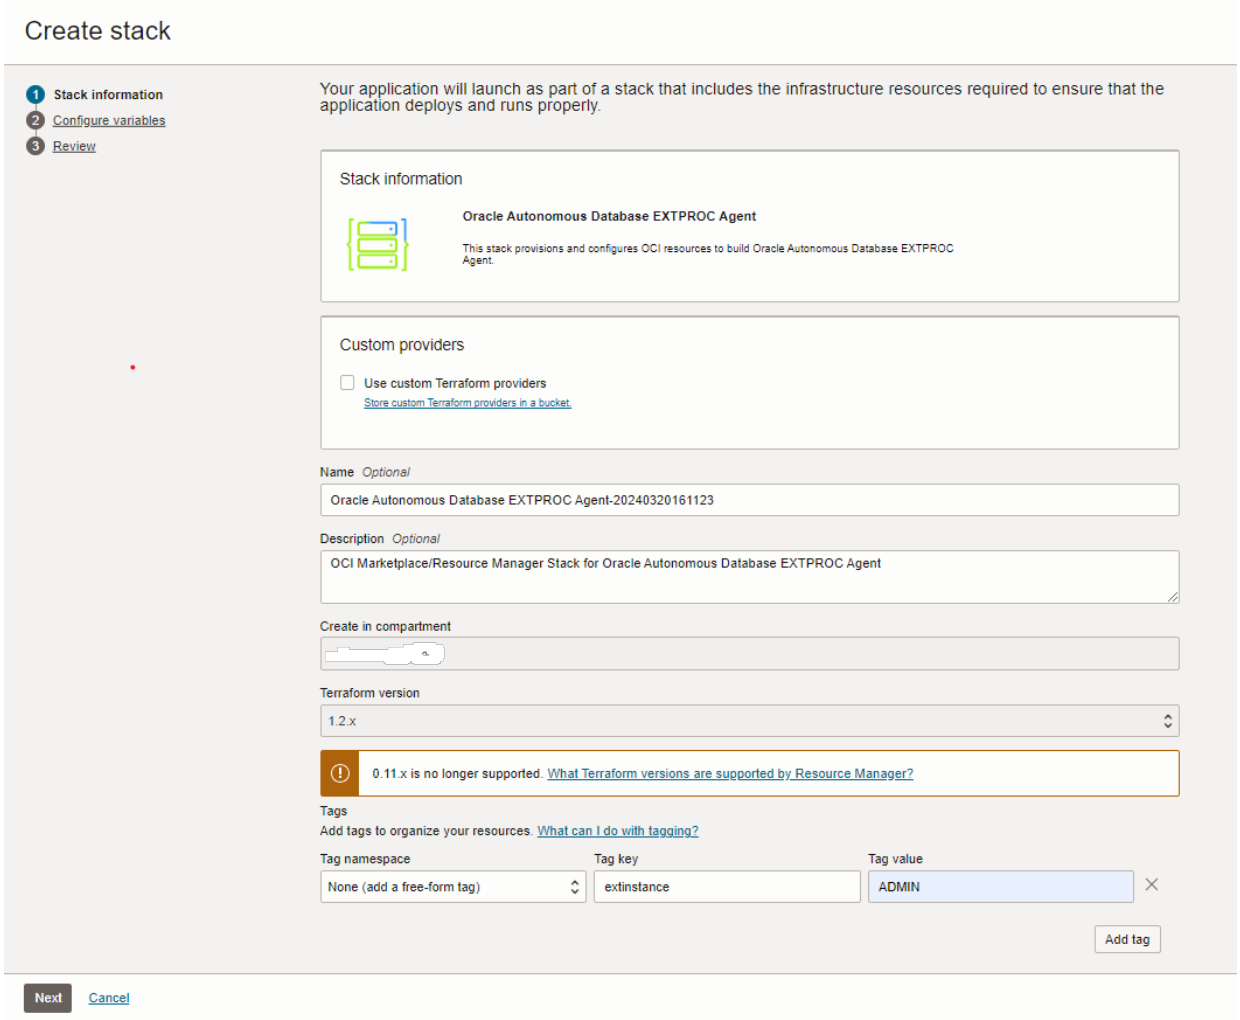
Shows the steps to create Stack for `EXTPROC` instance.

In the **Create stack** wizard, perform the following steps:

1. On the **Stack information** page, review and edit the following information as necessary:
   - **Stack information**
   - **Custom providers**
   - **Name (Optional)**: You can edit the default stack name. Avoid entering confidential information.
   - **Description (Optional)**: You can edit the default stack description. Avoid entering confidential information.
   - **Create in compartment**
   - **Terraform version**
   - **Tags**: Provide the following to assign tags to the stack.
     - **Tag namespace**: To add a defined tag, select an existing namespace. To add a free-from tag, leave the value blank.
     - **Tag key**: To add a defined tag, select an existing tag key. To add a free-form tag, type the key name that you want.
     - **Tag value**: Type the tag value that you want.

     Add tag: Click to add another tag.

     See Resource Tags for more information on tagging.



2. Click **Next**.

   This takes you to the **Configure variables** page which enables you to configure variables for the infrastructure resources that the stack creates when you run the apply job for this execution plan.

3. On the Configure variables page enter the information in the areas: **Configure the EXTPROC Agent**, **Network Configuration**, and **Compute configuration**.

   a. Provide information in the **Configure the EXTPROC Agent** area.

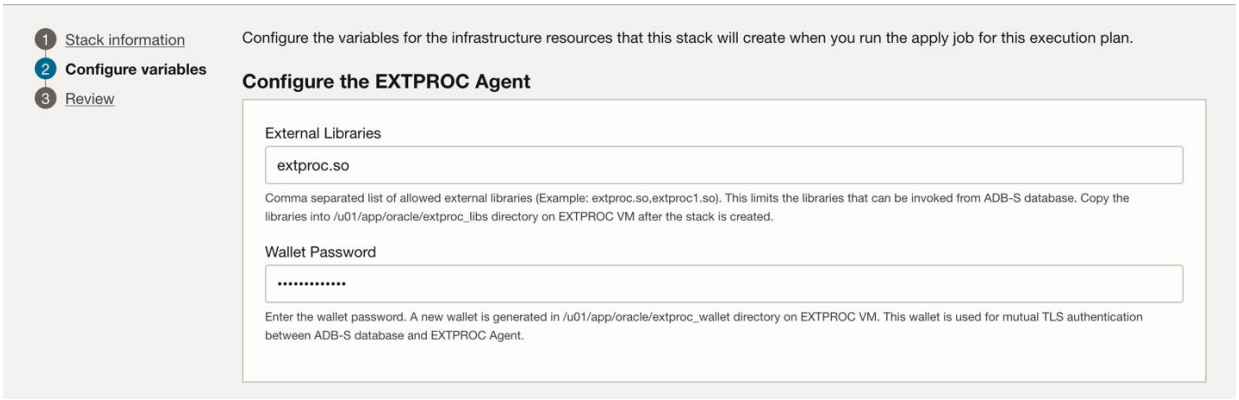
      - **External Libraries**: Provide a list of libraries, separated by comma (,), which you want to allow to be invoked from your Autonomous Database. For example, `extproc.so`, `extproc1.so`.

        After you create the stack, you must copy the libraries to the `/u01/app/oracle/extproc_libs` directory on the `EXTPROC` agent VM.

      - **Wallet Password:** Provide the wallet password.

        The wallet and a self-signed certificate is generated for mutual TLS authentication between the Autonomous Database and the `EXTPROC` agent VM. The wallet is created in the `/u01/app/oracle/extproc_wallet` directory.

> **Note:**
>
> After the wallet is created, the wallet password cannot be changed.

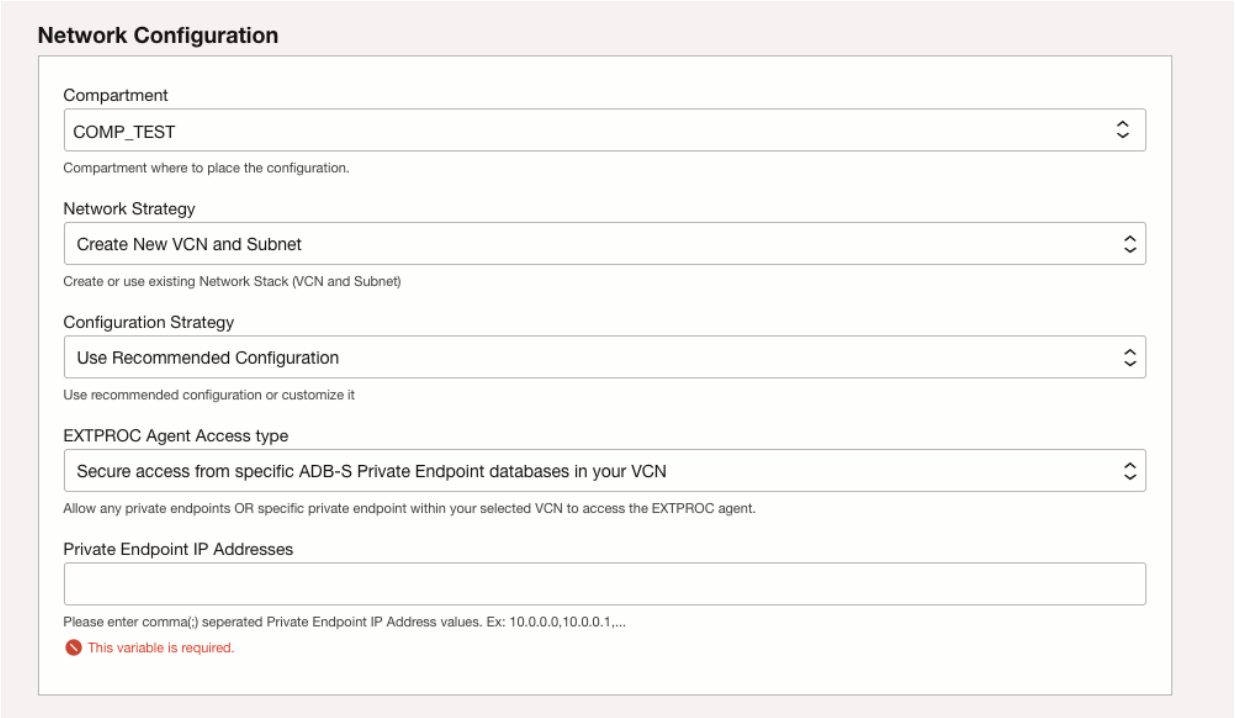


b. Provide information in the **Network Configuration** area.

- **Compartment**: From the drop-down list, choose the compartment where you want to place the configuration.
- **Network Strategy**: Choose one of the options from the drop-down list, **Create New VCN and Subnet** or **Use Existing VCN and Subnet**.
  - **Create New VCN and Subnet**: Choose this option if a private endpoint is not configured for your Autonomous Database. This creates a new VCN with public and private subnet that are preconfigured with security rules.

    If you select this option the page also shows the Configuration Strategy drop-down list:

    Choose **Use Recommended Configuration** from the **Configuration Strategy** drop-down list.



- **Use Existing VCN and Subnet**: Select this option to create the EXTPROC agent using an existing VCN. This creates the EXTPROC agent instance in the provided subnet.

  When you select this option, provide the following information for the existing VCN and Subnet:

  * Under **Virtual Cloud Network**:

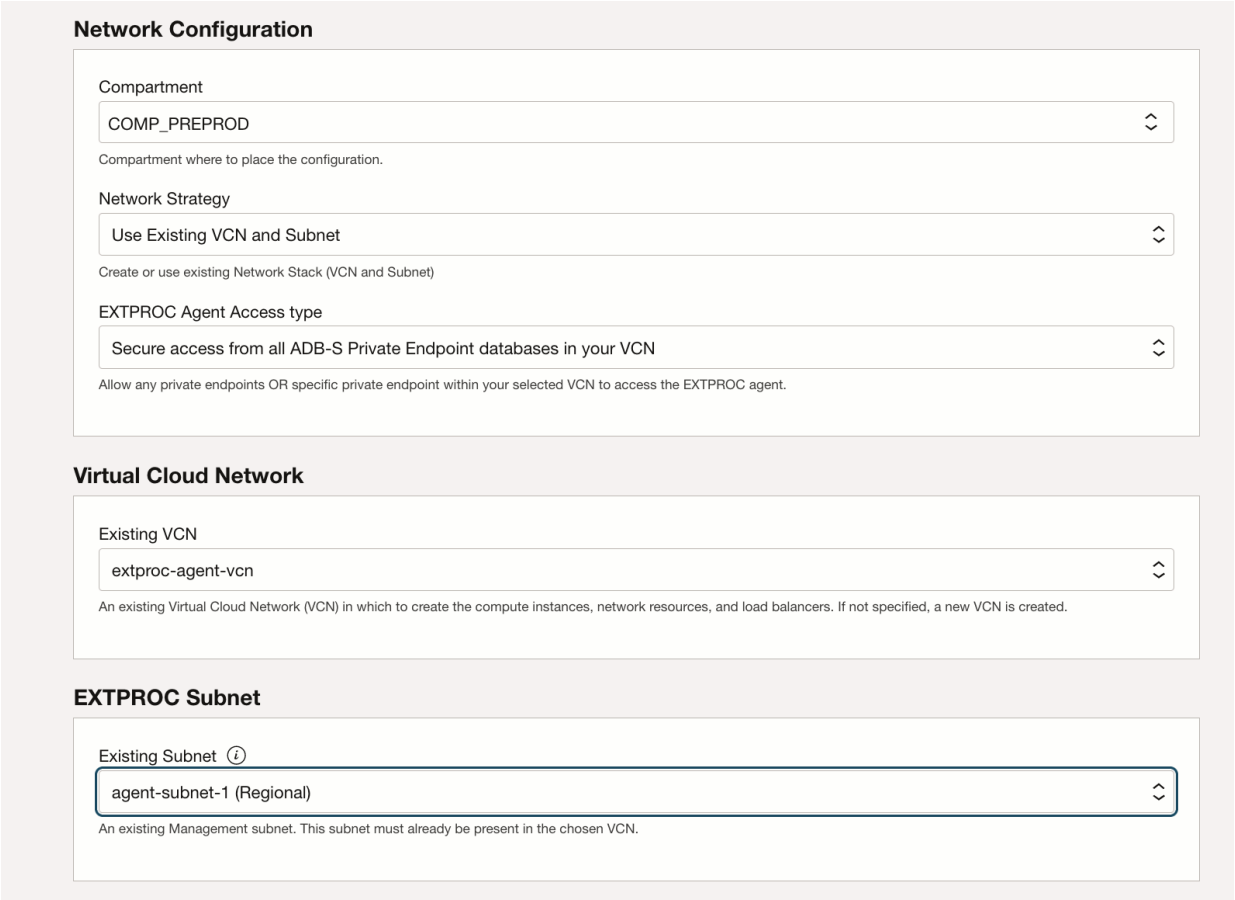
    From the **Existing VCN** drop-down list choose an existing VCN. If the specified VCN does not exist, a new VCN is created.

  * Under **EXTPROC Subnet**:

    From the **Existing Subnet** drop-down list choose an existing subnet.

    When you choose to use an existing VCN and subnet, add an ingress rule for the `EXTPROC` agent instance's port `16000`. You also add an egress rule on public subnet.

    See Configuring Network Access with Private Endpoints for more information.



- **EXTPROC Agent Access type**: Choose one of the following options from the drop-down list.
  - **Secure access from specific ADB-S Private Endpoint databases in your VCN**: Choose this option to allow only specified private endpoint IPs inside your Virtual Cloud Network (VCN) to connect to your `EXTPROC` agent.

    When this option is chosen, you provide a list of allowed private endpoint IP Addresses in the next step.
  - **Secure access from all ADB-S Private Endpoint databases in your VCN**: Choose this option to allow any private endpoint inside your Virtual Cloud Network (VCN) to connect to your `EXTPROC` agent.
- **Private Endpoint IP Addresses**

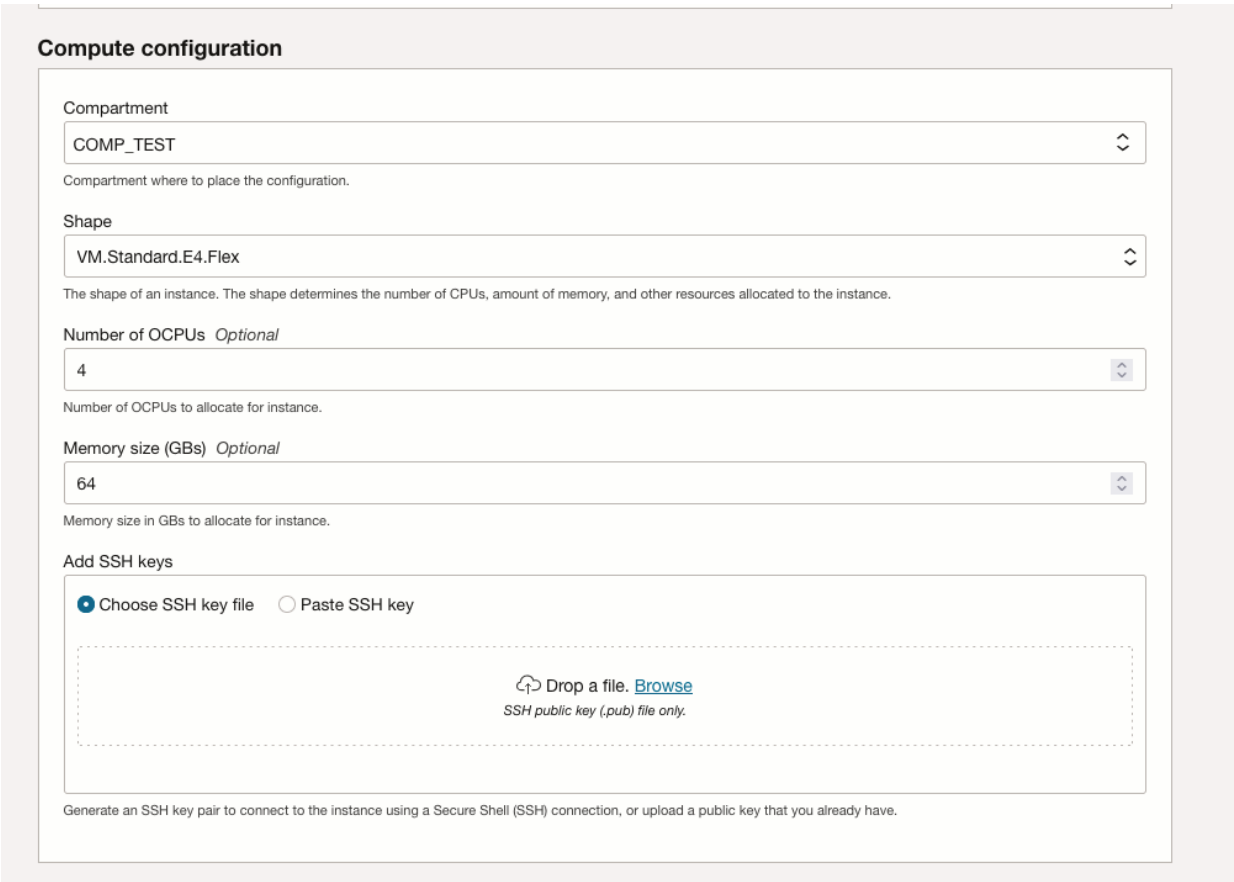
  Provide a list of private endpoint IP addresses separated by comma (,) for the Private Endpoint IP Addresses variable. For example, `10.0.0.0`, `10.0.0.1`.

> **Note:**
>
> This field only shows when you select **Secure access from specific ADB-S Private Endpoint databases in your VCN** for the **EXTPROC Agent Access type**.

c. Provide the **Compute configuration** information.

- **Compartment**: Select the compartment where you want to create the stack.

- **Shape**: Select a shape based on the workload requirements of the `EXTPROC` agent instance. The shape determines the resources allocated to the `EXTPROC` agent instance.
- **Number of OCPUs**: Choose the number of OCPUs that you want to allocate to the `EXTPROC` agent instance.
- **Memory size (GBs)**: Choose the amount of memory in Gigabytes (GB) that you want to allocate to the `EXTPROC` agent instance.
- **Add SSH keys**: Upload an SSH public key or paste the public key. Select one of the following options:
  - **Choose SSH key file**: Upload the public key portion of your key pair. Either browse to the key file that you want to upload, or drag and drop the file into the box.
  - **Paste SSH key**: Paste the public key portion of your key pair in the box.

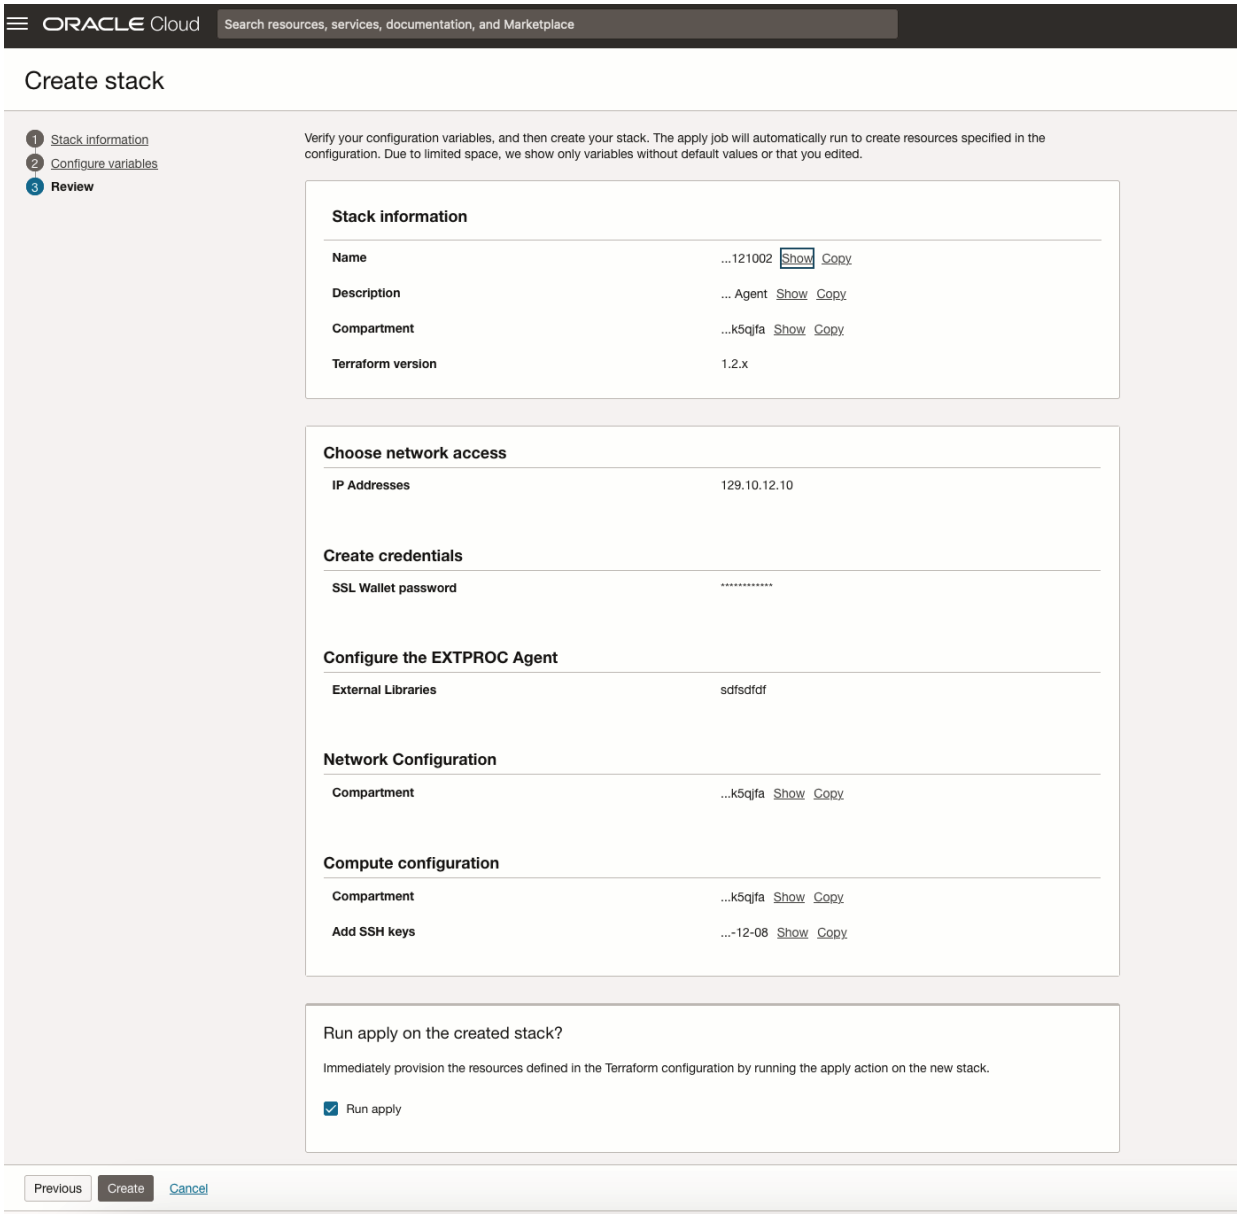


4. Click **Next**.

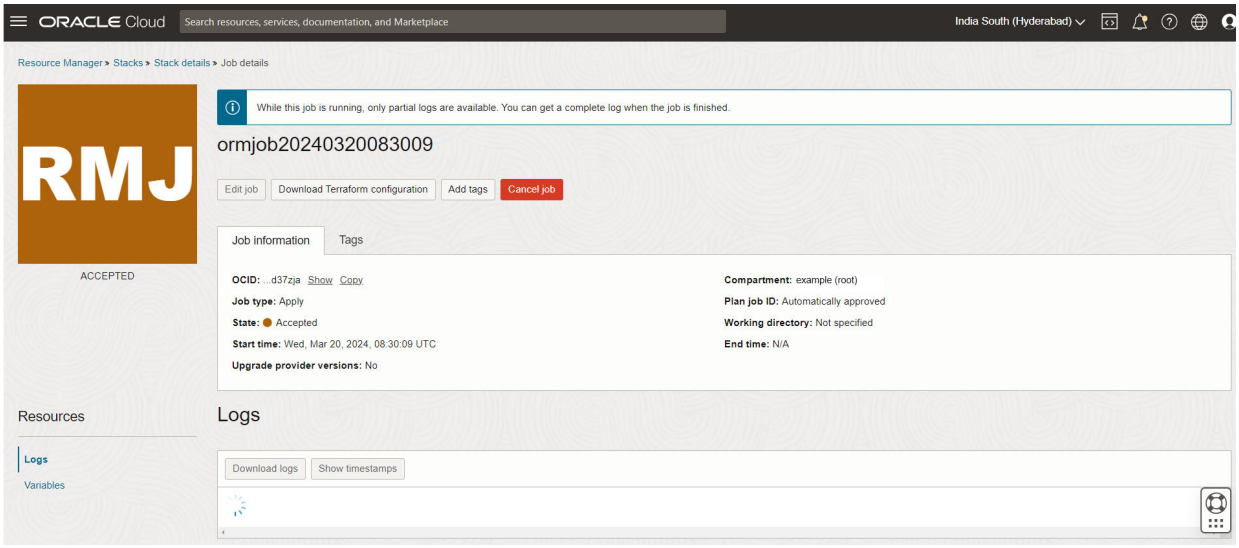
   This takes you to the **Review** page.

5. On the **Review** page perform the following steps:
   a. Verify the configuration variables.
   b. Select the **Run apply** checkbox under **Run apply on the created stack?**
   c. Click **Create**.

> **Note:**
>
> This area does not show variables that have default values or variables that you have not changed.



Resource Manager runs the apply job to create stack resources accordingly. This takes you to the **Job details** page and the job state is **Accepted**. When the apply job starts the status is updated to **In Progress**.



> **Note:**
>
> The information you need to connect to the instance created as part of the stack is available in the **Application Information** tab.

Upload Wallet to Create Secure Connection to the EXTPROC Agent Instance

A self-signed wallet is created as part of the `EXTPROC` agent application creation. This wallet allows you to access the `Extrpoc` agent instance.

To execute remote procedures at the `EXTPROC` agent instance, the Autonomous Database and the `EXTPROC` agent connect using Mutual Transport Layer Security (mTLS). When using Mutual Transport Layer Security (mTLS), clients connect through a TCPS (Secure TCP) database connection using standard TLS 1.2 with a trusted client certificate authority (CA) certificate. See About Connecting to an Autonomous Database Instance for more information.

> **Note:**
>
> You can also obtain and use a public certificate issued by a Certificate Authority (CA).

As a prerequisite, you must export the wallet to Object Storage from the `/u01/app/oracle/extproc_wallet` directory on the VM where `EXTPROC` runs.

Follow these steps to upload the wallet to your Autonomous Database:

1. Import the wallet, `cwallet.sso`, containing the certificates for the `EXTPROC` agent instance from Object Storage in your Autonomous Database. Note the following for the wallet file:
   - The wallet file, along with the Database user ID and password provide access to the `EXTPROC` agent instance. Store wallet files in a secure location and share them only with authorized users.
   - Do not rename the wallet file. The wallet file in Object Storage must be named `cwallet.sso`.

2. Create credentials to access your Object Storage where you store the wallet file `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See About Using Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

   ```
   CREATE DIRECTORY wallet_dir AS 'directory_location';
   ```

   See Create Directory in Autonomous Database for more information creating directories.

4. Use `DBMS_CLOUD.GET_OBJECT` to upload the wallet. For example:

   ```
   BEGIN
     DBMS_CLOUD.GET_OBJECT (
       credential_name     => 'DEF_CRED_NAME',
       object_uri          => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
       directory_name      => 'WALLET_DIR'
   );
   END;
   /
   ```

   In this example, `namespace-string` is the Oracle Cloud Infrastructure Object Storage namespace and `bucketname` is the bucket name. See Object Storage Namespaces for more information.

   The wallet is copied to the directory created in the previous step, *WALLET_DIR*. The wallet that allows you to connect to the `EXTPROC` agent instance is now available on your Autonomous Database instance.

Steps to Invoke an External Procedure as a SQL Function

Shows the steps to invoke an external Procedure as a SQL function.

After you launch the OCI Marketplace `EXTPROC` stack application and configure it to run external procedures, you create a library of SQL wrapper functions that reference and call their respective external procedures.

As a prerequisite, the whitelisted libraries must be copied into the `/u01/app/oracle/extproc_libs` directory on the `EXTPROC` VM.

Follow these steps to create a library in your Autonomous Database and register C routines as an external procedure in the library:

1. Create a library.

   An external procedure is a C language routine stored in a library. To invoke external procedures with Autonomous Database, you create a library.

   Run `DBMS_CLOUD_FUNCTION.CREATE_CATALOG` to create a library. For example:

   ```
   BEGIN
       DBMS_CLOUD_FUNCTION.CREATE_CATALOG (
           library_name               => 'demolib',
   ```

```
        library_listener_url       => 'remote_extproc_hostname:16000',
        library_wallet_dir_name    => 'wallet_dir',
        library_ssl_server_cert_dn => 'CN=VM Hostname',
        library_remote_path        => '/u01/app/oracle/extproc_libs/
library name'
);
END;
/
```

This creates the `demolib` library in your Autonomous Database and registers the dynamic link library in your database. The `EXTPROC` agent instance is pre-configured to host external procedures on port 16000.

See CREATE_CATALOG Procedure for more information.

Query DBA_CLOUD_FUNCTION_CATALOG View and USER_CLOUD_FUNCTION_CATALOG View views to retrieve the list of all the catalogs and libraries in your database.

Query the USER_CLOUD_FUNCTION_ERRORS View view to list any errors generated during the connection validation to the remote library location.

2. Create the function.

   For example:

```
CREATE OR REPLACE FUNCTION ftest(
      x VARCHAR2,
      y VARCHAR2)
RETURN VARCHAR2 AS LANGUAGE C
      LIBRARY test
      NAME "demolib"
      PARAMETERS(
          x STRING,
          y STRING)
      AGENT IN (x);
/
```

3. You can drop an existing library using `DROP_CATALOG` procedure. For example:

```
BEGIN
    DBMS_CLOUD_FUNCTION.DROP_CATALOG (
      LIBRARY_NAME  => 'demolib'
  );
END;
/
```

This drops the `DEMOLIB` library.

See DROP_CATALOG Procedure for more information.

Make External Calls Using a Customer-Managed Wallet

When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet with procedures in `UTL_HTTP`, `DBMS_LDAP`, `UTL_SMTP`, or `UTL_TCP`. You can also use a customer-managed wallet when the scheduler sends SMTP email notifications for various events related to scheduler jobs.

- About Using a Customer-Managed Wallet with External Calls
  When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet to handle external calls, or with the scheduler when the scheduler sends email for various events related to scheduler jobs.
- Prerequisites to Use a Customer-Managed Wallet with External Calls
  Shows the prerequisite steps to use a customer-managed wallet with external calls or with scheduler SMTP email notifications.
- Use a Customer-Managed Wallet for External Calls with UTL_HTTP
  When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet to handle external calls.
- Use a Customer-Managed Wallet with Scheduler Email Notifications
  Describes the steps to use the scheduler SMTP email server with a customer-managed wallet.
- Notes for Using a Customer-Managed Wallet with External Calls
  Provides notes for using a customer-managed wallet with external calls.

About Using a Customer-Managed Wallet with External Calls

When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet to handle external calls, or with the scheduler when the scheduler sends email for various events related to scheduler jobs.

On Autonomous Database you can make external calls for any of the of the following purposes:

- To use web services with `UTL_HTTP`.
- To access data from LDAP servers using `DBMS_LDAP`.
- To send email with `UTL_SMTP`.
- To communicate with external TCP/IP-based servers using TCP/IP with `UTL_TCP`.
- For Oracle Scheduler job email notifications.

By default when you use procedures in these packages Autonomous Database maintains an internal wallet and always uses secure connections (the Oracle managed wallet contains more than 90 of the most common trusted root and intermediate SSL certificates). When your Autonomous Database resides on a private endpoint you have the option to use the default Oracle managed wallet with the trusted and intermediate SLL certifications, or you can supply a customer-managed wallet.

When your Autonomous Database resides on a private endpoint you can specify a customer-managed wallet for `UTL_HTTP`, `UTL_SMTP`, `DBMS_LDAP`, and `DBMS_NETWORK_ACL_ADMIN` using the following PL/SQL procedures:

```
UTL_HTTP.SET_WALLET (
   path                 IN VARCHAR2,
   password             IN VARCHAR2 DEFAULT NULL);
UTL_HTTP.REQUEST (
   wallet_path          IN VARCHAR2 DEFAULT NULL,
   wallet_password      IN VARCHAR2 DEFAULT NULL)
UTL_HTTP.REQUEST_PIECES (
   wallet_p ath         IN VARCHAR2 DEFAULT NULL,
   wallet_password      IN VARCHAR2 DEFAULT NULL,
UTL_HTTP.CREATE_REQUEST_CONTEXT (
 wallet_path            IN VARCHAR2 DEFAULT NULL,
```

```
 wallet_password        IN VARCHAR2 DEFAULT NULL)
UTL_TCP.OPEN_CONNECTION
   wallet_path          IN  VARCHAR2 DEFAULT NULL,
   wallet_password      IN  VARCHAR2 DEFAULT NULL);
UTL_SMTP.OPEN_CONNECTION
   wallet_path          IN  VARCHAR2 DEFAULT NULL,
   wallet_password      IN  VARCHAR2 DEFAULT NULL)
DBMS_LDAP.OPEN_SSL(
  sslwrl                IN VARCHAR2,
  sslwalletpasswd       IN VARCHAR2)
DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE
  wallet_path IN VARCHAR2
DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACL(
  wallet_path IN VARCHAR2
```

In these calls, depending on the procedure, use either the `path` or `wallet_path` parameter to specify a customer-managed wallet. You set the wallet directory with the `DIR:` prefix and include a wallet path. For example:

```
UTL_HTTP.set_wallet('DIR:WALLET_DIR', 'password');
```

The current user invoking the API must have `READ` privileges on the directory object or be granted the `CREATE ANY DIRECTORY` system privilege.

The `DIR:` prefix is the preferred form to use to specify a customer-managed wallet. In addition, the `file:` prefix is supported. For example:

```
UTL_HTTP.set_wallet('file:WALLET_DIR/wallet.sso', 'password');
```

See Use a Customer-Managed Wallet for External Calls with UTL_HTTP for more information:

About Using a Customer-Managed Wallet with Scheduler Email Server

The scheduler email server is available to send email notifications for various events related to the scheduler, such as notification of started, failed, or completed jobs. By default, the scheduler SMTP email server uses the wallet defined in the `SSL_WALLET` property for SSL/TLS communications. Optionally, you can use a customer-managed wallet with the scheduler SMTP email server.

The following global attributes support using a customer-managed wallet:

- `EMAIL_SERVER_WALLET_DIRECTORY`: is set to a directory object that specifies the path where the SSL wallet resides.
- `EMAIL_SERVER_WALLET_CREDENTIAL`: is set to a credential object with a *username*/*password* pair, where the *username* is any value and the *password* is the SSL wallet password.

You set values for these attributes using `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE`.

See the following for more information:

- Use a Customer-Managed Wallet with Scheduler Email Notifications
- SET_SCHEDULER_ATTRIBUTE Procedure

Prerequisites to Use a Customer-Managed Wallet with External Calls

Shows the prerequisite steps to use a customer-managed wallet with external calls or with scheduler SMTP email notifications.

Perform the prerequisite steps:

1. Verify that the Autonomous Database instance is configured with a private endpoint.

   See Configure Network Access with Private Endpoints for more information.

2. Set the `private_target` parameter to value `TRUE` when you grant the required ACLs with `dbms_network_acl_admin.append_wallet_ace`, or set `ROUTE_OUTBOUND_CONNECTIONS` to the value `PRIVATE_ENDPOINT`.

   See Use a Customer-Managed Wallet for External Calls with UTL_HTTP and Enhanced Security for Outbound Connections with Private Endpoints and for more information.

3. Obtain or create a customer-managed wallet.

   For example, to create a wallet with `orapki`:

   ```
   -- Create an SSL Wallet and load the Root CERTs using orapki utility
   $ORACLE_HOME/bin/orapki wallet create -wallet /u01/web/wallet -pwd ********
   $ORACLE_HOME/bin/orapki wallet add -wallet /u01/web/wallet -trusted_cert -
   cert MyWebServer.cer -pwd ********
   -- Store the credentials in the SSL Wallet using mkstore utility
   $ORACLE_HOME/bin/mkstore -wrl /u01/web/wallet -createCredential secret-
   from-the-wallet 'example@oracle.com' ********
   Enter wallet password: ********
   ```

   See Managing Public Key Infrastructure (PKI) Elements for more information.

4. Store the wallet to a bucket on Cloud Object Storage.

   After you obtain or create the customer-managed wallet containing self-signed certificates, store the wallet to a location on your Cloud Object Storage.

Use a Customer-Managed Wallet for External Calls with UTL_HTTP

When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet to handle external calls.

These steps describe using a customer-managed wallet with `UTL_HTTP`. The steps are the same for the other supported packages, including: `DMBS_LDAP`, `UTL_SMTP`, and `UTL_TCP`.

Perform the prerequisite steps to use a customer-managed wallet. See Prerequisites to Use a Customer-Managed Wallet with External Calls for more information.

To configure an Autonomous Database to use a customer-managed wallet:

1. Create a credential using `DBMS_CLOUD.CREATE_CREDENTIAL` to access Cloud Object Storage.

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'user1@example.com',
       password => 'password'
   ```

```
  );
END;
/
```

The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

This creates the credential you use to access the Cloud Object Storage where the customer-managed wallet resides.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

2. Use an existing directory or create a new a directory for the wallet file.

   For example:

   ```
   CREATE DIRECTORY wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.

3. Use `DBMS_CLOUD.GET_OBJECT` to upload the customer-managed wallet to the directory you created in the previous step, *WALLET_DIR*.

   For example:

   ```
   BEGIN
       DBMS_CLOUD.GET_OBJECT(
           credential_name => 'DEF_CRED_NAME',
           object_uri => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
           directory_name => 'WALLET_DIR');
   END;
   /
   ```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

4. Grant the required ACLs to allow you to read the credentials from the specified directory.

   ```
   BEGIN
     dbms_network_acl_admin.append_wallet_ace(
         wallet_path => 'dir:WALLET_DIR',
         ace         => xs$ace_type(
              privilege_list => xs$name_list('use_client_certificates',
   'use_passwords'),
              principal_name => 'USER_NAME',
              principal_type => xs_acl.ptype_db)
       );
   END;
   /
   ```

5. Set the wallet path for use with `UTL_HTTP` procedures.

```
BEGIN
    UTL_HTTP.set_wallet('DIR:WALLET_DIR', 'password');
END;
/
```

   To specify the wallet directory with `UTL_HTTP.set_wallet` you can use either the `dir:` prefix or the `file:` prefix.

   The `dir:` prefix is only available on Autonomous Database. See UTL_HTTP for information on the `file:` prefix.

6. Now you can run `UTL_HTTP` procedures to access an endpoint using the customer-managed wallet with a self-signed certificate.

   For example:

```
SELECT UTL_HTTP.REQUEST('https://example.com') from dual;
```

Use a Customer-Managed Wallet with Scheduler Email Notifications

Describes the steps to use the scheduler SMTP email server with a customer-managed wallet.

Perform the prerequisite steps to use a customer-managed wallet. See Prerequisites to Use a Customer-Managed Wallet with External Calls for more information.

To use a customer-managed wallet with the scheduler email server:

1. Create a credential using `DBMS_CLOUD.CREATE_CREDENTIAL` to access your Cloud Object Storage.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   This creates the credential you use to access Cloud Object Storage where the customer-managed wallet resides.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

2. Use an existing directory or create a new a directory for the wallet file.

For example:

```
CREATE DIRECTORY wallet_dir AS 'directory_path_of_your_choice';
```

See Create Directory in Autonomous Database for information on creating directories.

3. Use `DBMS_CLOUD.GET_OBJECT` to upload the wallet to the directory you created in the previous step, *WALLET_DIR*.

   For example:

```
BEGIN
    DBMS_CLOUD.GET_OBJECT(
        credential_name => 'DEF_CRED_NAME',
        object_uri => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
        directory_name => 'WALLET_DIR');
END;
/
```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

4. Run the commands to set up the scheduler to send SMTP email for scheduler job notifications.

   For example:

```
BEGIN
    DBMS_SCHEDULER.set_scheduler_attribute('EMAIL_SERVER','smtp.email.us-
ashburn-1.oci.oraclecloud.com:587');
    DBMS_CLOUD.create_credential('EMAIL_CRED', 'ocid1.user.oc1..username',
'password');

DBMS_SCHEDULER.set_scheduler_attribute('EMAIL_SERVER_CREDENTIAL','ADMIN.EMA
IL_CRED');

DBMS_SCHEDULER.set_scheduler_attribute('EMAIL_SERVER_ENCRYPTION','STARTTLS'
);
END;
/
```

   These commands set the scheduler email SMTP server, create the credential object containing the SMTP credentials and set the scheduler attribute for the SMTP credentials, and specify to use TLS for email sent for scheduler job notification.

   See SET_SCHEDULER_ATTRIBUTE Procedure for more information.

5. Create a credential to store the password for the customer-managed wallet.

```
BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
         credential_name  => 'WALLET_CRED',
         username         =>  'any_user',
         password         => 'password');
```

```
END;
/
```

This creates the credential you use in the next step to provide the password for the customer-managed wallet.

6. Set the scheduler wallet directory and the wallet credential.

```
BEGIN

DBMS_SCHEDULER.set_scheduler_attribute('EMAIL_SERVER_WALLET_DIRECTORY','WAL
LET_DIR');

DBMS_SCHEDULER.set_scheduler_attribute('EMAIL_SERVER_WALLET_CREDENTIAL',
'ADMIN.WALLET_CRED');
END;
/
```

7. Query the `DBA_SCHEDULER_GLOBAL_ATTRIBUTE` view to verify the values you set in the previous steps.

```
SELECT attribute_name, value
       FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE
       WHERE attribute_name LIKE 'EMAIL_SERVER%' ORDER BY 1, 2;

ATTRIBUTE_NAME                 VALUE
------------------------------
-----------------------------------------------
EMAIL_SERVER                   smtp.email.us-
ashburn-1.oci.oraclecloud.com:587
EMAIL_SERVER_CREDENTIAL        "ADMIN"."EMAIL_CRED"
EMAIL_SERVER_ENCRYPTION        STARTTLS
EMAIL_SERVER_WALLET_CREDENTIAL "ADMIN"."WALLET_CRED"
EMAIL_SERVER_WALLET_DIRECTORY  "WALLET_DIR"
```

Notes for Using a Customer-Managed Wallet with External Calls

Provides notes for using a customer-managed wallet with external calls.

- `DBMS_CLOUD` requests do not honor the custom wallet you set with `UTL_HTTP.set_wallet`. This includes `DBMS_CLOUD.SEND_REQUEST` and all object storage access for `DBMS_CLOUD` external tables that you define with `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`, `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`, or `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`. When you perform a query on an external table that you created with a `DBMS_CLOUD` procedure, the queries do not honor the custom wallet you set with `UTL_HTTP.set_wallet`.
- `APEX_WEB_SERVICE` requests do not honor the custom wallet you set with `UTL_HTTP.set_wallet`.

  To use a customer-managed wallet with APEX, specify the `p_wallet_path` parameter in `APEX_WEB_SERVICE` API calls or set the Wallet Path instance setting in APEX Administration Services.

  See Access Oracle APEX Administration Services for more information.

- Both auto-login wallets and password protected wallets are supported. When you use an auto-login wallet, specify `NULL` for the `wallet_password` parameter.
- The current user invoking the `UTL_HTTP.set_wallet` API must have `READ` privileges on the directory object or be granted the `CREATE ANY DIRECTORY` system privilege.
- The `UTL_HTTP.SET_AUTHENTICATION_FROM_WALLET` API is allowed. See SET_AUTHENTICATION_FROM_WALLET Procedure for more information.
- The `file:` prefix is supported with `UTL_HTTP.set_wallet` as long as the specified file path is `PATH_PREFIX` compliant.

  You can determine the `PATH_PREFIX` compliance for a path provided as input with the `DBMS_PDB_IS_VALID_PATH` procedure (granted to `PUBLIC` including the `ADMIN` user).

  For example:

```
with function check_path_prefix_compliance(file_path varchar2)
  return varchar2 as
BEGIN
  if dbms_pdb_is_valid_path(file_path) then
    return 'YES';
  else
    return 'NO';
  end if;
END;
SELECT
  check_path_prefix_compliance('/u03/dbfs/1276CDexample/data/dpdump') as
PATH_PREFIX_COMPLIANT,
  check_path_prefix_compliance('/u01/app/oracle/diag') as
PATH_PREFIX_COMPLIANT
FROM
  dual;
/
```

- To ensure backward compatibility when you use `UTL_HTTP.set_wallet`, in cases where the wallet path is ignored, input values such as `file:`, `NULL`, and so on, are accepted. These values are ignored and specify to use the default SSL wallet path with `UTL_HTTP.set_wallet`.
- The `DBMS_NETWORK_ACL_ADMIN` wallet ACL APIs, such as `APPEND_WALLET_ACL` are supported. These procedures allow you to grant/revoke wallet ACL privileges. See DBMS_NETWORK_ACL_ADMIN for more information.
- To support using the password credentials in an SSL wallet for authentication, the current user invoking `UTL_HTTP` APIs must have the "`use-passwords`" ACL privilege on the wallet path.
- Notes for setting `EMAIL_SERVER_WALLET_DIRECTORY` and `EMAIL_SERVER_WALLET_CREDENTIAL` with `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE`:
  - To set the attribute values with `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE` you must be an administrative user or a user with `MANAGE SCHEDULER` privileges (the ADMIN user has these privileges).
  - In addition to `MANAGE SCHEDULER` privilege, the user invoking `DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE` must have of `READ` privilege on the directory object you set with `EMAIL_SERVER_WALLET_DIRECTORY`, and `EXECUTE` privilege on the credential object you set with `EMAIL_SERVER_WALLET_CREDENTIAL`.

Use Cloud Tables to Store Logging and Diagnostic Information

You can create Cloud Tables where table data resides on Oracle managed Cloud Storage and the table data does not consume database storage.

- About Cloud Tables
  You can create Cloud Tables as a complementary alternative to in-database tables. All Cloud Table data is stored in Oracle managed Object Storage. Oracle managed Object Storage is external storage, outside of the database, that Autonomous Database creates and manages.
- Create Cloud Tables
  Shows the steps to create a Cloud Table on Autonomous Database.
- Cloud Table Notes
  Provides notes for Cloud Tables:

About Cloud Tables

You can create Cloud Tables as a complementary alternative to in-database tables. All Cloud Table data is stored in Oracle managed Object Storage. Oracle managed Object Storage is external storage, outside of the database, that Autonomous Database creates and manages.

You can use Cloud Tables to store infrequently used application logging data, diagnostic information, or to store other data. In some existing applications that do not run on Autonomous Database you might store this kind of information in files on a local file system (for example using `UTL_FILE` APIs). Such logging mechanisms and the associated files can be very helpful when you need to diagnose and resolve application errors. However, storing information in database tables can use large amounts of database storage for data that is infrequently used. Using Cloud Tables the persistent data is saved in Oracle managed Object Storage, without consuming database storage.

SELECT and DML Restrictions for Cloud Tables

Cloud Tables function like ordinary database tables with some restrictions. You can use SELECT and DML, data manipulation statements, with the following exceptions:

- `MERGE` statements are not supported.
- `LOB` columns are limited to 10MB of data.
- DML concurrency control is different, and therefore:
  - `LOCK TABLE` may not prevent concurrent DML as it does for a database table.
  - `INSERT` does not acquire a lock on the table, and therefore INSERT is never blocked by concurrent DML operations.
  - `UPDATE` and `DELETE` operations both acquire an exclusive lock on a Cloud Table. Therefore, `UPDATE` or `DELETE` transactions block concurrent `UPDATE` or `DELETE` operations on a Cloud Table.
- Only NOT NULL constraints are enforced.
- DML is allowed in a Read-Write Autonomous Database as it is for any other table; Cloud Tables also allow DML operations in a Refreshable Clone.

Cloud Tables do not support the following:

- Indexes

- Invisible columns
- Virtual columns
- DML triggers
- More than 996 columns
- Boolean data type columns

Lifecycle Management Operations and Cloud Tables

Cloud Table data is stored in Oracle managed Object Storage. This means certain operations on Autonomous Database handle Cloud Tables differently than in-database tables, as follows:

- Cloud Table data is excluded from an Autonomous Database instance's backup and recovery (the data is not backed up and you cannot restore Cloud Table data).
- Cloud Table Data is protected through Oracle managed Object Storage.
- The lifecycle management operations that impact the state of an Autonomous Database instance do not have an impact on the data stored in Cloud Tables.

Cloud Table naming in Object Storage is defined uniquely for each Autonomous Database instance, based on its OCID. This means that any operation that changes or introduces a new OCID for an existing database has an impact on Cloud Tables. The following illustrates the impact of lifecycle operations on Cloud Table data.

Lifecycle Operation	Cloud Table Data Availability
Same region database clone	Cloud Table is cloned without Cloud Table data
Cross-region database clone	Cloud Table is cloned without Cloud Table data
Same region (local) Autonomous Data Guard Standby	Cloud Table and Cloud Table data are accessible
Cross-region Autonomous Data Guard Standby	Cloud Table is available on the standby, without the Cloud Table data
Same region (local) Backup-Based Disaster Recovery peer	Cloud Table and Cloud Table data are accessible
Cross-region Backup-Based Disaster Recovery peer	Cloud Table is available on the standby, without Cloud Table data
Lifecycle management operations impacting the SCN/timestamp of an Autonomous Database instance, including: • Long term backup • Restore database (point in time restore) • Clone from backup	Cloud Table will continue to be updated and the old state of Cloud Table data is not preserved or restored. This means only the current Cloud Table data is available.
Lifecycle Management operations, including: • Manage resource allocation • Move • Shrink • Rename • Mode: Read-only/read-write • Change workload type: for example from Data Warehouse to Transaction Processing	No impact on Cloud Tables or on Cloud Table data

Create Cloud Tables

Shows the steps to create a Cloud Table on Autonomous Database.

To create a Cloud Table:

1. Run the `CREATE_CLOUD_TABLE` procedure.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CLOUD_TABLE(
      table_name  => 'CLOUD_TABLE_TEST',
      column_list => 'I INTEGER, STR1 VARCHAR2(32)' );
   END;
   /
   ```

   See CREATE_CLOUD_TABLE Procedure for more information.

2. Insert data into the Cloud Table.

   ```
   INSERT INTO cloud_table_test VALUES (1, 'xyz');
   ```

3. Select data from a Cloud Table.

   ```
   SELECT * FROM cloud_table_test;

   I          STR1
   ---------- --------------------------------
   1          xyz
   ```

Use `DROP TABLE` when you want to drop a Cloud Table.

For example:

```
DROP TABLE CLOUD_TABLE_TEST;
```

Cloud Tables do not support the recycle bin.

See Cloud Table Notes for additional information.

Cloud Table Notes

Provides notes for Cloud Tables:

- You can grant `SELECT`, `INSERT`, and `UPDATE` privileges for a Cloud Table. No other privileges can be granted to a Cloud Table.

  See Configuring Privilege and Role Authorization for more information.

- Cloud Table constraints are limited to constraints in `RELY DISABLE NOVALIDATE` mode, which means the constraint is not enforced. The only exception to this is for `NOT NULL` constraints.

  Cloud Tables support all `NOT NULL` constraint modes including the default mode (`ENABLE VALIDATE`). `PRIMARY KEY`, `UNIQUE`, `FOREIGN KEY`, and `NOT NULL` constraints are supported; `CHECK` constraints are not supported.

  You can declare constraints inline as part of `COLUMN_LIST`.

For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CLOUD_TABLE(
        table_name  => 'CLOUD_TAB_WITH_CONSTRAINTS',
        column_list => 'PK INTEGER,
            DATE_ID INT REFERENCES DATE_DIM(DATE_ID) RELY DISABLE
NOVALIDATE,
            VAL NUMBER NOT NULL,
            CONSTRAINT CLOUD_TAB_PK PRIMARY KEY(PK) RELY DISABLE
NOVALIDATE');
END;
/
```

See Cloud Table Notes for additional Cloud Table limitations.

- The `DBMS_CLOUD` package is an invoker's rights package. The `DBMS_CLOUD.CREATE_CLOUD_TABLE` procedure only allows you to create a table in the invoker's schema.

  See Invoker's Rights and Definer's Rights Clause for more information.

- The `column_list` parameter in a `DBMS_CLOUD.CREATE_CLOUD_TABLE` procedure call can include the `DEFAULT` clause, which functions like the `DEFAULT` clause in `CREATE TABLE`. See CREATE TABLE for more information.

  For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CLOUD_TABLE(
   table_name  => 'CLOUD_TABLE_TEST_DEFAULT',
   column_list => 'I INTEGER, STR2 VARCHAR2(32) DEFAULT ''ABC''');
END;
/
```

  Then you can insert with default values. For example:

```
INSERT INTO cloud_table_test_default (i) VALUES (1);
1 row created.
INSERT INTO cloud_table_test_default VALUES (2, default);
1 row created.
INSERT INTO cloud_table_test_default VALUES (3, null);
1 row created.
INSERT INTO cloud_table_test_default VALUES (4, 'xyz');
1 row created.
COMMIT;
Commit complete.
SELECT * FROM cloud_table_test_default ORDER BY i;

I STR2
- ----
1 ABC
2 ABC
3 null
4 xyz
```

Analyze

Provides information on the built-in tools that allow you to explore your data with reports, analytics, and visualization.

- Build Reports and Dashboards Using Oracle Analytics
  You can use Oracle Analytics Cloud and Oracle Analytics Desktop with Autonomous Database.
- Creating Dashboards, Reports, and Notebooks with Autonomous Database
  Autonomous Database includes support for building dashboards, reports, and notebooks for data analysis using Oracle Analytics Desktop and Oracle Machine Learning Notebooks.
- Use Oracle Spatial with Autonomous Database
  Oracle Spatial Database is included in Autonomous Database, allowing developers and analysts to get started easily with location intelligence analytics and mapping services.
- The Data Analysis Tool
  The Data Analysis tool enables you to create Analytic Views with multidimensional metadata.
- The Catalog Tool
  The Catalog Tool allows you browse, search and discover data in, and connected to, the Oracle Autonomous Database.
- The Data Insights Page
  The Data Insights page displays information about patterns and anomalies in the data of entities in your Oracle Autonomous Database.
- Use Oracle OLAP with Autonomous Database
  Oracle OLAP is available on Autonomous Database. Oracle OLAP supports uses such as planning, forecasting, budgeting, and analysis.

Build Reports and Dashboards Using Oracle Analytics

You can use Oracle Analytics Cloud and Oracle Analytics Desktop with Autonomous Database.

Working with Oracle Analytics Cloud

You can use Oracle Analytics Cloud with Autonomous Database. Use Oracle Analytics Cloud to select interactive visualizations and automatically create advanced calculations to reveal the insights in your data.

For more information, see Use Oracle Analytics Cloud with Autonomous Database.

Working with Oracle Analytics Desktop

You can use Oracle Analytics Desktop with Autonomous Database. Just connect to Autonomous Database, select the elements that you're interested in, and let Oracle Analytics Desktop find the best way to visualize it. Choose from a variety of visualizations to look at data in a specific way.

For more information see Use Oracle Analytics Desktop with Autonomous Database.

Creating Dashboards, Reports, and Notebooks with Autonomous Database

Autonomous Database includes support for building dashboards, reports, and notebooks for data analysis using Oracle Analytics Desktop and Oracle Machine Learning Notebooks.

Oracle Analytics Desktop is designed for business users and report developers. Oracle Analytics Desktop enables you to gain insight into your data and create reports and build interactive visualizations. It also gives you a preview of the self-service visualization capabilities included in Oracle Analytics Cloud, which extends the data exploration and visualization experience by offering secure sharing and collaboration across the enterprise, additional data sources, and a full mobile experience including proactive self-learning analytics delivered to your device.

Oracle Machine Learning Notebooks is a built-in browser-based interactive data analysis environment that is part of Autonomous Database. Oracle Machine Learning Notebooks is designed for data scientists who want use the extensive library of in-database machine learning features.

- Create Dashboards and Reports to Analyze and Visualize Your Data
  Gain insight into your data with Oracle Analytics Desktop and Oracle Analytics Cloud. These tools let you explore your Autonomous Database data through advanced analytics and interactive visualizations.
- Create Notebooks, Workspaces, and Projects with Oracle Machine Learning Notebooks
  Oracle Machine Learning Notebooks provides a collaborative interface for creating notebooks and for performing real-time analytics.

Create Dashboards and Reports to Analyze and Visualize Your Data

Gain insight into your data with Oracle Analytics Desktop and Oracle Analytics Cloud. These tools let you explore your Autonomous Database data through advanced analytics and interactive visualizations.

- Use Oracle Analytics Desktop with Autonomous Database
  Gain insight into your data with Oracle Analytics Desktop. Oracle Analytics Desktop lets you explore your Autonomous Database data through interactive visualizations.
- Use Oracle Analytics Cloud with Autonomous Database
  You can use Oracle Analytics Cloud with Autonomous Database. Oracle Analytics Cloud provides a complete set of tools for deriving and sharing data insights.

Use Oracle Analytics Desktop with Autonomous Database

Gain insight into your data with Oracle Analytics Desktop. Oracle Analytics Desktop lets you explore your Autonomous Database data through interactive visualizations.

Oracle Analytics Desktop provides powerful personal data exploration and visualization in a simple per-user desktop download. Oracle Analytics Desktop is the perfect tool for quick exploration of sample data from multiple sources or for rapid analysis and investigation of your own local data sets.

Oracle Analytics Desktop makes it easy to visualize your Autonomous Database data so you can focus on exploring interesting data patterns. Just connect to Autonomous Database, select the elements that you're interested in, and let Oracle Analytics Desktop find the best way to visualize it. Choose from a variety of visualizations to look at data in a specific way.

Oracle Analytics Desktop also gives you a preview of the self-service visualization capabilities included in Oracle Analytics Cloud, Oracle's industrial-strength cloud analytics platform. Oracle Analytics Cloud extends the data exploration and visualization experience by offering secure sharing and collaboration across the enterprise, additional data sources, greater scale, and a full mobile experience including proactive self-learning analytics delivered to your device. Try Oracle Analytics Desktop for personal analytics and to sample a taste of Oracle's broader analytics portfolio.

Oracle Analytics Desktop's benefits include:

- A personal, single-user desktop application.
- Offline availability.
- Completely private analysis.
- Full control of data source connections.
- Lightweight single-file download.
- No remote server infrastructure.
- No administration tasks.

See the *User's Guide for Oracle Analytics Desktop* for information on connecting Oracle Analytics Desktop to Autonomous Database.

To get started with Oracle Analytics Desktop use the following link to visit the software download page which includes more information about system requirements and provides instructions for installing Oracle Analytics Desktop on different platforms:

Oracle Analytics Desktop Download Details

Use Oracle Analytics Cloud with Autonomous Database

You can use Oracle Analytics Cloud with Autonomous Database. Oracle Analytics Cloud provides a complete set of tools for deriving and sharing data insights.

- Data preparation: Analysts can ingest, profile, and cleanse data using a variety of algorithms.
- Data flow: Analysts can prepare, transform and aggregate data, and then run machine-learning models at scale.
- Data discovery: Subject matter experts can easily collaborate with other business users, blending intelligent analysis at scale, machine learning, and statistical modeling.
- Data visualization: Analysts can visualize any data, on any device, on-premise and in the cloud.
- Data collaboration: Large organizations and small teams can share data more simply, as you don't need to manage or consolidate multiple versions of spreadsheets.
- Data-driven: Application developers can utilize interfaces that enable them to extend, customize, and embed rich analytic experiences in the application flow.

See *Visualizing Data and Building Reports in Oracle Analytics Cloud* for details on connecting Autonomous Database with Oracle Analytics Cloud.

Create Notebooks, Workspaces, and Projects with Oracle Machine Learning Notebooks

Oracle Machine Learning Notebooks provides a collaborative interface for creating notebooks and for performing real-time analytics.

- Using Oracle Machine Learning User Interface on Autonomous Database
  Oracle Machine Learning Notebooks provide a browser-based interactive data analysis environment where you can develop, document, share, and automate analytical methodologies.

- Work with Oracle Machine Learning User Interface for Data Access, Analysis, and Discovery
  You can use Oracle Machine Learning Notebooks to access data and for data discovery, analytics, and notebooks.

Using Oracle Machine Learning User Interface on Autonomous Database

Oracle Machine Learning Notebooks provide a browser-based interactive data analysis environment where you can develop, document, share, and automate analytical methodologies.

Oracle Machine Learning Notebooks includes:

- **Oracle Machine Learning User Administration Application**
  - Web based administrative UI for managing (list, create, update, delete) Oracle Machine Learning users
  - Notebook users map to database users.
  - Access to the User Management feature is limited to the database administrator account (ADMIN). See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for more information.
- **Oracle Machine Learning Notebooks Application**
  - Web based application for data scientists
  - Allows for creation of workspaces, projects, and notebooks

  See Work with Oracle Machine Learning User Interface for Data Access, Analysis, and Discovery for information on accessing Oracle Machine Learning user workspaces, projects, and notebooks from your Autonomous Database.

Work with Oracle Machine Learning User Interface for Data Access, Analysis, and Discovery

You can use Oracle Machine Learning Notebooks to access data and for data discovery, analytics, and notebooks.

To access Oracle Machine Learning Notebooks you can use the Oracle Cloud Infrastructure Console or Database Actions.

To access Oracle Machine Learning Notebooks from the Oracle Cloud Infrastructure Console:

1. From the Display Name column, select an Autonomous Database.
2. On the Autonomous Database Details page click the **Tools** tab.
3. In the **Tools** column, select the **Oracle ML User Administration** link.
4. Enter your **Username** and **Password**.

   The Administrator creates OML users. See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for details.
5. Click **Sign in**.

To access Oracle Machine Learning Notebooks from Database Actions:

1. On the Oracle Cloud Infrastructure Console, from the Display Name column select an Autonomous Database.
2. On the Autonomous Database Details page select **Database Actions** and click **View all database actions**.

3. On the Database Actions Launchpad, under **Development**, select **Oracle Machine Learning**.

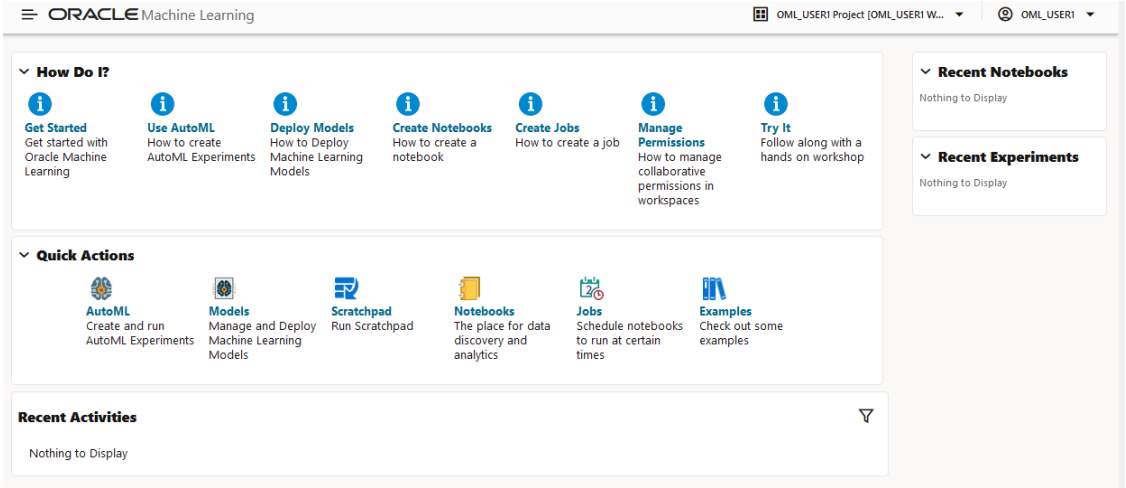
   If you do not see the **Oracle Machine Learning** card then your database user is missing the required `OML_DEVELOPER` role. See Required Roles to Access Tools from Database Actions for more information.

4. Enter your username and password.

   The Administrator creates OML users. See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for details.

5. Click **Sign In**.

This shows Oracle Machine Learning user application.



Oracle Machine Learning Notebooks allows you to access your data in your database and build notebooks with the following:

- Data Ingestion and Selection
- Data Viewing and Discovery
- Data Graphing, Visualization, and Collaboration
- Data Analysis

You can also create and run SQL statements and create and run SQL scripts that access your data in your database.

Use Oracle Spatial with Autonomous Database

Oracle Spatial Database is included in Autonomous Database, allowing developers and analysts to get started easily with location intelligence analytics and mapping services.

- About Oracle Spatial with Autonomous Database
- Oracle Spatial Limitations with Autonomous Database
  Autonomous Database includes Oracle Spatial, with some limitations.

About Oracle Spatial with Autonomous Database

Oracle Spatial allows developers and analysts to use spatial analysis in every application from basic spatial search and analysis to advanced geospatial applications and Geographic Information Systems (GIS).

Organizations can manage different types of geospatial data, perform hundreds of spatial analytic operations, and use interactive map visualization tools with the spatial features in Oracle Autonomous Database and Oracle Database.

The spatial features provide a schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial features in Autonomous Database. Spatial consists of the following:

- A schema (MDSYS) that prescribes the storage, syntax, and semantics of supported geometric data types
- A spatial indexing mechanism
- Operators, functions, and procedures for performing area-of-interest queries, spatial join queries, and other spatial analysis operations
- Utility functions and procedures for validating, loading, extracting, and working with spatial data
- GeoRaster, a feature that lets you store, index, query, analyze, and deliver GeoRaster data, that is, raster image and gridded data and its associated metadata
- Features for geocoding address data and for reverse geocoding longitude/latitude data to a street address:
  - SDO_GCDR.ELOC_GEOCODE
  - SDO_GCDR.ELOC_GEOCODE_AS_GEOM

> **Note:**
>
> `SDO_GCDR.ELOC_GEOCODE` and `SDO_GCDR.ELOC_GEOCODE_AS_GEOM` functions are only available on Autonomous Database.

See the following for more information:

- Spatial Concepts
- Oracle Database Spatial
- Geocoding Address Data

Oracle Spatial Limitations with Autonomous Database

Autonomous Database includes Oracle Spatial, with some limitations.

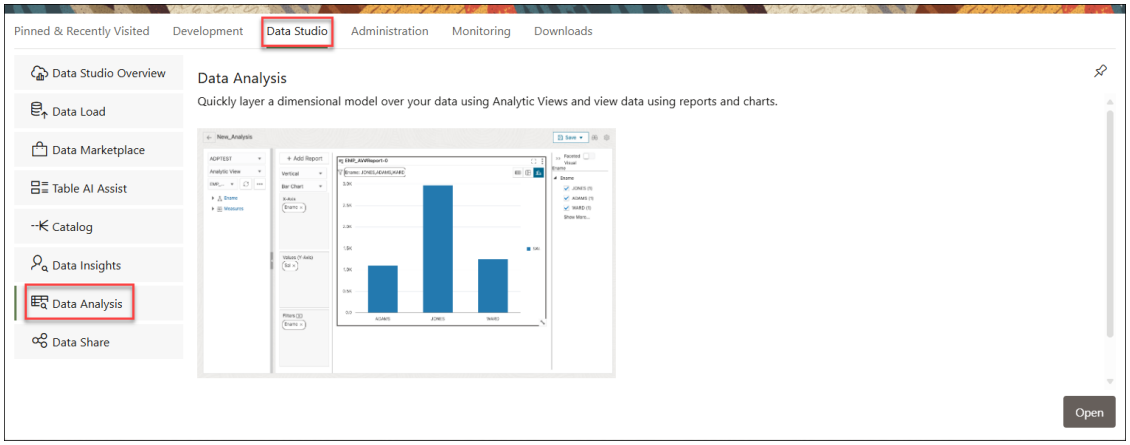
You can use the Oracle spatial features with Autonomous Database, with the following limitations:

- The following Oracle Spatial components require that you download applications from Oracle Cloud Marketplace:
  - Oracle Spatial Studio
  - Oracle Spatial Map Visualization
  - Network Data Model
  - Geospatial Consortium Web Services
- The following is not available in Autonomous Database:
  - Router

The Data Analysis Tool

The Data Analysis tool enables you to create Analytic Views with multidimensional metadata.

To reach the **Data Analysis** page, select the **Data Analysis** menu in the Data Studio tab of the Launchpad.

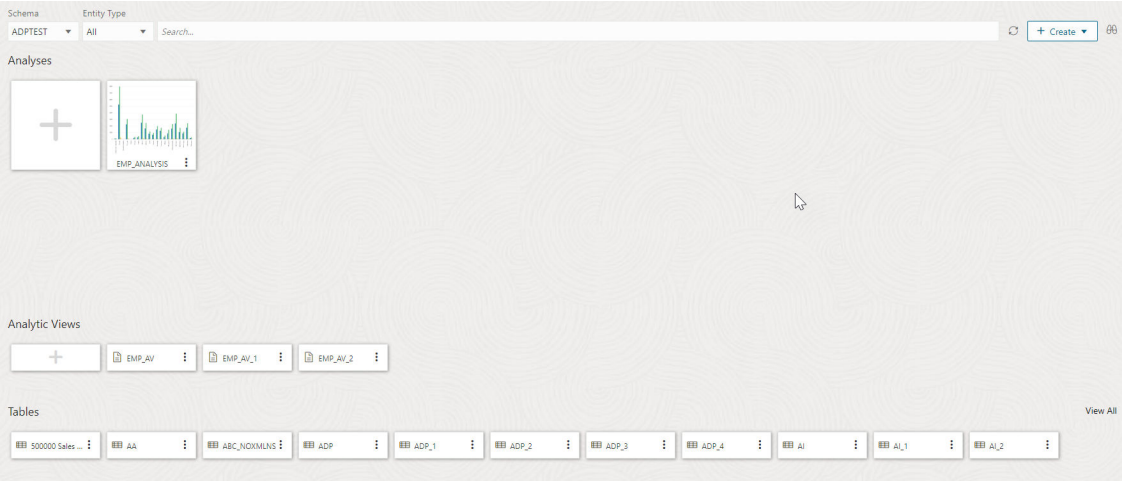


You create Analytic Views on top of a fact table with several dimensions and hierarchies. Analytic views refer to tables in the database and allow users to create hierarchies for dimensions. You can also create Analyses and reports using information from the Analytic Views. The Data Analysis homepage enables you to search for Analyses, view and perform tasks such as edit, delete, view or rename Analyses. You can also analyze, find errors, export, edit, compile and delete Analytic Views. You can analyze tables and generate SQL reports from them.

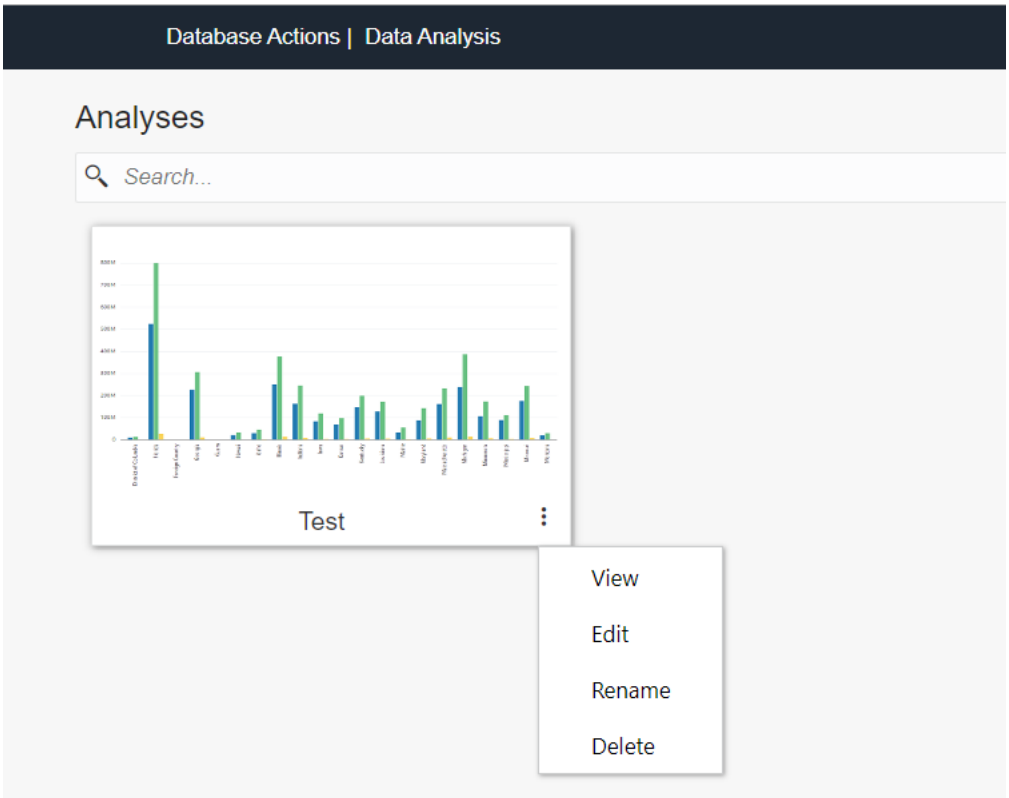
Select the **Data Analysis** card from the Data Studio suite to access this tool. You can also access it by clicking the Selector icon and selecting Data Analysis from the Data Tools menu in the navigation pane.

> **Note:**
>
> If you do not see the Data Analysis card then your database user is missing the required DWROLE role.

The Data Analysis home page consists of three parts: Analyses, Analytic Views and Tables.



Analyses



The top section of the homepage comprises of a list of Analyses. Use the search field to search for Analyses you create. The top section of the homepage comprises of a list of Analyses. Use the search field to search for Analyses you create.

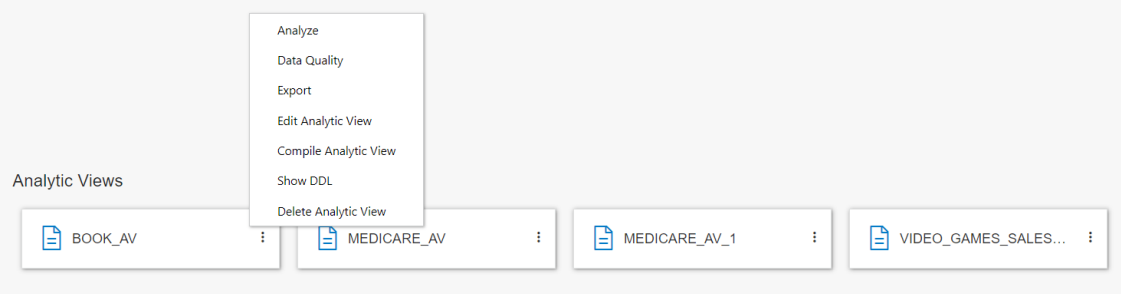
Analyses are analysis of multiple Analytic Views. The Analyses card displays the name of the analysis. Click **Actions** (three vertical dots) to open the context menu.

The actions available are:

- **View:** Opens the Analysis View page in a new window where you can view the analysis.
- **Edit:** Opens the selected Analysis page where you can edit the reports present in the analysis.

- **Rename:** Allows you to rename the Analysis. Click **save** to modify the new name.
- **Delete:** Opens the delete Analysis dialog where you can delete the analysis.

Analytic Views



The bottom section of the homepage displays list of existing Analytic Views. Each Analytic View card displays the name of the Analytic View. The Actions icon enables you to manage the Analytic View. Click **Actions** (three vertical dots) to open the context menu. The actions available are:

- **Analyze:** Opens the Analytic View browser and the Analysis View page in a new window where you can view the Analysis.
- **Data Quality:** Opens the Data Quality page where the tool validates the selected Analytic View for errors and lists them out.
- **Export:** Allows you to export the Analytic View to Tableau and PowerBI.
- **Edit Analytic View:** Opens the Edit Analytic View dialog box where you can edit the properties of the selected Analytic View.
- **Compile Analytic View:** This option compiles the Analytic View and returns compilation errors if there are any.
- **Show DDL:** Displays the DDL statements for the Analytic View.
- **Delete Analytic View:** Deletes the selected Analytic View.

The **+Create** button enables you to create **Analysis** and create **Analytic View** from the home page.

You can select both hierarchies and measures from Analytic Views. Hierarchies are DB objects that allow users to define relationships between various levels or generations of dimension members. As the name implies, hierarchies organize data using hierarchical relationships. With this tool you can analyze and visualize data in different Points of View (POV). You can export the metadata and visualize it with sophisticated tools like Oracle Analytics Cloud (OAC) and Tableau.

Advantages of Data Analysis tool

With Data Analysis tool you can:

- Visualize, analyze and inspect your data clearly and efficiently with pivot tables
- Calculate total number of errors present in the Analytic View you create and provide solutions to minimize the errors
- Automatically display meaningful insights to help you make better decisions
- Analyze your data across dimensions with support for hierarchical aggregation and drill-down
- Share your Analytic Views with the tool of your choice over various options of raw data consumption to draw meaningful insights and make them accessible to any user

By identifying relationships among tables and columns, Analytic Views enable your system to optimize queries. They also open new avenues for analyzing data. These avenues include data insights, improved hierarchy navigation, and the addition of hierarchy-aware calculations.

This tool runs complex and hierarchical SQL queries along with SQL extensions in the background, which simplifies real-time calculations. It makes complex data more accessible and easier to understand.

The Data Analysis Page

The following section describes searching and obtaining information about Analytic Views, creating Analytic Views, inspecting your data, discovering insights and visualizing data using tools like Oracle Analytics Cloud (OAC), Tableau, and Microsoft Power BI.

> **Note:**
>
> - OAC has in-built tools to search and utilize Analytic Views.
> - We have no direct support for Microsoft Power BI, yet its users can map their tool to the AV transparency views to avail some of the benefits of Analytic Views.

Read these topics for detailed descriptions on Analyses and Analytic Views:

- Searching and obtaining information about Analytic Views
  When you first open the Data Analysis page, it displays the list of schemas and Analytic Views. With Select Schema, you can select a preferred Schema from a list of schemas available in the drop-down.
- Creating Analytic Views
  You can create Analytic Views and view information about them. You can also edit and perform other actions on them.
- Working with Analyses
  Analyses are a collection of multiple reports on a single page, which provides quick access to multiple data analyses collected from different Analytic Views.
- Viewing Analyses
  Analyses provide you an insight into the performance of your data.
- Workflow to build Analyses
  Here is the workflow to build an analyses.
- Creating Analyses
  Use the Data Analysis tool to create and edit your Analyses. The analysis provides you customized view of Analytic View data. An analysis consists of one or more reports that displays the results of analysis.
- Creating Reports
  A single report you generate analyzes an AV based on the Levels and measures you select.
- Run Natural Language Query in the Data Analysis Tool
  You can query the Oracle Autonomous Database by using Natural Language Query rather than having to write SQL Query.
- Generate Natural Language explanation from SQL Query using AI Explain
  You can translate SQL queries to natural language that is understood by you.

- Vector Search in the Data Analysis Tool
  You can use Oracle AI Vector Search capabilities to search for relevant text from your source data on a specific column.
- Format Numeric Columns in the Data Analysis Tool
  The custom formatting of numeric columns enables you to select your format type such as **Number**, **Currency** and **Percentage** using Mapping numeric column wizard in the Data Analysis tool.
- Using Calculation Templates
  The Data Analysis tool provides templates for all of the calculations typically in demand for business intelligence applications.
- Oracle Autonomous Database for Excel
  The Oracle Autonomous Database for Excel integrates Microsoft Excel spreadsheets with the Autonomous Database to retrieve and analyze data from Analytic Views in the database. You can also directly run SQL queries to view their results in the worksheet.
- Oracle Autonomous Database for Google Sheets
  The Oracle Autonomous Database add-on enables you to query tables using SQL or Analytic Views using a wizard directly from Google Sheets for analysis.

Searching and obtaining information about Analytic Views

When you first open the Data Analysis page, it displays the list of schemas and Analytic Views. With Select Schema, you can select a preferred Schema from a list of schemas available in the drop-down.

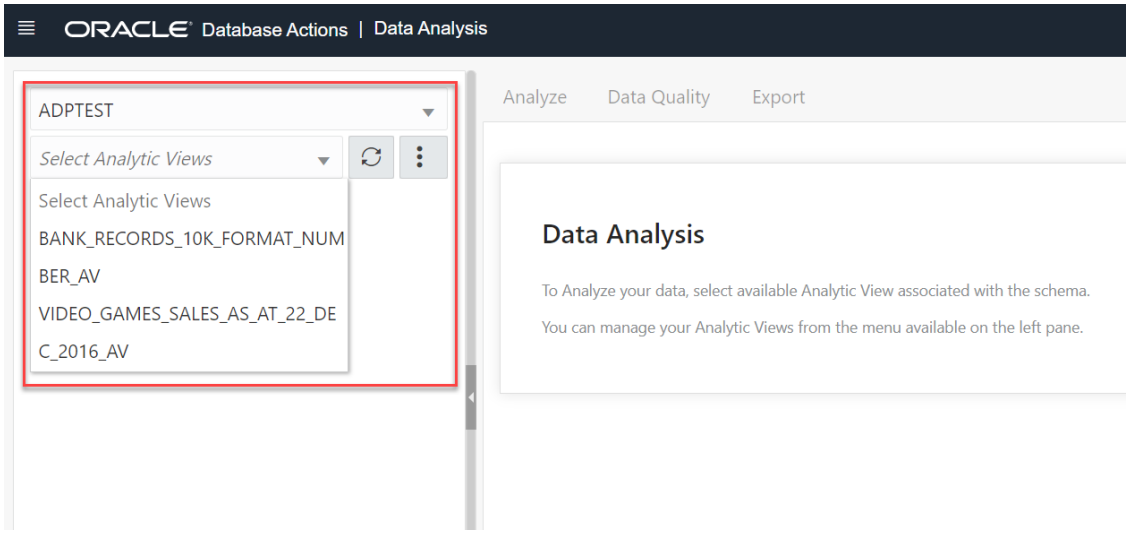
The **Select Analytic Views** drop-down enables you to select an available Analytic View associated with the schema. When you create an Analytic View, it appears in the drop-down option with your schema. The Refresh AV icon refreshes the contents of the selected Analytic View.

The **Action** icon next to the Refresh AV button enables you to manage Analytic Views. You can Create Analytic View, Edit Analytic View, Compile Analytic View, Show the Data Definition Language (DDL) that generates the Analytic View or Delete Analytic View from the menu.

Obtain information about Analytic Views

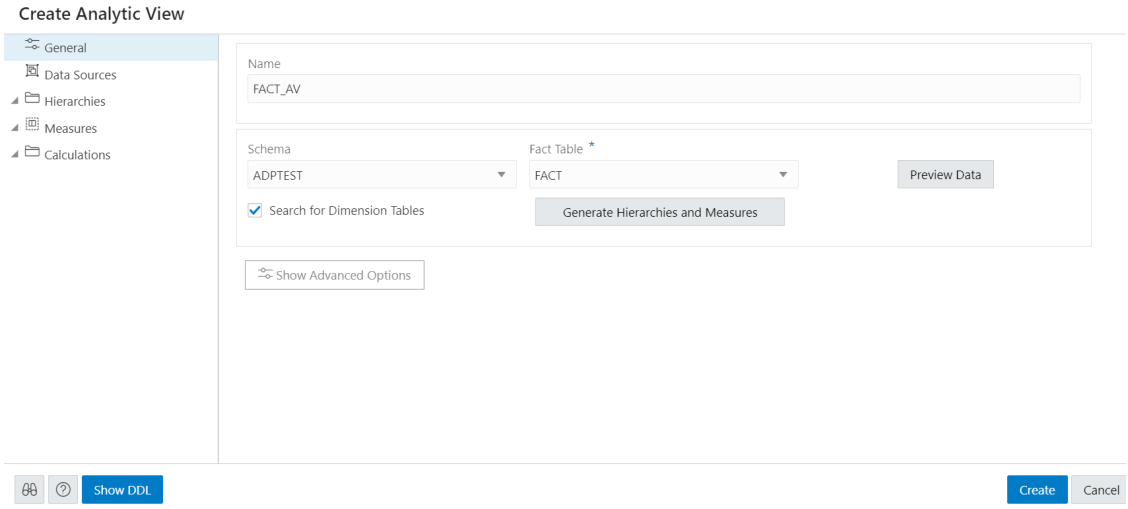
By default, Analytic Views are filtered by the current user's schema, as indicated by the schema list below the menu-bar. You can remove the selected schema filter by selecting another user's schema. To search for Analytic Views in other schemas, select one of the schemas from the drop-down.

If there is no Analytic View associated with the schema selected, the tool prompts you to create an Analytic View.



Creating Analytic Views

You can create Analytic Views and view information about them. You can also edit and perform other actions on them.



When you create an Analytic View, you identify a fact table that contains the data to inspect. The **Generate Hierarchies and Measures** button looks at the contents of that table, identifies any hierarchies in the fact table, and searches for other tables that may contain related hierarchies.

While creating an Analytic View, you can enable or disable the following advanced options:

- Autonomous Aggregate Cache, which uses the dimensional metadata of the Analytic View to manage a cache and that improves query response time.
- Analytic View Transparency Views, which presents Analytic Views as regular database views and enables you to use your analytic tools of choice while gaining the benefits of Analytic Views.
- Analytic View Base Table Query Transformation, which enables you to use your existing reports and tools without requiring changes to them.

Create Analytic View

To create Analytic View, click **Create** from the Data Analysis home page and select **Create Analytic View** to begin the process.

Click **Cancel** to cancel the creation of the Analytic View at any time.

Specify Attributes of the Analytic View

On the **General** tab of the **Create Analytic View** pane, specify the following:

- The name for the Analytic View
- The fact table for the view
- Advanced options

You can also preview the data of the fact table and see statistics about that data.

In the **Name** field, specify a name of your choice.

The **Schema** field has the current user's schema. You can only create an Analytic View in that schema.

In the **Fact Table** field, expand the drop-down list and click **More Sources**. The **Select Sources** dialog box has a list of the available tables and views. Select a table or view from the list.

To filter the list, begin typing characters in the Filter field. As you type, the list changes to show the tables or views that contain the characters. Clear the field to show the complete list again. After you select a table or view, click OK.

To enable or disable the advanced options, on the **Create Analytic View** pane, click the **Show Advanced Options** icon at the bottom left. Select or deselect options as desired.

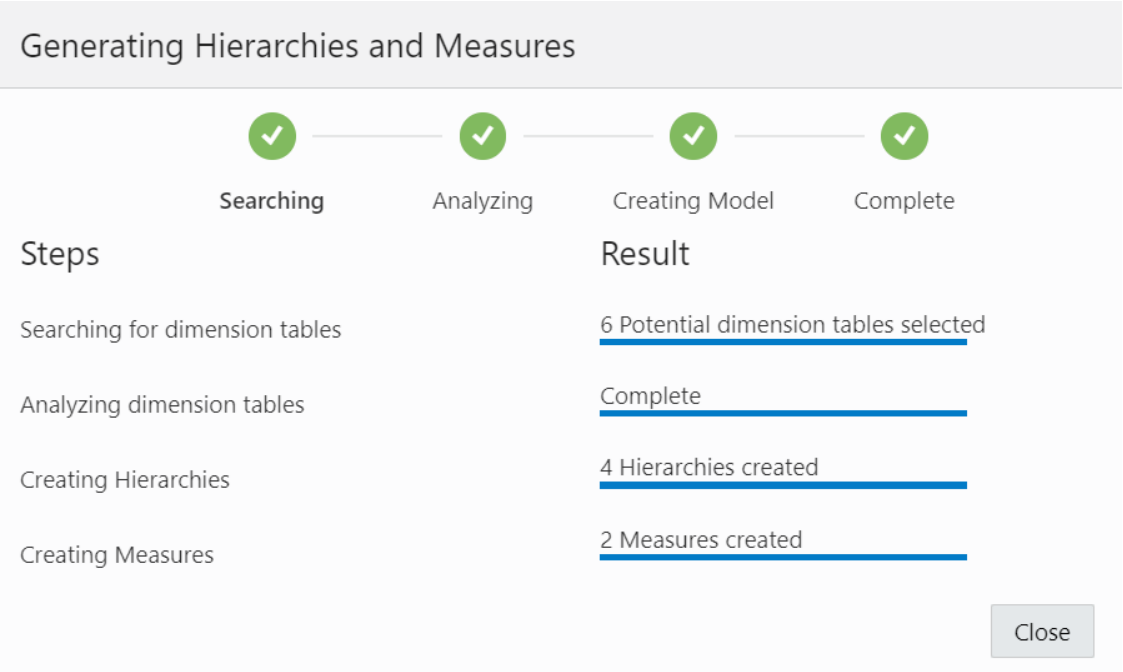
To view the data in the fact table and statistics about the data, click the **Preview Data** button. In the Preview and Statistics pane, the Preview tab shows the columns of the table and the data in the columns.

The Statistics tab shows the size of the table and the number of rows and columns. The statistics may take a few moments to appear, during which time the message, "No statistics available..." may appear. The statistics include the names of the columns, their data types, the number of distinct values and null values, the maximum and minimum values, and other information. The bar graph displays the top unique column values and the number of their occurrences for the selected column. Point to a bar in the graph to see the number of occurrences of the unique value.

Click **Close** to close the Preview and Statistics pane and return to the Create Analytic View pane.

Click on **Generate Hierarchies and Measures** icon.

The Generating Hierarchies and Measures dialog box displays the progress of searching for dimension tables, analyzing the dimension tables and identifying and creating the data sources, joins, hierarchies, and measures to use. When the process completes, click **Close**.



The **Search for Dimension Tables** check box when selected, enables you to search for dimension tables while generating hierarchies and measures.

After the hierarchies and measures are generated, they are displayed under their respective tabs. Review the hierarchies and measures created for you.

Specify the **Name**, **Fact Table** and select **Advanced Options** in the **General** tab of **Create Analytic View** pane. Click **Create** to generate an Analytic View.

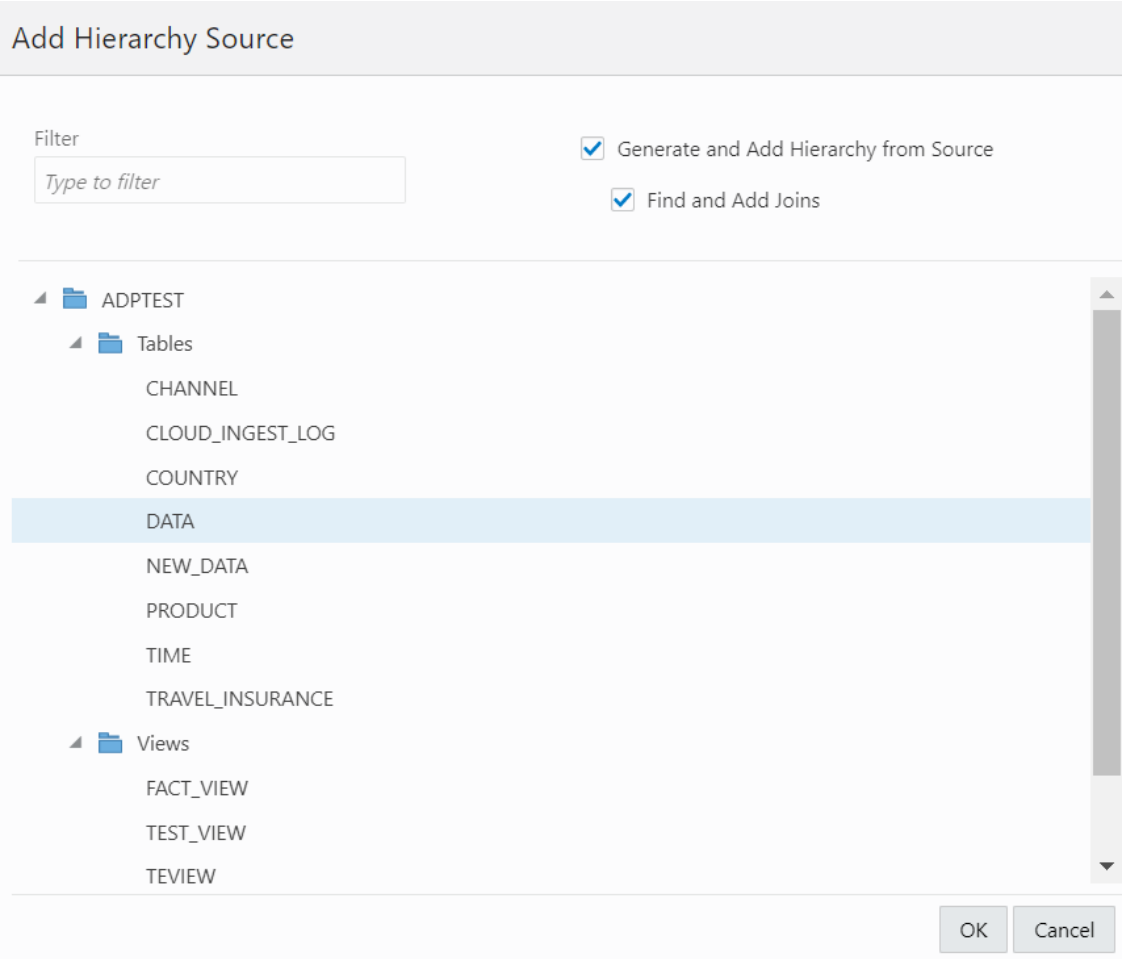
View Data Sources

The Data Sources tab displays the sources of the data and the relationships among them. It has a graphical display of the fact table and the related dimension tables. For example, a fact table of health insurance data might have columns for geography identifiers, income codes, and gender codes. The Data Sources tab would display items for the fact table and for the geography, income, and gender dimension tables.

You can add hierarchies from data sources even after generating hierarchies from the existing fact table. You can add one or more hierarchies to your new or existing analytic view. Multiple hierarchies can be defined and used in an analytical view, however only one will be used by default.

Right-click the Data Sources tab and select **Add Hierarchy Sources** or select **Add Hierarchy Sources**.

Selecting **Add Hierarchy Sources** launches an **Add Hierarchy Source** dialog box.



You can view all the fact tables and views associated with the analytic view.

In the filter field, you can either manually look for the source or start typing to search for the fact table or views from the list of available fact tables and views. After typing the full name of the source, the tool automatically matches the fact table or view.

Select **Generate and Add hierarchy from Source** to generate analysis and hierarchies associated with the source data you select.

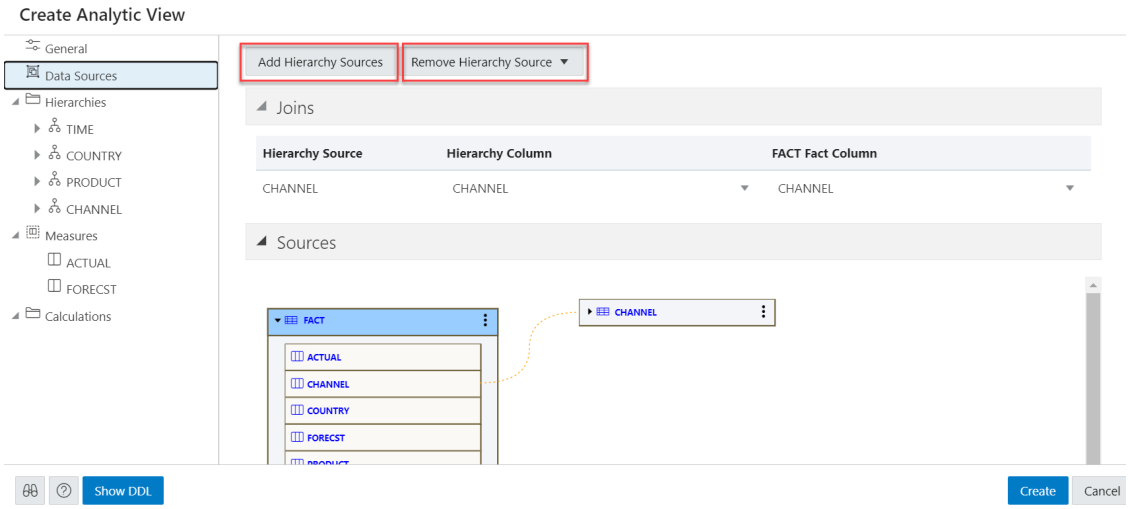
Select **Find and Add Joins** to link all the data sources with the fact table. You can add multiple join entries for a single hierarchy.

Click **OK** to select the source.

The Generating Hierarchies and Measures dialog box displays the progress of analyzing the dimension tables and creating the hierarchies. When the process completes, click **Close**.

> **Note:**
>
> When you add a hierarchy from the data source, you see the new hierarchy in the list of hierarchies in the Hierarchies tab. You can navigate between the Data Sources tab, the Hierarchies tab, the Measures tab, the Calculations tab. You can add a hierarchy from a source that is not connected by navigating back to the Data Sources tab.

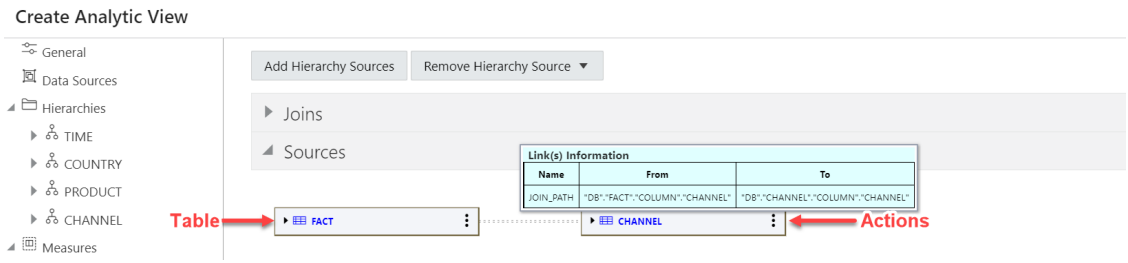
Select **Remove Hierarchy Source** to remove the hierarchies you create from the data sources. You cannot remove hierarchies generated from the fact table you select from this option.



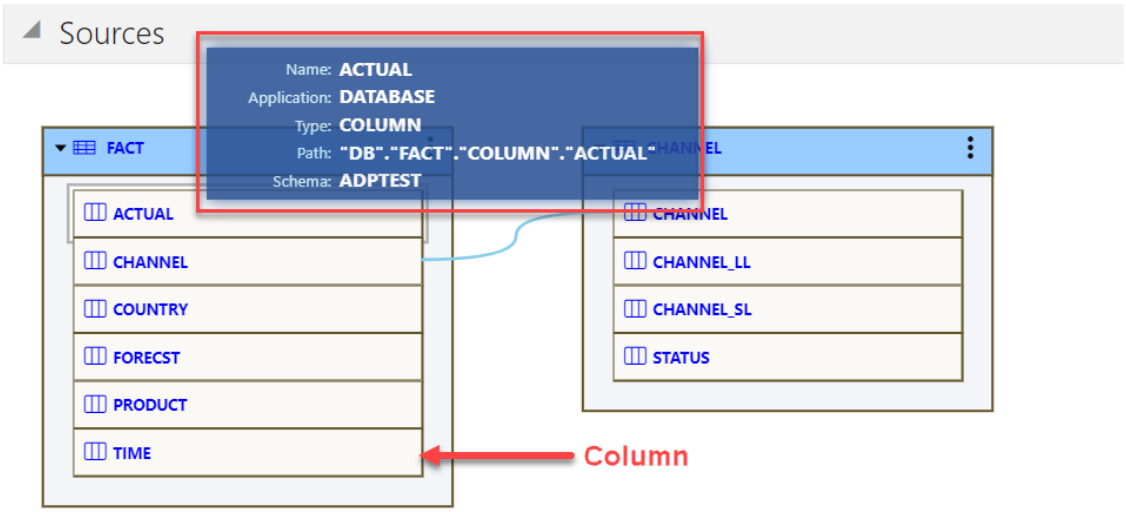
Expand **Joins** to view the **Hierarchy Source**, **Hierarchy Column** and the **Fact column** mapped with the Analytic View. The **Joins** is visible only when the hierarchy table differs from the fact table. You can add multiple join entries for a single hierarchy.

Expand **Sources** to view the fact table associated with the Analytic View. The data model expands to include the data from the source that you added.

Pointing to an item displays the name, application, type, path and the schema of the table. Click the **Actions** (three vertical dots) icon at the right of the item to display a menu to expand or collapse the view of the table.



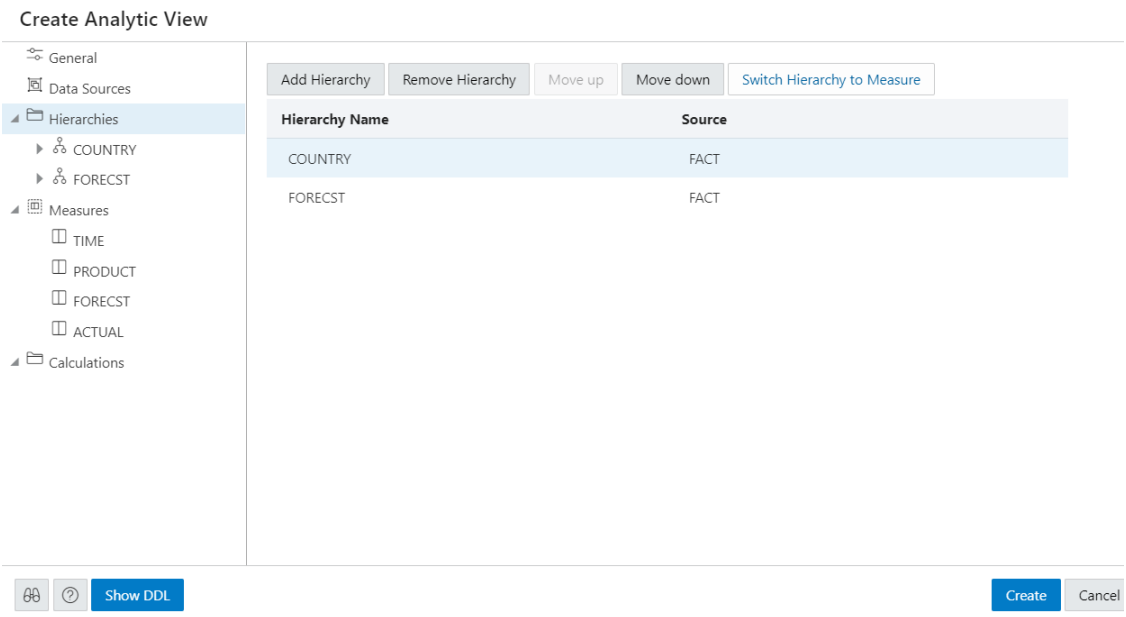
An expanded item displays the columns of the table. Pointing to a column displays the name, application, type, path, and schema of the column.



The lines that connect the dimension tables to the fact table indicate the join paths between them. Pointing to a line displays information about the join paths of the links between the tables. If the line connects a table that is collapsed, then the line is dotted. If the line connects two expanded tables, then the line is solid and connects the column in the dimension table to the column in the fact table.

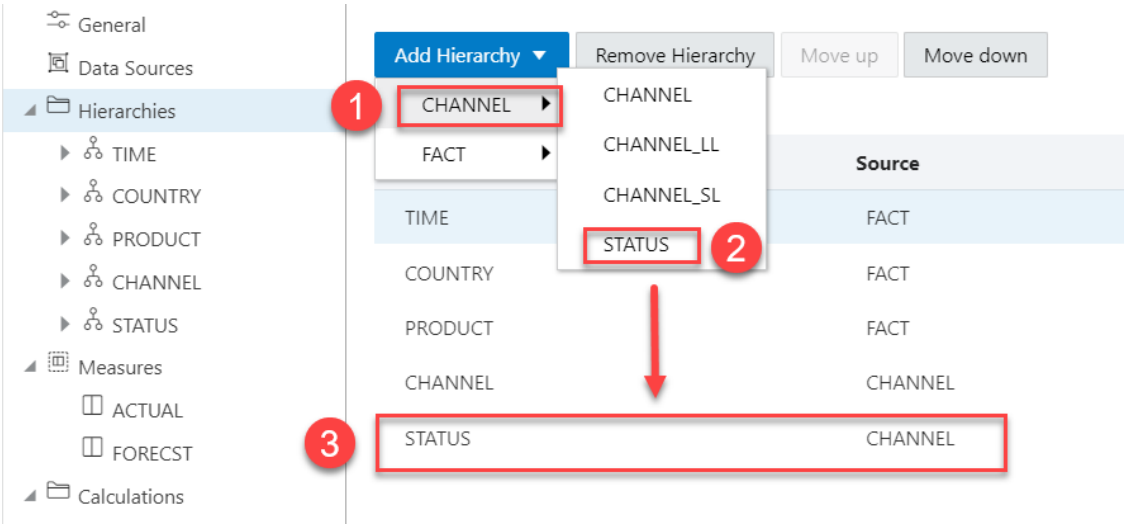
View and Manage Hierarchies

The Hierarchies tab displays the hierarchies generated by the Analytic View creation tool. The display includes the name of the hierarchy and the source table.



An analytic view must include at least one hierarchy.

To add a Hierarchy, click **Add Hierarchy**. This results in a display as a list of column in that table. Select a column that operates as the detailed level of the hierarchy and be the join-key to the fact table.



To remove the hierarchy, select the hierarchy you want to remove from the list and click **Remove Hierarchy**

Select **Move Up** or **Move Down** to position the order of the Hierarchy in the resulting view.

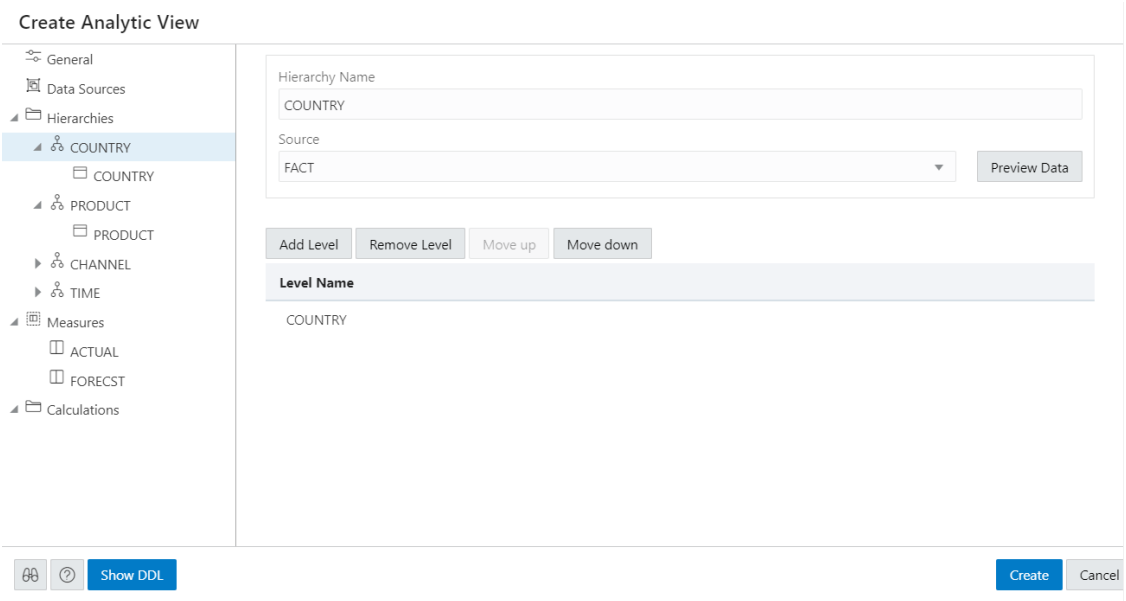
Click **Switch Hierarchy to Measure** to change the hierarchy you select to a measure in the Measures list.

You can also **Add Hierarchy** and **Add Hierarchy From Table** by right-clicking the Hierarchy tab.

If you click on a hierarchy name, a dialog box displays the Hierarchy Name and Source.

To change the source, select a different source from the drop-down list.

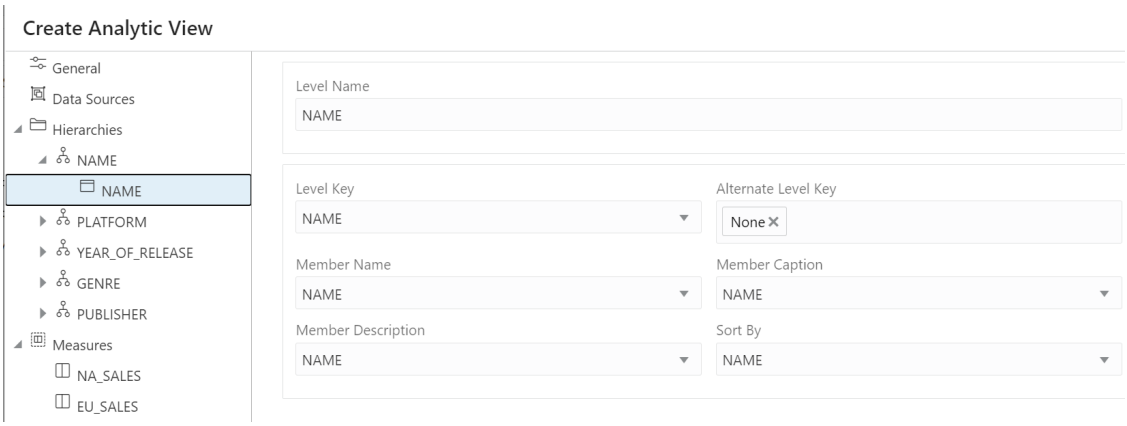
Select **Add Level** to add a level to the hierarchy. Click **Remove Level** to remove the selected level from the hierarchy.



To view the data in the fact table and statistics about the data, click the **Preview Data** button. In the Preview and Statistics pane, the Preview tab shows the columns of the table and the data in the columns. The Statistics tab shows the size of the table and the number of rows and columns.

If you click on a particular level in the Hierarchy tab, a dialog box displays it's respective Level Name, Level Key, Alternate Level Key, Member Name, Member Caption, Member Description, source, and Sort By drop-down. To change any of the field values, enter the value in the appropriate field.

> **Note:**
>
> You can enter multiple level keys Member Name, Member Caption, Member Description and Sort By.



Member Captions and Member Descriptions generally represent detailed labels for objects. These are typically end-user-friendly names. For example, you can caption a hierarchy representing geography areas named GEOGRAPHY_HIERARCHY as "Geography" and specify its description as "Geographic areas such as cities, states, and countries."

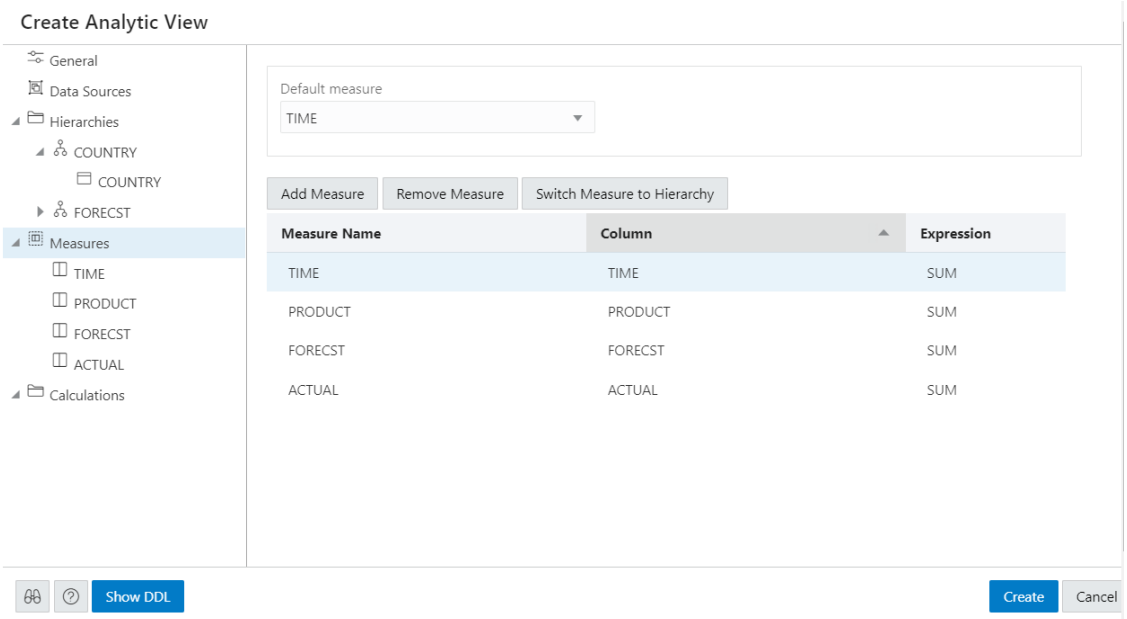
To see the measures for the Analytic View, click **Measures** tab. To immediately create the Analytic View, click **Create**. To cancel the creation, click **Cancel**.

View and Manage Measures

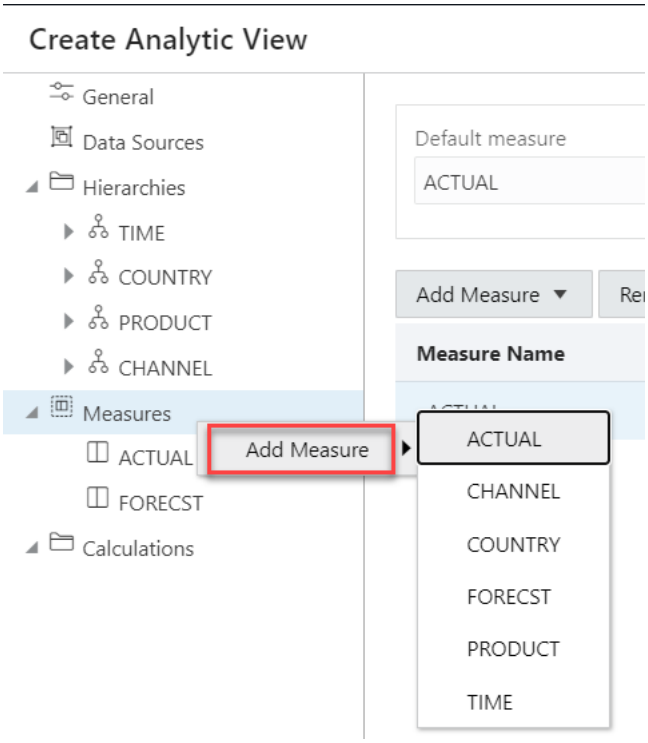
The Measures tab displays the measures suggested for the Analytic View. It displays the Measure Name, Column, and operator Expression for each measure.

The measures specify fact data and the calculations or other operations to perform on the data.

To add measures, click **Add Measure**. You can view a new measure at the bottom of the measures list. To remove the measure, select the measure you want to remove from the list and click **Remove Measure**.



To alternatively add a measure from the data source, right- click the Measures tab. This pops up a list of columns that can be used as measures. Select one measure from the list.



You can exclude a column from the measures on right-clicking the Measures tab and selecting Remove Measure.

Click **Switch Measure to Hierarchy** to change the measure you select to hierarchy in the Hierarchies list.

You must specify a measure as the default measure for the analytic view; otherwise, the first measure in the definition is the default. Select **Default Measure** from the drop-down.

To add a measure, right-click the Measures tab and select **Add Measure**. To remove a measure, select the particular measure you want to remove, right-click on it and select **Remove Measure**.

You can select a different column for a measure from the Column drop-down list. You can select a different operator from the Expression drop-down list.

In creating an analytic view, you must specify one or more hierarchies and a fact table that has at least one measure column and a column to join to each of the dimension tables outside of the fact table.

Create new calculated measures

You can add measure calculations to a query of an analytic view.

The measures and hierarchies associated with the analytic views enable us to create new calculated measures.

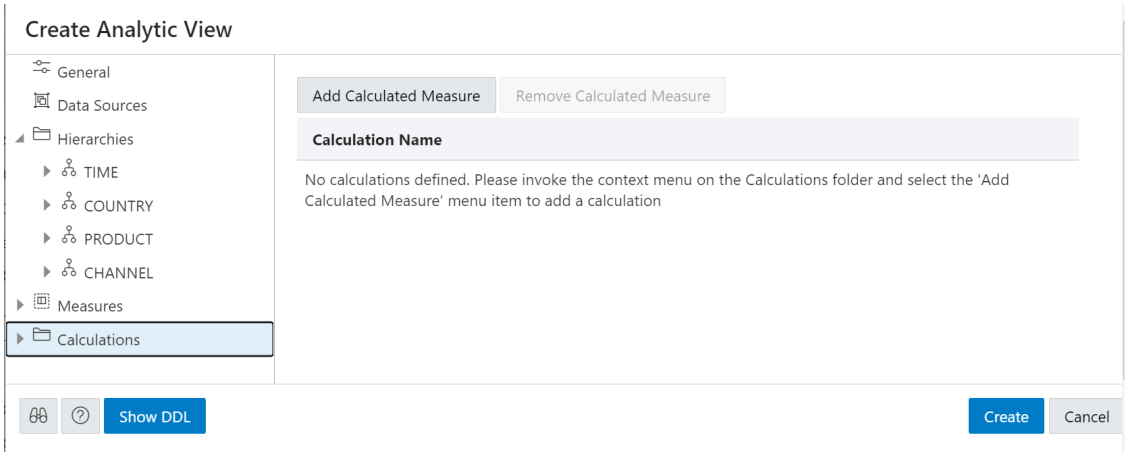
Calculated measures return values from data stored in one or more measures. You compute these measures at run time.

> **Note:**
>
> You can create the measures without increasing the size of the database since the calculated measures do not store the data. However, they may slow performance. You need to decide which measures to calculate on demand.

The Analytic Views provides easy-to-use templates for creating calculated measures.

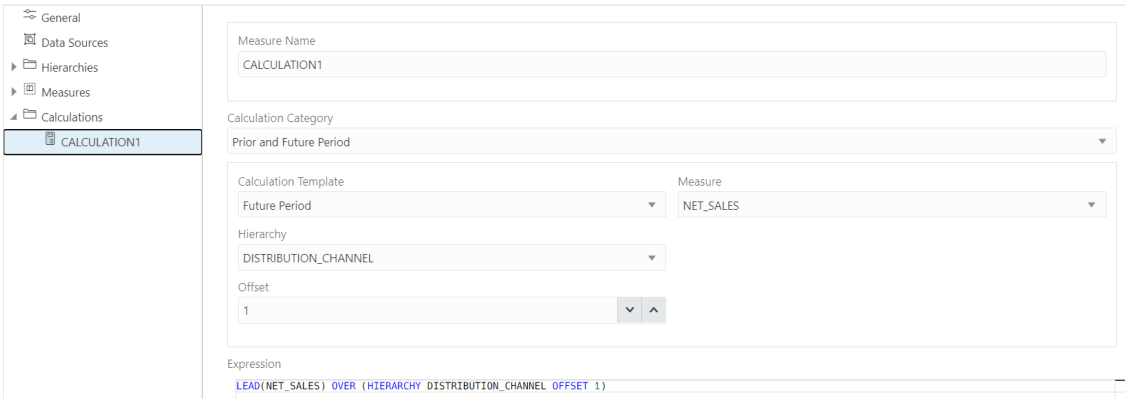
Once you create a calculated measure, it appears in the list of measures of the Analytic View .You can create a calculated measure at any time which is available for querying in SQL.

The Data Analysis tool provides easy-to-use templates for creating calculated measures.



Click **Add Calculated Measure** to add calculations to the measures. You can view the new calculation with system generated name in the **Calculations** tab.

Click the newly created calculated measure.



In the **Measure Name** field, enter the name of the calculated measure.

You can select preferred category of calculation from a list of options such as Prior and Future Period, Cumulative Aggregates, Period To Date, Parallel Period, Moving Aggregates, Share, Qualified Data Reference, and Ranking using the **Calculation Category** drop-down.

Your choice of category of calculation dynamically changes the **Calculation Template**.

For more details on how to use Calculation templates, see Using Calculation Templates.

Select the **Measure** and **Hierarchy** on which you want to base the calculated measures.

Select **Offset** value by clicking the up or the down arrow. The number specifies the number of members to move either forward or backward from the current member. The ordering of members within a level is dependent on the definition of the attribute dimension used by the hierarchy. The default value is 0 which represents POSITION FROM BEGINNING.

The Expression field lists the expressions which the calculated measure uses.

On the creation of the Analytic view, the calculated measure appears in the navigation tree in the Calculated Measures folder.

Click **Create**. A confirmation dialog box appears that asks for your confirmation. Select **Yes** to proceed with the creation of Analytic View.

After creating the Analytic View, you will view a success message informing you of its creation.

On editing the Analytic View you create, you can view the calculated measure in the navigation tree in the Calculations folder.

Click the **Tour** icon for a guided tour of the worksheet highlighting salient features and providing information if you are new to the interface.

Click the **help** icon to open the contextual or online help for the page you are viewing.

Click **Show DDL** to generate Data Definition Language statements for the analytic view.

Edit Analytic View

You might want to edit an Analytic View to make changes to the data sources, the hierarchies, or the measures.

To edit an Analytic View, click the **Action** icon on the Analytic View item, then click **Edit Analytic View**. On the Edit Analytic View screen, select a tab and make changes as desired.

When you have completed the changes, click **Update**.

Working with Analyses

Analyses are a collection of multiple reports on a single page, which provides quick access to multiple data analyses collected from different Analytic Views.

Analyses enable you to monitor performance, create reports and set estimates and targets for future work. It provides you a visual representation of performance with charts and graphs.

You can access the Analyses page by clicking the Analyses tile on the Data Analysis home page.

Viewing Analyses

Analyses provide you an insight into the performance of your data.

You can use the Analysis and the Analyze pane to search or browse Analytic Views, view their analysis, or reports you have access to. Clicking on the Analyses takes you to a page where you can view the Analyze pane. Here you can view default hierarchy level and measures selected. You can drag and drop any levels and measures from the Analytic View browser to rows/columns and Values in the drop area respectively. This defines your analysis criteria. Once the values are dropped, the Data Analysis tool generates a query internally. The tool displays the results of the analysis in the form of reports in the Analyses that matches your analysis criteria. You can add multiple reports to the Analysis. You can also examine and analyze the reports and save them as a new analysis. You can just save the Analysis and not a single report. Once you save all the reports, it will be part of that single Analysis. Reports are unnamed.

Workflow to build Analyses

Here is the workflow to build an analyses.

Following are few common tasks to start building Analyses:

- **Create a useful analysis:** Before creating your first analysis, you can construct a useful analysis over a single Analytic View. This way you can generate analyses on which you can create reports that you display on the Analyses.
- **Create Analysis:** Create an analysis to display data from analysis.
- **Create Reports:** An Analysis can have multiple reports that are independent of one another. This can be used to compare and analyze data generated from different Analytic Views.
- **Save Analysis:** Create customized Analyses that enable you to view reports and their analyses in the current state and save it for future reference.

Format Numeric Columns in the Data Analysis Tool

The custom formatting of numeric columns enables you to select your format type such as **Number**, **Currency** and **Percentage** using Mapping numeric column wizard in the Data Analysis tool.

> **Note:**
>
> Mapping wizard can be viewed only in tabular mode and Chart mode of viewing output.

To map the numeric column:

1. From the Table browser column in the left, drag and drop the numeric column to the measure drop area.
2. Click the respective column on the drop area. The Formatting dialog box appears that enables you to perform changes to the numeric column.
3. The options available depends on the Format Type of the respective column you select. The various format types are **Number**, **Currency** and **Percentage**.
4. The following options are available from the Formatting dialog box when you select **Number** as format type:
   - **Precision**:
     It represents the total number of digits. You can select **Default**, **0.0**, **0.00** or **0.000**.

     For example: To view the number 1.2, map the precision to **0.0**.
   - **Thousand Split**: With this formatting you can insert a comma after every third significant figure.. For example, select **1,234** from the drop-down to view the number as 3,454 instead of 3454.
   - Select **Abbreviate** to view the abbreviated form of the number. For example, you will view 1000 as 1k.
   - **Aggregation**: This column performs aggregation operations such as **Sum**, **Min**, **Max**, **Avg**, **Count** and **Distinct Count** on the selected input column.
5. If your column is of **Currency** Type, you can view the following options:
   - **Select Currency**: You can select various currencies from the drop-down list.

     Select **Highlight Negative Numbers** to highlight negative Numbers.

     You can also view **Precision**, **Thousand Split**, **Abbreviate** and **Aggregation** options.
6. If your column is of **Percentage** Type, you can view **Precision**, **Thousand Split**, **Abbreviate** and **Aggregation** options.

Creating Analyses

Use the Data Analysis tool to create and edit your Analyses. The analysis provides you customized view of Analytic View data. An analysis consists of one or more reports that displays the results of analysis.

You can create a Basepay analysis and add content to track your team's pay. You can view the analysis in a pivot view or tabular view or in the form of charts. You can create an analysis that displays these three views.

In this example, you create a new analysis called New_Analysis.

1. On the Data Analysis home page, click the **Create Analysis** button.
2. You can make changes to existing Analyses by adding different values from hierarchies and measures.
3. The AV name you view on the report represents the AV used to create the report. With a different Analytic View you can create a different report.

> **Note:**
>
> You must have at least one report to build an analysis.

4. To edit the existing analysis, In the Analytic View browser, select the objects to analyze in the navigation pane and drag and drop them to the drop area in Columns, Rows or Values and Filters of the Analyze tab.
5. The report updates based on the artifacts (levels and measures) you select.

The new analysis which contains the updated report will now be visible in the Data Analysis home page for further editing.

- Saving Analyses
  You can save the personalized settings you made for the Analysis and use them on any other Analyses for future reference.

Saving Analyses

You can save the personalized settings you made for the Analysis and use them on any other Analyses for future reference.

You won't have to make these decisions manually every time you open the Analyses page if you save these preferences.

1. Open the analysis for editing from the Data Analysis home page. Select **Edit** from the Analysis tile you wish to edit.
2. Click on the **Save As** icon. Enter a descriptive name for your Analysis.
3. Click **Save**.

Creating Reports

A single report you generate analyzes an AV based on the Levels and measures you select.

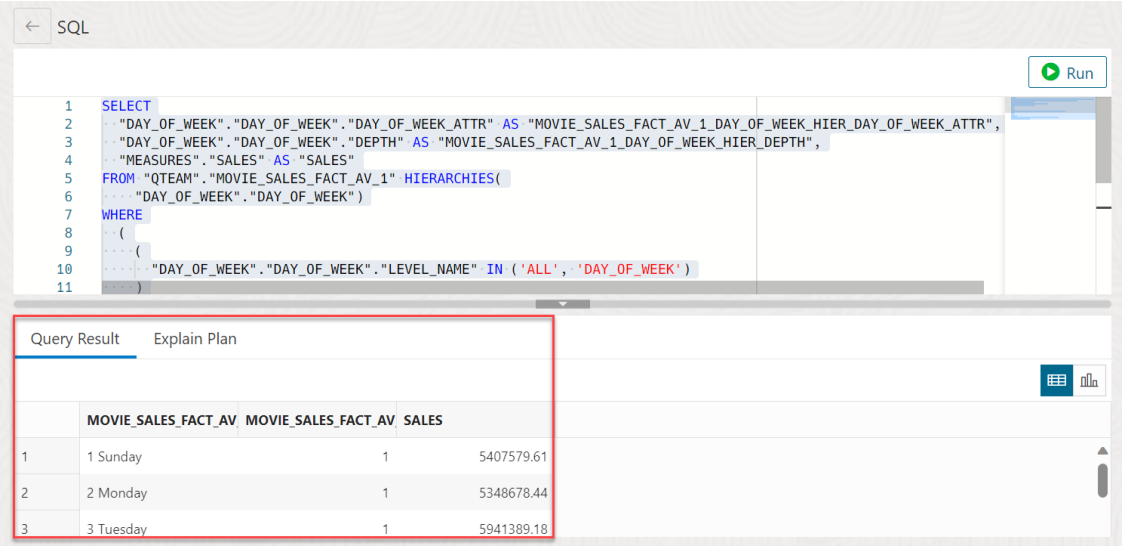
You can add multiple reports to the newly created analysis. One report is independent of another report. To add a report in the Analysis.

1. Open the Analysis for editing from the Data Analysis home page. Select **Edit** from the Analysis tile you wish to edit.
2. Click on the **+ Report** icon to add one or more reports to the Analysis. You can use a report to add configured Analyses to the Analyses page.
3. Click on the report to select it. The resize arrow in the report resizes the report window.
4. Click the cross icon on the selected report to delete the report from the Analysis.
5. The header displays the name of the Analytic View you select.
6. You can expand or collapse the report with their respective arrows.

When you add a report to the Analysis, the report provides the following actions:

- Edit SQL
- Performance
- Rename Report: Click Rename Report to rename it. Click **Save Report** to save the current report.
- Delete Report: Click **Delete Report** to delete the report.

Edit SQL
You can view the SQL output when you click **Edit SQL**. The lower right pane in SQL displays the output of the operation executed in the SQL editor. The following figure shows the output pane on the SQL page.



The output pane has the following tabs:

- **Query Result**: Displays the results of the most recent Run Statement operation in a display table.
- **Explain Plan**: Displays the plan for your query using the Explain Plan command. The default view is the diagram view. For more information, see the description of Explain Plan Diagram in subsequent sections.

Performance menu
The Performance menu displays the PL/SQL procedures in the worksheet area which describes the reports associated with the Analytic Views.

The top part of the performance output consists of the worksheet editor for running SQL statements and an output pane to view the results in different forms. You can view the results in a Diagram View, Chart View, Clear Output from the SQL editor, Show info about the SQL statements and Open the performance menu in a new tab.

The following figure shows the output pane of the performance menu:

The output pane has the following tabs:

- **Diagram View**: Displays the plan of your query in the diagram view.
- **Chart View**: Displays the plan of the query in a chart view.
- **Clear Output**: Clears the PL/SLQ statements from the worksheet.
- **Show info**: Displays the SQL statement for which the output is displayed.
- **Open in new tab**: Opens the explain plan in a new window. An Explain Plan displays the plan for your query.

Explain Plan Diagram
The Explain Plain diagram view is a graphical representation of the contents of the insert row statements in the SQL Query. The plan depicts the hierarchical nature of the steps in the execution plan.

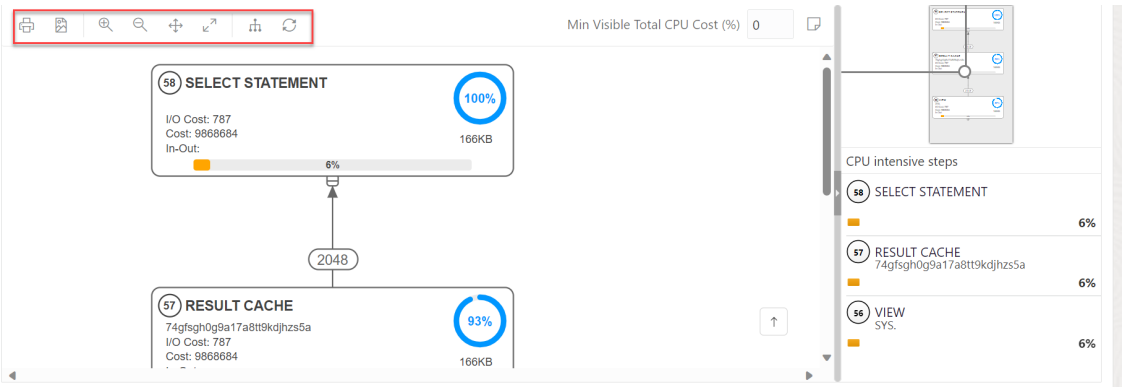
By default, three levels of steps are visible in the diagram. You can use the **+/-** signs at the

bottom of each step (available when the step has children) to expand or collapse. Use Expand All in the toolbar to view all steps in the diagram.
The diagram also provides the following details:

- Cardinality (number on the arrow to the parent step), which is the number of rows processed
- Operation and options applied in that step
- Execution order, which is the sequential number in the order of execution
- Access predicates CPU cost in percentage (orange bar)
- Total CPU cost for the step in percentage (blue circle)
- Estimated I/O Cost, Bytes processed, and Cost metrics

You can see a brief description pop-up when you hover over any of these statistics in a step.

The icons in the toolbar are:



- **Advanced View**: This is the default view of the query when you click Performance. Displays data from SQL Query in mixed tabular/tree view. There is a Diagram View icon that you can use to switch back to the diagram view.
- **Chart View**: Displays data from the SQL query in the form of charts.
- **Print Diagram**: Prints the diagram.
- **Save to SVG**: Saves the diagram to file

- **Zoom In, Zoom Out**: If a step is selected in the diagram, clicking the Zoom In icon ensures that it remains at the center of the screen.
- **Fit Screen**: Fits the entire diagram in the visible area.
- **Actual Size**: Sets the zoom factor to 1.
- **Expand All**: Displays all steps in the diagram.
- **Reset Diagram**: Resets the diagram to the initial status, that is, only three levels of steps are displayed.
- **Show Info**: Shows the SELECT statement used by the Explain Plan functionality.
- **Open in New Tab**: Opens the diagram view in a new tab for better viewing and navigation. The diagram is limited to the initial SELECT statement.
- **Min Visible Total CPU Cost(%)**: Defines the threshold to filter steps with total CPU cost less than the provided value. Enter a value between 0 and 100. There is no filtering for 0.
- **Plan Notes**: Displays the Explain Plan notes.

Properties in Explain Plan Diagram

Double-click or press **Enter** on a selected step to open the Properties slider, which provides more information about that step. See PLAN_TABLE in Oracle Database Reference for a description of each property. The Properties slider shows:

- Displays information for that step extracted from PLAN_TABLE in a tabular format. Nulls are excluded. You can select **JSON** to view the properties in JSON format.
- Information from OTHER_XML column of PLAN_TABLE. The information is displayed in JSON format.

- Working with Reports
  Reports help you in analyzing Analytic Views and Queries.
- Creating Reports on a Query
  This section describes the steps to create reports on an SQL query.
- Creating Reports on an Analytic View
  This section describes the steps to create reports on an Analytic View:

Working with Reports

Reports help you in analyzing Analytic Views and Queries.

The reports are based on the levels and measures you select for the Analytic View and the columns you select for a query.

Click **Analyze** in the Analytic View and click the Table you want to analyze to view the Analyses page.

The Analyses page comprises the following components:

1. **Analytic View Browser**: Select **Analytic View** from the drop-down if you choose to create reports on Analytic Views to view an Analytic View browser. The Analytic View browser displays the Hierarchies, Levels, and Measures associated with the selected Analytic View.

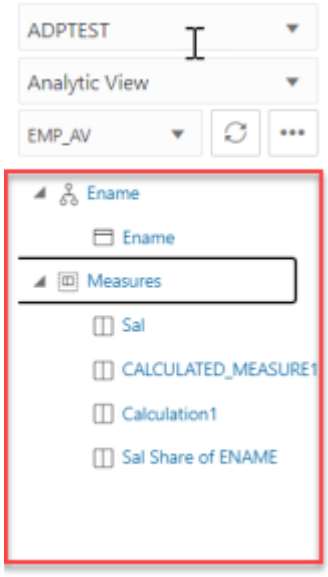


Table Browser: Select **Query** from the drop-down if you choose to create a report on SQL query to view a Table browser. If you select SQL Query, the Table browser displays the available tables and their corresponding columns. You can drill down tables to view their corresponding columns.

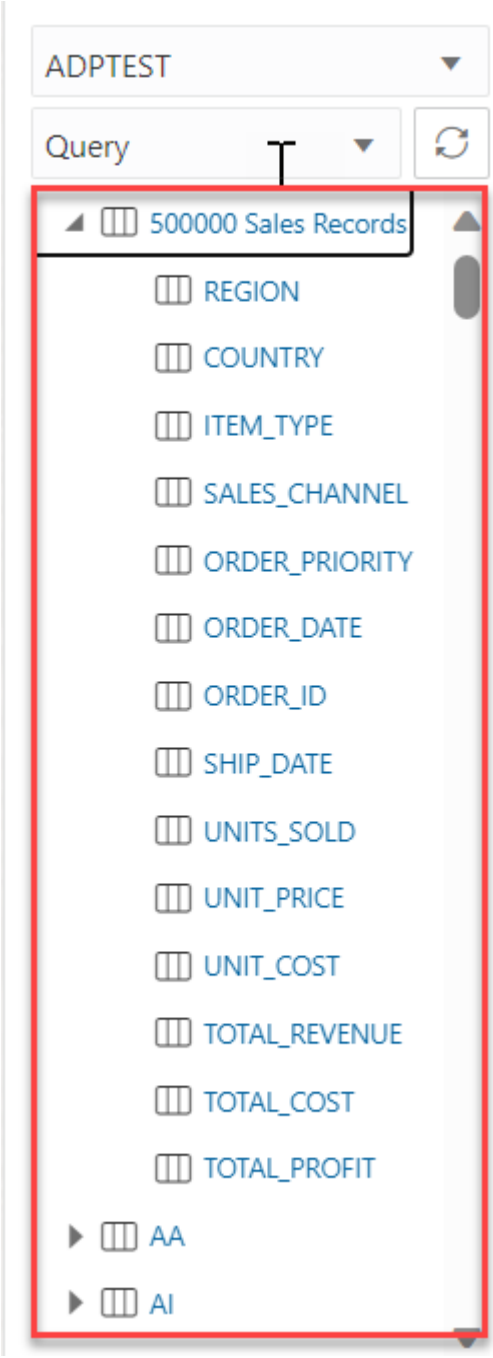
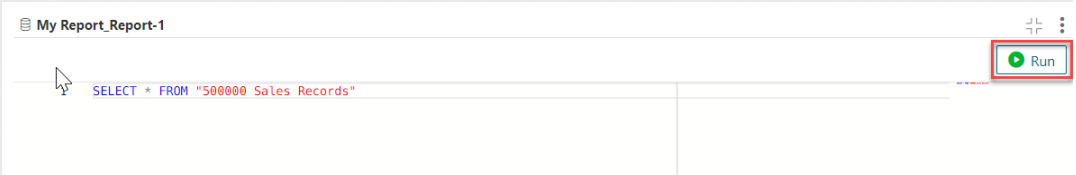
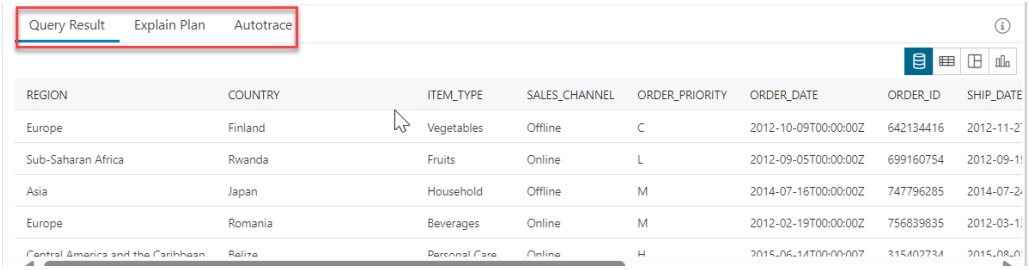


2. **SQL Worksheet editor with the Run icon:** You can view this component only when you generate a report on a SQL Query and not an Analytic View.
The SQL editor area enables you to run SQL statements and PL/SQL scripts from the tables you want to query displayed on the Table browser. By default, the SQL editor displays the Select * statement to display all the columns from the first table. Click **Run** to run the statements in the editor.



3. **Output pane:** The output pane, when you view the results of a SQL Query, consists of the following tabs:
   - **Query Result:** Displays the results of the most recent Run Statement operation in a display table.
   - **Explain Plan:** Displays the plan for your query using the Explain Plan command. For more information, refer to the **Explain Plan Diagram** in Creating Reports section.
   - **Autotrace:** Displays the session statistics and execution plan from `v$sql_plan` when running an SQL statement using the Autotrace feature.



4. **Modes of visualization in the Query Result tab**: You can select any of the four modes to visualize the results of the SQL query report you generate.

The four modes of visualization, when you view the reports generated on a SQL query, are:

- **Base Query**: This type of view is by default. Query written in the SQL editor is the Base Query.
- **Table**: You can view the SQL results in tabular form. By selecting this view, a Column drop zone appears which enables you to drag and drop selected columns from the Table browser. By dropping the selected columns in the drop zone, you can view only those columns in the Query Result tab. Select the cross mark beside the Column name to remove it from the drop zone.
- **Pivot**: You can view the results of the SQL query in pivot format. By selecting this format, a Columns, Rows, and Values drop zone appears where you can drag and drop the selected columns, rows or values from the Tables browser.

> **Note:**
>
> Values must be a NUMBER type.

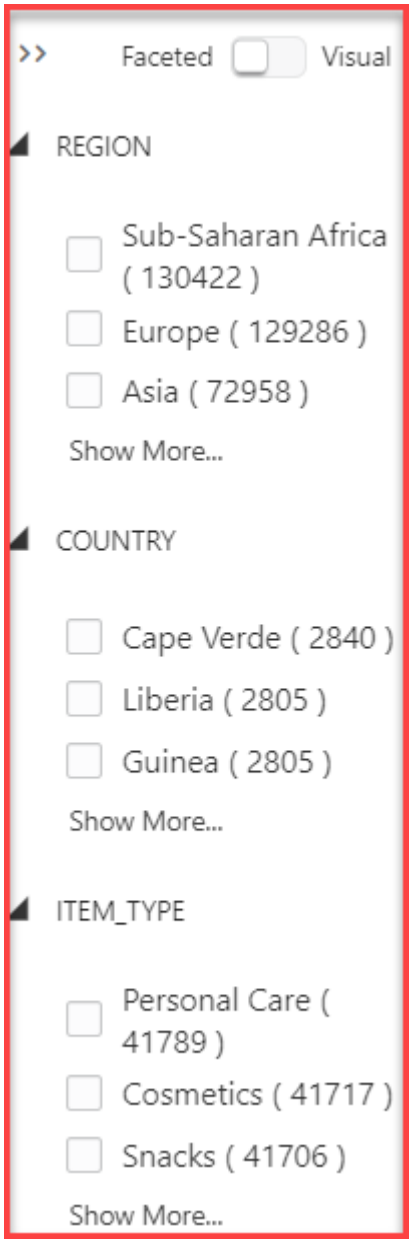
- **Chart**: You can view the SQL results in the form of a chart. By selecting this view an X-axis and Y-axis drop zone appears. Drag and drop selected columns from the Table browser to the drop zone. You must ensure that only the columns with NUMERIC data type can be dropped in the Y axis. Otherwise, the display result would fail with a `Must be a NUMBER type` error. You can add multiple values to the Y-axis. To view the results in the chart view of only a particular y axis, select the Y axis value from the drop-down.

5. **Modes of visualization of reports generated on an Analytic View:** You can select any of the three modes to visualize the results of the report you generate on an Analytic View.

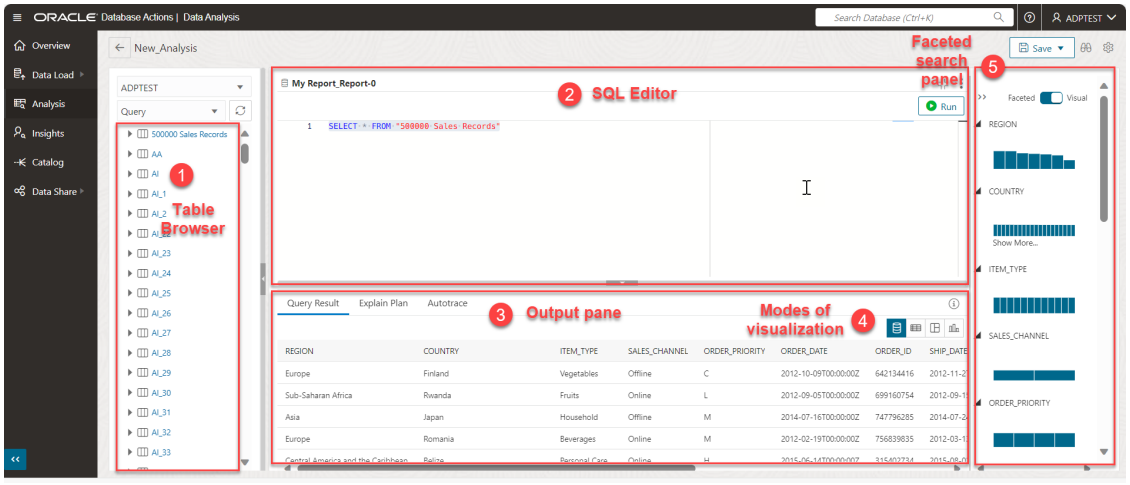
The three modes of visualization when you view the reports generated on an Analytic View are:

- **Table:** You can view the SQL results in tabular form. By selecting this view, a Rows and Filters drop zone appears which enables you to drag and drop selected Hierarchies and Measures from the Analytic View browser. This way you can view the report results that consist of the selected hierarchies and measures.
- **Pivot**: You can view the results of the Analytic View report in the pivot format. By selecting this format, a Columns, Rows,Values and Filters drop zone appears where you can drag and drop the selected hierarchies and measures from the Analytic View browser.Note: Values must be a NUMBER type.
- **Chart**: You can view the report you generate on an Analytic View in the form of a chart. By selecting this view an X-axis, Y-axis, and Filters drop zone appears. Drag and drop selected columns from the Table browser to the drop zone. You must ensure that only the columns with NUMERIC data type can be dropped in the Y axis. Otherwise, the display result would fail with a `Must be a NUMBER type` error. You can add multiple values to the Y-axis. You can select Horizontal and Vertical from the drop-down to view Horizontal and Vertical Charts respectively. You also have the option to select Area Chart, Bar Chart, Line Chart, and Pie Chart from the drop-down.

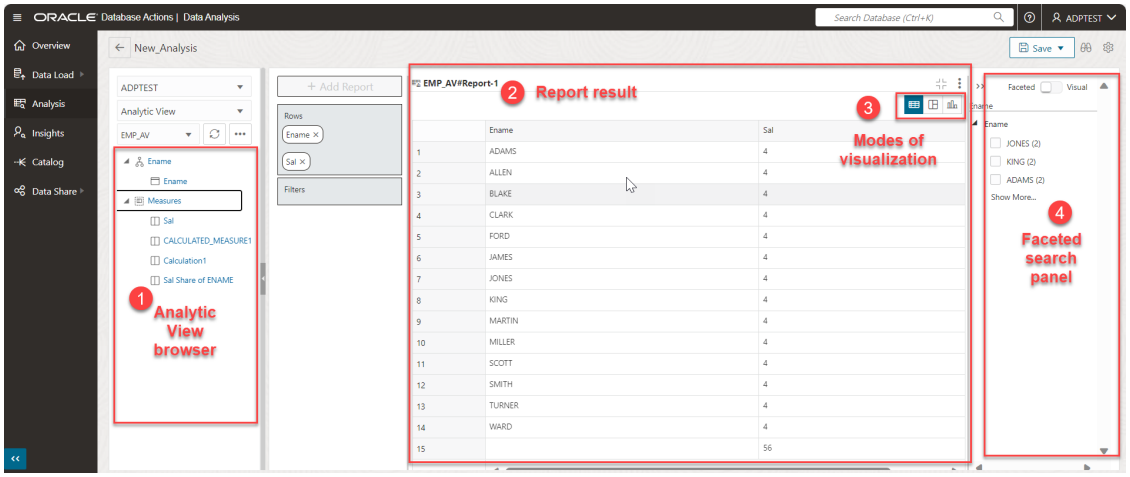
6. **Faceted search panel:** For the reports you generate on a SQL query and an Analytic View, you can view a Faceted search column. For a SQL report, this panel allows you to add filters to the report. The tool generates a filter for each value in the column that is retrieved from the query result. You can filter different columns on the faceted search panel and view the results in the Query result to get only the data you wish to view. You can view the data retrieved from the SQL query in either text or visual format. For reports you generate on an Analytic View, select **Faceted** from the radio button. This filter behaves differently than the Faceted search you generate on an SQL Query. See *Adding filters to a report you generate on an Analytic View*.



The Analyses page when you create a report on an SQL query looks like this:



The Analyses page when you create a report on an Analytic View looks like this:



The following topics describes how to create a report and access the Analyses page:

Creating Reports

1. You can create Reports using either of the following ways:
   - On a Query
   - On an Analytic View
2. Adding filters to a report you generate on an Analytic View

Creating Reports on a Query

This section describes the steps to create reports on an SQL query.

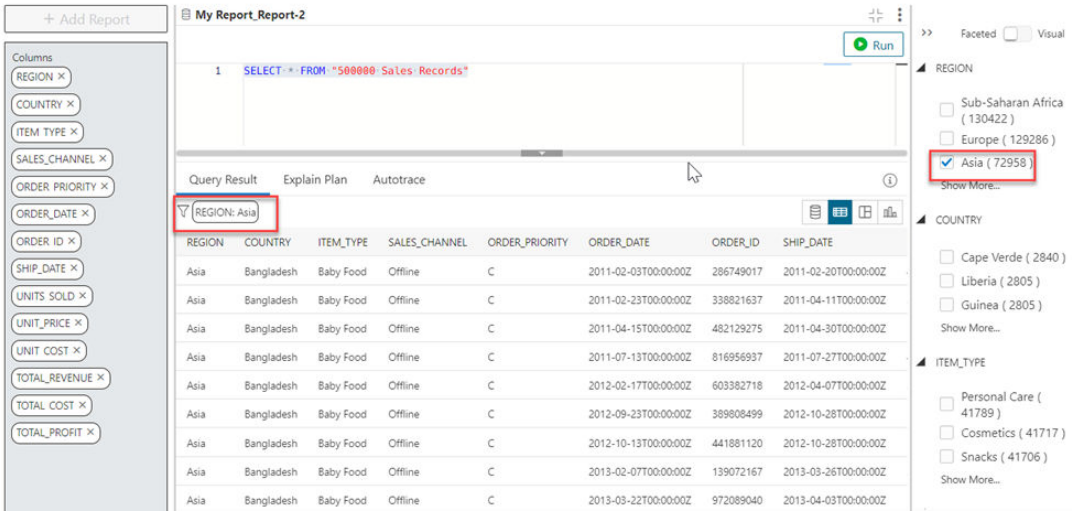
1. From the Analysis home page, select any of the Tables you want to create a report on. You will view the Analyses page with a default query displayed on the SQL editor.

> **Note:**
>
> By default, you will view “Select * from the <Tablename> you select.

2. Click **Run** to run the SQL statement.

   The Query Results tab displays the result in whichever mode you select. The default view is Base Query.

3. Add a filter to the report by displaying the Sales Records of only **Asia** region. Select **Asia** from the faceted search panel.



4. You will view a funnel icon in the Query Result tab which displays a filter with the **REGION** column as **Asia**. The Query Result will display only the records with **REGION** as **Asia**.

Creating Reports on an Analytic View

This section describes the steps to create reports on an Analytic View:

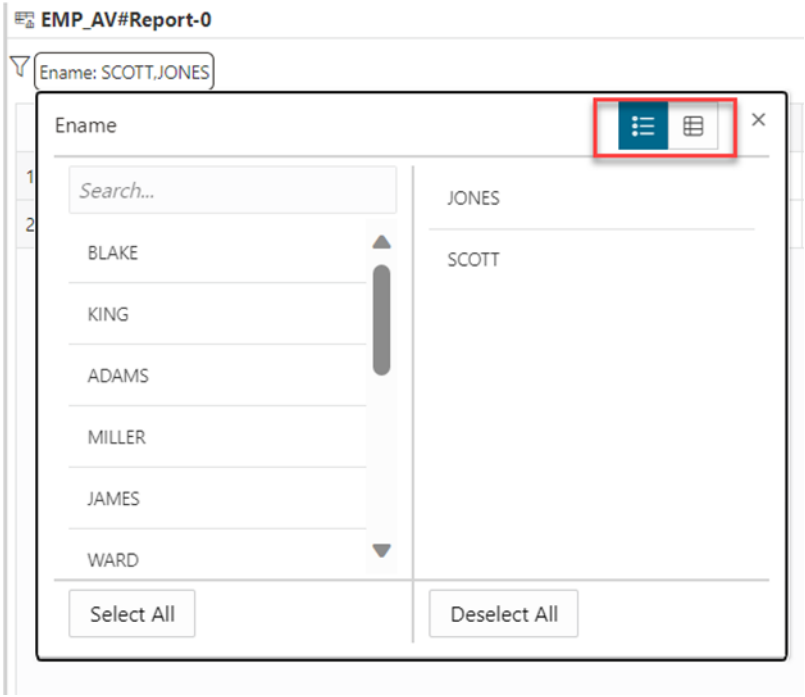
1. From the Analysis home page, under the Analytic View section, select any of the Analytic Views you want to create a report on. You will view the Analyses page with a default report displayed as the output.
2. Drag and drop hierarchies and measures from the Analytic View browser to edit the results you view in the output. For more information, refer to Working with Reports.
3. Click **Expand Report** to expand the view of the report and click **Collapse Report** to minimize the view of the report. The default view of the report you generate on an Analytic View is Pivot.

Adding filters to a report you generate on an Analytic View

Let us add a filter to the report you generated on an Analytic View. Let's say you wish to view the salary of an employee named **SCOTT**.

1. From the Analyses page which displays the report you generated on an **Employee Analytic View**, select “**Scott** from the faceted search panel. You will view the report displaying the result of employees named **Scott**.
2. You can select more filters by selecting the values from the faceted search panel, or by clicking the funnel.

3. Clicking the funnel icon displays all the values of the Employee name column. Select **Jones** to filter the report results further displaying the salary of employees named **Scott** and **Jones**. You can view the values in a list view or a multi select view.



4. Select **Deselect All** to remove all filters.

You can now view the original report result that does not consist of any filters.

Run Natural Language Query in the Data Analysis Tool

You can query the Oracle Autonomous Database by using Natural Language Query rather than having to write SQL Query.

Prerequisites

To utilize the Natural Language Query, you must have:

- An OpenAI, or Cohere or An Azure OpenAI account service with credit
- An access to `DBMS_CLOUD_AI` package.

> **Note:**
>
> - You must set your AI profile using the Natural Language Query feature. Follow the steps mentioned in this chapter to Use Select AI to Generate SQL from Natural Language Prompts.
> - After you have created and configured your AI profile, set your AI profile in Data Studio Preferences wizard on the Connections page to use AI features such as generating SQL from Natural Language in the Data Studio tool.

You can run Natural Language Queries on both Analytic Views and Tables.

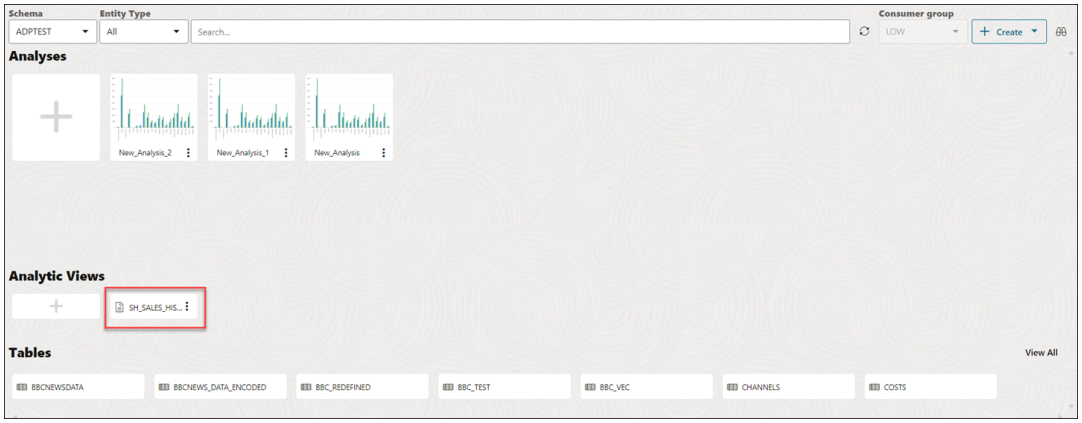
- Generate SQL Queries From Natural Language on Analytic Views
  You can create SQL queries on Analytic Views.
- Generate SQL Queries From Natural Language on Tables
  You can create SQL queries on Tables.
- Generate SQL Queries From Natural Language on Analytic Views
  To run a natural language query from SQL query on Analytic Views, perform the following steps:
- Generate SQL Queries from Natural Language on Tables
  Follow the procedure mentioned below to generate SQL queries from Natural Language on Tables:

Generate SQL Queries From Natural Language on Analytic Views

To run a natural language query from SQL query on Analytic Views, perform the following steps:

Let's say you wish to view sales amount in a categorized way.

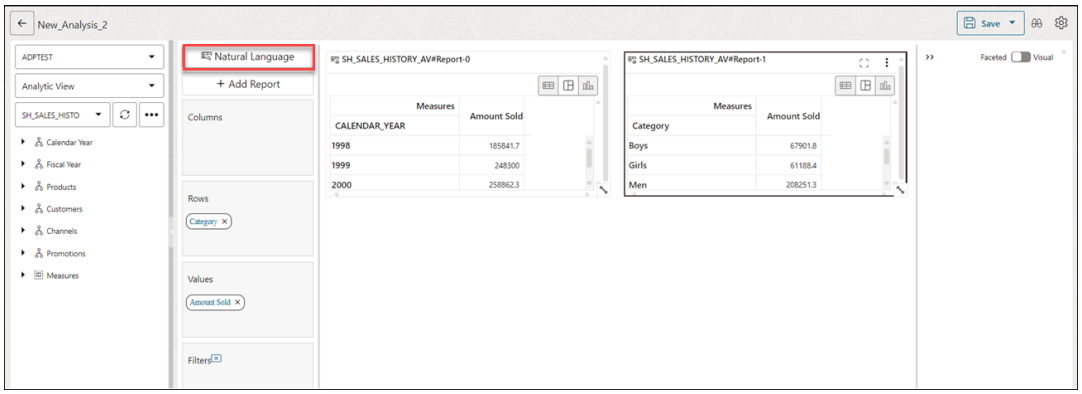
1. On the Data Analysis home page, click on any of the Analytic Views you wish to query.



In this example, you will query the `SH_SALES_HISTORY` Analytic View.

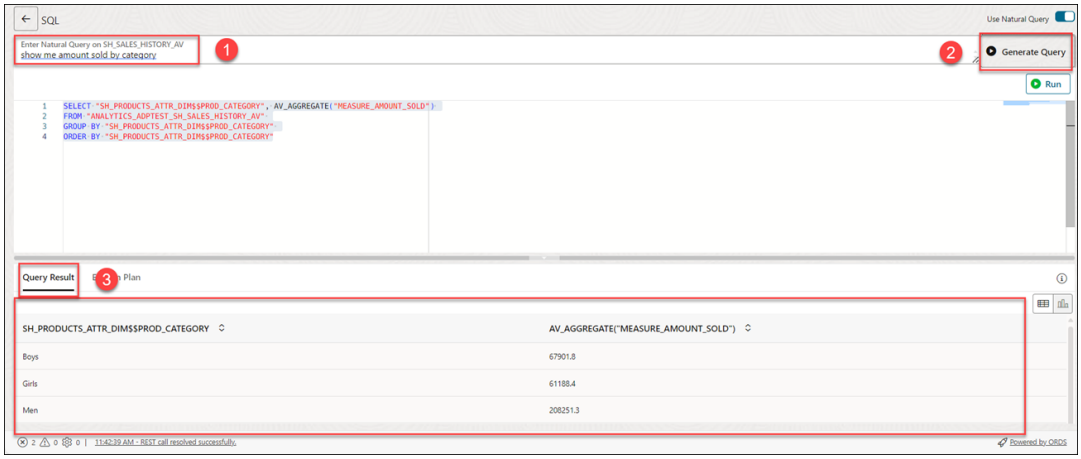
This opens the Analyses page.

2. Select **Natural Language**. Selecting Natural Language opens the SQL worksheet area with a predefined SQL query on the worksheet area.



> **Note:**
>
> You can view **Natural Language** option only after you have configured and set AI profile using the Use Select AI to Generate SQL from Natural Language Prompts procedure and set the Data Studio Settings wizard on the Connections page.

3. Enter the following natural Query you wish to run on `SH_SALES_HISTORY` in the Natural Query field: `show me amount sold by category`.
4. Click **Generate Query**.



5. After the tool generates the query, the **Query Result** tab displays the result of the query. You can also view the graphical representation of the contents of the `PLAN_TABLE` in the **Explain Plan** tab.

   You can alternatively view the query result in chart view by switching the display mode in **Chart View or Diagram View**.

Generate SQL Queries from Natural Language on Tables

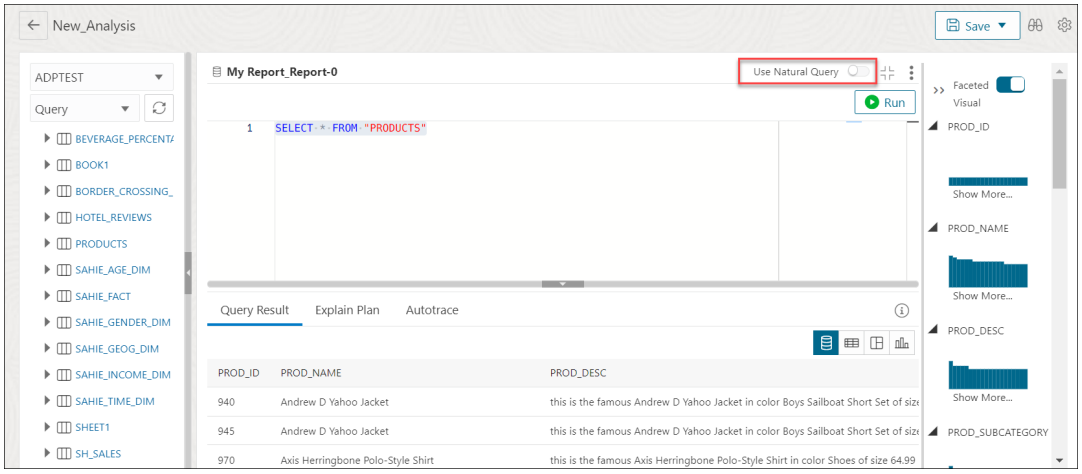
Follow the procedure mentioned below to generate SQL queries from Natural Language on Tables:

Let's say you want to view the product with the minimum product price.

1. On the Data Analysis home page, click on any of the Tables you wish to query. In this example, we select the `PRODUCTS` table.

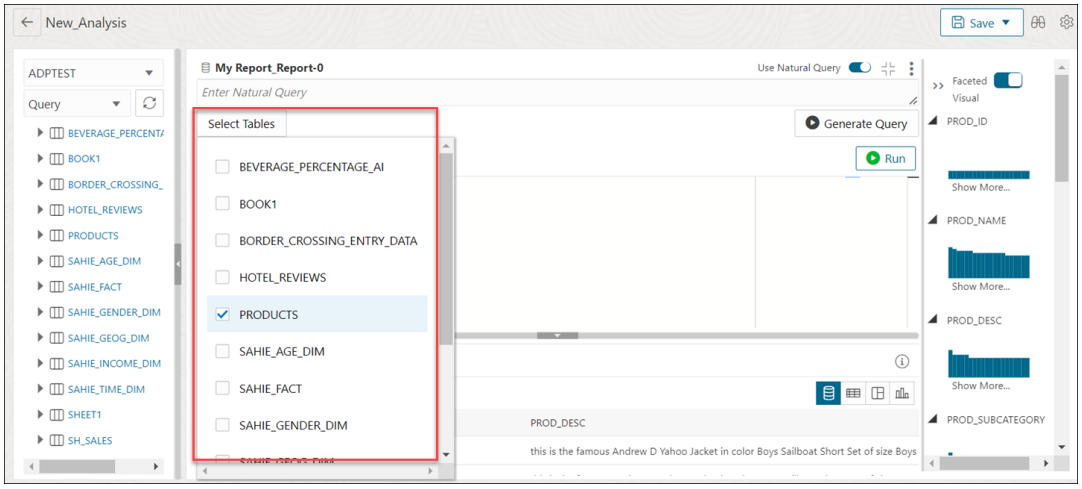
This opens the Analyses page with a query that retrieves all the columns from the selected table `PRODUCTS`.

2. Select **Use Natural Query**.



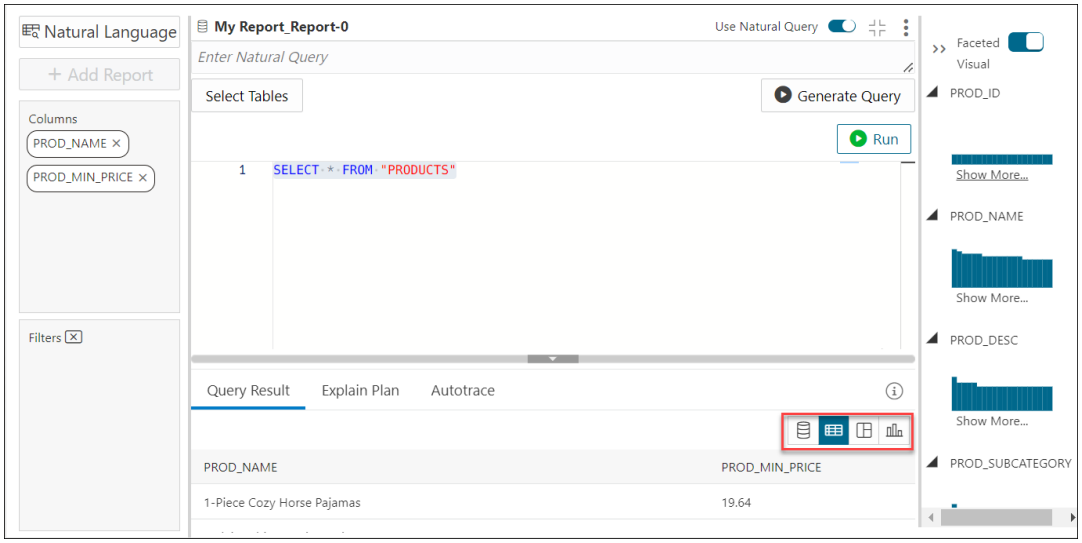
3. Selecting **Use Natural Query** lets you select multiple tables from the **Select Tables** icon.

> **Note:**
>
> You can view **Natural Language** option only after you have configured and set AI profile using the Use Select AI to Generate SQL from Natural Language Prompts procedure and set the Data Studio Settings wizard on the Connections page.

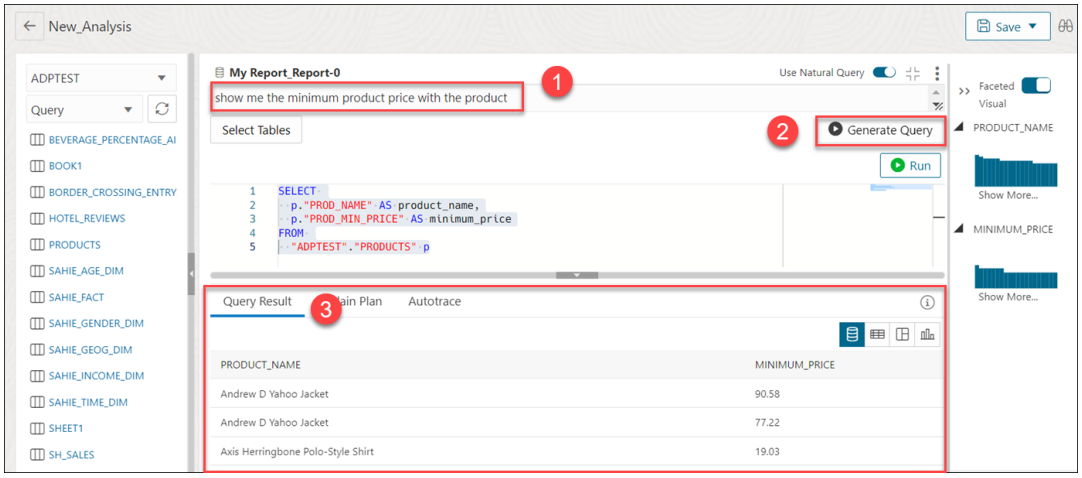


Select the tables you wish to generate the SQL query from. You can use the columns from the selected table in the text field where you enter the Natural Query.

> **Note:**
>
> You can click Tabular View, drag and drop columns from the navigator to the Columns and Filter drop area to select the intended columns to query.



4. Click **Base Query** mode of visualization to enter Natural Language.
Enter the following in the Natural Query Text field: `show me the minimum product price with the product.`



Click **Generate Query**.

Selecting **Generate Query** converts the Natural language to the equivalent SQL query and displays results under the Query Results tab.

You can alternatively view the query result in tabular view, pivot, and chart view. You can drag and drop rows, columns, and filters from the Tables Browser to the drop area.

> **Note:**
>
> From the Chart view you can view the result in horizontal and vertical sheet.

Generate Natural Language explanation from SQL Query using AI Explain

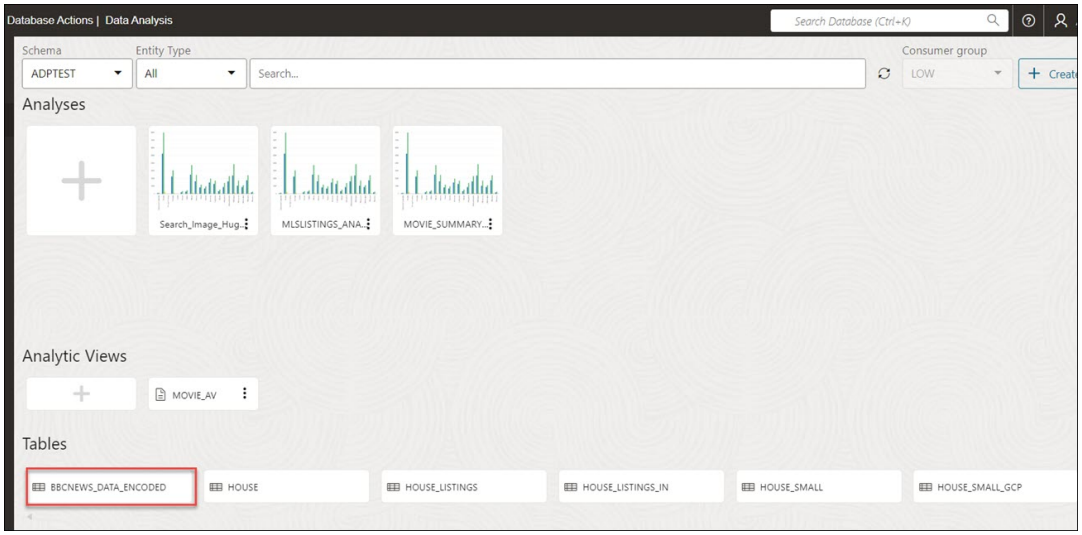
You can translate SQL queries to natural language that is understood by you.

> **Note:**
>
> This feature is available for SQL based reports on Queries and not on reports on Analytic Views.

To run an SQL query and view it's Natural Language explanation, perform the following steps:

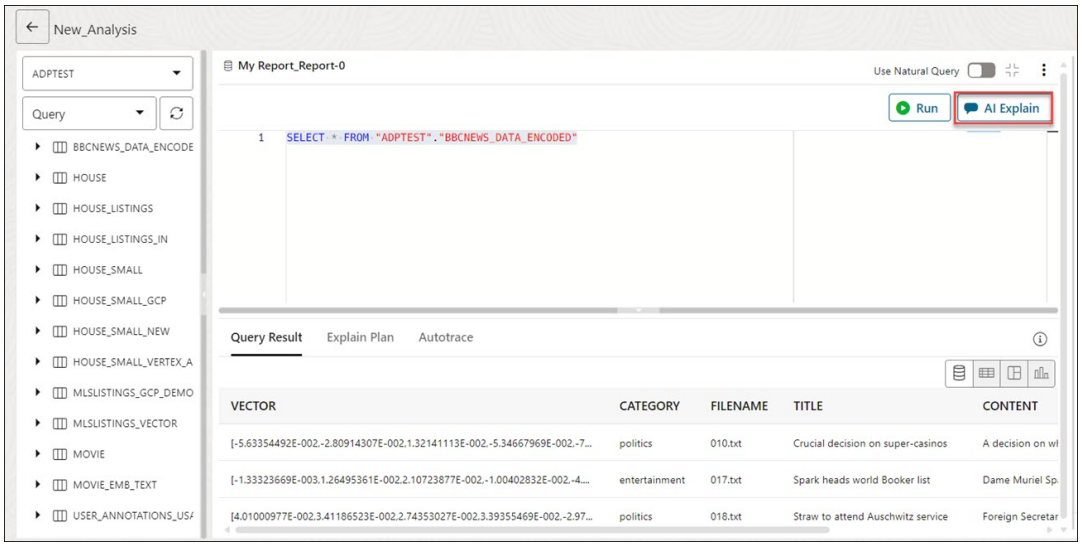
Let's say you wish to view the explanation of a query that retrieves all records of a table.

1. On the Data Analysis home page, click on any of the Tables you wish to query.

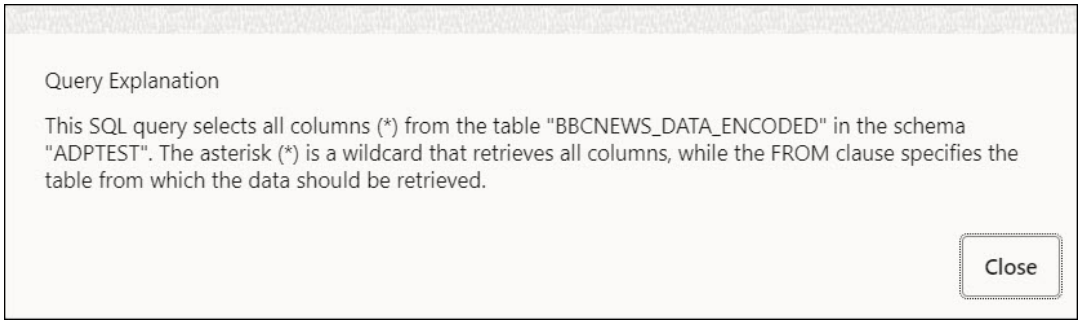


In this example, you will query the `BBCNEWS_DATA_ENCODED` table. This opens the Analyses page.

2. You can view the default query displayed on the worksheet area that retrieves all the records of the table along with the columns displayed in the Query Results tab of the output pane.



3. Click **AI Explain**.



You can view a Query Explanation dialog box that explains the query displayed on the worksheet area.

Click **Close** to close the dialog box.

Vector Search in the Data Analysis Tool

You can use Oracle AI Vector Search capabilities to search for relevant text from your source data on a specific column.

The Vector search helps quickly locate and match data that is similar to the text you provide as your search input.

Prerequisites

For using the vector search feature in the Data Analysis tool, you need the following:

- You must have 23ai Database with Vector support.
- The ORDS REST APIs must support VECTOR data type.
- You must use the Data Studio Settings page to select the same credential you use for vector search.
- The source data must already have a non-numeric column to be embedded first.
- To utilize the Vector Search in the Data Analysis tool, you must have:
  - An OpenAI, or Cohere or An Azure OpenAI account service with credit
  - An access to `DBMS_VECTOR` and `DBMS_VECTOR_CHAIN.UTL_TO_EMBEDDING` package.

> **Note:**
>
> - You must set your AI profile. Follow the steps mentioned in this chapter to Use Select AI to Generate SQL from Natural Language Prompts.
> - After you have created and configured your AI profile, set your AI profile in the Data Studio Settings wizard on the Data Studio navigation menu to use AI features such as generating SQL from Natural Language and Vector Search in the Data Studio tool.

The Data Analysis tool utilizes the Vector Utility PL/SQL package `DBMS_VECTOR` and `DBMS_VECTOR_CHAIN.UTL_TO_EMBEDDING` to provide the third-party REST APIs that let you interact with external embedding models such as Cohere, Google AI, Hugging Face, Oracle

Cloud Infrastructure (OCI) Generative AI, OpenAI, or Vertex AI. You must understand the terms of using third-party embedding models.

> **Note:**
>
> Certain features of the database may allow you to access services offered separately by third-parties, for example, through the use of JSON specifications that facilitate your access to REST APIs.
>
> Your use of these features is solely at your own risk, and you are solely responsible for complying with any terms and conditions related to use of any such third-party services. Notwithstanding any other terms and conditions related to the third-party services, your use of such database features constitutes your acceptance of that risk and express exclusion of Oracle's responsibility or liability for any damages resulting from such access.

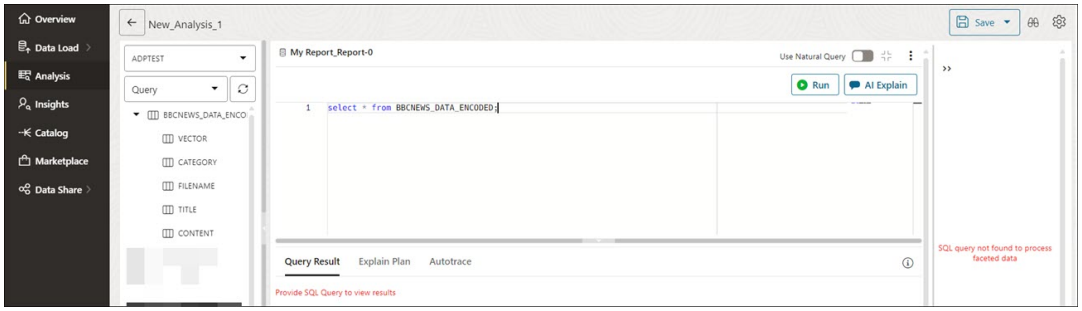
Suppose you are a finance enthusiast and you want to learn about finance through news to gain better sense of financial products and investments. In this example, you can use the Vector Search feature to find news related to the word `Bank`.

Consider a table that has the columns `CATEGORY`, `FILENAME`, `TITLE`, `CONTENT` and a different column labeled `VECTOR`, that contains the vector representation of the `CONTENT` column. Since we can use vector search on source columns with non-numeric data (image or text), any of the non-numeric column can be embedded and stored as a vector column. But in this example, we need to search for relevant text from `CONTENT` column.

You can use the Data Analysis tool to perform vector search.

To indicate which column's embedding is kept in the vector column, we must first map the appropriate column with the appropriate vector using the Data Analysis tool, search for similar text, and then run the query. The Query Result tab will display the content similar to `Bank`.

1. From the Data Analysis tool, click **+** under Analyses to create a new Analysis.
2. Select the Schema from **Schema** drop-down and Query from the **Type** drop-down.
3. Select the table you want to query from the table browser. In this example, you will select `BBCNEWS_DATA_ENCODE`.

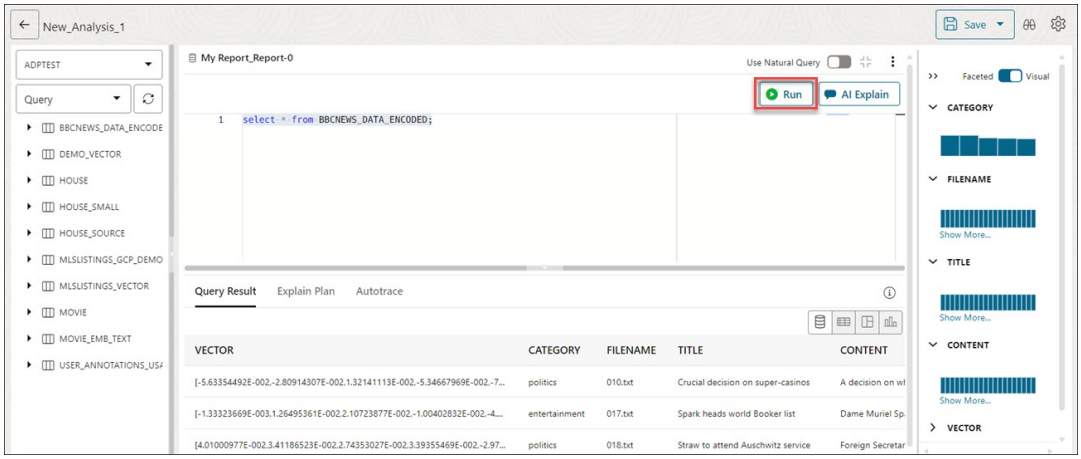


4. Enter the Select statement in the SQL Worksheet edit area to retrieve all the columns from the `BBCNEWS_DATA_ENCODE` table.

Specify the following command:

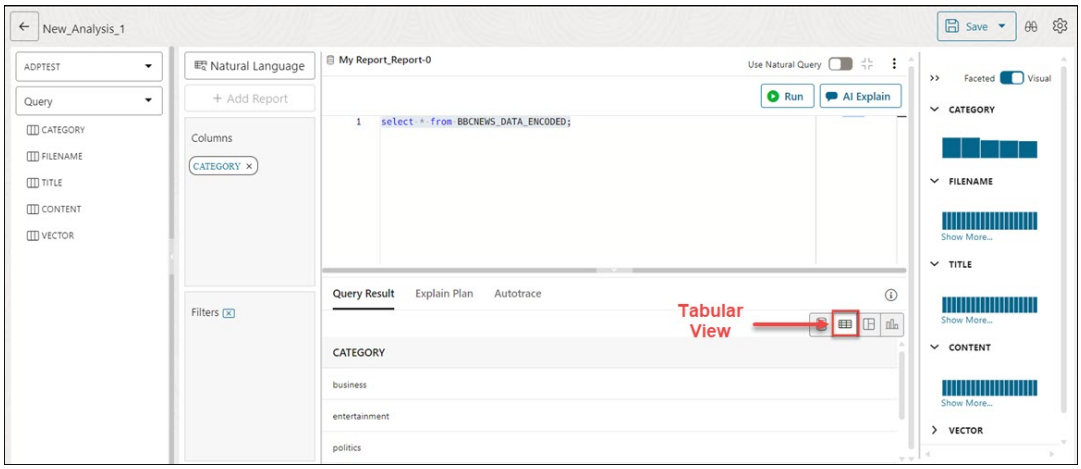
```
Select * from BBCNEWS_DATA_ENCODE;
```

5. Click **Run**.

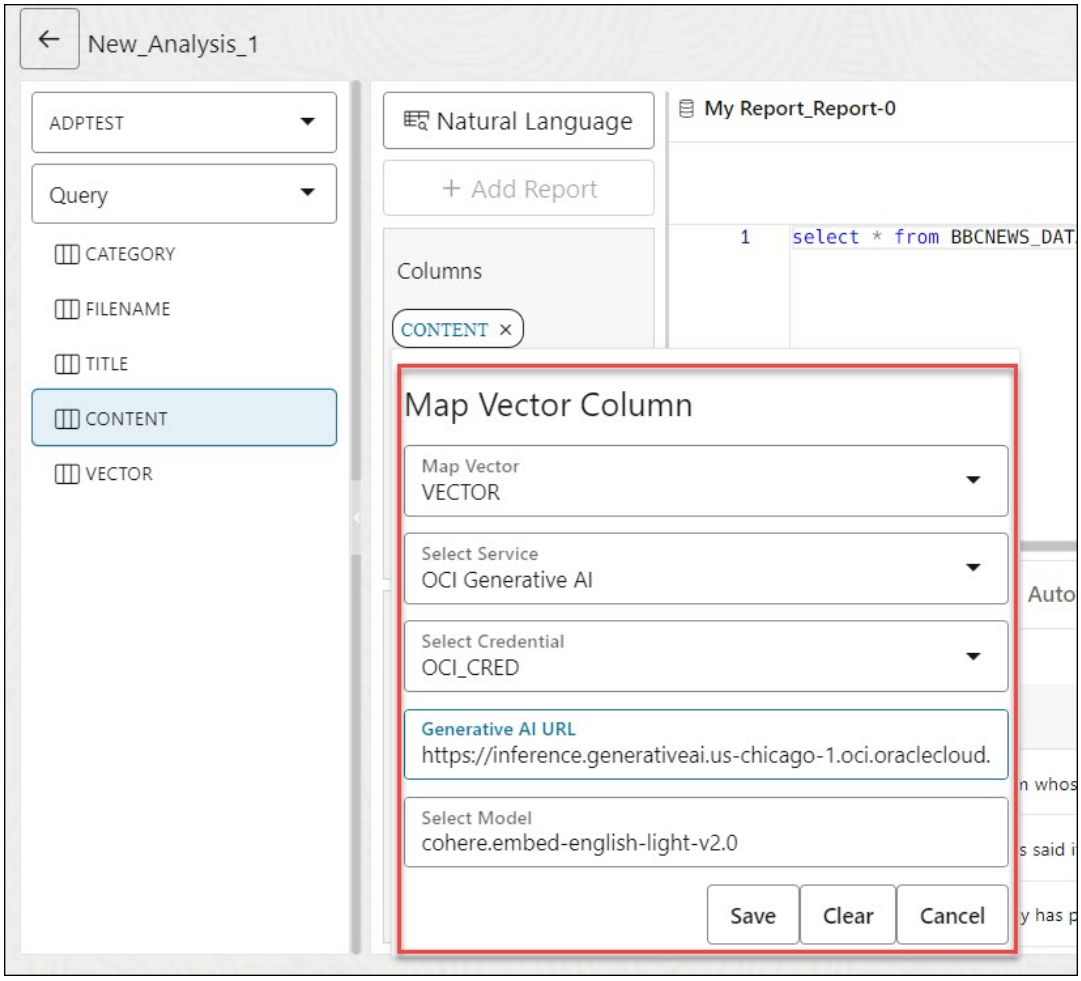


You can view all the columns of the `BBCNEWS_DATA_ENCODE` table in the Query Results tab.

6. Select tabular view of mode from the icons that display various modes of visualizing the query result.

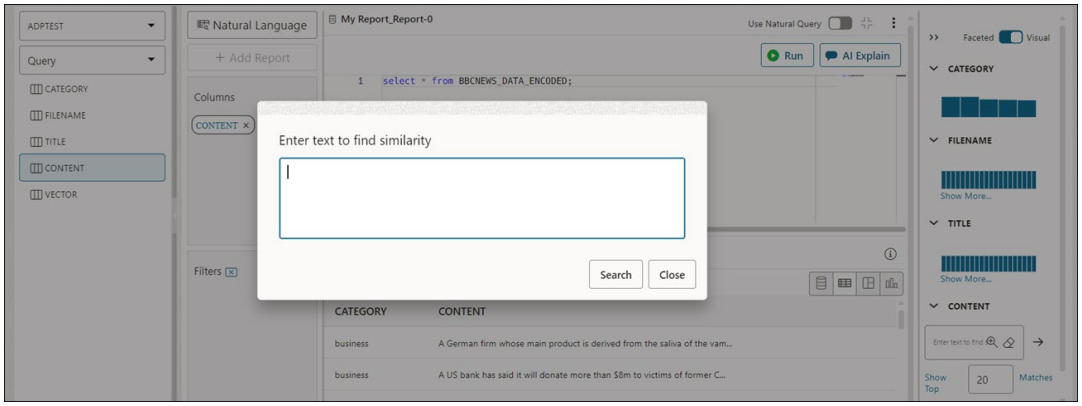


7. Drag and drop the `CONTENT` column to the Column drop area and click it to map the vector column.



8. On the Map Vector Column wizard, specify the following field values:
   - **Map Vector**: Select the column that consists of the vector embeddings of the selected column from the drop-down list. In this example, it is *VECTOR*.
   - **Select Service**: Select the AI service you will use to utilize this feature of the tool. In this example, it is *OCI Generative AI*.
   - **Select Credential**: Enter the credential you create from the Data Studio Settings to access the third party service provider. You require these credentials to enable access during REST API calls to your chosen third-party service provider.
   - **Generative AI URL**: Specify the Generative AI URL you will use to call the third-party service provider, such as Cohere, Google AI, Hugging Face, Oracle Cloud Infrastructure (OCI) Generative AI, OpenAI, or Vertex AI.
   - **Select Model**: Specify the embed model you will use to generate embeddings from the text. In this example, you will enter *cohere.embed-english-light-v2.0*.

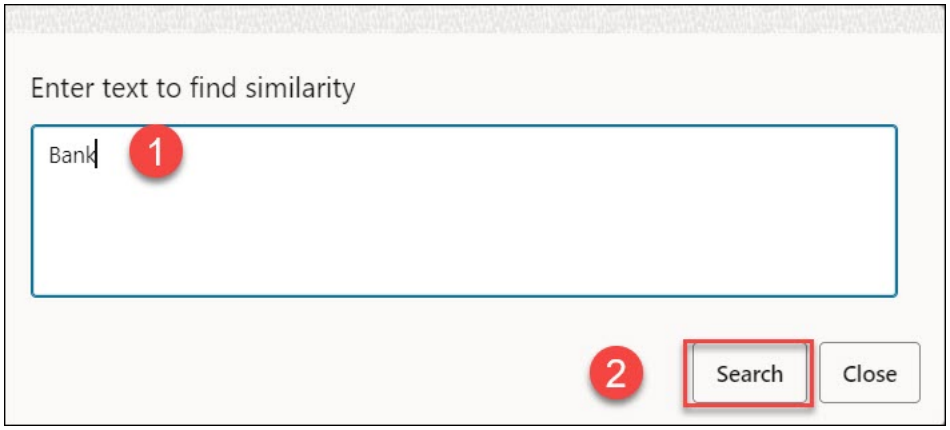
   Click **Save** to save the mapping. Select **Clear** to clear the field values you mention in this step.
9. On the Faceted Filters, you can view text box under the Content column. Click the **+** sign on it to expand the text box.



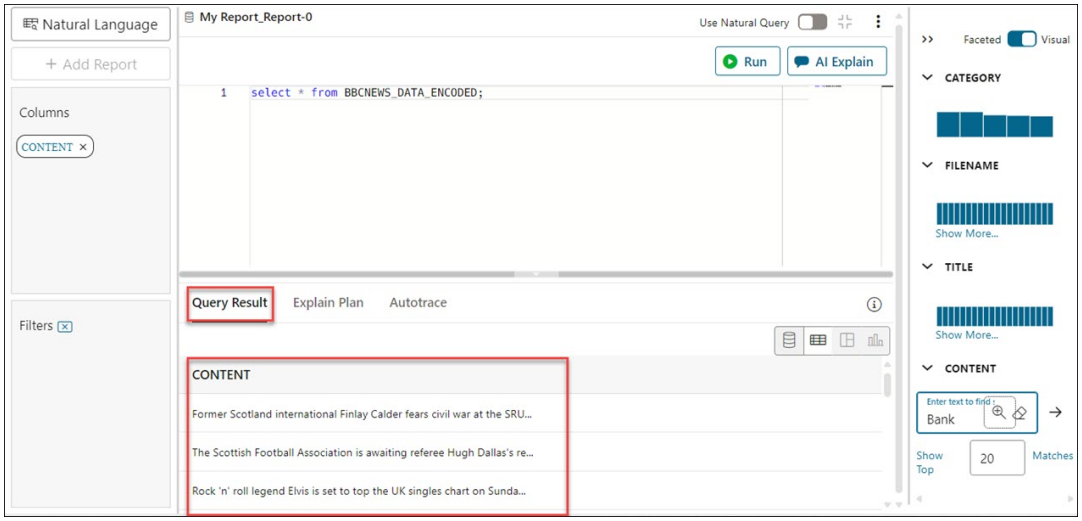
10. Enter the following text in the text box to content similar to the word `Bank` in the `CONTENT` column:

    ```
    BANK
    ```

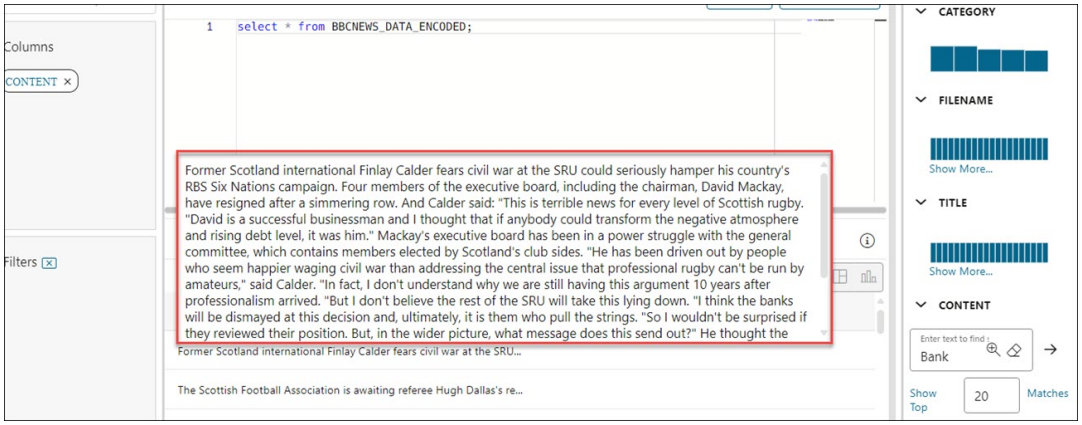
    Click **Search**.



11. The Query Results tab of the Output panel displays the content column that consists of content related to `Bank`.



You can hover over each content to view it's expanded form.



Using Calculation Templates

The Data Analysis tool provides templates for all of the calculations typically in demand for business intelligence applications.

The following topics describe the types of calculations available as calculation templates in the tool.

- Cumulative Aggregates
- Prior and Future Period
- Period to Date
- Parallel Period
- Moving Aggregates
- Share
- Rank

- Cumulative Aggregates
  Cumulative calculations start with the first time period and calculate up to the current member, or start with the last time period and calculate back to the current member.
- Prior and Future Period
  The Data Analysis tool provides several calculations for prior or future time periods.
- Period to Date
  Period-to-date functions perform a calculation over time periods with the same parent up to the current period.
- Parallel Period
  Parallel periods are at the same level as the current time period, but have different parents in an earlier period. For example, you may want to compare current sales with sales for the prior year at the quarter and month levels.
- Moving Aggregates
  Moving aggregates are performed over the time periods surrounding the current period.
- Share
  Share calculates the ratio of a measure's value for the current dimension member to the value for a related member of the same dimension.
- Rank
  Rank orders the values of a dimension based on the values of the selected measure. When defining a rank calculation, you choose the dimension, a hierarchy, and the measure.

Cumulative Aggregates

Cumulative calculations start with the first time period and calculate up to the current member, or start with the last time period and calculate back to the current member.

The tool provides several aggregation methods for cumulative calculations:

- **Cumulative Average**: Calculates a running average across time periods.
- **Cumulative Maximum**: Calculates the maximum value across time periods.
- **Cumulative Minimum**: Calculates the minimum value across time periods.
- **Cumulative Total**: Calculates a running total across time periods.

You can choose the measure, the time dimension, and the hierarchy. For selecting the time range see "Choosing a Range of Time Periods" in *Oracle OLAP User's Guide*.

Cumulative Calculation Example

This template defines a calculated measure using Cumulative Minimum.

```
Cumulative minimum of SALES in the TIME dimension and TIME.CALENDAR hierarchy within
ancestor at level TIME.CALENDAR_YEAR. Total from beginning to current member.
```

These are the results of a query against the calculated measure, which displays values for the descendants of calendar year 2021. The minimum value for quarters begins with Q1-21 and ends with Q4-21, and for months begins with Jan-21 and ends with Dec-21.

```
TIME     TIME_LEVEL                SALES  MIN_SALES
-------- -------------------- ---------- ----------
Q1.21    CALENDAR_QUARTER       32977874   32977874
Q2.21    CALENDAR_QUARTER       35797921   32977874
Q3.21    CALENDAR_QUARTER       33526203   32977874
Q4.21    CALENDAR_QUARTER       41988687   32977874
JAN-21   MONTH                  11477898   11477898
```

```
FEB-21   MONTH                10982016   10982016
MAR-21   MONTH                10517960   10517960
APR-21   MONTH                11032057   10517960
MAY-21   MONTH                11432616   10517960
JUN-21   MONTH                13333248   10517960
JUL-21   MONTH                12070352   10517960
AUG-21   MONTH                11108893   10517960
SEP-21   MONTH                10346958   10346958
OCT-21   MONTH                14358605   10346958
NOV-21   MONTH                12757560   10346958
DEC-21   MONTH                14872522   10346958
```

Prior and Future Period

The Data Analysis tool provides several calculations for prior or future time periods.

Here are the calculations used for for prior or future time periods:

- **Prior Period**: Returns the value of a measure at an earlier time period.
- **Difference From Prior Period**: Calculates the difference between values for the current time period and an earlier period.
- **Percent Difference From Prior Period**: Calculates the percent difference between the values for the current time period and an earlier period.
- **Future Period**: Returns the value of a measure at a later time period.
- **Difference From Future Period**: Calculates the difference between the values for the current time period and a later period.
- **Percent Difference From Future Period**: Calculates the percent difference between the values for the current time period and a later period.

When creating a calculation for prior or future time periods, you choose the measure, the time dimension, the hierarchy, and the number of periods from the current period.

Prior Period Example

This template defines a calculated measure using Prior Period:

```
Prior period for measure SALES in TIME dimension and TIME.CALENDAR hierarchy 1 period
ago.
```

These are the results of a query against the calculated measure. The `PRIOR_PERIOD` column shows the value of Sales for the preceding period at the same level in the Calendar hierarchy.

```
TIME     TIME_LEVEL           SALES PRIOR_PERIOD
-------- -------------------- ---------- ------------
2020     CALENDAR_YEAR         136986572    144290686
2021     CALENDAR_YEAR         140138317    136986572
Q1.20    CALENDAR_QUARTER       31381338     41988687
Q2.20    CALENDAR_QUARTER       37642741     31381338
Q3.20    CALENDAR_QUARTER       32617249     37642741
Q4.20    CALENDAR_QUARTER       35345244     32617249
Q1.21    CALENDAR_QUARTER       36154815     35345244
Q2.21    CALENDAR_QUARTER       36815657     36154815
Q3.21    CALENDAR_QUARTER       32318935     36815657
Q4.21    CALENDAR_QUARTER       34848911     32318935
```

Period to Date

Period-to-date functions perform a calculation over time periods with the same parent up to the current period.

These functions calculate period-to-date:

- **Period to Date**: Calculates the values up to the current time period.
- **Period to Date Period Ago**: Calculates the data values up to a prior time period.
- **Difference From Period to Date Period Ago**: Calculates the difference in data values up to the current time period compared to the same calculation up to a prior period.
- **Percent Difference From Period To Date Period Ago**: Calculates the percent difference in data values up to the current time period compared to the same calculation up to a prior period.

When creating a period-to-date calculation, you can choose from these aggregation methods:

- Sum
- Average
- Maximum
- Minimum

You also choose the measure, the time dimension, and the hierarchy.

Period to Date Example

This template defines a calculated measure using Period to Date.

```
Gregorian Year to date for SALES in the TIME dimension and TIME.CALENDAR hierarchy.
Aggregate using MINIMUM from the beginning of the period.
```

These are the results of a query against the calculated measure. The `MIN_TO_DATE` column displays the current minimum `SALES` value within the current level and year.

```
TIME     TIME_LEVEL               SALES MIN_TO_DATE
-------- -------------------- ---------- -----------
Q1.21    CALENDAR_QUARTER       36154815    36154815
Q2.21    CALENDAR_QUARTER       36815657    36154815
Q3.21    CALENDAR_QUARTER       32318935    32318935
Q4.21    CALENDAR_QUARTER       34848911    32318935
JAN-21   MONTH                   13119235    13119235
FEB-21   MONTH                   11441738    11441738
MAR-21   MONTH                   11593842    11441738
APR-21   MONTH                   11356940    11356940
MAY-21   MONTH                   13820218    11356940
JUN-21   MONTH                   11638499    11356940
JUL-21   MONTH                    9417316     9417316
AUG-21   MONTH                   11596052     9417316
SEP-21   MONTH                   11305567     9417316
OCT-21   MONTH                   11780401     9417316
NOV-21   MONTH                   10653184     9417316
DEC-21   MONTH                   12415325     9417316
```

Parallel Period

Parallel periods are at the same level as the current time period, but have different parents in an earlier period. For example, you may want to compare current sales with sales for the prior year at the quarter and month levels.

The Data Analysis tool provides several functions for parallel periods:

- **Parallel Period**: Calculates the value of the parallel period.
- **Difference From Parallel Period**: Calculates the difference in values between the current period and the parallel period.
- **Percent Difference From Parallel Period**: Calculates the percent difference in values between the current period and the parallel period.

To identify the parallel period, you specify a level and the number of periods before the current period. You can also decide what happens when two periods do not exactly match, such as comparing daily sales for February (28 days) with January (31 days).

You also choose the measure, the time dimension, and the hierarchy.

Parallel Period Example

This template defines a calculated measure using Parallel Period.

```
Parallel period for SALES in the TIME dimension and TIME.CALENDAR hierarchy 1
TIME.CALENDAR.QUARTER ago based on position from beginning to ending of period.
```

These are the results of a query against the calculated measure, which lists the months for two calendar quarters. The parallel month has the same position within the previous quarter. The prior period for `JUL-21` is `APR-21`, for `AUG-21` is `MAY-21`, and for `SEP-21` is `JUN-21`.

```
TIME     PARENT      SALES    LAST_QTR
-------- ---------- ---------- ----------
APR-21   CY2006.Q2    11356940   13119235
MAY-21   CY2006.Q2    13820218   11441738
JUN-21   CY2006.Q2    11638499   11593842
JUL-21   CY2006.Q3     9417316   11356940
AUG-21   CY2006.Q3    11596052   13820218
SEP-21   CY2006.Q3    11305567   11638499
```

Moving Aggregates

Moving aggregates are performed over the time periods surrounding the current period.

The Data Analysis tool provides several aggregation methods for moving calculations:

- **Moving Average**: Calculates the average value for a measure over a fixed number of time periods.
- **Moving Maximum**: Calculates the maximum value for a measure over a fixed number of time periods.
- **Moving Minimum**: Calculates the minimum value for a measure over a fixed number of time periods.
- **Moving Total**: Returns the total value for a measure over a fixed number of time periods.

You can choose the measure, the time dimension, and the hierarchy. You can also select the range, as described in "Choosing a range of time periods" in *Oracle OLAP User's Guide* , and the number of time periods before and after the current period to include in the calculation.

Moving Aggregates Example

This template defines a calculated measure using Moving Minimum.

```
Moving minimum of SALES in the TIME dimension and TIME.CALENDAR hierarchy. Include 1
preceding and 1 following members within level.
```

These are the results of a query against the calculated measure, which displays values for the descendants of calendar year 2021. Each value of Minimum Sales is the smallest among the current value and the values immediately before and after it. The calculation is performed over all members of a level in the cube.

```
TIME     TIME_LEVEL           SALES  MIN_SALES
-------- -------------------- ---------- ----------
Q1.21    CALENDAR_QUARTER       32977874   32977874
Q2.21    CALENDAR_QUARTER       35797921   32977874
Q3.21    CALENDAR_QUARTER       33526203   33526203
Q4.21    CALENDAR_QUARTER       41988687   31381338
JAN-21   MONTH                  11477898   10982016
FEB-21   MONTH                  10982016   10517960
MAR-21   MONTH                  10517960   10517960
APR-21   MONTH                  11032057   10517960
MAY-21   MONTH                  11432616   11032057
JUN-21   MONTH                  13333248   11432616
JUL-21   MONTH                  12070352   11108893
AUG-21   MONTH                  11108893   10346958
SEP-21   MONTH                  10346958   10346958
OCT-21   MONTH                  14358605   10346958
NOV-21   MONTH                  12757560   12757560
DEC-21   MONTH                  14872522   12093518
```

Share

Share calculates the ratio of a measure's value for the current dimension member to the value for a related member of the same dimension.

You can choose whether the related member is:

- **Top of hierarchy**: Calculates the ratio of each member to the total.
- **Member's parent**: Calculates the ratio of each member to its parent.
- **Member's ancestor at level**: Calculates the ratio of each member to its ancestor, that is, a member at a specified level higher in the hierarchy.

When creating a share calculation, you can choose the measure, dimension, and hierarchy. You also have the option of multiplying the results by 100 to get percentages instead of fractions.

Share Example

This template defines a calculated measure using `SHARE`:

```
Share of measure SALES in PRODUCT.PRIMARY hierarchy of the PRODUCT dimension as a ratio
of top of hierarchy.
```

These are the results of a query against the calculated measure. The `TOTAL_SHARE` column displays the percent share of the total for the selected products.

```
PRODUCT            PROD_LEVEL          SALES TOTAL_SHARE
------------------- --------------- ---------- -----------
Total Product        TOTAL             144290686         100
```

```
Hardware             CLASS          130145388          90
Desktop PCs          FAMILY          78770152          55
Portable PCs         FAMILY          19066575          13
CD/DVD               FAMILY          16559860          11
Software/Other       CLASS           14145298          10
Accessories          FAMILY           6475353           4
Operating Systems    FAMILY           5738775           4
Memory               FAMILY           5430466           4
Modems/Fax           FAMILY           5844185           4
Monitors             FAMILY           4474150           3
Documentation        FAMILY           1931170           1
```

Rank

Rank orders the values of a dimension based on the values of the selected measure. When defining a rank calculation, you choose the dimension, a hierarchy, and the measure.

You can choose a method for handling identical values:

- **Rank**: Assigns the same rank to identical values, so there may be fewer ranks than there are members. For example, it may return `1`, `2`, `3`, `3`, `4` for a series of five dimension members.
- **Dense Rank**: Assigns the same minimum rank to identical values. For example, it may return `1`, `2`, `3`, `3`, `5` for a series of five dimension members.
- **Average Rank**: Assigns the same average rank to identical values. For example, it may return `1`, `2`, `3.5`, `3.5`, `5` for a series of five dimension members.

You can also choose the group in which the dimension members are ranked:

- **Member's level**: Ranks members at the same level.
- **Member's parent**: Ranks members with the same parent.
- **Member's ancestor at level**: Ranks members with the same ancestor at a specified level higher in the hierarchy.

Rank Example

This template defines a calculated measure using Rank:

```
Rank members of the PRODUCT dimension and PRODUCT.PRIMARY hierarchy based on measure
SALES. Calculate rank using RANK method with member's parent in order lowest to highest.
Rank NA (null) values nulls last.
```

These are the results of a query against the calculated measure in which the products are ordered by `RANK`:

```
PRODUCT              SALES       RANK
-------------------- ---------- ----------
Monitors                4474150          1
Memory                  5430466          2
Modems/Fax              5844185          3
CD/DVD                 16559860          4
Portable PCs           19066575          5
Desktop PCs            78770152          6
```

Oracle Autonomous Database for Excel

The Oracle Autonomous Database for Excel integrates Microsoft Excel spreadsheets with the Autonomous Database to retrieve and analyze data from Analytic Views in the database. You can also directly run SQL queries to view their results in the worksheet.

> **Note:**
>
> - The **Download Microsoft Excel/Google Sheets add-in** is available to you under the **Downloads** menu of your Database Actions instance only if you have the `ADPUSER` role.
> - You require ADMIN privileges to grant roles.
> - To grant yourself an `ADPUSER` role, you must log into your Database Actions instance and enter the following command in the SQL worksheet area displayed in the **SQL** tab under **Development** tools present in the Launchpad:
>
>   ```
>   Grant ADPUSER to USER;
>   ```

- Install the add-in from Microsoft AppSource
  The **Oracle Autonomous Database for Excel** is available in **Microsoft AppSource**.
- Install the add-in from Database Actions
  You can install the add-in from Database Actions. This is accessed by users with Oracle Account.
- Uninstall the add-in
  The following section describes the steps to uninstall the Oracle Autonomous Database add-in.
- Using Oracle Autonomous Database for Excel
  After you install the add-in, a new ribbon tab, **Oracle Autonomous Database** appears in MS Excel.
- Connection management
  Each time you start the add-in for Excel, you must create a connection.
- Log Settings
  The Settings icon enables you to set the log levels using the Excel add-in.
- Run Direct SQL queries in an Excel worksheet
  The Oracle Autonomous Database for Excel lets you run Direct SQL queries to work with your data in an Excel worksheet.
- Read and Access Data Using Table Hyperlinks in Excel Sheet
  Table Hyperlinks in Oracle Autonomous Database provide secure, preauthenticated URLs that allow read-only access to data stored in tables, views, or the result of SQL queries.
- Reporting and Analysis in Excel
  You can view Reports and Analytic Views or visualizing data for analysis purpose using the **Analysis and Reports** menu.
- Query an Analytic View in an Excel worksheet
  The Query Wizard menu enables you to query an Analytic View and retrieve the results in an Excel Worksheet. Once the wizard retrieves the data, it becomes local to Excel. You can further edit the data in Excel but not write back to the Autonomous Database.

- Data Analysis in Excel Sheet
  The Data Analysis tool enables you to analyze data in the Autonomous Database by running SQL queries or querying an Analytical View using an intuitive drag-and-drop interface. You can also write custom queries to be run. You now can dynamically apply filters to the result set retrieved using the new faceted search capability on specific columns.
- Natural Language in Excel Sheet
  You can use Natural Language Query to query the Oracle Autonomous Database using the **Natural Language** menu in the **Oracle Autonomous Database for Excel** .
- FAQs for Troubleshooting errors with Excel Add-in
  If you experience issues with Oracle Autonomous Database for Excel, refer to frequently asked questions in this section to identify and resolve issues.
- Oracle Autonomous Database for Excel Privacy Policy Details
  This topic covers details for writing policies to control access to Autonomous Database resources.

Using Oracle Autonomous Database for Excel

After you install the add-in, a new ribbon tab, **Oracle Autonomous Database** appears in MS Excel.

You can connect to multiple Autonomous Databases, work with Analytic Views, tables, and Views, and view the data in the worksheet.

This ribbon provides buttons that let you connect to the Autonomous Database.

Click **Connections** to connect to an Autonomous Database. You must Refer to the *Connection management* for more details.

Click **Settings** to view the logging level settings of the Excel Add-in. You can also clear the logs or export the log files by copying the logging information to the clipboard.

Click **About** to view the Add-in and the supported Excel versions. The About window also displays whether the spreadsheet is connected to the database. It also shows version information for the database and Oracle Rest Data Services.

Click **Direct SQL** to run custom SQL queries. See

Click **Data Analysis** to query an existing Analytic View and run queries.

Click **Natural Language** to run Natural Language Queries on Tables.

Read and Access Data Using Table Hyperlinks in Excel Sheet

Table Hyperlinks in Oracle Autonomous Database provide secure, preauthenticated URLs that allow read-only access to data stored in tables, views, or the result of SQL queries.

They enable easy sharing and retrieval of database data without requiring additional authentication beyond the hyperlink itself. You can read and access data in a Microsoft Excel sheet using a Table Hyperlink through the Oracle Autonomous Database Add-in for Excel, which allows direct retrieval and viewing of tabular data from the Autonomous Database within Excel.

You can use **Table Hyperlinks** with the add-in.

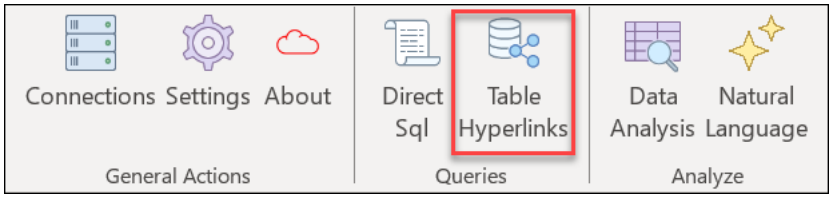
For more information of Table Hyperlinks, refer to the Use Table Hyperlinks for Read Only Data Access on Autonomous Database Chapter.

> **Note:**
>
> This feature allows read-only access to data through secure, table hyperlink URLs without requiring an additional database connections or an Oracle Autonomous Database account.

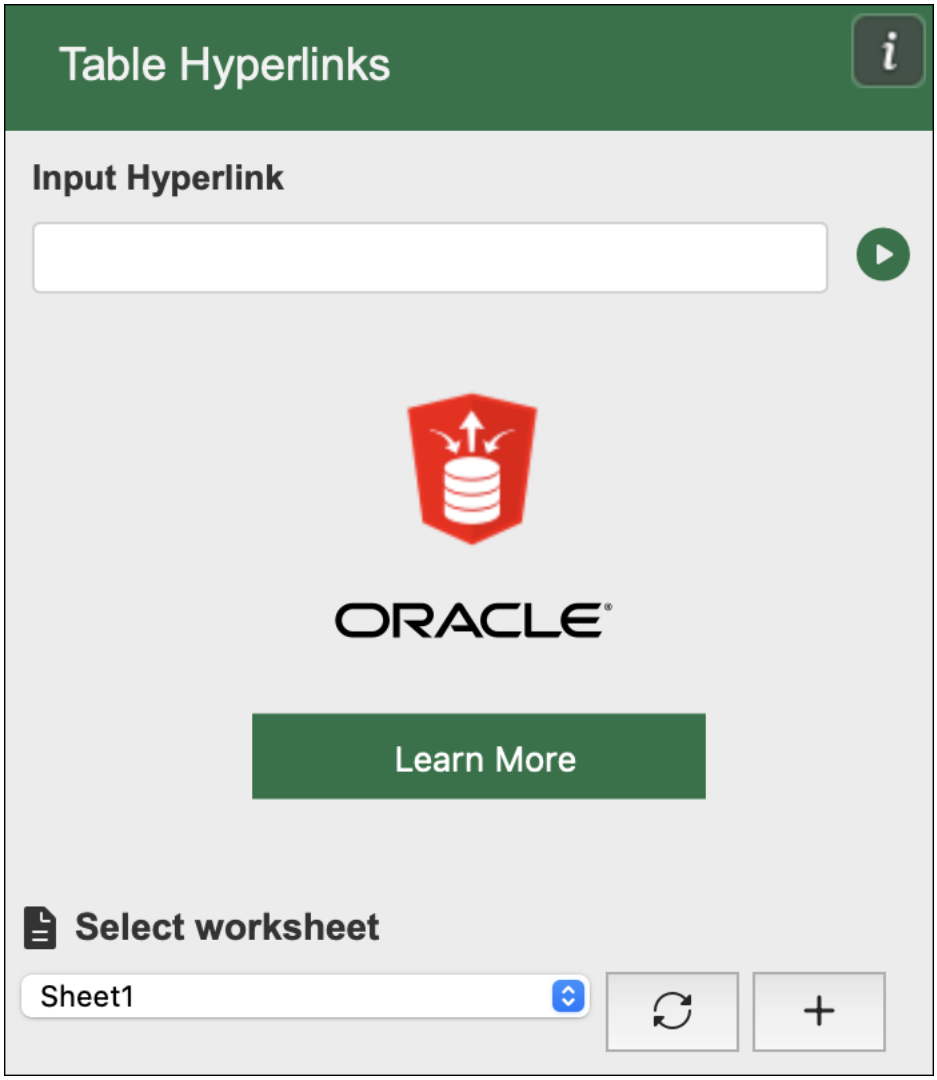
Use **Table Hyperlinks** to read and access data and view the data in a tabular format.

To return data from the add-in using Table Hyperlinks:

1. On the Excel sheet, select the menu **Autonomous Database**.
2. Select **Table Hyperlinks**.



3. Selecting Table Hyperlinks opens a **Table Hyperlinks** panel.



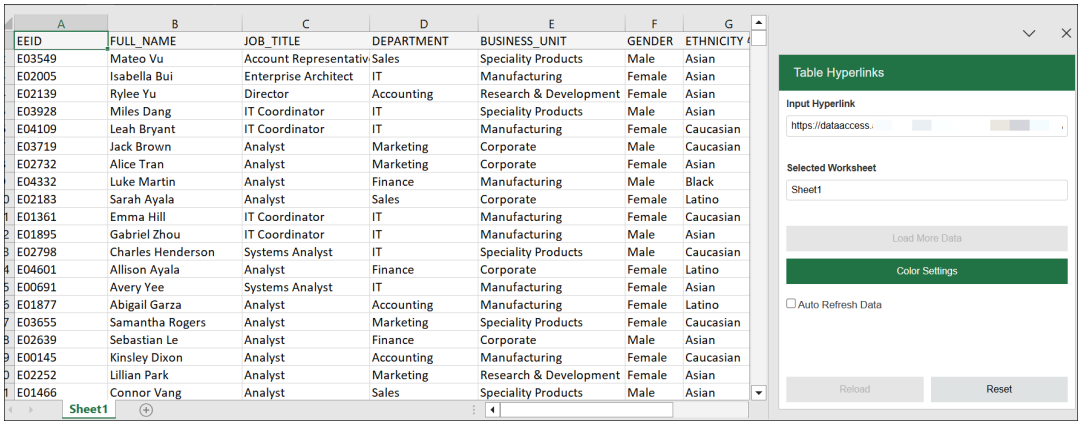
4. On the **Input Hyperlink** field, enter the input Table Hyperlink the producer shares with you. A Producer generates a PAR URL in their database and provides it to you. For example, *https://dataaccess.adb.eu-frankfurt-1.oraclecloudapps.com/adb/p/F5Sn....*
You can create Table Hyperlinks in Oracle Autonomous Database Serverless using the `DBMS_DATA_ACCESS` PL/SQL package and share them with the consumers.

   See DBMS_DATA_ACCESS Package for more information on this topic.

   Select Worksheet: Enter the name of the sheet where you want to display the results. For example, *Sheet1*.

   You can click the + sign beside the Select worksheet drop-down to display the results in a new worksheet.

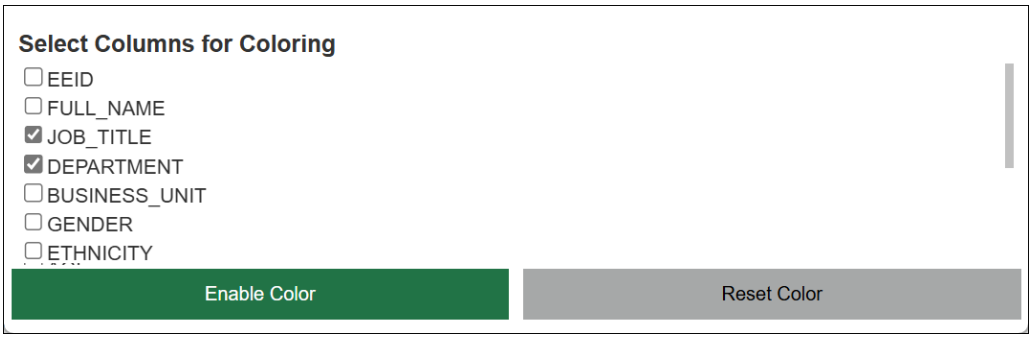
5. Click the **Play** button to load the Autonomous Data table in the worksheet.
The result data gets retrieved in the worksheet. You can view only first 10000 records in the first load.



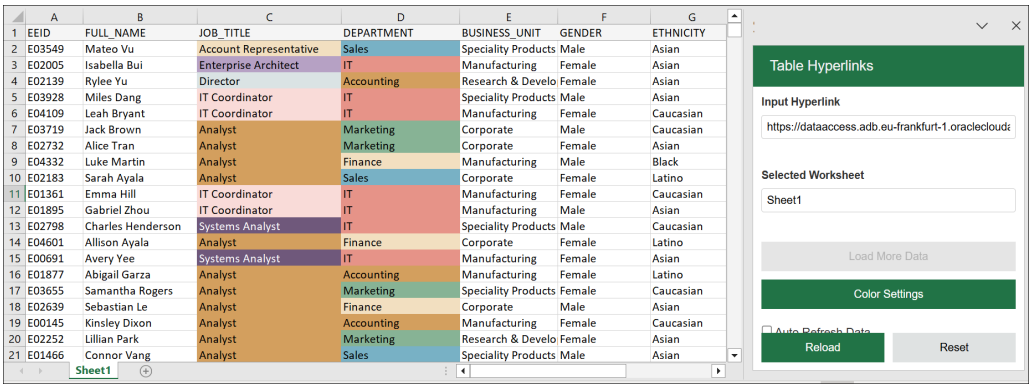
After selecting the play icon, along with the results retrieved in the worksheet, you can also see the following generated fields:

- **Load More Data**:
  Select **Load More Data** to retrieve the next 10000 rows from the table.
- **Color Settings**:
  Select this icon to enable color in the column from a predefined pool of colors. If the feature runs out of colors, the pool is refilled with the same colors for the new value keys.

  Click the icons you want to add color to. In this example, select *JOB_TITLE* and *BUSINESS_UNIT*.



- Select **Enable Color** to color the selected columns in the data.



You can select **Reset Color** to reset your current selection, remove colors from all the selected columns and choose different columns you wish to enable color to.

- **Auto Refresh Data**:
  Enable this option to automatically update data at regular intervals with the latest data from its source database. This automatic refresh keeps the tabular data in worksheet in sync with the current data within a specific refresh frequency.

  You can select the frequency from the frequency slider where the selection varies from a range of 5 minutes to 1 day.
- **Reload**: Select **Reload** to reload the preloaded table hyperlink data.

> **Note:**
>
> This button loads a maximum of 50,000 records.

- **Reset**: Select **Reset** to clear all data from the sheet, reset your selection of all the current options and enter the **Input hyperlink** again.

Install the add-in from Microsoft AppSource

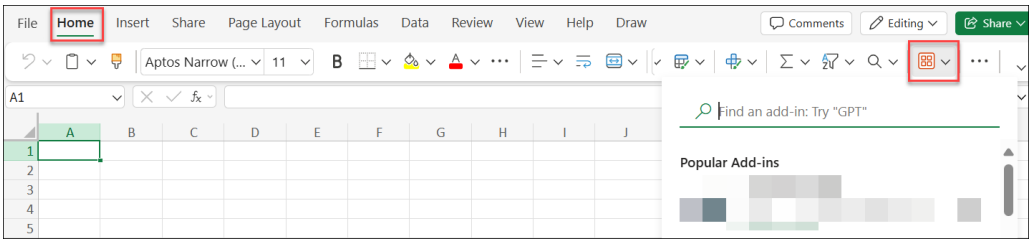
The **Oracle Autonomous Database for Excel** is available in **Microsoft AppSource**.

Prerequisites

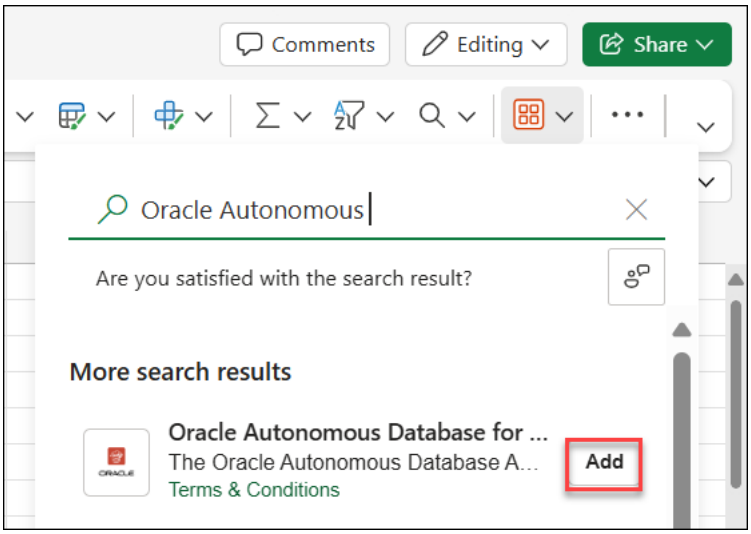
- You must have an active Microsoft account or an account with access to Microsoft 365.
- You can access the web version of Excel or the (Licensed version) from desktop.
- You must verify within your organization whether external apps from AppSource are permitted to be installed in your Microsoft 365 accounts. If not, you can Install the add-in from Database Actions.

Follow these steps to install the add-in:

1. **Start Excel and open a new or existing workbook**:
   - You can access the web version of Microsoft Excel with your Microsoft AppSource account:
     - Go to your Microsoft 365 Copilot (earlier known as MS Office) app link:https://m365.cloud.microsoft
     - Login with your account.
     - Select Excel Workbook from the Microsoft 365 Copilot home page.
2. **Install the Add-in from Office Add-ins**:
   - From the Home menu, go to **Add-ins** and search for "*Oracle Autonomous*" in the search bar.



- You can view the Oracle Autonomous Database for Excel in the search results.

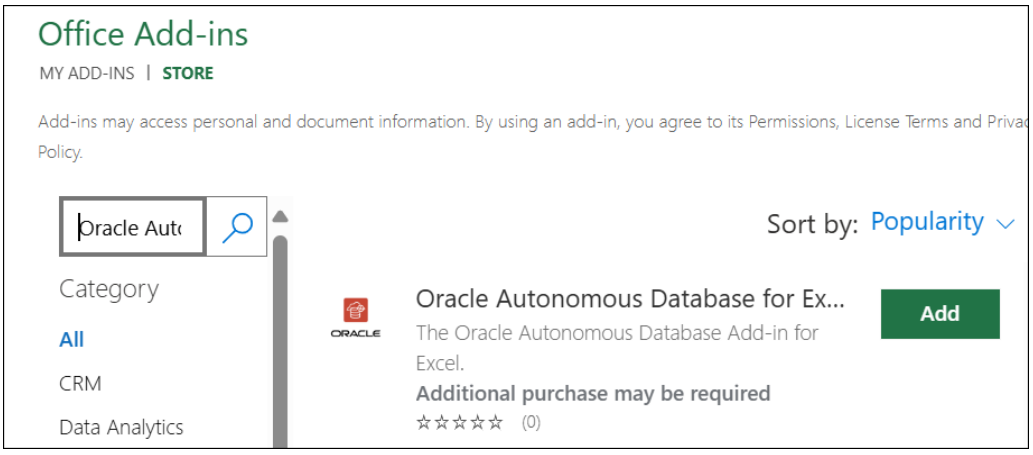


- Click **Add** to install the add-in.

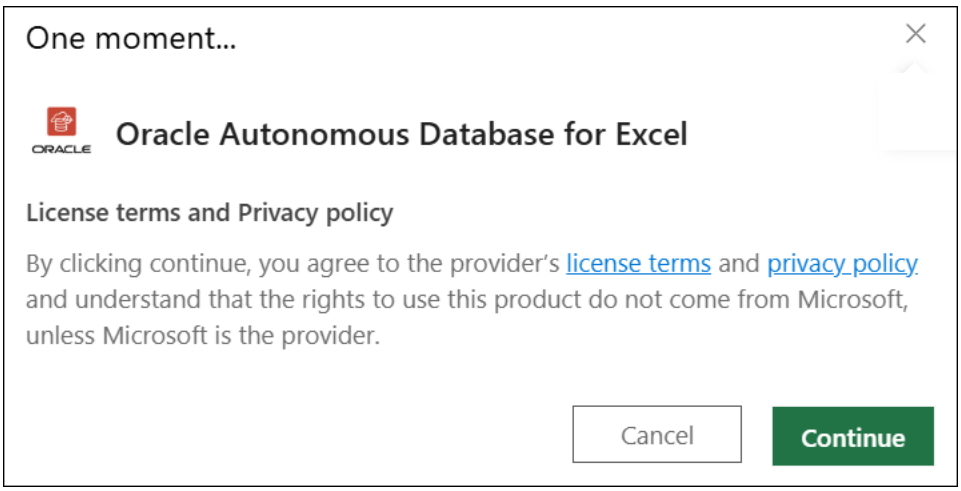
OR

- You can alternatively click the **Add-ins** icon from the **Home**menu and select **+ More Add-ins** from the bottom of the Add-ins drop-down list.

- Enter "*Oracle Autonomous*" in the search field of the **STORE** tab of **Office Add-ins** and click the **search** icon.

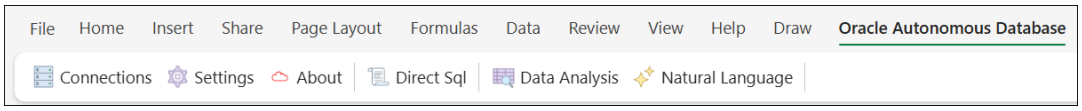


- You can view the Oracle Autonomous Database for Excel in the search results.
- Click **Add** to install the add-in in Excel.
- You will view a dialog to accept Oracle's license terms and Oracle Autonomous Database for Excel Privacy Policy Details. Click **Continue** to agree to it.



You will view a message confirming the add-in loaded successfully.

A new **Oracle Autonomous Database** ribbon tab appears in MS Excel.



After you have installed the add-in, you can now connect to the Autonomous Database to analyze and query the data. Refer to the Connection management chapter for more details on this topic.

Refer to the Uninstall the add-in chapter to uninstall the add-in you installed from Microsoft AppSource.

Install the add-in from Database Actions

You can install the add-in from Database Actions. This is accessed by users with Oracle Account.

Prerequisites:

- You must have an Oracle Cloud Account.
- You can install the add-in only from the licensed desktop version of Microsoft Excel.

The following instructions outline how to install the add-in depending on your operating system, specifically for Mac and Windows.

- Install the add-in on Mac
- Install the add-in on Windows

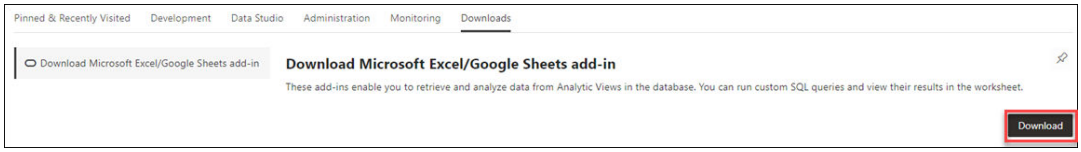
- Install the add-in on Mac
  The Oracle Autonomous Database for Excel is supported on Mac OS running Microsoft Office 365.
- Install the add-in on Windows
  The Oracle Autonomous Database for Excel is supported on Windows 10 and Windows 11 operating systems running Microsoft Excel 365.

Install the add-in on Mac

The Oracle Autonomous Database for Excel is supported on Mac OS running Microsoft Office 365.

To install the Autonomous Database for Excel, run the installer script file from your Autonomous Database instance by following the steps below:

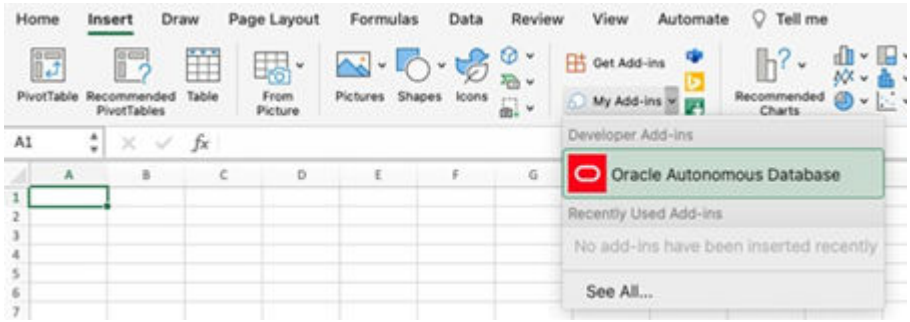
- Open the Database Actions Launchpad.
- On the **Downloads** tab of the Database Actions page, click the **Download Microsoft Excel/Google Sheets Add-in** pane.



- Click **Download**.
- Click the Microsoft Excel tab and select the **Download Add-in** button to download the **oracleplugin.zip** file.
- You can now view the zip file in the Downloads folder.
- Create a new folder named **Add-in** on your system.
- Extract the contents of the zip file in the **Add-in** folder.

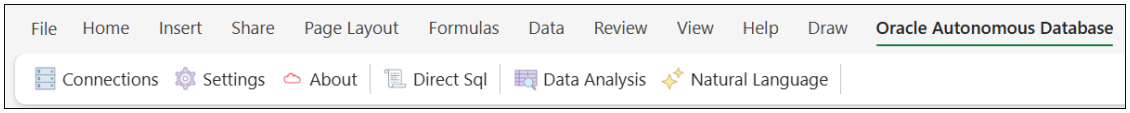
Follow these steps to install the add-in.

1. Quit Excel before you run the installer.
2. Navigate to the *install.sh* file in the **Add-in** folder.
3. Right-click *install.sh* and select the following options as shown : **Open With** -> **Other…** -> **Enable: All Applications** ->**Utilities**->**Terminal**
4. On completion, close the Terminal window.
5. Start Excel and open a new or existing workbook.
6. From the **Insert** menu in the Excel ribbon, select the drop-down menu of **My Add-ins**. A new **Oracle Autonomous Database** entry appears under the **Developer Add-Ins** dialog box.



7. Select **Oracle Autonomous Database**.

A new **Oracle Autonomous Database** ribbon tab appears in MS Excel.



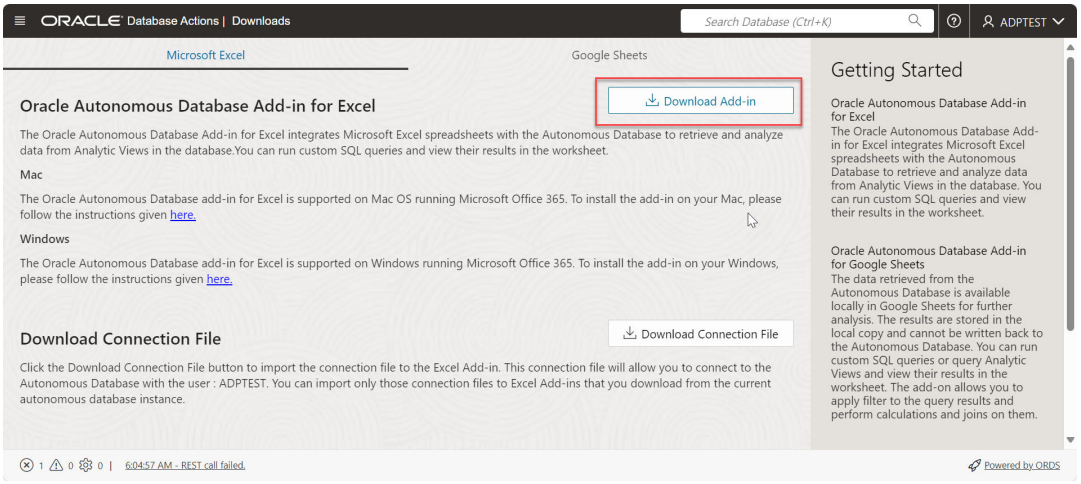
Install the add-in on Windows

The Oracle Autonomous Database for Excel is supported on Windows 10 and Windows 11 operating systems running Microsoft Excel 365.

To install the Oracle Autonomous Database for Excel, download the *oracleplugin.zip* file and extract it to get the *install.cmd* script file from your Database Actions instance.

- Open the Database Actions Launchpad.
- On the **Downloads** tab of the Database Actions page, click the **Download Microsoft Excel/Google Sheets Add-in** pane.

- Click **Download**.
- Click the **Download Add-in** icon in the Microsoft Excel tab to download the Oracle Autonomous Database Add-in for Excel.



- Extract the *oracleplugin.zip* file to a new folder in the Downloads of your system. The extracted folder consists of an installer (install.cmd file), a manifest.xml file and a readme.txt file.

Follow these steps to install the add-in.

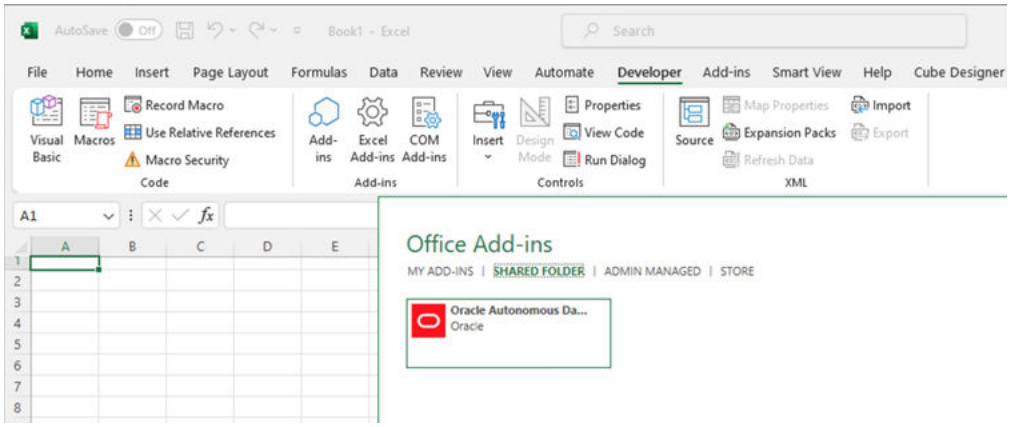
1. Quit Excel before you run the installer.
2. Right-click the *install.cmd* file that you downloaded.

> **Note:**
>
> After running the installer on Windows, the add-in automatically creates a network share and adds the shared location as a trusted catalog location for Office add-ins. A catalog is used to store the manifest for the Excel Add-in. It enables publishing and management of the Excel add-in as well as other add-ins that are available in the Office Store and licensed for corporate use. You can acquire the Excel add-in by specifying the shared manifest folder as a trusted catalog.

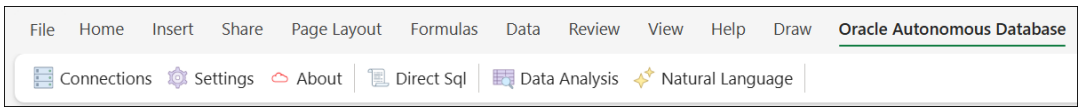
3. Select **Run as administrator**.

> **Note:**
>
> You must have Administrator privileges to install the Excel add-in for Oracle Autonomous Database successfully.

4. Start Excel and open a new or existing workbook.
5. From the **Developer** menu in the Excel ribbon, click **Add-ins**, select the **SHARED FOLDER** tab on the pop-up window and select **Oracle Autonomous Database**.



6. After you install the add-in, a new **Oracle Autonomous Database** ribbon tab appears in MS Excel.



> **Note:**
>
> You can re-run the installer after the initial installation. Re-run the installer and choose the option of your preference. You can repair your existing installation by deleting it, selecting the installed trusted catalog or adding another manifest to the working installation.

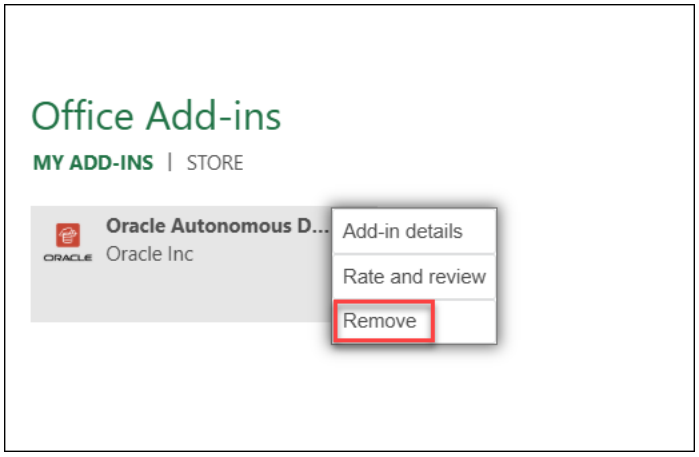
Uninstall the add-in

The following section describes the steps to uninstall the Oracle Autonomous Database add-in.

If you have installed **Oracle Autonomous Database for Excel** for Windows using the Microsoft AppSource, you can uninstall the add-in by following these steps:

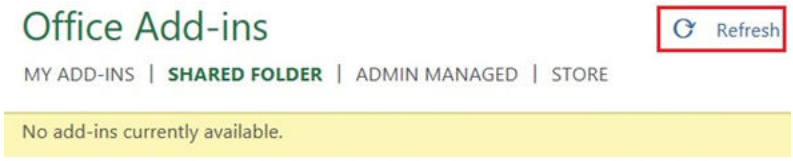
- Click the **Add-ins** icon from the **Home**menu and select **+ More Add-ins** from the bottom of the Add-ins drop-down list.

- Click **MY ADD-INS** from **Office Add-ins** and right-click the **Oracle Autonomous Database for Excel** add-in.
- Click**Remove** to uninstall the add-in from Excel.



If you have installed **Oracle Autonomous Database for Excel** for Windows using Database Actions, you can uninstall the add-in by following these steps:

- Delete the *manifest.xml* file from the folder located in *%LOCALAPPDATA% \Oracle\Autonomous Database\manifest* .
- Click **Refresh** in the Office Add-ins window to remove the Autonomous Database tab from MS Excel.



No add-ins will now be available from the Shared folder of the Office Add-ins window.

> **Note:**
>
> After uninstalling the Add-in, if you re-install it from a different Autonomous Database (ADB), the add-in attempts to load the old ADB. You must check if the shared manifest folder's location (share path) points to the correct location. For more details, refer to *Configuring the Excel Trusted Add-in Catalog* in FAQs for Troubleshooting errors with Excel Add-in.

Uninstall the add-in for Mac

To uninstall the Oracle Autonomous Database for Excel for Mac:

- Enter the following command in the terminal to remove the *manifest.xml* file.

```
rm ~/Library/Containers/com.microsoft.Excel/Data/Documents/wef/manifest.xml
```

The Oracle Autonomous Database for Excel is uninstalled from Mac.

Connection management

Each time you start the add-in for Excel, you must create a connection.

The connections feature lets you manage and connect to multiple Autonomous Databases with a single add-in. Multiple connections can be created. However, only one connection can remain active.

The connection panel lets you connect to the Autonomous Database through a connection where you provide the login credentials and access the Autonomous Database.

Within the Connections panel, you can:

- Create or delete multiple connections using a single add-in.
- Share connection information by exporting and importing connection information to a file.
- View existing connections.

Selecting **Connections** opens the Connections wizard.

> **Note:**
>
> This is an implicit type of connection. Refer to Authenticate using Implicit connection to understand more about implicit connection.

The Connections wizard consists of **Manage Connections** icon that has the following options available:

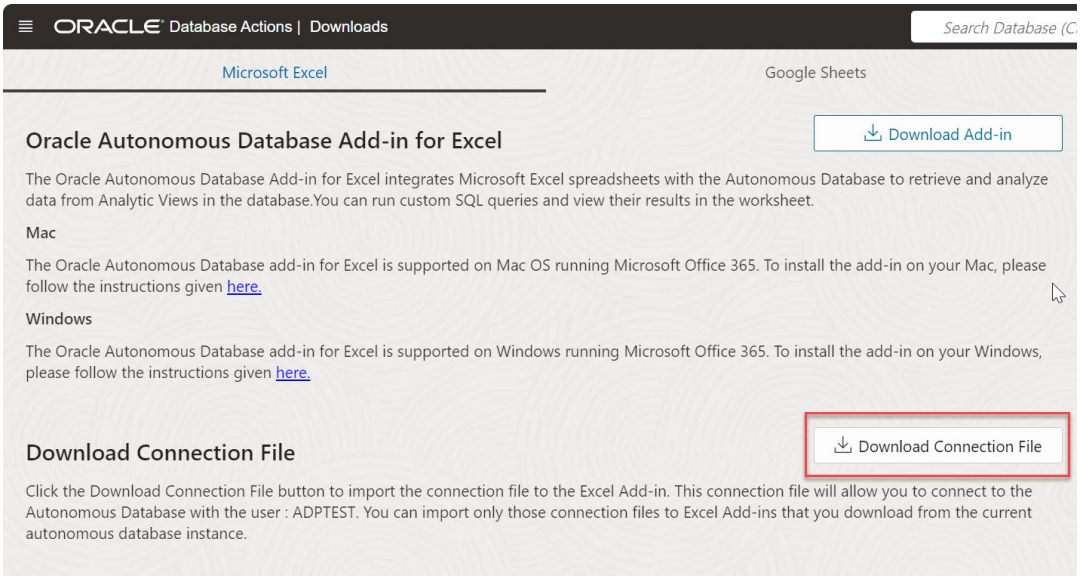
- **Add Connection**: Select **Add Connection** to Add a Connection. Refer to Add a connection section for more details.
- **Export Connection**: Select **Export Connection** to export connections. Refer to the Share a connection section for more details.
- **Import Connection**: Select **Import Connection** to launch the import wizard to choose a connection file. These files are in JSON format. Refer to the Share a connection section for more details.
- Import a Connection
  You can import a connection file that you can download from the Database Actions launchpad. This file is in JSON format.
- Add a connection
  You can manually create a connection to an autonomous database.
- Share a connection
  You can import or export a connection using the **Import Connection** and **Export Connection** menus from the **Manage Connections** drop-down field on the Connections panel.

Import a Connection

You can import a connection file that you can download from the Database Actions launchpad. This file is in JSON format.

Follow the below steps from the Database Actions instance, to download the connection file.

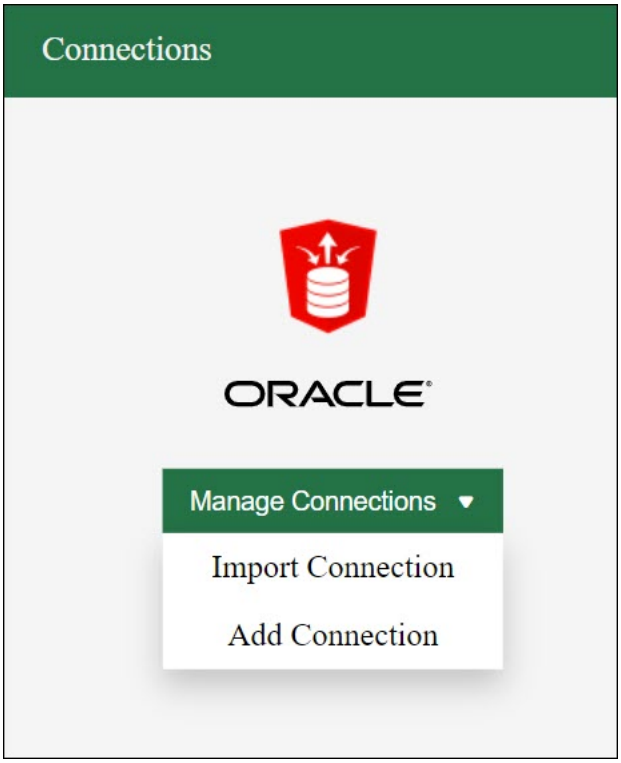
1. From the Downloads page of the Database Actions instance, click the **Download Connection File** icon to download the connection file in your system.



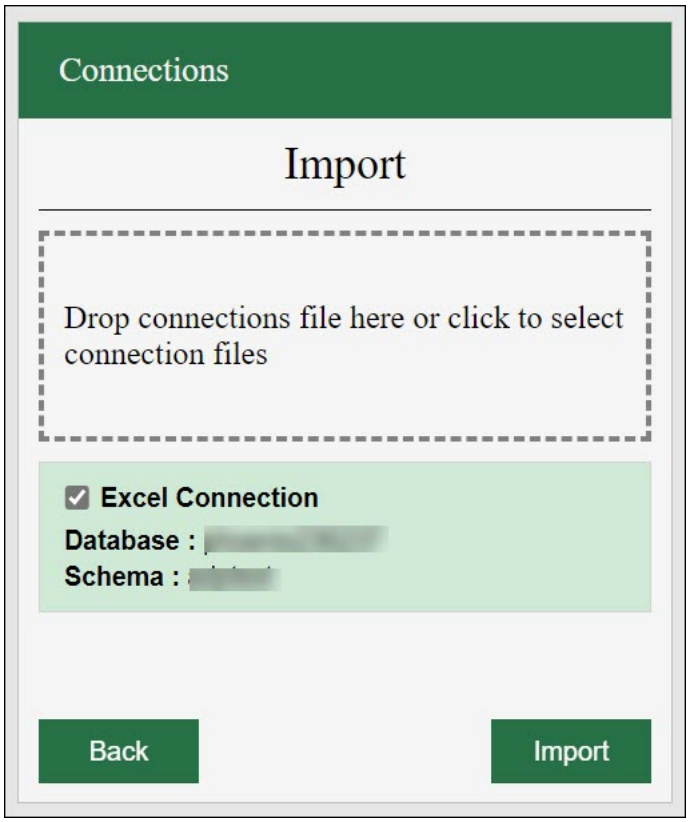
2. The file is downloaded onto your system.

To import a connection:

1. Select **Connections** from the Autonomous Database menu in the Excel sheet. This opens the Connections wizard that consists of a **Manage Connections** icon.
2. Click **Import Connection** to import the connection file you downloaded from the Database Actions instance.



3. Click and drop the connection file from your system to the drop area of the wizard. After the connection file loads, select the check box beside the connection file you want to import from the file.



4. Click **Import** to proceed.
5. Click the three vertical dots beside the connection file and select **Connect**.

> **Note:**
>
> If you view a red icon beside the connection file, the connection is inactive or incorrect. Click the three vertical dots beside the connection file and select **Edit** to update the connection file. Ensure the Autonomous Database URL is correct and click **Save**. An example of a correct URL is “https://<hostname>-<databasename>.adb.<region>.oraclecloudapps.com/"

6. Specify the schema name in the username field and the corresponding password in the credentials screen you view. Click **Sign in** to log in to the autonomous database.

Once signed in, you will view the connection highlighted in green. This means the connection is Active.

Add a connection

You can manually create a connection to an autonomous database.

> **WARNING:**
>
> This feature of adding connection manually is not recommended for this release.
>
> Please use the Import a Connection feature to import a connection file from the Downloads menu of the Database Actions launchpad.

Share a connection

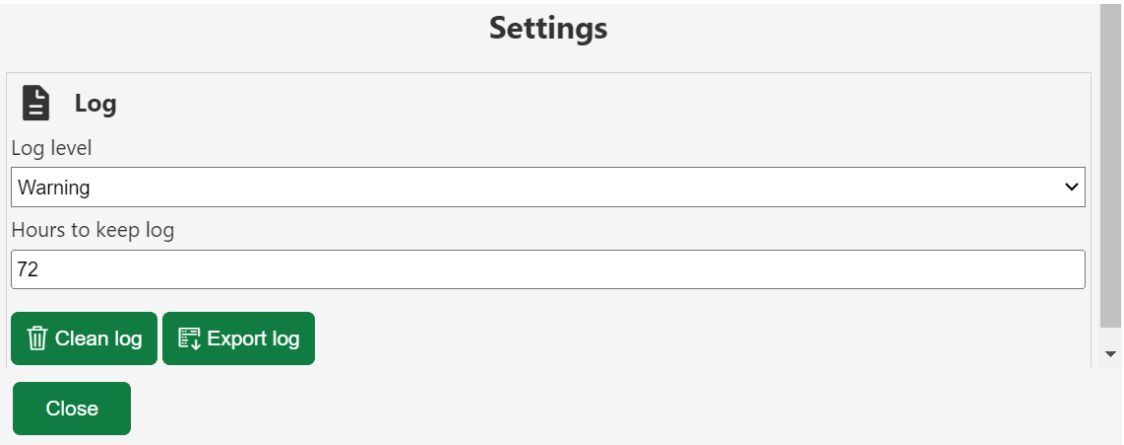
You can import or export a connection using the **Import Connection** and **Export Connection** menus from the **Manage Connections** drop-down field on the Connections panel.

- **Import Connection**: Click **Import Connection** from the **Manage Connections** drop-down icon and select a connection file from your local device. Once you import the connection file, you can view the connection in the Connection panel with a check box beside it. Select the check box and click **Import** to add the connection to the list of connections in the panel. The add-in copies the connection information you can use as a new connection. With the import feature, you do not have to enter the connection information to add a new connection.
- **Export Connection**: The export connection button exports an existing connection which you can import later. Clicking **Export Connection** opens a check box beside each connection in the connections list. You can select the connection you wish to export. Multiple selections are allowed. After you select the connection, click **Export**. Once the connection file is exported, you can view that the add-in for Excel downloads the connection file (*.json file) to your local device. The exported connection file is named spreadsheet_addin_connections.json.

Log Settings

The Settings icon enables you to set the log levels using the Excel add-in.

You can export or save the log. The log can be sent to the support team for diagnosing errors. The Log helps you troubleshoot errors. This field allows you to set the time limit for logging information that is stored in the log file. This setting automatically clears log information older than the entry made in this field. The default is 72 hrs. If the records are older than 72 hours, they will be deleted automatically.



Use Log Levels

Each log message is associated with a severity level. The level gives a rough guide to the importance and urgency of a log message. The log levels are specified with the following values ranging from one having lowest impact (left-most) to the one having highest impact (right-most):

```
STOP, ERROR, WARNING, INFO, VERBOSE
```

The following table lists the severity levels of log messages:

Log Level	Description
STOP	Records no information.
ERROR	Records events that may require corrective action, for example, a component is unavailable.
WARNING	Records issues that may lead to an error or require corrective action in the future. This is the default log level.
INFO	Records completed actions or the current state of a component, for example, the component is initializing.
VERBOSE	Displays detailed processing information along with errors, warnings and info types of severity levels.

Each logging level is cumulative, that is, each level contains all the data generated by the higher levels. For example, Warning logs contain all the data generated by the Error logs, plus the events that are specific to the Error category.

Log message format

The Log Settings writes a message to the specified log file consisting of a module, Timestamp, Severity, Server Name, Connection, Thread ID or User ID or Transaction ID, Message ID, and the Message, along with a stack trace if any. Each attribute is contained between angle brackets.

The following is an example of a message in the server log file (split for readability; in practice, the message might be on one line):

```
{"module":"ServerHelper","logMessage":"connection not is
      avialble","timestamp":1688901058020,"level":3,"payload":
{"conAlias":"Excel
      Connection","status":400},"id":161,"timeString":"9 Jul 2023
      16:40:58"},{"module":"ServerHelper","logMessage":"connection not is
      avialble","timestamp":1688901059724,"level":3}
```

Hours to keep a log

This field has the automatic cleaning operation. The log settings automatically clears old logs. If the logs are older than 72 hours which is the default value, they will be deleted automatically.

Clean Log

This button deletes all the logs.

Export Log

The Export Log button exports or saves logs to a file. Selecting the Export Log icon in Windows enables the add-in in downloading the exported log to “Downloads” folder.

Selecting the Export Log icon in Mac enables the add-in in copying the log information to clipboard. You can paste it to a file and save the log. The log you export will be in JSON format. The JSON file might contain sensitive information like your password, date of birth or any other data you want to secure.

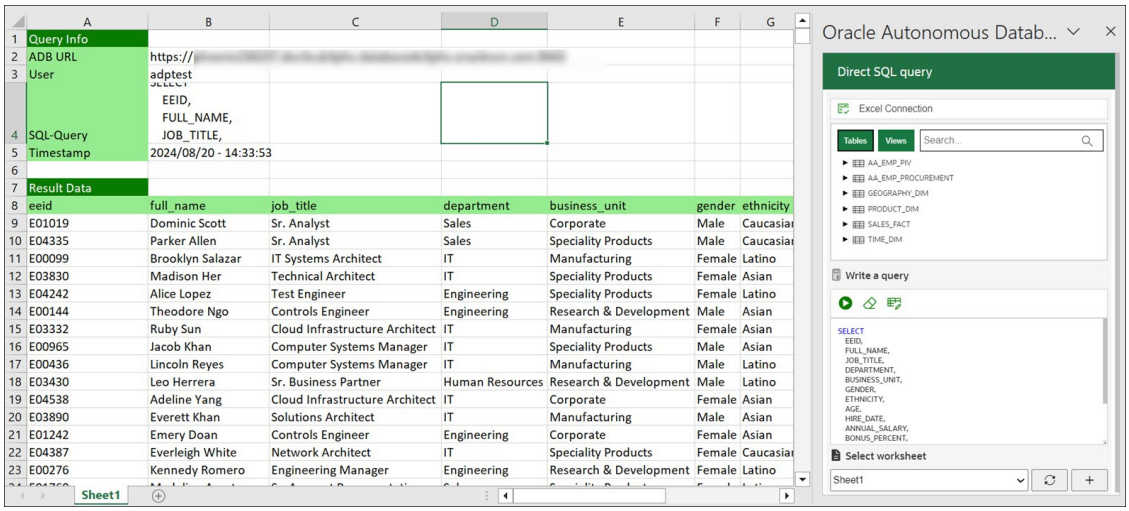
Run Direct SQL queries in an Excel worksheet

The Oracle Autonomous Database for Excel lets you run Direct SQL queries to work with your data in an Excel worksheet.

With the add-in, you can create a table and insert, update and delete rows from the existing tables or views. You can view the results in the current worksheet or different worksheets.

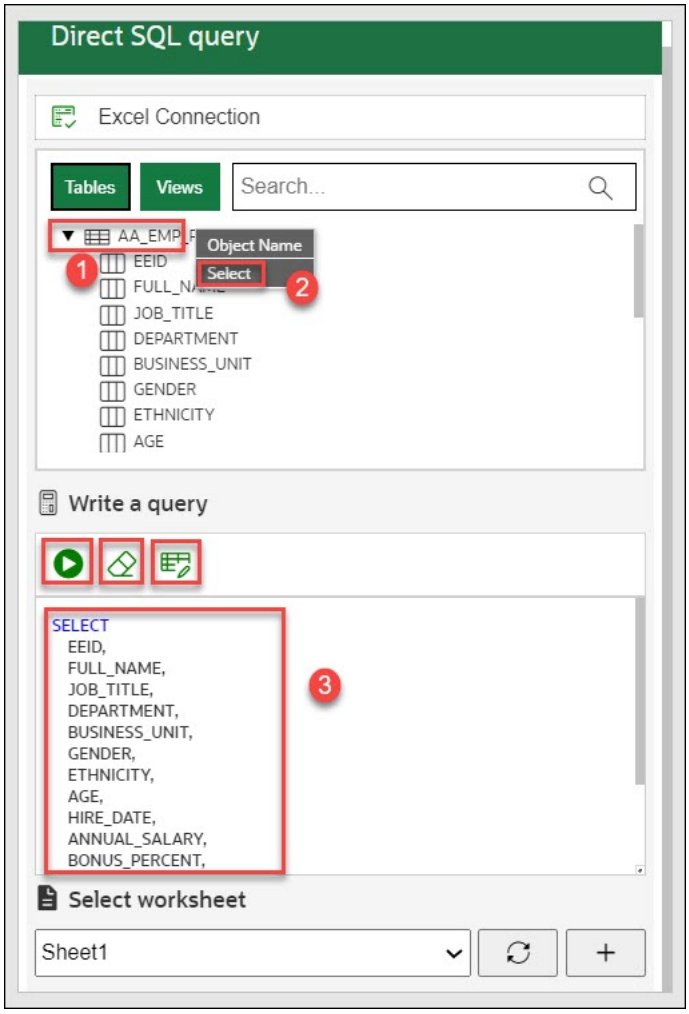
The following image shows your data retrieved from the Autonomous Database and displayed in the worksheet. The Query Info section comprising the Timestamp, User name and SQL Query are shown in Excel. You can edit custom queries and run them. The worksheet displays the results of queries from the retrieved data in tabular format.

The add-in maintains a live connection with the database. However, the data retrieved is local to Excel. In case of inactivity, the connection times out, and you must log in again. You can change the active connection from the connections panel. The image shows the results from a single query, but you can insert many queries in a single workbook.



To run a query using the add-in, run Excel and create a blank workbook using the standard Excel workbook file format.

1. In the Excel ribbon, select the **Autonomous Database**.
2. Click the **Direct SQL** icon from the ribbon. This opens an **Oracle Autonomous Database** dialog box in the Excel Task Pane with **Tables** and **Views** icons and a search field beside them.



3. Select **Table** to view all the existing tables in the schema. Click **Views** to see the current views in the schema.
4. You can right-click the table whose data you want to query and choose **Select** to view all the table's columns. The column names will be displayed in the Write a Query section. You can click on the table and view individual columns as well. Click the **Run** button to run the SQL query in the query editor. The query results will be displayed in the worksheet you select.

> **Note:**
>
> You will view an error message if you click the **Run** icon while the query editor is empty.

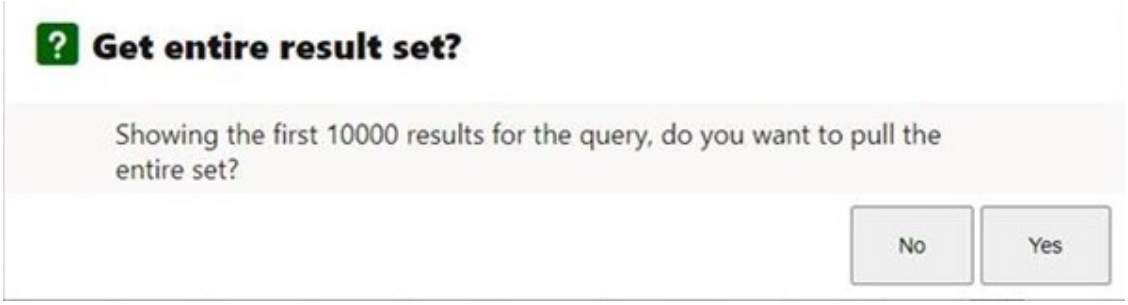
5. You can click **+** sign beside the **Select worksheet** drop-down to display the results in a new worksheet.

6. The worksheet also displays the timestamp, the user who creates and runs the query and the autonomous database URL.

To run another query follow these steps:

1. Click the eraser icon to clear the previous query from the SQL editor and write a new query.
2. Click **Retrieve query from Sheet** to import the SQL query from the existing worksheet and generates that query in the SQL editor.
3. In the **Select worksheet** drop-down, select a new sheet, *Sheet 2*, in this case. The Add-in adds a sheet for the user. If you work on the same sheet, the Add-in refreshes the data in the existing worksheet.
4. Click the **Run** icon to display the query results.

The worksheet displays the result of the query at a go. While this behavior works for most scenarios, sometimes, for large data sets, the query result might exceed 10K rows. Although you can view the 10K rows, a confirmation window asks if you want to view the rest of the results.



Select **Yes** to view the entire result set. Loading all the data may take a while. You must fetch all data before working with Pivot tables, or it will lead to incorrect results from aggregation in Pivot tables.

Close the Query Wizard panel to cancel the operation of fetching the result.

> **Note:**
>
> Close the Query Wizard panel to cancel the operation of fetching the result.

Reporting and Analysis in Excel

You can view Reports and Analytic Views or visualizing data for analysis purpose using the **Analysis and Reports** menu.

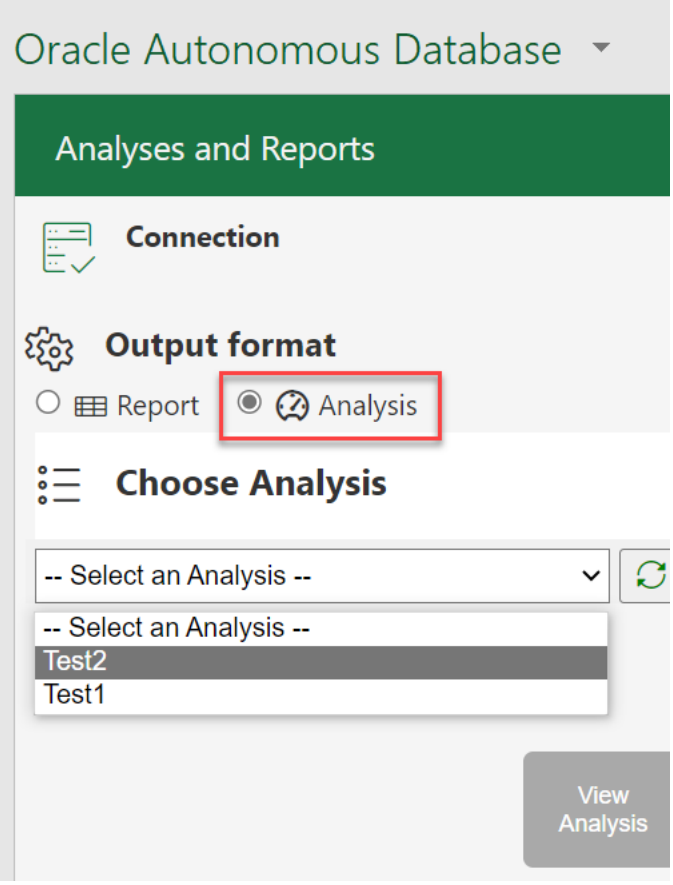
> **Note:**
>
> This menu is unavailable if you install **Oracle Autonomous Database for Excel** using Microsoft Store.

The reports and charts can be viewed in of different range of charts, namely, Bar Chart, Area Chart, Line Chart and Pie Chart. The Analyses and Reports icon enables you to retrieve Analyses and Reports from the Autonomous Database.

View Analysis

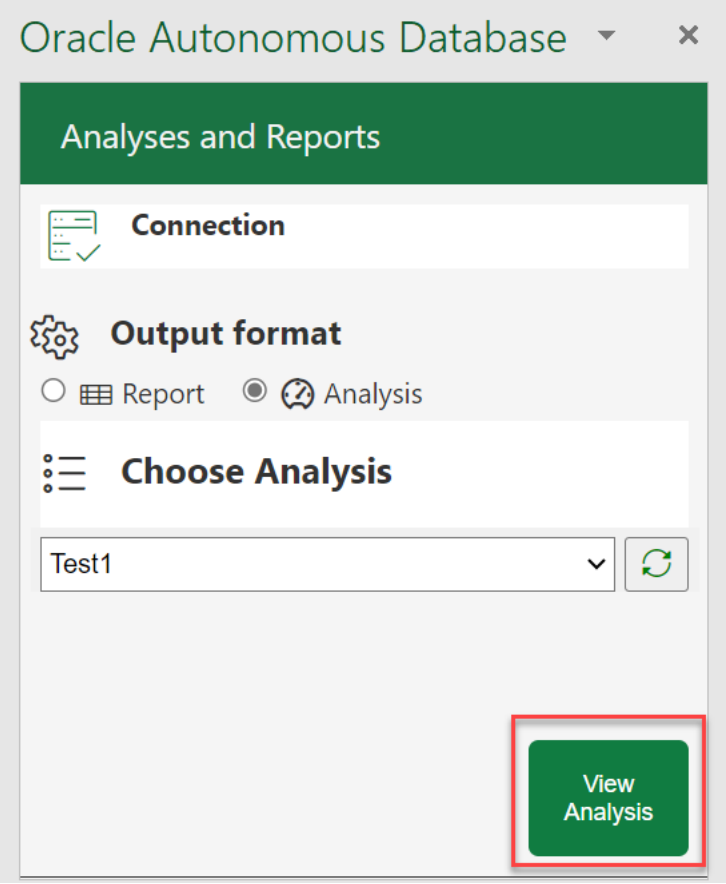
To view Analysis and explore the Analyses and Reports menu:

1. On the MS Excel ribbon, select the **Analyses and Reports** icon from the Autonomous Database menu.
2. Select **Analysis** under Output format.



3. Use the **Select an Analysis** drop down to choose the Analysis you want to view.

4. Click **View Analysis** to view analysis in a new excel sheet.

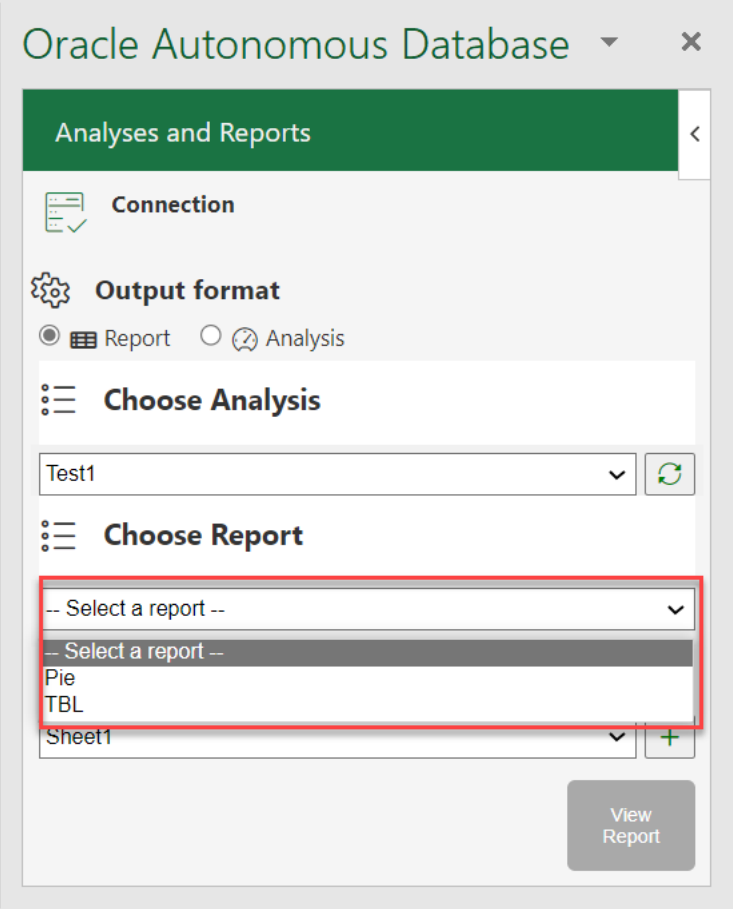


View Report

To view Reports :

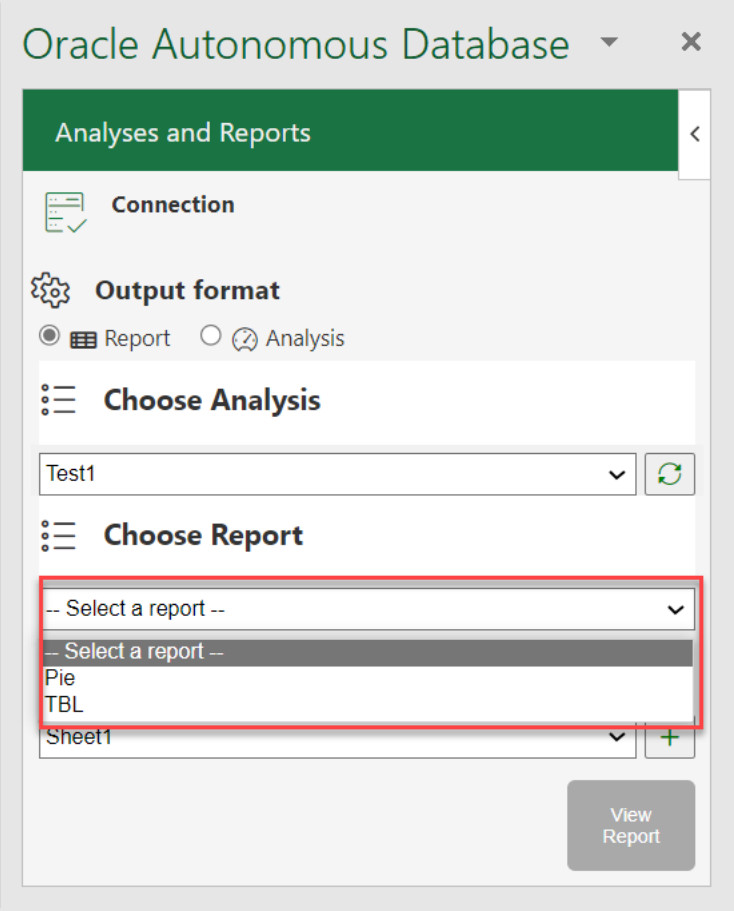
1. On the MS Excel ribbon, select the **Analyses and Reports** icon from the Autonomous Database menu.

2. Select **Report** under Output Format.



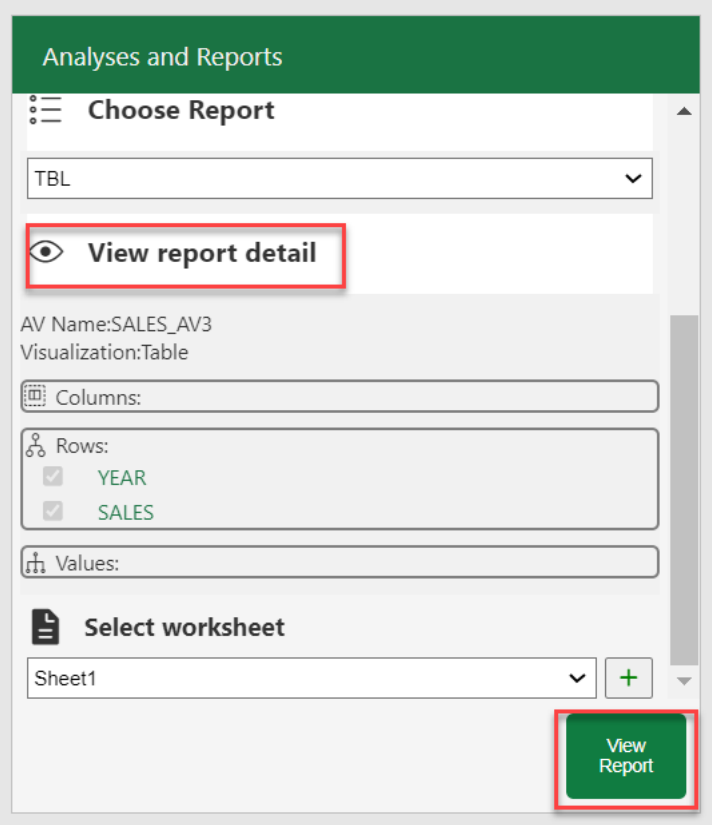
3. Use **Select an Analysis** drop down under **Choose Analysis** to choose the Analysis you want to view.

4. After you select the Analysis, to view the report present in the Analysis, click the **Select a report** drop-down and select the report you wish to view.



5. Click **View Report Detail** to view more information about the report namely, Analytic View Name, Type of visualization and rows, columns or values you select while creating the

report.



6. Select the worksheet from the drop-down where you would want to view the report.
7. Click **View Report** to view the report in the sheet you select from the previous step.

You can now view the report in the worksheet you select.

Query an Analytic View in an Excel worksheet

The Query Wizard menu enables you to query an Analytic View and retrieve the results in an Excel Worksheet. Once the wizard retrieves the data, it becomes local to Excel. You can further edit the data in Excel but not write back to the Autonomous Database.

> **Note:**
>
> This menu is unavailable if you install **Oracle Autonomous Database for Excel** using the Microsoft Store.

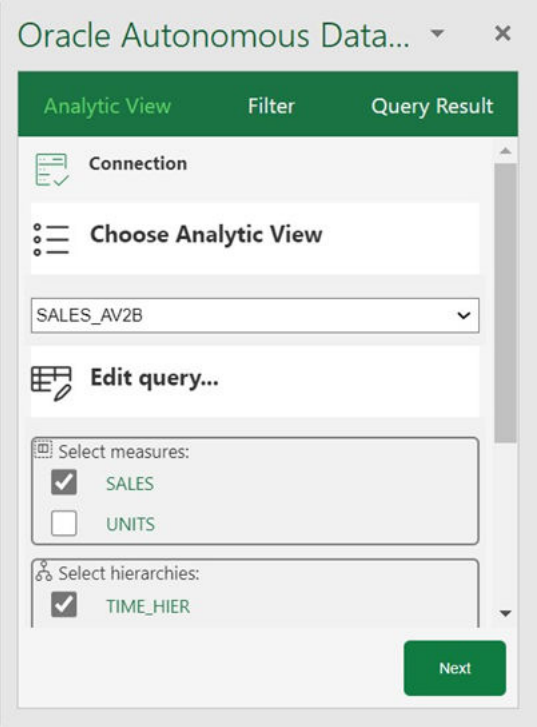
You can query an Analytic View to visualize the result data in the worksheet. You can search for the Analytic View, and select measures, hierarchies, and levels from the query. You can also add filters and calculated measures to the query and view the query result in the spreadsheet.

By default, the data is retrieved in tabular format. You also have the option to create an Excel pivot from this data.

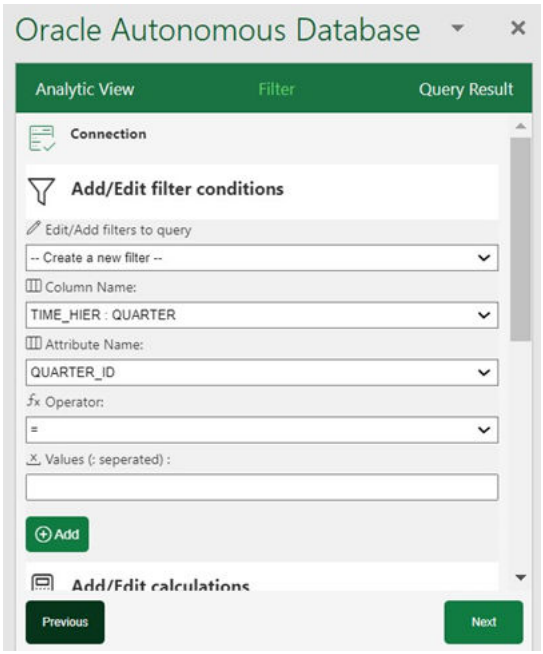
The Query Wizard has three panels:

1. **Analytic View panel:**The Analytic View panel contains a list of Analytic Views from which you build queries. You edit the query by selecting
   - measures
   - hierarchies,
   - and levels

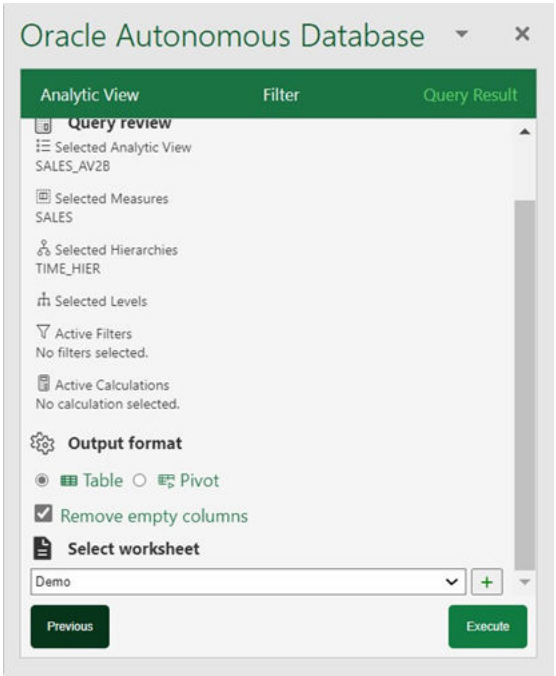
   and progress to the next panel.



2. **Filter panel:** The Filter panel displays to the right of the Analytic View panel when you click **Next** on the wizard. You can create filter conditions to filter the data and also add manual calculations to the Analytic View query in this panel.



3. **Query Result panel:**When you click **Next** on the wizard, the Query Result panel displays to the right of the Filter panel. You run the query once you select the filter criteria and determine what calculated measures to add to your query. You can view and revise the SQL query. After the SQL query runs, you view the query results in the worksheet. You can select the output format of the result here. You can view the results in tabular format or a Pivot table.



To query an analytic view and explore the Query Wizard menu in the MS Excel ribbon:

1. On the ribbon, select the Query Wizard icon.

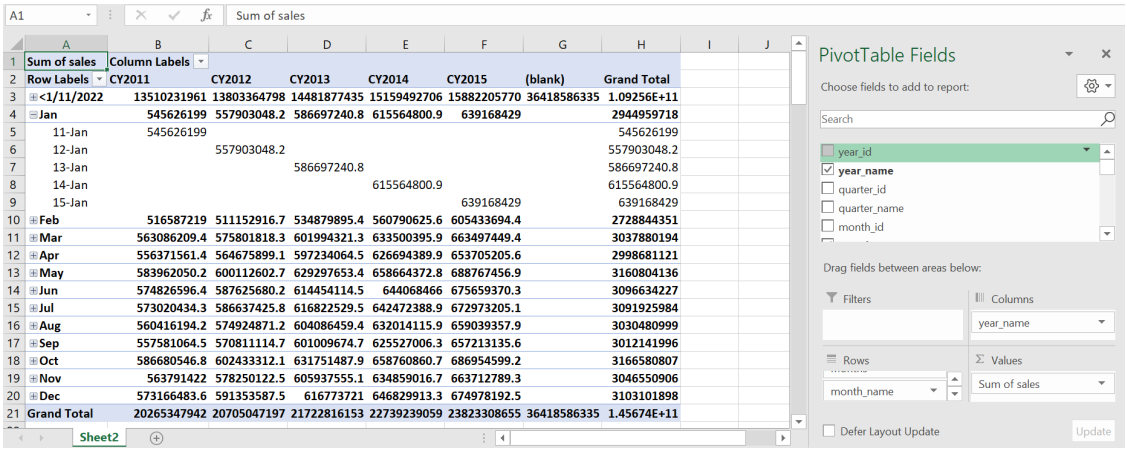
2. Selecting the Query Wizard opens an **Oracle Autonomous Database** dialog box in the Excel Task Pane.
3. Select an existing Analytic View from the drop-down in the Analytic View pane. As you select the Analytic View, it appears on the Analytic View field.
4. Select your choice of measures, hierarchies, and levels the available measures, hierarchies and levels associated with the Analytic View. Click **Next**.
5. The wizard window progresses to the **Filter** pane where you can add or edit filters to query.
6. Under Add or Edit filter conditions, do the following.
    - Select the column name and the attribute name from the drop-down- the values of the attribute change dynamically with the change in column names.
    - Select an operator in the Operator field to apply to the values that you specify in the Value field.
    - Specify a value or values from the list containing your selected column members. You need to enter the value into the Values field manually. For example, you can select > in the Operator field to use only values greater than the value that you select in the Value list. If you select 100,000 from the Value list, the filter uses values from the column greater than 100,000. You can use this information in an analysis to focus on products performing well. For multiple values use ":" as the separator.
    - Click **Add Filter** to add another filter condition.
7. Under Add or Edit Calculations, do the following.
    - Specify the column whose values you want to include in the group or calculated item.
    - On the Calc expression field, enter a custom calculated expression you want to perform on the column value. You can add functions or conditional expressions.
8. Click **Next** to progress to the **Query Result**.
9. You can view, edit, and review the query you have generated from the Query Review editor.
10. Select **Remove empty columns** to remove columns with no values returned in the result.
11. Select **Column per level** to retrieve all hierarchy levels in a single column.
12. Select the worksheet from the drop-down where you want to view the result.
13. Click **Execute** to run the query.
14. You can view the result of the query in the worksheet you select.
15. You can always modify the query in the Oracle Autonomous Database dialog box editor even after results are generated.
16. Select **Table** in the Query Result pane to view the results in the worksheet in a tabular format.
17. Select **Pivot** in the Query Result pane to view the results in a new worksheet in Pivot format.

View the results in Pivot tables

A Pivot table view is interactive and allows you to transpose rows and columns. A pivot table can summarize, sort, reorganize, count the total and perform an average of the result data. They are navigable and drillable.

Apart from tabular mode, to view the query results in pivot table mode, select the **Pivot Table** option in the Autonomous Database wizard. Click **Run** to view the query results in the Pivot table.

Clicking **Run** opens the query results in a new sheet with a PivotTable Fields wizard.

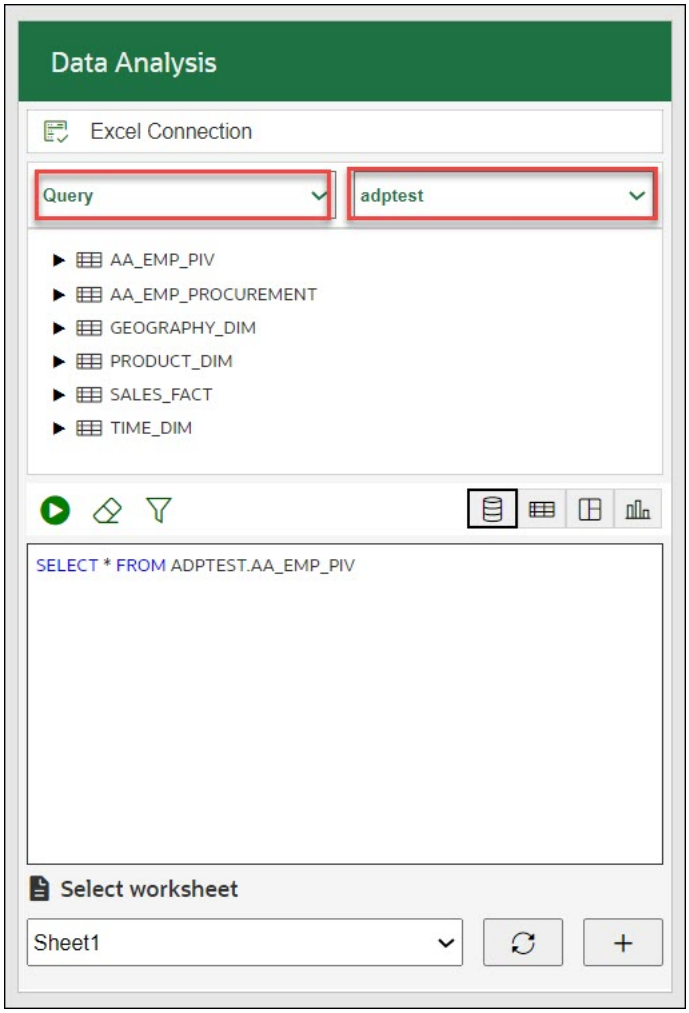


Data Analysis in Excel Sheet

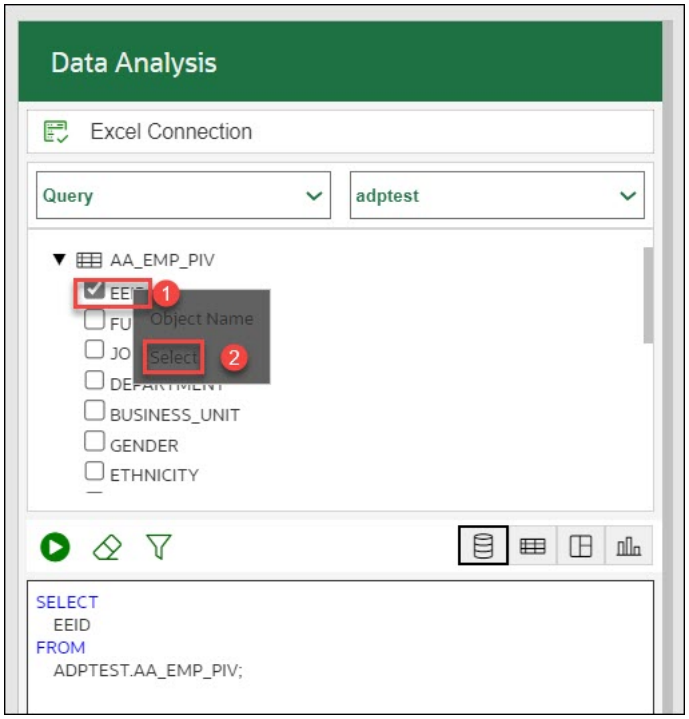
The Data Analysis tool enables you to analyze data in the Autonomous Database by running SQL queries or querying an Analytical View using an intuitive drag-and-drop interface. You can also write custom queries to be run. You now can dynamically apply filters to the result set retrieved using the new faceted search capability on specific columns.

Run query on database tables using the add-in:

1. On the Excel Sheet, select the menu item **Autonomous Database**.
2. Select **Data Analysis**. Selecting Data Analysis opens a Data Analysis panel. On the Data Analysis panel, select **Query** from the drop-down and the **schema** you want to use from the drop-down.



3. You can select a column of the table you want to query, right-click the column, and click **Select** to assist the add-in in forming a select query of the column from the table. Alternatively, you can drag and drop the selected column to the query area that enables the panel to produce a select query of the column in the query display area.



You will view the default query in the query editor area.

4. You can select any of the four modes to visualize the results of the SQL query report you generate.

- **Base Query**: This type of view is by default. The query written in the SQL editor is the Base Query. This query will be the base query of the other three modes.

> **Note:**
>
> All the numeric columns are displayed in different colours.

The Table browser now has all the columns from the base query.

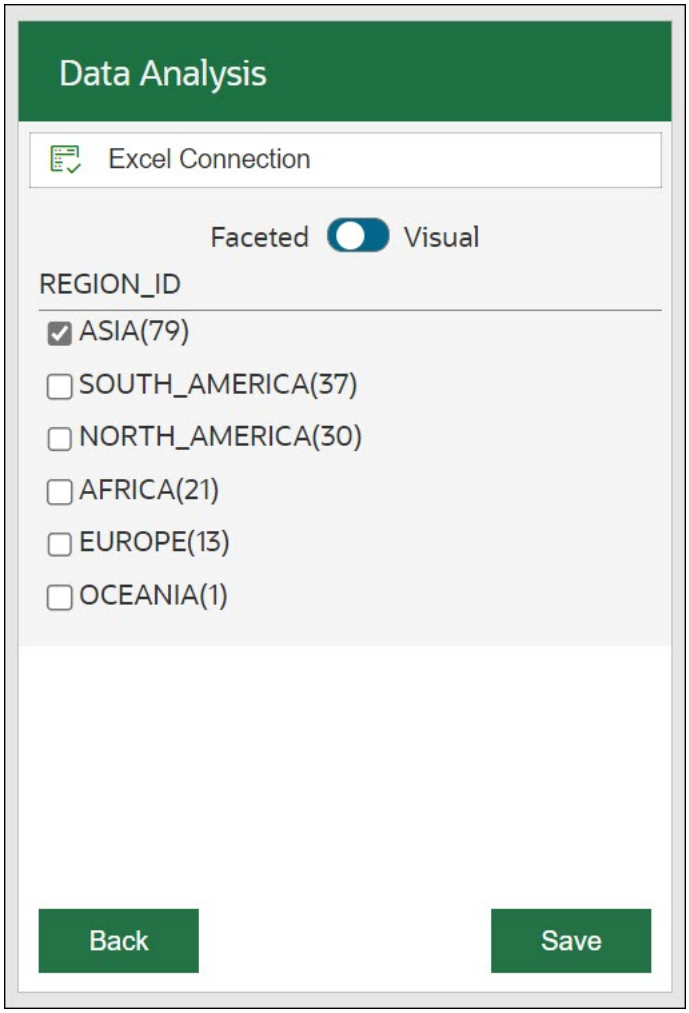
- **Table**: You can view the SQL results in tabular form. When you select this view, a column drop zone appears for selecting Rows, enabling you to drag and drop columns of the base query. Moving the selected columns in the drop zone allows you to view only those columns in the Result data generated in the worksheet. Select the cross mark beside the Column name to remove it from the drop zone.
- **Pivot**: You can view the SQL query results in pivot format. By selecting this format, an X and Y drop zone appears where you can drag and drop the selected columns from the Tables browser based on the Base Query to the drop area.

> **Note:**
>
> Only numeric values are allowed to be dropped in the values section.

- **Chart**: You can view *Area Chart*, *Bar Chart*, *Line Chart*, or *Pie Chart* when you select this option. The mappings displayed when you select one of the options are as follows:
  - **Orientation**: Choose between horizontal and vertical orientation types from the drop-down list.
  - **X axis label and Y axis label**: Optionally enter labels for X axis and Y axis.

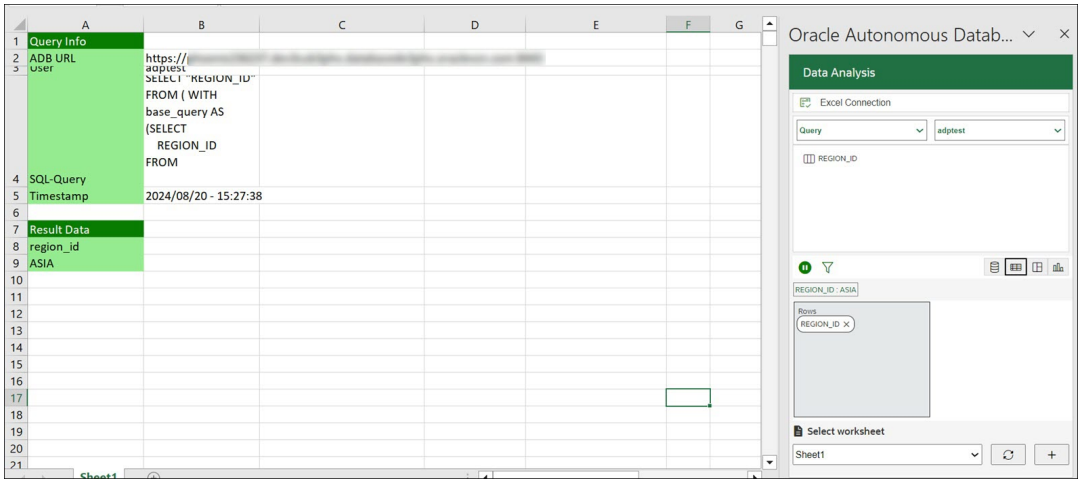
> **Note:**
>
> Only numeric values are allowed to be dropped in the Y axis drop zone.

5. Click the **funnel icon** (Faceted Filter) to add filters to the result. The panel generates a filter for each value in the column retrieved from the query result. You can filter different columns on the faceted filter panel and view the results in the worksheet to view only the data you wish. For example, to view the customer reports by Region, click the **faceted filter** and select **Asia** under `Region_ID`. The number in the brackets displays the count of the items with this property. In the example shown below, there are `79` records with the region as `ASIA`.



6. Click **Save** to view the results. Click **Back** to go back to the main panel.

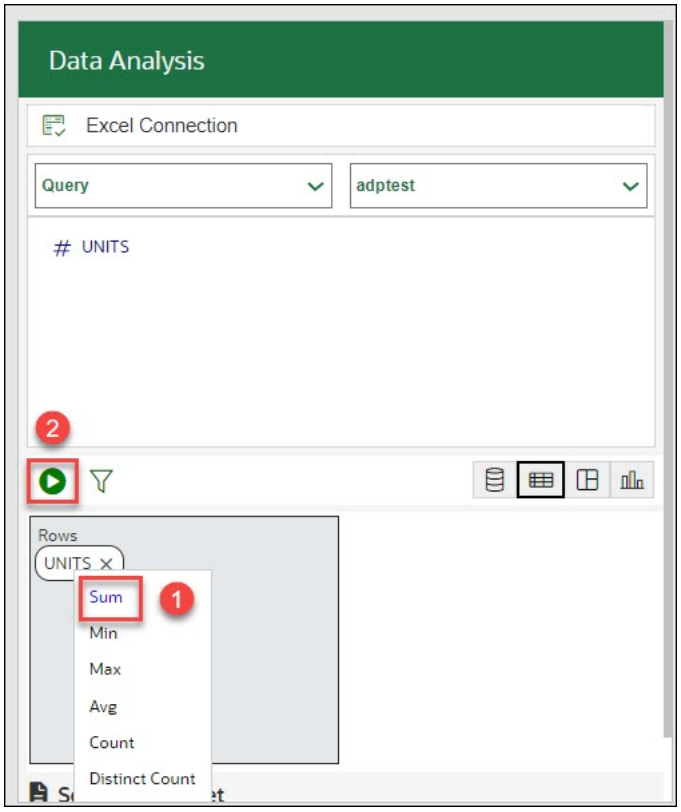
7. Select **Run** to generate the results of the custom query in the worksheet. Click **Pause** to make any changes to the query, such as updating the columns of the table without updating the worksheet.



Perform aggregate functions using the Excel add-in

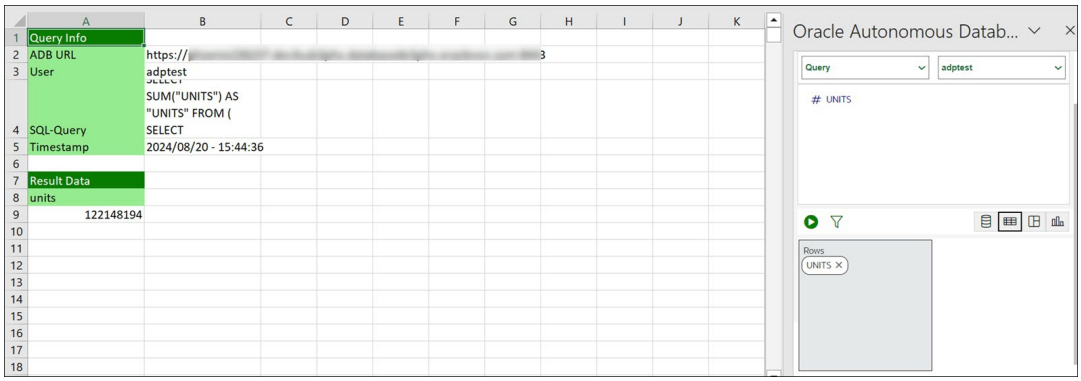
You can also perform aggregate functions such as `SUM`, `MIN`, `MAX`, `AVG`, `COUNT`, and `DISTINCT COUNT`. In this example, we're primarily going to focus on using the Data Analysis feature to gain insights from our sales data.

1. Select **Data Analysis**. Selecting Data Analysis opens a Data Analysis panel. On the Data Analysis panel, select **Query** from the drop-down and the **schema** you want to use from the drop-down.
   Drag and drop the sales value to the query editor and click **Table** to view the sales in tabular format.
2. To calculate the sum of the sales value, click the sales value and select **Sum** from the list of available aggregate functions.



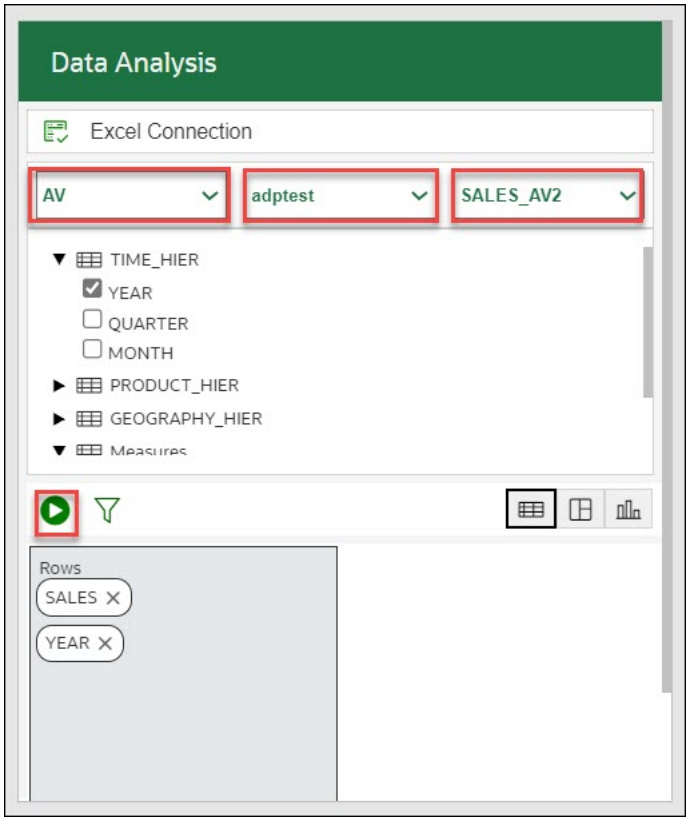
Click **Run** to generate the sum of sales amount in the tabular format.

You will view the result generated in the excel worksheet.



To query an Analytic View and explore the **Data Analysis** menu in the Excel Sheets:

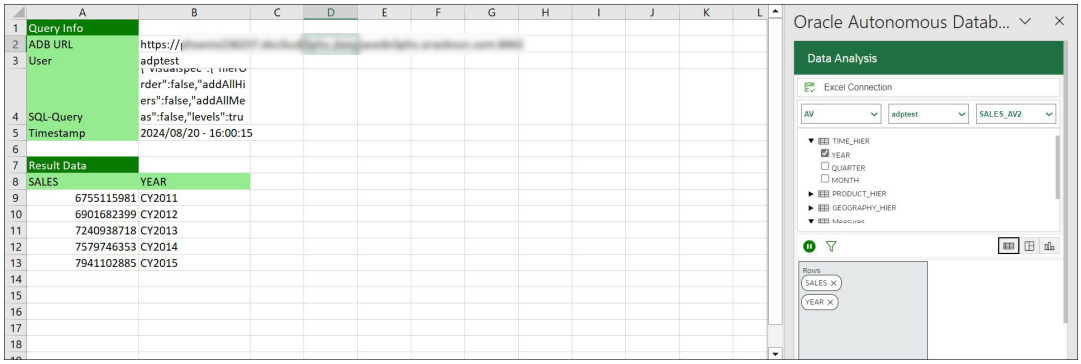
1. Select the ribbon item **Autonomous Database > Data Analysis** on the Excel Sheet. This opens a **Data Analysis** panel.
2. Select **AV** from the drop-down, select a schema you can access from the schema drop-down, and the Analytic View from the list of available Analytic Views.



3. You can select any of the three modes to visualize the results of the AV query you generate:
   - **Table**: You can view the AV query results in tabular form. By selecting this view, a column drop zone appears, enabling you to drag and drop selected columns from the Table browser. Moving the selected columns in the drop zone allows you to view only those columns in the Result data generated in the worksheet. Select the cross mark beside the Column name to remove it from the drop zone.
   - **Pivot**: You can view the SQL query results in pivot format. By selecting this format, an X and Y drop zone appears where you can drag and drop the selected columns from the Tables browser to the drop area.
   - **Chart**: You can view the results of the AV query in chart format. By selecting this format, an X and Y drop zone appears where you can drag and drop the chosen hierarchies and measures from the AV browser to the drop area.

   > **Note:**
   >
   > You are allowed to drop measures in the Y-axis.

4. Click **Run** to view the results in the worksheet . You can view the total Sales generated along with it's year of generation.



Natural Language in Excel Sheet

You can use Natural Language Query to query the Oracle Autonomous Database using the **Natural Language** menu in the **Oracle Autonomous Database for Excel** .

Prerequisites

- Before you use the Natural Language menu in the add-on, you must perform prerequisites to use `DBMS_CLOUD_AI` to configure AI profiles.
- Create and Set an AI Profile

After your AI Profile is ready, the Data Studio tool uses these profiles in the Data Studio Settings menu to configure access to a Large Language Model (LLM) and to setup for generating, running, and explaining SQL based on natural language prompts. This also enables chatting with the LLM.

> **Note:**
>
> You can run Natural Language Queries on Tables and not Analytic Views.

Generate SQL Queries from Natural Language on Tables

Using natural language to interact with your database data is now achievable with Oracle Autonomous Database add-on for Google Sheets.

This means you can use natural language, for example, plain English, to query the database. You can provide a natural language prompt instead of SQL code to interact with your data. When you select the **Generate SQL from natural query** icon, the add-on converts natural language to SQL.

To run a natural query using the add-on:

1. On the Excel Sheet, select the menu **Oracle Autonomous Database**.
2. Select **Natural Language**. Selecting **Natural Language** opens a **Natural Language** wizard.
3. On **Natural Language** wizard, select the **Table** on which you perform the query from the drop-down and the **AI profile** you want to use from the drop-down.

> **Note:**
>
> This is the same AI profile you configure in the Data Studio Settings.

4. Let's say you want details of the product with highest sales. Enter the following natural language query in the query display area:

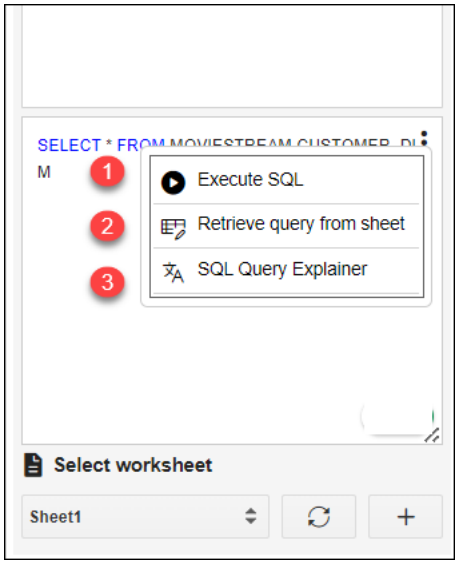
```
show movie with highest sales
```

5. Select **Generate SQL from natural query** to produce the equivalent SQL query in the bottom query display area.
You will view the following code in the bottom SQL code area.

```
SELECT
    *
FROM
    "MOVIESTREAM"."MOVIESALES_WEEKEND_USA" MS
WHERE
    MS."SALES_AMT" = (
        SELECT
            MAX("SALES_AMT")
        FROM
            "MOVIESTREAM"."MOVIESALES_WEEKEND_USA"
    )
```

6. Selecting the **Generate SQL from natural query** icon also displays the result of the natural language query in the Google Sheet.
You can click the **+** sign beside the **Select worksheet** drop-down to display the results in a new worksheet.
7. Click **Clear query content** to clear the content displayed on the natural language query area and the SQL code query area.

Actions you can perform from the SQL code area:



- **Execute SQL**: Runs SQL code and displays the query result in Google Sheet.
- **Retrieve query from Sheet**:
  You can retrieve SQL query displayed in the Google Sheet to the SQL code area in the Natural Query.

  This feature is to retrieve the latest data from the database for a future date. For example, if you want to receive the latest data from the table the next day, the connection may be inactive, but you can still connect to the instance, **retrieve query from Sheet** and **select Execute SQL** to display the latest query results in the Google Sheet.

- **SQL Query Explainer**: Explains SQL code in Natural language form.
  Select this icon to translate SQL queries to natural language that is understood by you. The natural language query is displayed in the natural language query display area of the wizard.

Ask Questions with Chats

Chats option in the Oracle Autonomous Database for Google Sheets refer to an interactive conversation between you and the add-on where the add-on uses natural language to query or interact with the autonomous database.

The data we use in this example is of a company called `Oracle MovieStream` to analyze movie sales data.

The Chats displays recommendations for the default table you select.

Let's find out the top 5 streamed movies in the Moviestream company by weekend gross:

1. Enter the text in the **Start typing your question..** text field.

   ```
   What are the top 5 movies by Weekend Gross?
   ```

2. Click **Enter**.
3. The Chat displays top 5 movies by Weekend Gross.

   It also displays equivalent SQL code of the result.

   Click **SQL** to expand the SQL.

Click **Copy to clipboard** to copy the SQL.

Click **Run SQL** to run the generated SQL query and display the query result in Google Sheet.

The **Chats** option remembers the context of previous chat history.

For example, if you enter `now show me top 10` in the text field.

It displays the top 10 movies by Weekend Gross. It remembers which metric top 10 to fetch without us having to type the whole thing.

Select **New Chat** for deleting the present conversation.

Select **Home** to go back to the main home page.

> **Note:**
>
> LLMs are remarkable at inferring intent from the human language and they are getting better all the time; however, they are not perfect! It is very important to verify the results.

FAQs for Troubleshooting errors with Excel Add-in

If you experience issues with Oracle Autonomous Database for Excel, refer to frequently asked questions in this section to identify and resolve issues.

1. Why is the **My Add-ins** icon from the **Insert** ribbon in the MS Excel workbook greyed out?

   Even before installing the Excel add-in, sometimes the **My Add-ins** icon from the **Insert** ribbon in the MS Excel workbook appears greyed out.

   a. From the **File** menu in the Excel ribbon, go to **Account** and select **Manage Settings** from the Account page.

   b. Ensure that you select the **Turn on optional connected experiences**.

   c. From the **File** menu in the Excel ribbon, go to **Options** and select the **Trust Center** option from Excel Options.

   d. Click **Trust Center Settings** and ensure that deselect **Disable all Application Add-ins** (if selected) from the Add-ins tab in the Trust Center dialog box.

   e. Select the **Trusted Add-in Catalogs** menu from the Trust Center dialog box and ensure that you deselect the **Don’t Allow any web add-ins to start** checkbox.

2. Why doesn’t the sign-in page of the Excel Add-in load or appear?

   Sometimes you might encounter issues with the Excel Add-in even after loading it correctly. For example, an add-in fails to load or is inaccessible. Check the compatibility version of Excel and the operating system you use.

   If the compatibility is correct and the sign-in page to the Excel Add-in still does not show up, or does not load properly, we recommend applying all pending Windows, Office, and browser updates.

   a. Select **Settings**, **Update** & **Security**, and then **Windows Update** from the Windows Start menu.

   b. If updates are available on the Windows Update page, review the updates and click **Install Now**.

> **Note:**
>
> The details of applying Windows updates can vary from version to version and if required, check with your system administrator for assistance.

3. Why doesn't the add-in work correctly after re-installing?

   Configure the Excel trusted Add-in catalog to set the add-in correctly after re-installation.

   To configure the Excel add-in, check or remove the add-in if it is pointing at the wrong location in the Trusted catalog address. This address should be the same as the shared manifest folder's location (share path).

   Click Excel's **File> More> Options>Trust Center >Trust Center Settings> Trusted Add-in Catalogs**

   Checking is only required the first time you use the installer, or if the shared manifest folder is changed. The change occurs during uninstalling and re-pointing to a new ADB.

   To remove the catalog from the trusted table and add a new catalog pointing to a different address:

   - Select the Catalog you want to remove from the trusted catalog table and click **Remove**.
   - Enter the correct share path of the shared manifest folder in the **Catalog URL field** and click **Add Catalog** to add the shared folder to the trusted catalog.

   Restart Excel to make the new shared folder active to access the add-in.

4. Why doesn't the add-in work correctly even after configuring the Excel trusted Add-in catalog?

   Let's say you configure the Excel trusted add-in catalog after re-installing the add-in but, it does not load correctly. Sometimes the database server changes are not reflected in Excel even after you set the share path of the shared manifest folder as a trusted add-in catalog. Clear the Office cache to resolve this issue.

   Refer to this page: https://docs.microsoft.com/en-us/office/dev/add-ins/testing/clear-cache#clear-the-office-cache-on-windows to clear the Office cache on Windows and Mac.

   Clearing the Office cache unloads the Excel add-in. Install the add-in and check the configuration of the Excel trusted add-in catalog. This should solve the issue of the Excel add-in needing to be correctly loaded.

5. What should you do if you cannot view My Add-ins icon from the Excel ribbon?

   After installing the add-in once, if you cannot view the **My Add-ins** icon from the Insert ribbon and instead you view the Add-ins icon

.

   Follow these instructions:

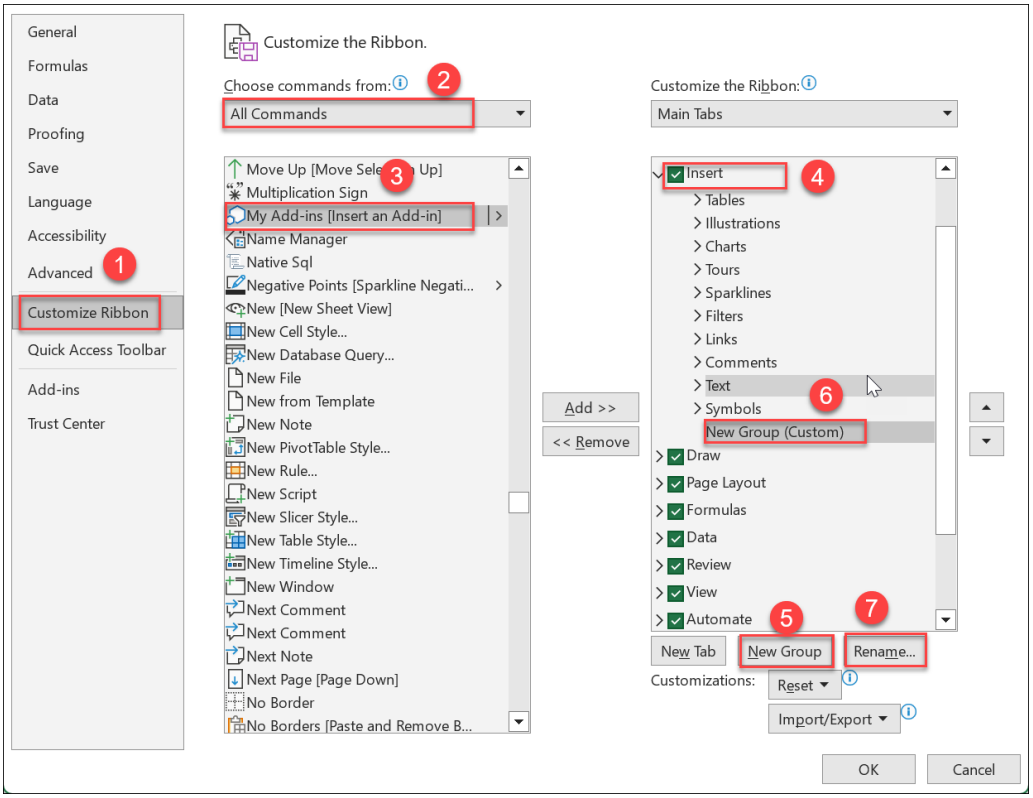
   a. From the **File** menu in the Excel ribbon, go to **Options** and select the **Customize Ribbon** option from Excel Options.

   b. Select **All Commands** drop-down from the **Choose commands from** drop-down.

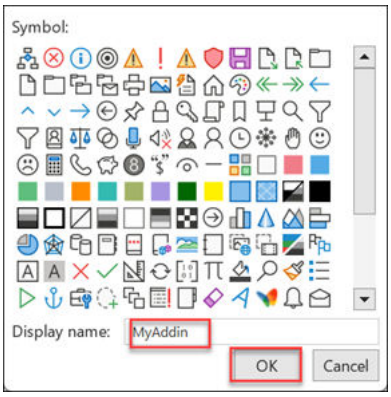
   c. Click **My Add-ins** and click **Insert** option from the Main Tabs list.

   d. Click **New Group** to add a new menu item under the **Insert** menu. You will view a **New Group (Custom)** menu option added to the Insert menu.

   e. Click **Rename** to rename the newly created menu.

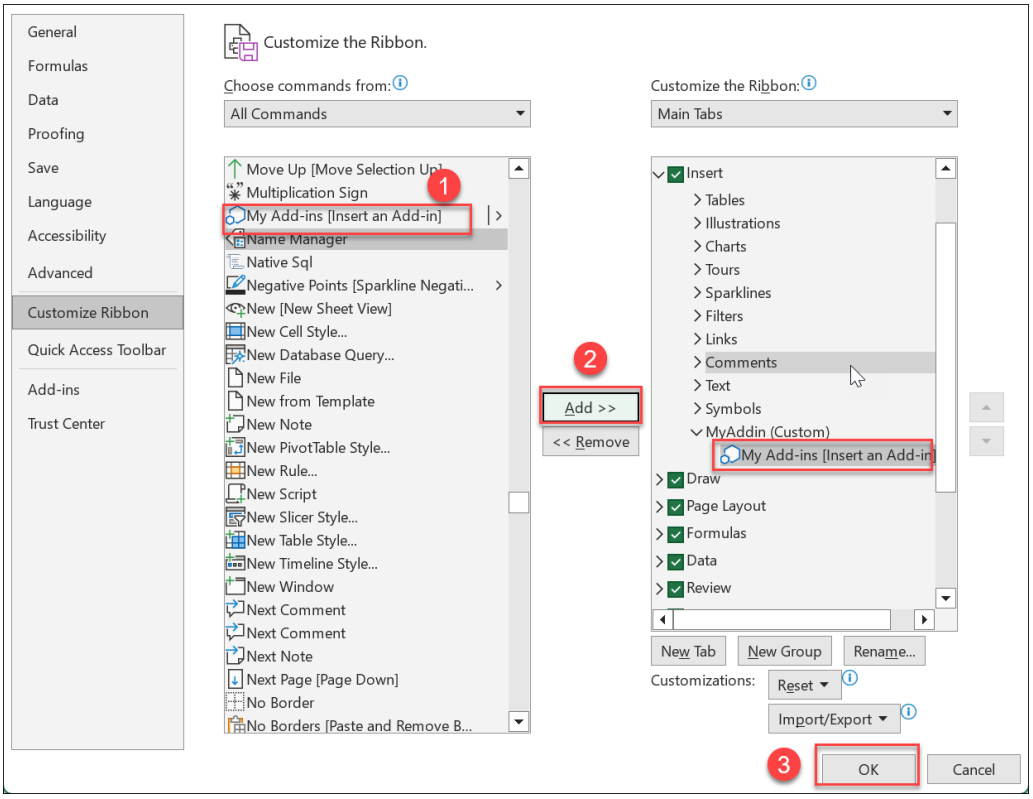


f. Specify the name of the add-in. For example, **My Addin**. Click **OK**.

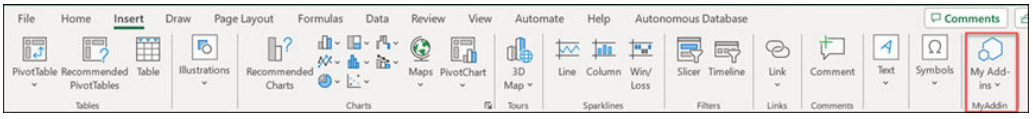


g. Click **My Add-ins[Insert and Add-in]** from All Commands list and select **Add**. My Add-ins menu is added to the newly created menu “MyAddin”.

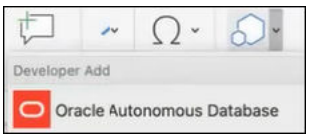
h. Click **OK** to save the changes.



i. Clicking **OK** takes you to the main Excel sheet page where you can view “**MyAdd-ins**” menu under the Insert menu.



j. Click **My Add-ins**. You can now view the Oracle Autonomous Database for Excel loaded.



6. What happens when you cannot view the latest added menu items in the **Oracle Autonomous Database for Excel** add-in?

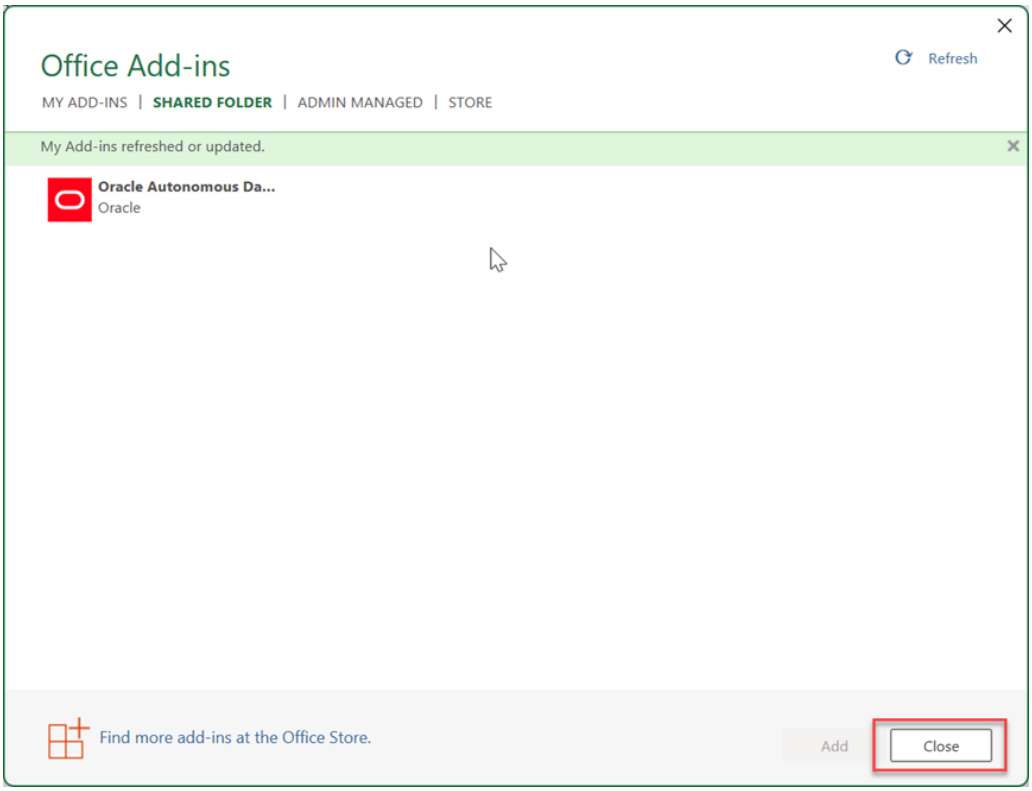
   Sometimes when you cannot view the changes updated in the latest version of the plug-in, you must:

   a. Select **My Add-ins** from the Insert menu on the Excel ribbon.

   b. Click the **Shared Folder** tab of the Office Add-ins dialog box. You will see the add-in under the Shared Folder list.

   c. Click **Refresh**.
   After the add-ins are refreshed, you will receive a notification on the dialog that says "*My Add-ins refreshed or updated*". The refresh button loads the manifest file again for the latest changes to appear.

   d. Click **Close** to close the dialog box.



Oracle Autonomous Database for Excel Privacy Policy Details

This topic covers details for writing policies to control access to Autonomous Database resources.

Data use by **Oracle Autonomous Database for Excel** complies with Oracle's Privacy Policy.

Oracle Autonomous Database for Google Sheets

The Oracle Autonomous Database add-on enables you to query tables using SQL or Analytic Views using a wizard directly from Google Sheets for analysis.

The data retrieved from the Autonomous Database is available locally in Google Sheets for further analysis. The results are stored in the local copy and cannot be written back to the Autonomous Database. You can run direct SQL queries or query Analytic Views and view their results in the worksheet. The add-on allows you to filter the query results, and perform table joins and calculations.

> **Note:**
>
> The Oracle Autonomous Database add-on for Google Sheets must comply with Privacy Policy. For information on details of privacy policy, see Oracle Autonomous Database for Google Sheets Privacy Policy Details.

How does the add-on for Google Sheets work?

To query an Analytic View or Tables from the Autonomous Database, you must select an Analytic View or Table to work with. While retrieving data from the Analytic View, you can configure the query according to your requirements. You can select specific hierarchies and create custom calculations on the wizard. The add-on configures your query and returns the result to the Google Sheets. You can save the results of your queries locally in the Google Sheet. The add-on can also query the schema directly to which you have access. Using the Web UI, you can also view reports and analyses you create in the Data Analysis menu in the Data Studio tool.

To use the add-on, you must enable Web Access on the Autonomous Database account. You must have the CONNECT, DWROLE, RESOURCE and ADPUSER roles grant in the SQL worksheet to access the Google Sheets add-on.

> **Note:**
>
> - The **Download Microsoft Excel/Google Sheets add-in** is available to you under the **Downloads** menu of your Database Actions instance only if you have the `ADPUSER` role.
> - The Oracle Autonomous Database add-on for Google Sheets is not supported in Safari web browser.

- Install and setup the add-on for Google Sheets
  Before you install the Oracle Autonomous Database add-on for Google Sheets, download the *oracleGoogleAddin* zip file from your Database Actions instance.

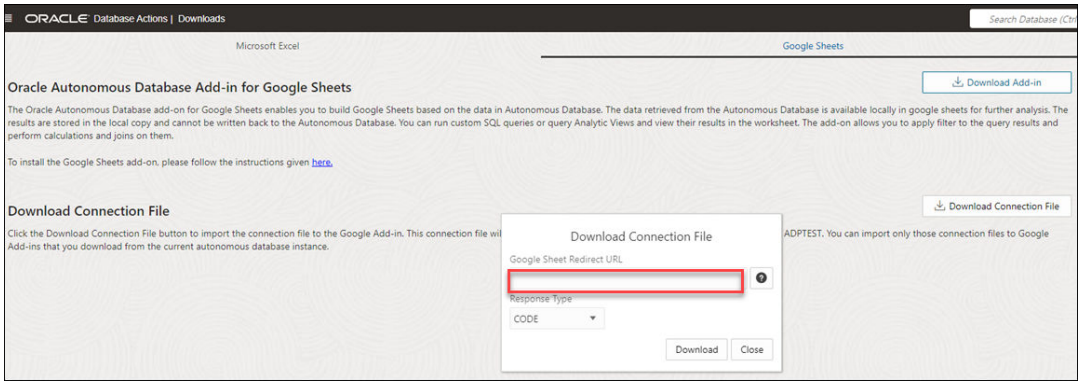
- Download Connection File
  To connect to the Autonomous Database, you can download a connection file from the Database Actions instance and import it to the Google Sheet add-on you have setup.
- Connecting to Autonomous Database
  The Oracle Autonomous Database add-on for Google Sheets enables you to connect to multiple Autonomous Databases with a single add-on using the Connections feature. The add-on connects to Google Sheets by providing authentication to Google. Multiple users or databases can connect simultaneously to the add-on. However, only one connection can remain active.
- Generate Client ID and Client Secret using UI
  In this section you use the Web UI to obtain the `client_id` and `client_secret` .
- Authorize Google Sheets to use Autonomous Database
  After your identity is determined using OAuth authentication, Google Sheets needs permission to access the Autonomous Database.
- Natural Language in Google Sheets
  You can use Natural Language Query to query the Oracle Autonomous Database using the **Natural Language** menu in the **Oracle Autonomous Database for Google Sheets** "add-on".
- Data Analysis in Google Sheets
  Selecting **Data Analysis** opens an Oracle Autonomous Database wizard in the Google sheet.
- Run Direct SQL Queries
  The Oracle Autonomous Database add-on for Google Sheets lets you run SQL queries to work with your data in a Google Sheet. With the add-on, you can type your SQL code in the SQL editor area and click **Run** to run the command.
- Reporting and Analysis in Google Sheets
  You can view Reports and Analytic Views or visualize data for analysis purposes.
- Clear Sheet
  Once the add-on runs the query and retrieves the data into the worksheet, you can view the Timestamp, User, AV-query and SQL-query of the Analytic View in the automatically generated query results.
- Delete all sheets
  Use this option to delete all the sheets existing in the spreadsheet.
- About Oracle Autonomous Database menu
  Use this option to view details about the add-in
- Share or Publish
  Once you generate the query results in the Google Sheet, you can share it with other users. With sharing, creates a copy of the worksheet and sends it with the design tools hidden and worksheet protection turned on.
- Oracle Autonomous Database for Google Sheets Privacy Policy Details
  Effective Date: `10/4/2024`
- Oracle Autonomous Database for Google Sheets Support
  Welcome to the support page for the **Oracle Autonomous Database for Google Sheets**. This resource is designed to assist you with any issues or questions you may have while using the add-on.

Download Connection File

To connect to the Autonomous Database, you can download a connection file from the Database Actions instance and import it to the Google Sheet add-on you have setup.

Follow the steps shown below to download the connection file.

1. Navigate to the launchpad of your Database Actions instance, and select the **DOWNLOAD MICROSOFT EXCEL/ GOOGLE SHEETS ADD-IN** Card. Click the **Download Connection File** button in the Google Sheets tab of the **Downloads** page to import the connection file to the Google Add-in.
2. This connection file will allow you to connect to the Autonomous Database with the logged-in user. You can import only those connection files to Google Add-ins that you download from the current Autonomous Database instance.



3. Selecting the Download Connection File button opens a Download Connection File wizard. Specify the following field values in the wizard:
   - **Google Sheet Redirect URL**: This is the **Web application deployment URL** you copied from step number nine of Deploy the Google Script as a Web app section.
   - Choose a **Response Type**:
     - **Explicit Connection**
       You use the OAuth Client ID and OAuth Client Secret values to authenticate and authorize Google Sheets to use the Autonomous Database. Use this when you use **CODE** as the Response Type while downloading the connection file from the Database Actions page. This is the more secure method and is preferred to use if the Autonomous database has public access.
     - **Implicit Connection**
       You will need an OAuth Client ID to implicitly access the Autonomous Database. Use this when you use Token as the **Response Type** while downloading the connection file from the Database Actions page. Use this when the autonomous database is in a private subnet or within a customer firewall.

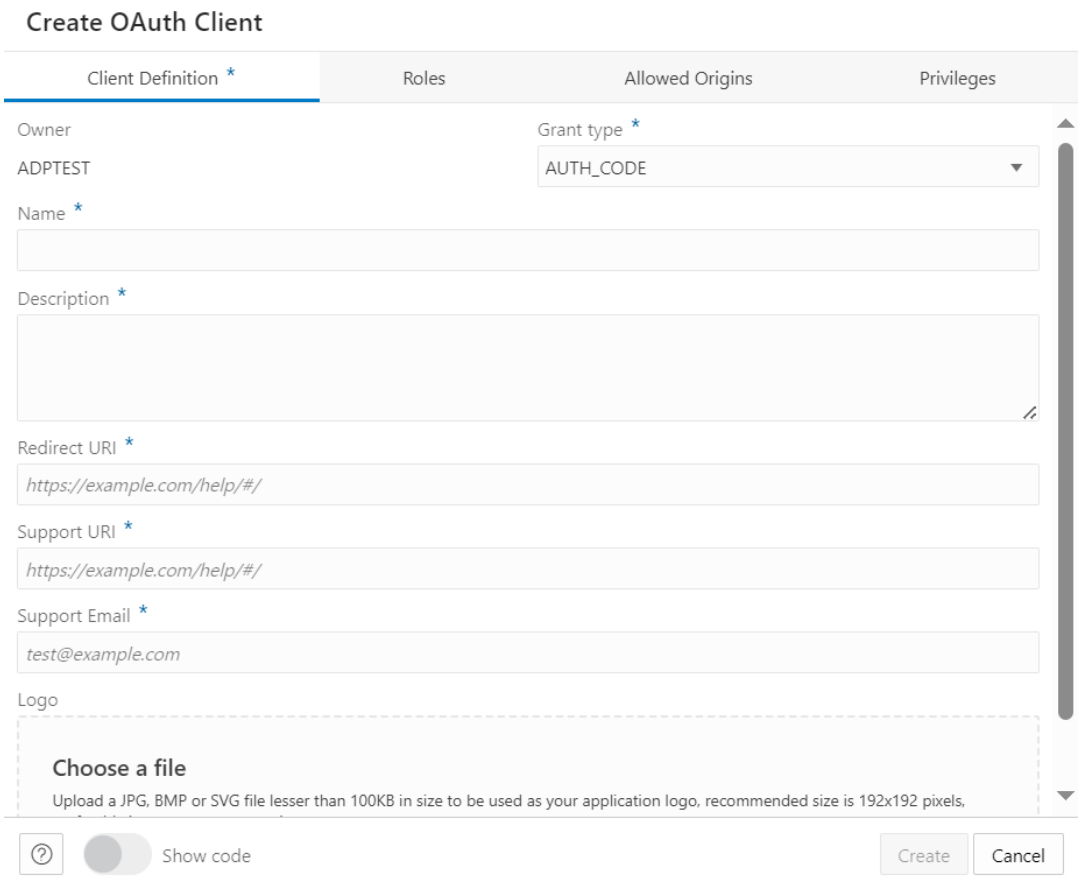
Generate Client ID and Client Secret using UI

In this section you use the Web UI to obtain the `client_id` and `client_secret` .

You generate the client keys by accessing the Autonomous Database instance URL appending with oauth/clients.

For example, if your instance is “ https://<hostname>-<databasename>.adb.<region>.oraclecloudapps.com/ords/<schema Name>/_sdw/", you need to sign in to the link " https://<hostname>-<databasename>.adb.<region>.oraclecloudapps.com/ords/<schema Name>/oauth/clients/". Be sure to include the trailing slash.

1. Sign in to Database Actions with the "https://machinename.oraclecloudapps.com/ords/SchemaName/oauth/clients/" link. You can view an OAuth Clients page in the link "https://localhost:port/ords/schemaName/_sdw/?nav=rest-workshop&rest-workshop=oauth-clients".
2. Click the **+Create OAuth Client** button to create a new client.

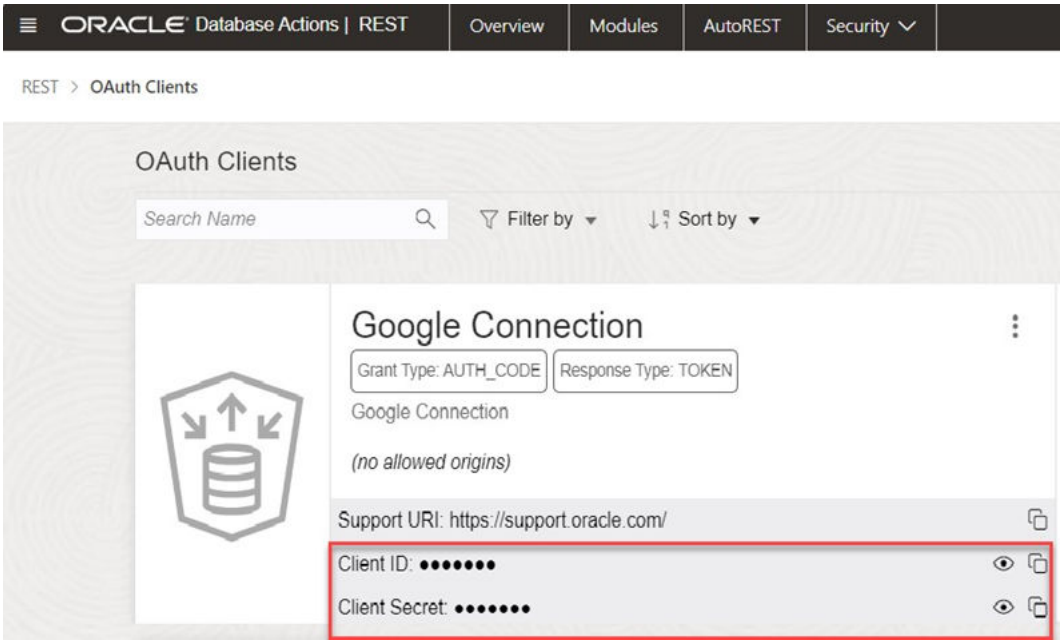


3. From the Grant type drop-down, select the type of client connection you want. You can select the following options:
   - AUTH_CODE: Select this option for implicit connection. Use this response type when the autonomous database is in a private subnet or within a customer firewall.
   - IMPLICIT: Select this option for explicit connection. This is the more secure method and is preferred to use if the Autonomous database has public access.
4. Enter the following fields. The fields with an asterisk (*) are mandatory:
   - **Name**: Name of the client.
   - **Description:** Description of the purpose of the client.
   - **Redirect URI**: web application deployment URL you copied from step 10 of Deploy the Google Script as a Web app

- **Support URI**: Enter the URI where end users can contact the client for support. Example: *https://script.google.com/*
- **Support Email**: Enter the email where end users can contact the client for support.
- **Logo**: Optionally, select an image from your local system to insert a logo for your new client.

Navigate to the **Roles** tab to select the roles of the client. This is not a mandatory field.

5. Progress to the **Allowed Origins** tab. Specify and add the list of URL prefixes in the text field. This is not a mandatory field.
6. Progress to the **Privileges** tab to add any privilege. You are not required to have any privileges to create an OAuth Client.
7. Click **Create** to create the new OAuth Client. This registers the OAuth Client which you can view on the OAuth Clients page.

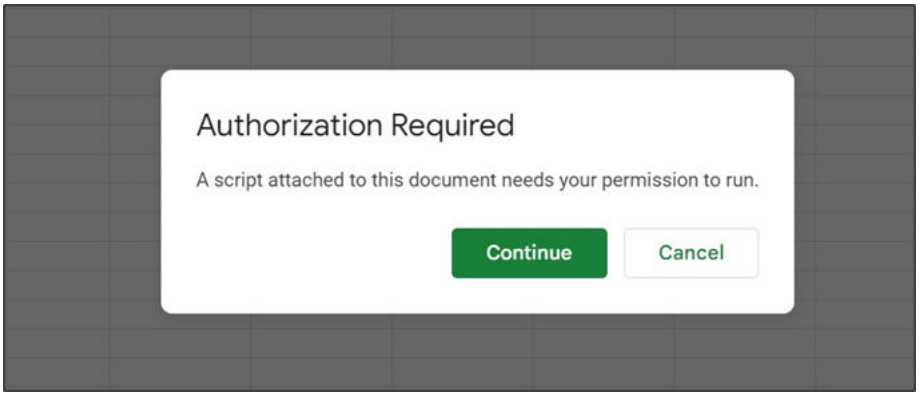


8. Click the show icon to view the `Client ID` and the `Client Secret` fields.

How do I connect manually?

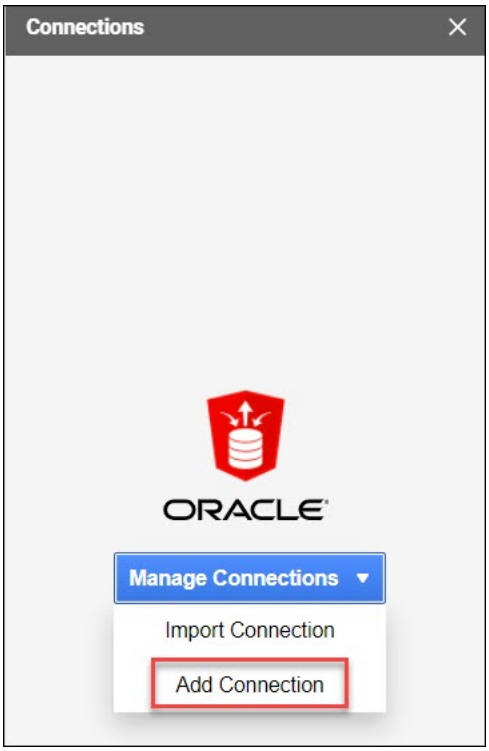
The following sections demonstrate how to connect using implicit and explicit connections. Google Sheets needs permission to access the Autonomous Database. You must first complete the authorization to connect to the autonomous database. The add-on requires one-time authentication for the setup.

1. On the Google Sheet, click **Oracle Autonomous Database** and select **Connections**. Selecting Connections requires one-time Google authentication.
   - Clicking **Connections** opens a pop-up window that asks your permission to run the authorization. Click **Continue**.

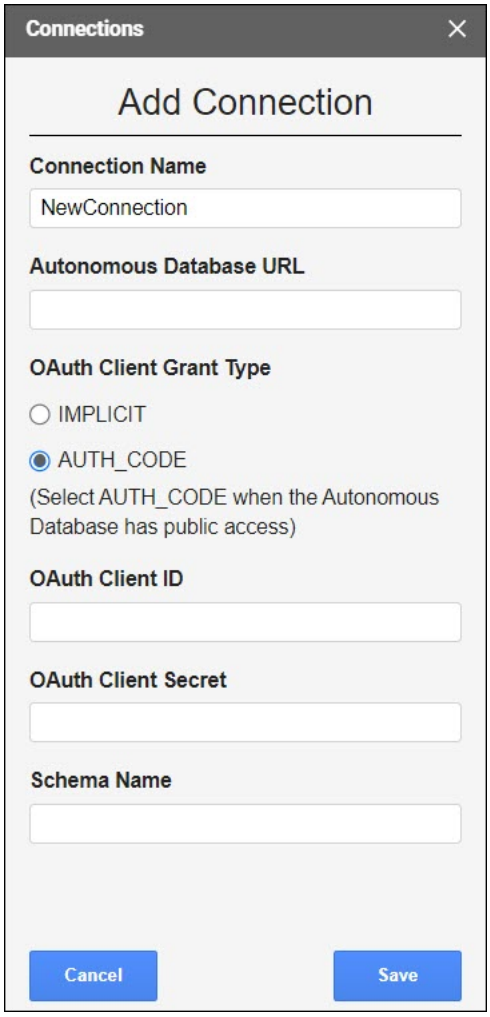


- You will now view a window that informs you that the application requests access to sensitive information in your Google account.
- Click **Advanced** and select the **Go to Untitled project (unsafe)** link. Selecting the link opens new window, ensuring you trust the application. Click **Allow** to continue. You have now completed the setup.

2. On the Connections wizard, click **Add Connection** from the **Manage Connections** drop-down menu to add a connection.



3. Selecting Add Connection opens an **Add Connection** wizard in the Connections wizard's connection list panel.



4. Specify the following field values in the wizard:

   Connection Name: Enter the connection's name—for example, *TestConnection*.

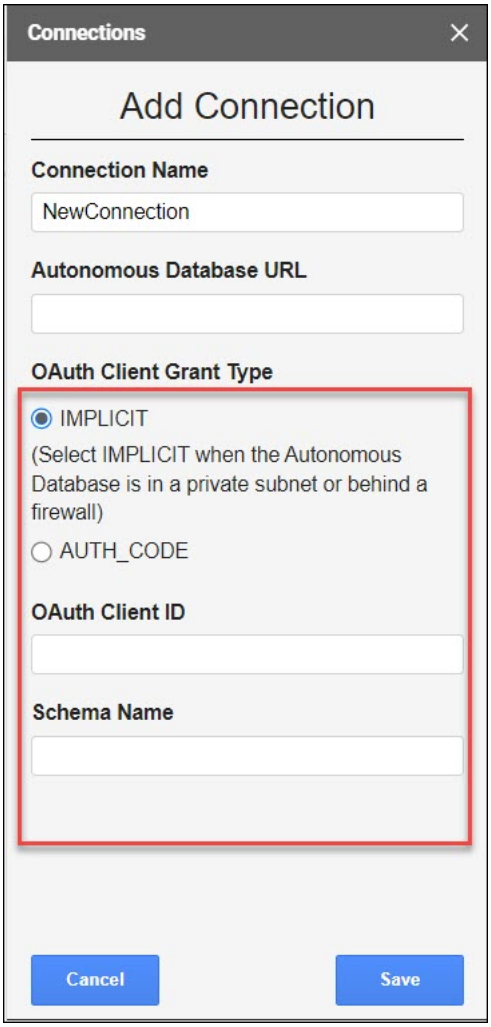
   Autonomous Database URL: Enter the URL of the Autonomous Database you wish to connect to. For example, "*https://<hostname>-<databasename>.adb.<region>.oraclecloudapps.com/*"

   In the OAuth Client Grant Type field, select one of the two options based on the type of connections you want. Refer to the Generate Client ID and Client Secret using the UI section.

   This option varies with implicit and explicit connections.

   Implicit: Select this option for implicit connection. Use this response type when the autonomous database is in a private subnet or within a customer firewall.
   AUTH_CODE: Select this option for explicit connection. This is the more secure method and is preferred to use.

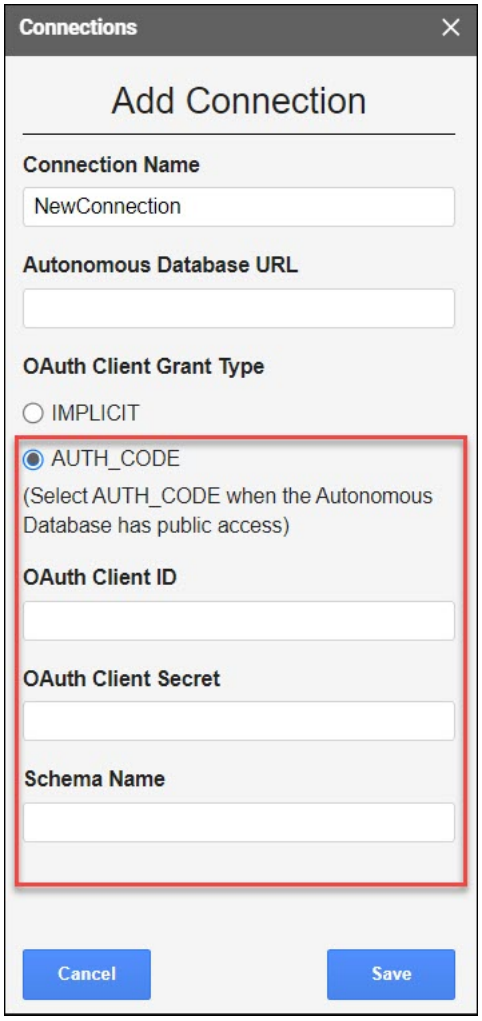
   When you select the Implicit option, you can view the following fields:



OAuth Client ID: `client_id` you generate using the *Create New Client* wizard in the UI. Refer to the Generate Client ID and Client Secret using the UI section.

Schema Name: Specify the name of the schema.

When you select AUTH_CODE, you can view the following fields:



OAuth Client ID: `client_id` you generate using the Create New Client wizard in the UI. Refer to the *Generate Client ID and Client Secret using the UI* section.

OAuth Client Secret: `client_secret` you generate using the Create New Client wizard in the UI. Refer to the *Generate Client ID and Client Secret using the UI* section.

Schema Name: Specify the name of the schema.

Click **Save**.

After you click **Save**, you can view the new connection in the connection list panel. The connection list displays the connection's name, the schema's name, and the OAuth type you grant. However, it is still in a disconnected state.

5. Click the three vertical dots beside the connection name and perform the following operations:

Connect: Select **Connect** to the Autonomous Database and change the connection status to active. Selecting **Connect** opens the sign-in page of the Autonomous database. After you log in, you will view a page that shows that database access has been granted to you. Close the window and return to Google Sheets. You will now see that the connection is active.

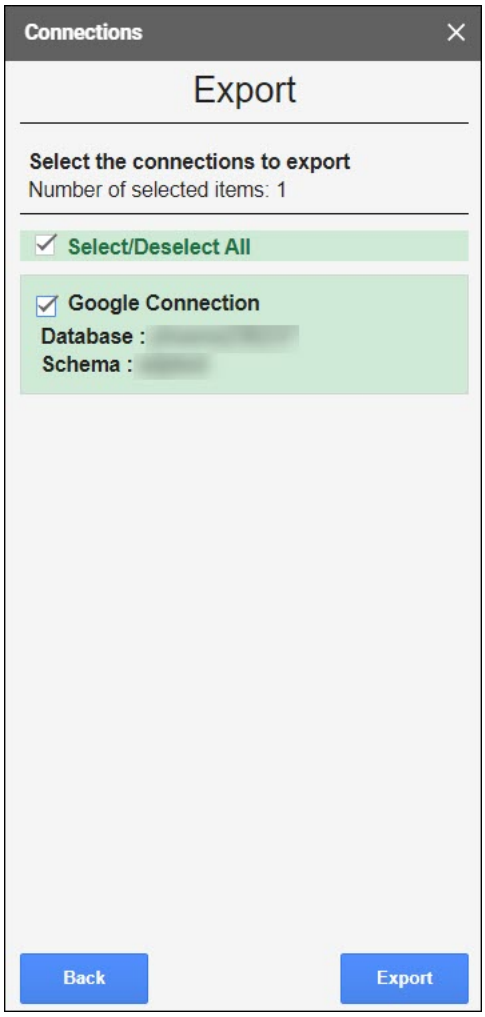
Edit: Select **Edit** to update any value of the connection. Click **Save** to update the edited values.

Duplicate: Select **Duplicate** to create a duplicate connection.

Remove: Select **Remove** to remove the connection from the connection list.

Exporting Connections

1. Click **Export Connection** from the **Manage Connections** drop-down menu to export the selected connection.
2. Select the connection you want to export, and click **Export**.



3. Click **Export**.
4. The exported connection downloads in your local system. The connection file is saved as *spreadsheet_addin_connections.json*.

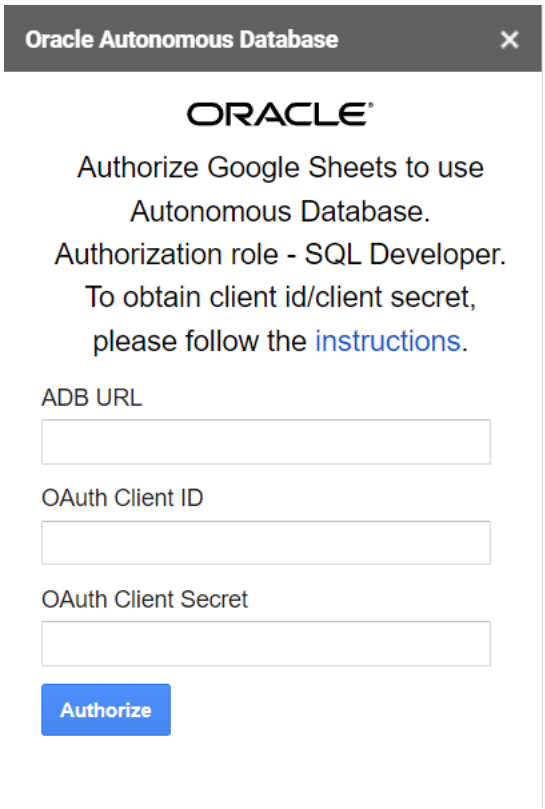
Authorize Google Sheets to use Autonomous Database

After your identity is determined using OAuth authentication, Google Sheets needs permission to access the Autonomous Database.

The `client_id` and `client_secret` values you generate during OAuth authentication are used for authorization.

1. Click on the **Oracle Autonomous Database** menu in the Google Sheet you are working on and select **Register**. This requires one-time Google authentication.

2. Clicking Register opens a pop-up window that asks your permission to run the authorization. Click **Continue**. Selecting Continue will redirect you to the Google Accounts page, where you must select your Gmail account.
3. You will now view a window that informs you that the application requests access to sensitive information in your Google account. Click Advanced and select the Go to Untitled project (unsafe) link.
4. Selecting the link opens a new window, ensuring you trust the application. Click **Allow** to continue.
5. You have now completed the setup. Select **Register** from the Oracle Autonomous Database menu in the Google sheet.
   This opens an Oracle Autonomous Database wizard in the Google sheet. Specify the following fields:
   - **ADB URL**: Enter the ADB URL. For example, "*https://<hostname>-<databasename>.adb.<region>.oraclecloudapps.com/ords/<Schema Name>*".
   - **OAuth Client ID**: client_id you generate during authentication.
   - **OAuth Client Secret**: client_secret you generate during authentication. Refer to the Create Connections with the Google spreadsheet section for more details.



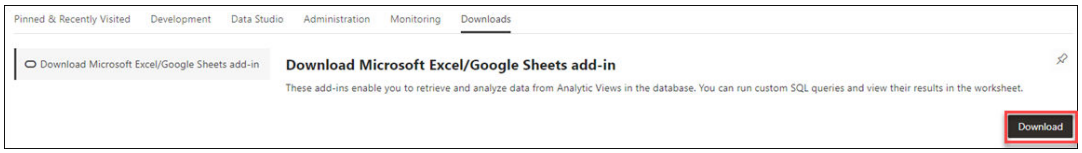
6. Select **Authorize**.

After successfully authorizing the credentials, you can view **Connections**, **Direct SQL**, **Data Analysis**, **Analyses and Reports Clear Sheet**, **Delete All Sheets**, **About Autonomous Database**, and **Sign Out** menu items under **Oracle Autonomous Database**.

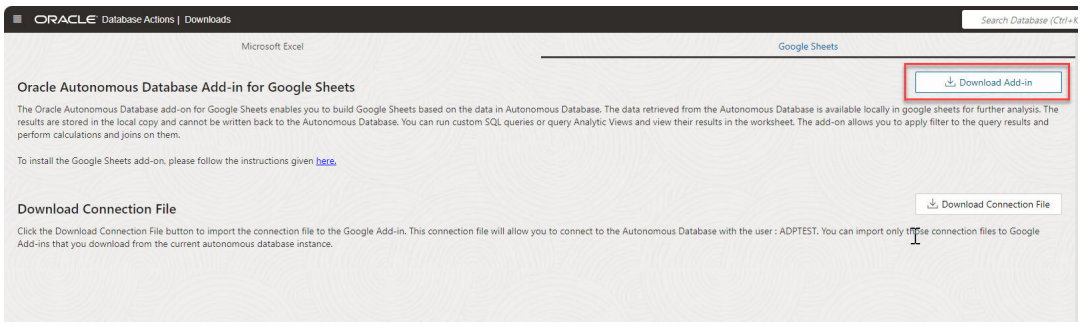
Install and setup the add-on for Google Sheets

Before you install the Oracle Autonomous Database add-on for Google Sheets, download the *oracleGoogleAddin* zip file from your Database Actions instance.

- Open the Database Actions Launchpad.
- Under the Downloads tab, select the **DOWNLOAD MICROSOFT EXCEL/GOOGLE SHEETS ADD-IN** pane.



- This opens a Download screen with Microsoft Excel and Google Sheets tabs. Click the Google Sheets tab and select **Download Add-in**.



You can now view a zip file in the your system's Downloads folder. Extract the contents of the zip file onto your system.

To set up the Oracle Autonomous Database add-on for Google Sheets, import the files in the *oracleGoogleAddin* folder to Google Apps Script.

> **Note:**
>
> Importing the files is a one-time activity, and typically, this is done by an administrator.

After you import or upload the files to Google Apps Script follow these steps to complete the setup of the Oracle Autonomous Database add-on for Google Sheets:

- Deploy the Google Script as a web app.
- Generate Client ID and Client Secret keys using UI.
- Upload oracleGoogleAddin files to Google Apps Script using Clasp
  To upload all the files present in the oracleGoogleAddin folder, you must use the Command Line Apps Script Project (clasp).
- Deploy the Google script as a web app
  After all the files from the oracleGoogleAddin folder are imported or uploaded to the Google Apps Script files, you must deploy the Google script as a web app.

Upload oracleGoogleAddin files to Google Apps Script using Clasp

To upload all the files present in the oracleGoogleAddin folder, you must use the Command Line Apps Script Project (clasp).

Clasp is an open-source tool to develop and manage the Google Apps Script projects from your terminal.

> **Note:**
>
> Clasp is written in Node.js. and distributed via the Node Package Manager (NPM) tool. It is required to install Node.js version 4.7.4 or later to use clasp.

1. Enter *sheet.new* in the web browser's address bar to open Google Sheets. Make sure you are logged in with your Google account.
2. Select **Apps Script** from the **Extensions** menu. You can view the Apps Script editor window.

3. Select the Code.gs file in the Apps Script editor window, which already exists by default. Click on the vertical dots beside the Code.gs file. Select **Delete** to delete the existing Code.gs file.
4. After you install Node.js, enter the following npm command in the command prompt to install clasp. You must enter this command in the location where you have downloaded and extracted the oracleGoogleAddin folder.

```
C:\Users\username\Desktop\oracleGoogleAddin>npm install @google/clasp -g
```

To run the command as an administrator for UNIX- and Linux-based systems, enter the following command:

```
sudo npm install @google/clasp -g
```

After you install Clasp, the command is available from any directory on your computer.

5. Enter the following command to log in and authorize managing your Google account's Apps Script projects.

```
clasp login
```

Once this command is run, the system launches the default browser and asks you to sign into your Google account where your Google Apps Script project will be stored. Select **Allow** for clasp to access your Google Account.

> **Note:**
>
> If you have not enabled the Apps Script API in Google Apps Script, the above command will not be successful. Enable the API by visiting the https://script.google.com/home/usersettings site and allow site and enabling the Google Apps Script API by selecting the **On** button.

6. In your existing Google Apps Script project, click the Project Settings in your left pane. Click **Copy to Clipboard** to copy the Script ID under IDs.
7. Go back to the command prompt and enter the following command with the Script ID you copied in the previous step as displayed in the image below:

   ```
   clasp clone <Script ID>
   ```

8. Push all the files from your folder to the Google Apps Script files by specifying the following command:

   ```
   clasp push
   ```

   This command uploads all of the script project's files from your computer to Google Apps Script files.
9. Go to the newly created Google Sheet, click the Extensions menu, and select **Apps Script**. Under Files, you can view all the files in the *oracleGoogleAddin* folder.
10. After you import or upload the files to Google Apps Script, follow these steps to complete the set up of the Oracle Autonomous Database add-on for Google Sheets:
    - Deploy the Google Script as a web app
    - Generate Client ID and Client Secret keys using UI

Deploy the Google script as a web app

After all the files from the oracleGoogleAddin folder are imported or uploaded to the Google Apps Script files, you must deploy the Google script as a web app.

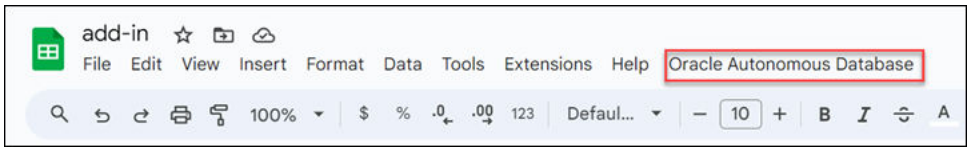
To deploy the Google script as a web app:

1. Click on the **Extensions** menu in the Google Sheet you are working on and select **Apps Script**. This opens the window.
2. Click **Deploy** button on the top right and select New deployment. A New deployment window opens.
3. Next to **Select type**, click the **settings** icon and select **Web app**.
4. Under Configuration, specify a Description of the deployment in the **Description** field. For example, *Web app deployment*.
5. Under **Web app** , select the Google account you used to log in from the **Execute as** drop-down. Optionally, you can choose anyone who has access to this deployment.
6. Select **Deploy**.

> **Note:**
>
> - If you receive a window that asks you to Authorize access, select it. This will redirect you to the Google Accounts page where you must to select your Gmail account.
> - Click **Advanced** and select the **Go to Untitled project (unsafe)** link.
> - Selecting the link opens a new window, ensuring that you trust the application. Click **Allow** to continue.
>
> If you Authorize access at this stage, you need not follow steps 2-4 in the *Authorize Google Sheets to use Autonomous Database*.

7. Click **Done** to close the New Deployment window.
8. Click the **Deploy** button on the top right and select **Manage Deployments**.
9. On the Manage Deployments page, you can view a Web app URL. Use the **Copy to Clipboard** to copy the Web app URL. For example, here is a sample of the web app URL "*https://script.google.com/macros/s/abcdefghijk/exec*". This is the **Web application deployment URL**.
10. Save this URL, which you will use later in the **Google Sheet Redirect URL** field when downloading a connection file from Database Actions or manually creating a connection from the Google Sheet to the Autonomous Database.

    For details on selecting **Response Type**, see Download Connection File.
11. You can close the Apps Script browser tab and navigate to the Google Sheets browser tab. You are now ready to create a connection to the Autonomous Database.
12. Ensure you save the worksheet after uploading all the files to Apps Script. Click the **Refresh** button once you have uploaded all the files. You can now view a new **Oracle Autonomous Database** menu in the Google Sheets.



> **Note:**
>
> Generate **OAuth Client ID** and **OAuth Client Secret** fields by using the UI.

Connecting to Autonomous Database

The Oracle Autonomous Database add-on for Google Sheets enables you to connect to multiple Autonomous Databases with a single add-on using the Connections feature. The add-on connects to Google Sheets by providing authentication to Google. Multiple users or databases can connect simultaneously to the add-on. However, only one connection can remain active.

The connection icon enables you to manage one or more database connections to databases in your Google Sheets. You can connect, edit, duplicate, and remove a connection.

You use the OAuth authentication and credentials to access the Oracle Autonomous Database for Google Sheets. The Add-on connects with the database using implicit and explicit types of connections.

Explicit Connection

You use the OAuth Client ID and OAuth Client Secret values to authenticate and authorize Google Sheets to use the Autonomous Database. Use this when you use **CODE** as the **Response Type** while downloading the connection file from Database Actions page.

Implicit Connection

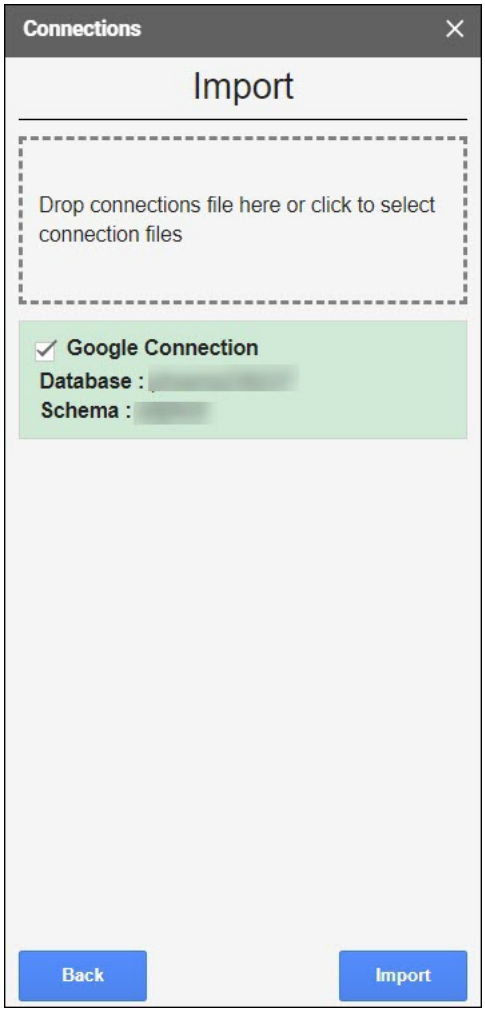
You will need an OAuth Client ID to implicitly access the Autonomous Database. Use this when you use **Token** as the **Response Type** while downloading the connection file from the Database Actions page.

Connection Management in Google Sheets

Import the connections file

Import an existing connection by clicking the **Import Connection** menu in the **Manage Connections** drop-down field.

1. Click the drop connection area and drag and drop the connection file saved in your local system to import the connection. You can import the **Connection File** you downloaded from the Download Connection File section.
2. Click and drop the connection file from your system to the drop area of the wizard. After the connection file loads, select the check box beside the connection file you want to import from the file.



3. Click **Import**. After you import the connection, you can view the connection in the list of connections.
4. Select the **three vertical dots** beside the connection name and click **Connect** to connect to the database.

Manual connection to the database

If you do not have a connections file to connect to the autonomous database and have access to the Schema via SQL Developer web, follow the steps outlined here to connect to the database.

Natural Language in Google Sheets

You can use Natural Language Query to query the Oracle Autonomous Database using the **Natural Language** menu in the **Oracle Autonomous Database for Google Sheets** "add-on".

Prerequisites

- Before you use the Natural Language menu in the add-on, you must perform prerequisites to use `DBMS_CLOUD_AI` to configure AI profiles.
- Create and Set an AI Profile

After your AI Profile is ready, the Data Studio tool uses these profiles in the Data Studio Settings menu to configure access to a Large Language Model (LLM) and to setup for generating, running, and explaining SQL based on natural language prompts. This also enables chatting with the LLM.

> **Note:**
>
> You can run Natural Language Queries on Tables and not Analytic Views.

Generate SQL Queries from Natural Language on Tables

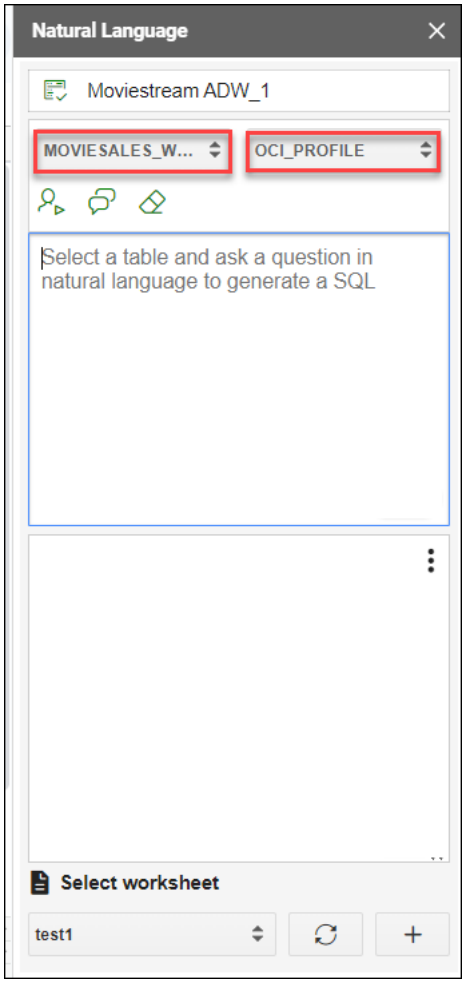
Using natural language to interact with your database data is now achievable with Oracle Autonomous Database add-on for Google Sheets.

This means you can use natural language, for example, plain English, to query the database. You can provide a natural language prompt instead of SQL code to interact with your data. When you select the **Generate SQL from natural query** icon, the add-on converts natural language to SQL.

To run a natural query using the add-on:

1. On the Google Sheet, select the menu item **Oracle Autonomous Database**.
2. Select **Natural Language**. Selecting **Natural Language** opens a **Natural Language** wizard.
3. On **Natural Language** wizard, select the **Table** on which you perform the query from the drop-down and the **AI profile** you want to use from the drop-down.

> **Note:**
>
> This is the same AI profile you configure in the Data Studio Settings.



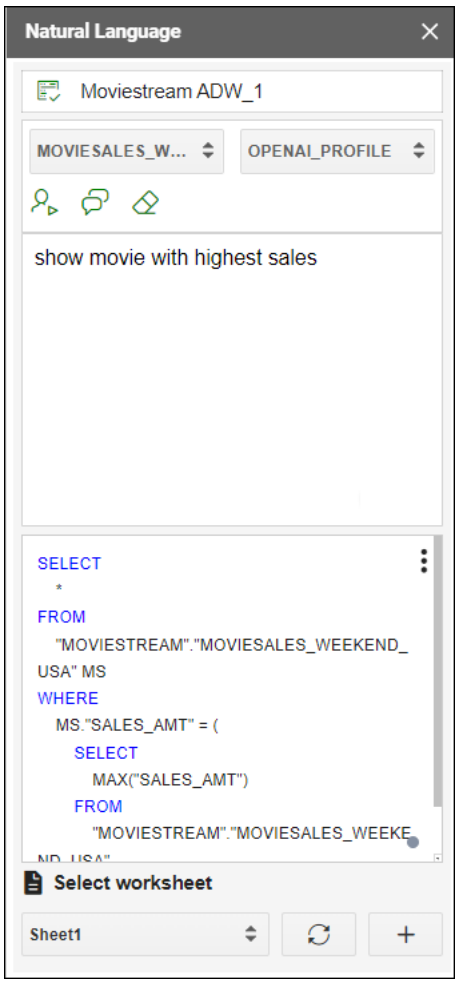
In this example, `MOVIESALES_WEEKEND_USA` is the name of the **Table** and `OCI_PROFILE` is the **AI Profile**.

4. Let's say you want details of the product with highest sales. Enter the following natural language query in the query display area:

```
show movie with highest sales
```

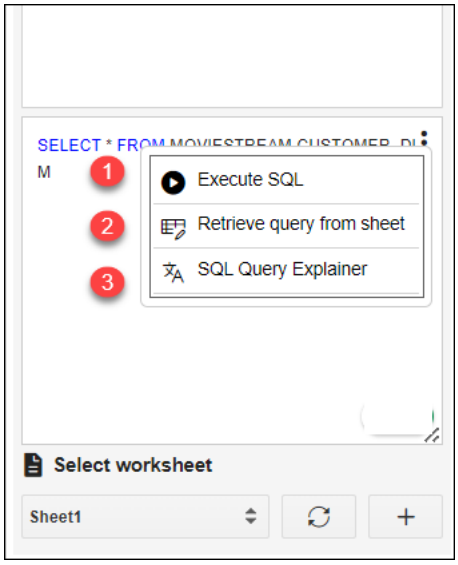
5. Select **Generate SQL from natural query** to produce the equivalent SQL query in the bottom query display area.
You will view the following code in the bottom SQL code area.

```
SELECT
    *
FROM
    "MOVIESTREAM"."MOVIESALES_WEEKEND_USA" MS
WHERE
    MS."SALES_AMT" = (
        SELECT
            MAX("SALES_AMT")
        FROM
            "MOVIESTREAM"."MOVIESALES_WEEKEND_USA"
    )
```



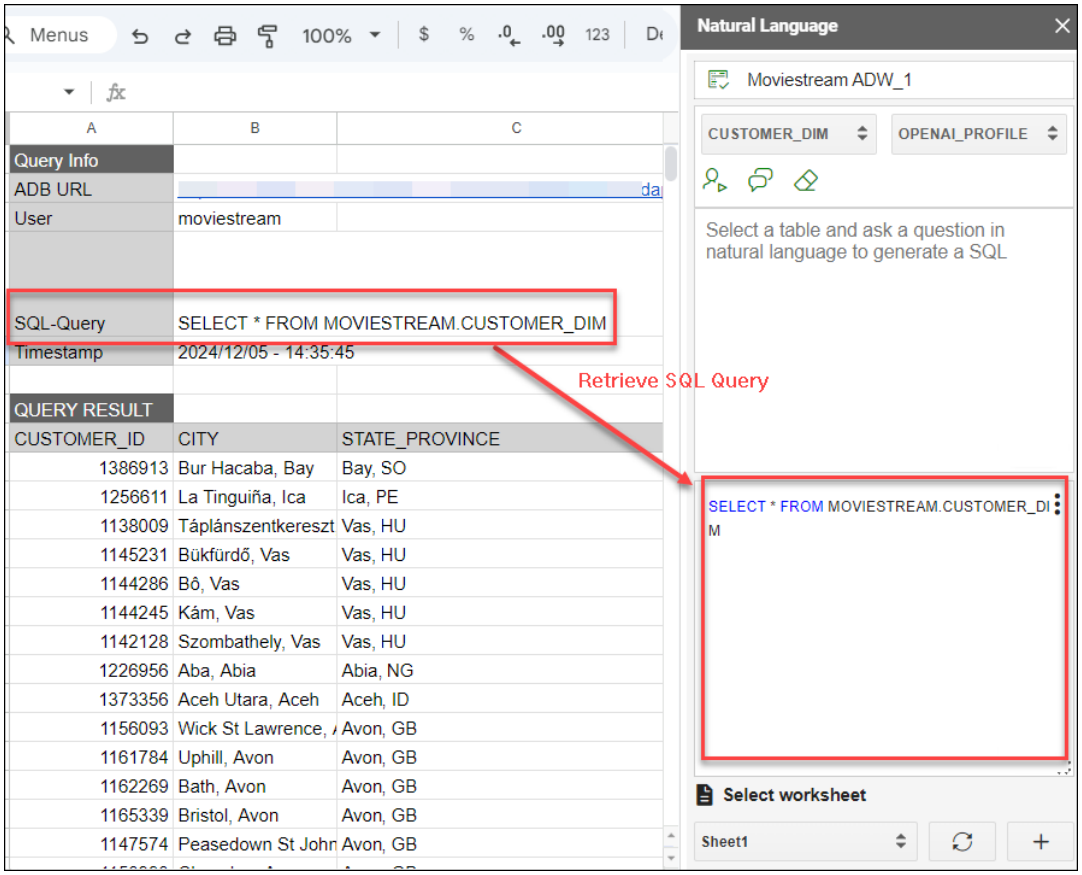
6. Selecting the **Generate SQL from natural query** icon also displays the result of the natural language query in the Google Sheet.
   You can click the **+** sign beside the **Select worksheet** drop-down to display the results in a new worksheet.
7. Click **Clear query content** to clear the content displayed on the natural language query area and the SQL code query area.

Actions you can perform from the SQL code area:



- **Execute SQL**: Runs SQL code and displays the query result in Google Sheet.
- **Retrieve query from Sheet**:
  You can retrieve SQL query displayed in the Google Sheet to the SQL code area in the Natural Query.

  This feature is to retrieve the latest data from the database for a future date. For example, if you want to receive the latest data from the table the next day, the connection may be inactive, but you can still connect to the instance, **retrieve query from Sheet** and **select Execute SQL** to display the latest query results in the Google Sheet.



- **SQL Query Explainer**: Explains SQL code in Natural language form.
  Select this icon to translate SQL queries to natural language that is understood by you. The natural language query is displayed in the natural language query display area of the wizard.

Ask Questions with Chats

Chats option in the Oracle Autonomous Database for Google Sheets refer to an interactive conversation between you and the add-on where the add-on uses natural language to query or interact with the autonomous database.

The data we use in this example is of a company called `Oracle MovieStream` to analyze movie sales data.

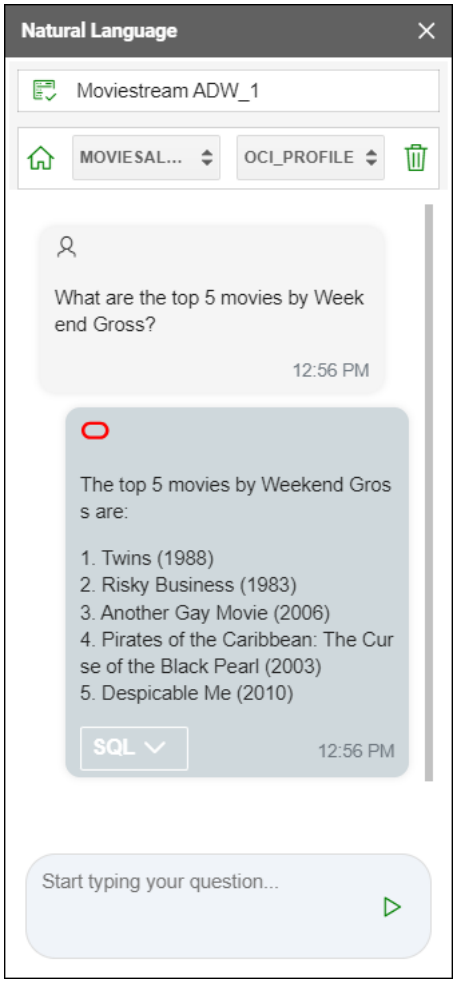
The Chats displays recommendations for the default table you select.

Let's find out the top 5 streamed movies in the Moviestream company by weekend gross:

1. Enter the text in the **Start typing your question..** text field.

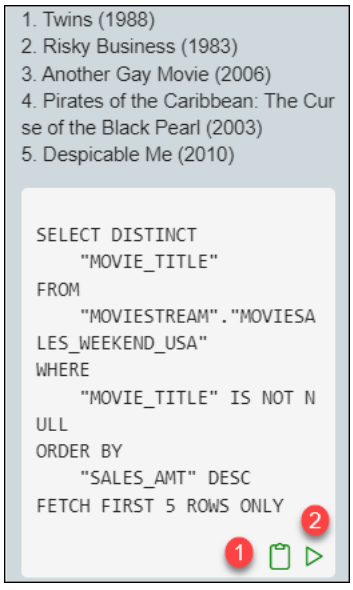
   ```
   What are the top 5 movies by Weekend Gross?
   ```

2. Click **Enter**.
3. The Chat displays top 5 movies by Weekend Gross.



It also displays equivalent SQL code of the result.

Click **SQL** to expand the SQL.



Click **Copy to clipboard** to copy the SQL.

Click **Run SQL** to run the generated SQL query and display the query result in Google Sheet.

The **Chats** option remembers the context of previous chat history.

For example, if you enter `now show me top 10` in the text field.

It displays the top 10 movies by Weekend Gross. It remembers which metric top 10 to fetch without us having to type the whole thing.

Select **New Chat** for deleting the present conversation.

Select **Home** to go back to the main home page.

> **Note:**
>
> LLMs are remarkable at inferring intent from the human language and they are getting better all the time; however, they are not perfect! It is very important to verify the results.

Data Analysis in Google Sheets

Selecting **Data Analysis** opens an Oracle Autonomous Database wizard in the Google sheet.

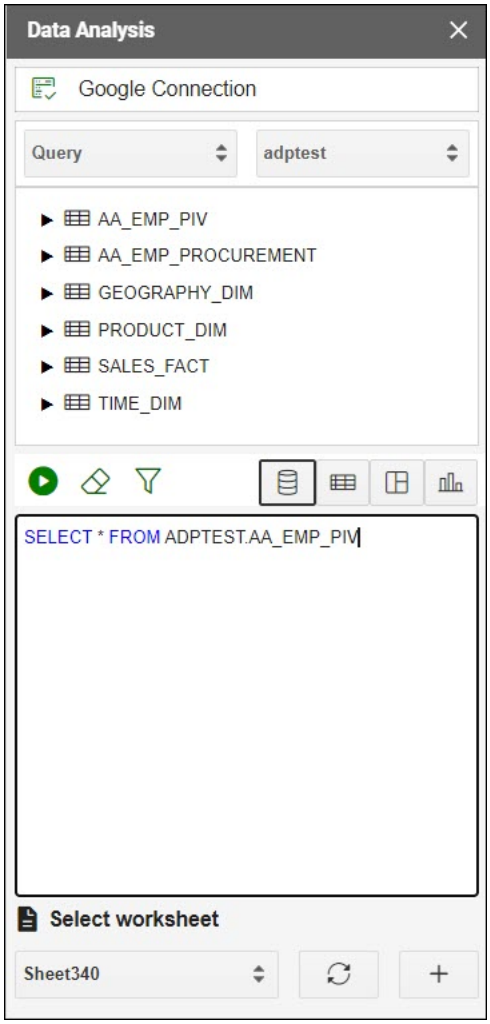
The add-on enables you to receive a copy of data from the Autonomous Database to the Google sheet. You can query an existing Analytic View and run SQL Query using the Oracle Autonomous Database Wizard.

You can retrieve the Analytic View and manipulate the query according to your requirements to visualize the result data in the worksheet. You can search for the Analytic View and select measures, hierarchies, and levels from the query. You can also add filters and calculated measures to the query and view the result in the sheet. By default, the data is retrieved in tabular format.

You can run custom queries. The add-on enables you to apply a filter to the query results. The add-on lets you to view query results that can be customized with selected columns using a faceted filter.

To run a custom query using the add-on:

1. On the Google Sheet, select the menu item **Oracle Autonomous Database**.
2. Select **Data Analysis**. Selecting Data Analysis opens a Data Analysis wizard. On the Data Analysis wizard, select **Query** from the drop-down and the **schema** you want to use from the drop-down.

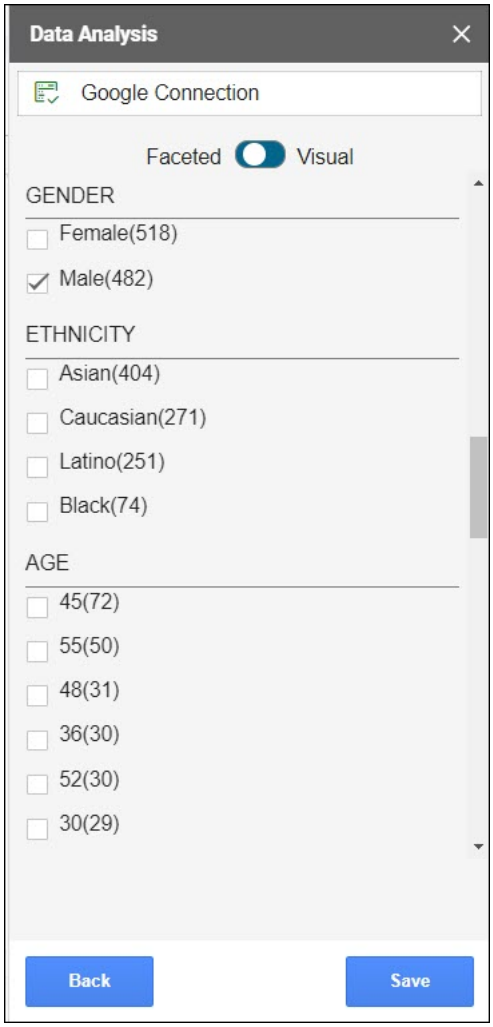


3. You will view the default query in the query editor area. You can select any of the four modes to visualize the results of the SQL query report you generate:

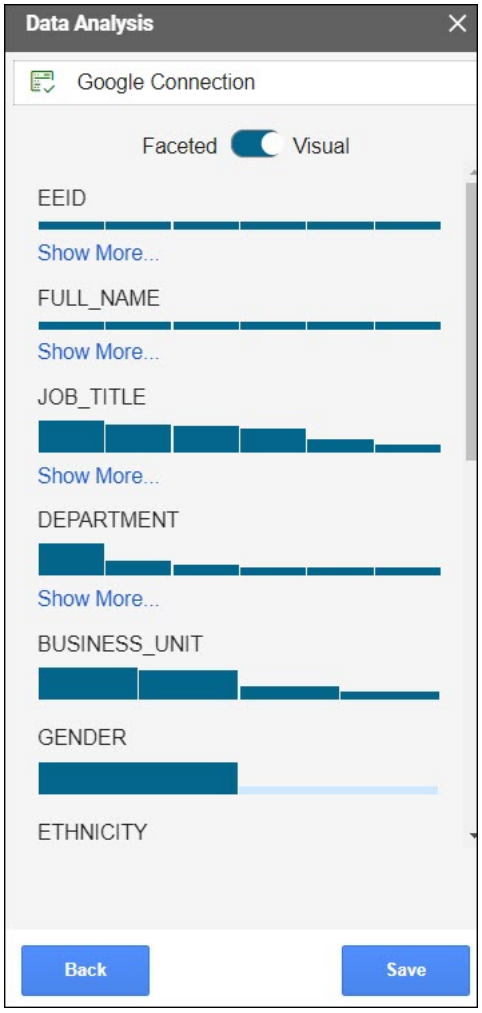
- **Base Query**: This type of view is by default. The query written in the SQL editor is the Base Query.
- **Table**: You can view the SQL results in tabular form. By selecting this view, a column drop zone appears, enabling you to drag and drop selected columns from the Table browser. Moving the selected columns in the drop zone allows you to view only those columns in the Result data generated in the worksheet. Select the cross mark beside the Column name to remove it from the drop zone.
- **Pivot**: You can view the SQL query results in pivot format. By selecting this format, an X and Y drop zone appears where you can drag and drop the selected columns from the Tables browser to the drop area.
- **Chart**: You can view *Area Chart*, *Bar Chart*, *Line Chart*, or *Pie Chart* when you select this option.. The mappings displayed when you select one of the options are as follows:

- **Orientation**: Choose between horizontal and vertical orientation types from the drop-down list.
- **X axis label and Y axis label**: Optionally enter labels for X axis and Y axis.

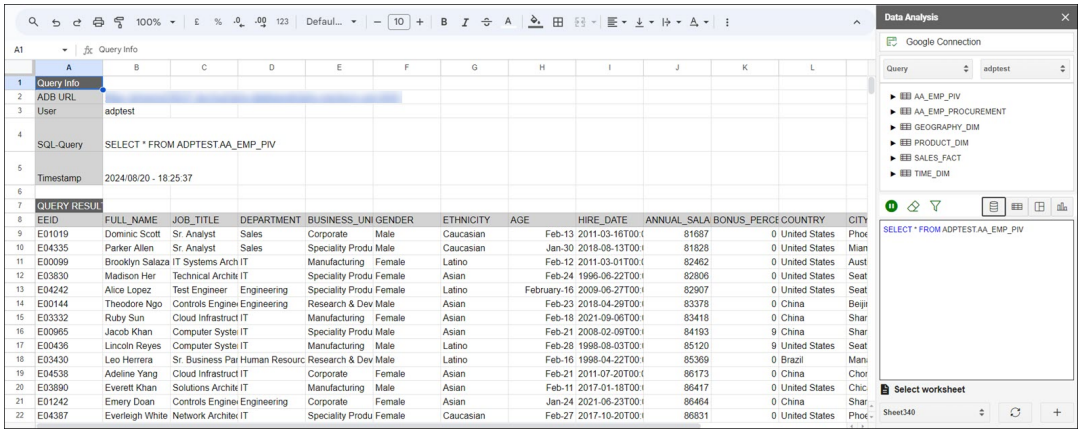
4. Click the **funnel icon** (Faceted Filter) to add filters to the result. The wizard generates a filter for each value in the column retrieved from the query result. You can filter different columns on the faceted filter panel and view the results in the worksheet to view only the data you wish to view. For example, to view the customer reports by Gender, click the **faceted filter** and select **Male** under Gender.



Use the Visual facet: Use the visual indicator to graphically represent the faceted filter.



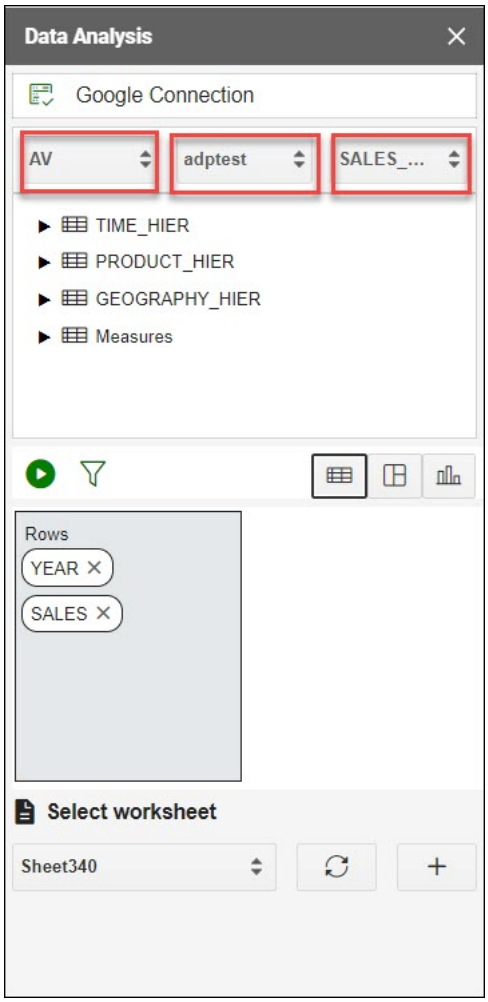
5. Select **Run** to generate the results of the custom query in the worksheet.



To query an Analytic View and explore the **Data Analysis** menu in the Google Sheets:

1. Select the menu item **Oracle Autonomous Database > Data Analysis** on the Google Sheet. This opens a **Data Analysis** wizard in the Google task pane.

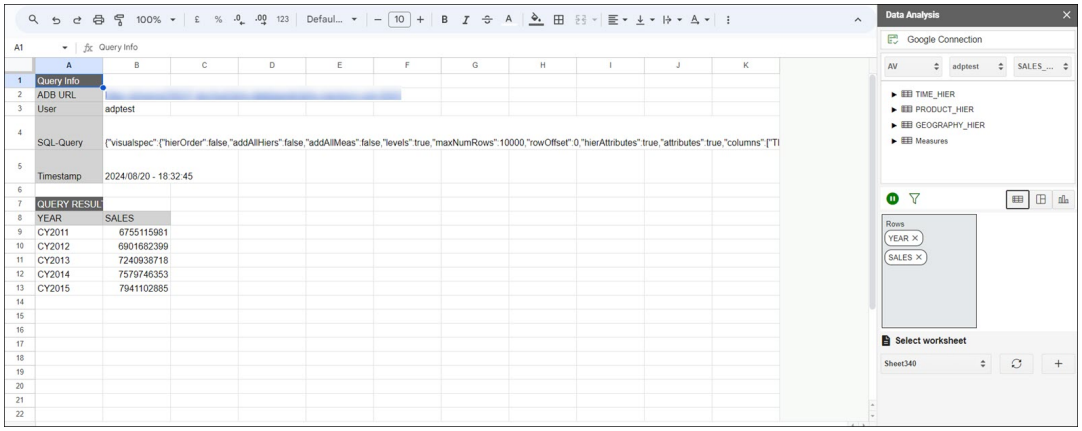
2. Select **AV** from the **AV** or **Query** drop-down, select a schema you can access from the schema drop-down, and the AV from the available Analytic Views.



3. You can select any of the three modes to visualize the results of the AV query you generate:
   - **Table**: You can view the AV query results in tabular form. By selecting this view, a column drop zone appears, enabling you to drag and drop selected columns from the Table browser. Moving the selected columns in the drop zone allows you to view only those columns in the Result data generated in the worksheet. Select the cross mark beside the Column name to remove it from the drop zone.
   - **Pivot**: You can view the SQL query results in pivot format. By selecting this format, an X and Y drop zone appears where you can drag and drop the selected columns from the Tables browser to the drop area.
   - **Chart**: You can view the results of the AV query in chart format. By selecting this format, an X and Y drop zone appears where you can drag and drop the chosen hierarchies and measures from the AV browser to the drop area.

> **Note:**
>
> You are allowed to drop measures in the Y-axis.

4. Click the **funnel** icon to view the Faceted and Visual Filter list. The wizard generates a filter for each value in the column retrieved from the query result. You can filter different columns on the faceted filter panel and view the results in the worksheet to view only the data you wish to view.
5. Click **Save**.
6. Click **Run** to view the results in the worksheet you select.



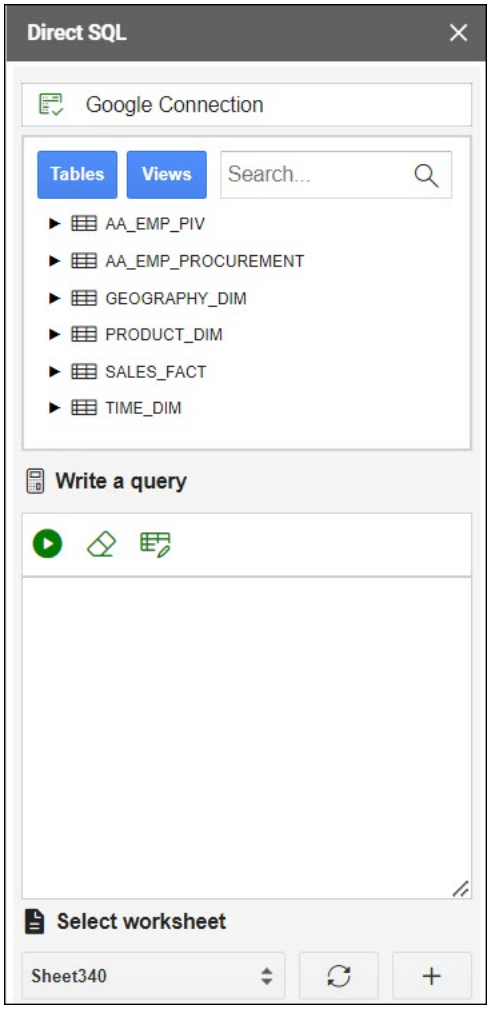
Run Direct SQL Queries

The Oracle Autonomous Database add-on for Google Sheets lets you run SQL queries to work with your data in a Google Sheet. With the add-on, you can type your SQL code in the SQL editor area and click **Run** to run the command.

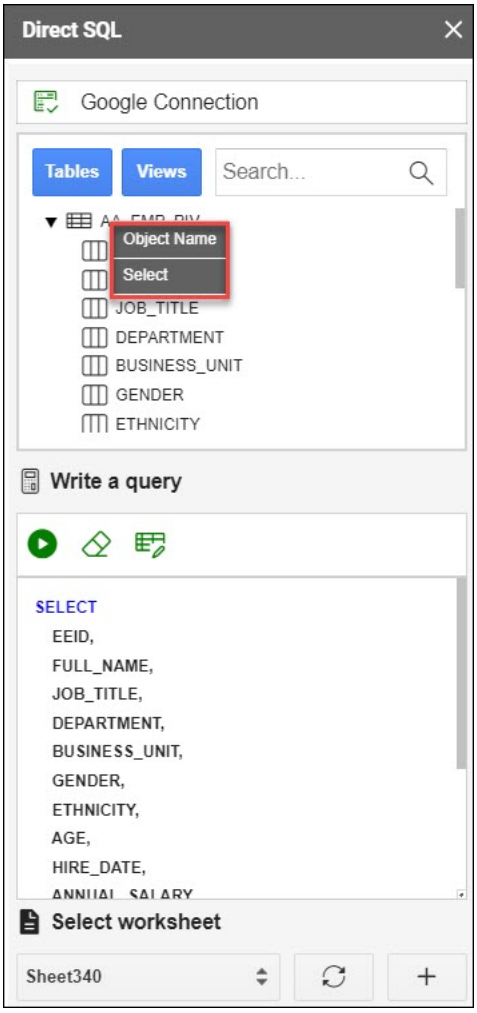
The add-on loads the result in the Google Sheet. The time taken to load the results depends on the number of records and the complexity of the query.

To run a query using the add-on, open Google Sheets and a blank workbook.

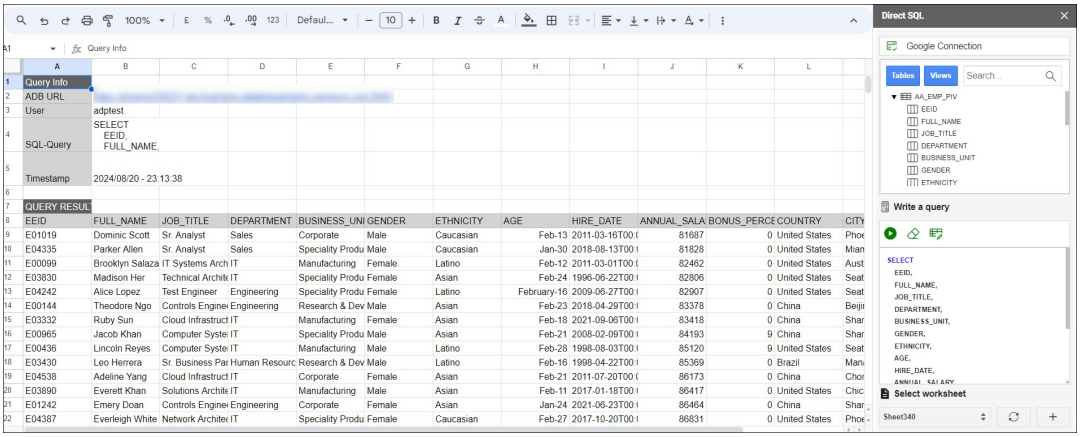
1. In the Google Sheet, select the menu item **Oracle Autonomous Database**.
2. Select **Direct SQL** to type and run the SQL command.
3. The Oracle Autonomous Database wizard opens Tables and Views icons and a search field beside it.



4. Select **Table** to view all the tables in the database. Perform the same operations for Views.
5. You can right-click on the table whose data you want to query and choose **Select** to view all the table's columns. The column names will be displayed in the **Write a Query** section. You can click on the table and view individual columns as well.



6. Click **Run** to run the query and display the results in the worksheet. You can click the **+** sign beside the **Select worksheet** drop-down to display the results in a new worksheet.
7. The worksheet also displays the timestamp, the user who creates and runs the query, the ADB URL, and the SQL Query.



Reporting and Analysis in Google Sheets

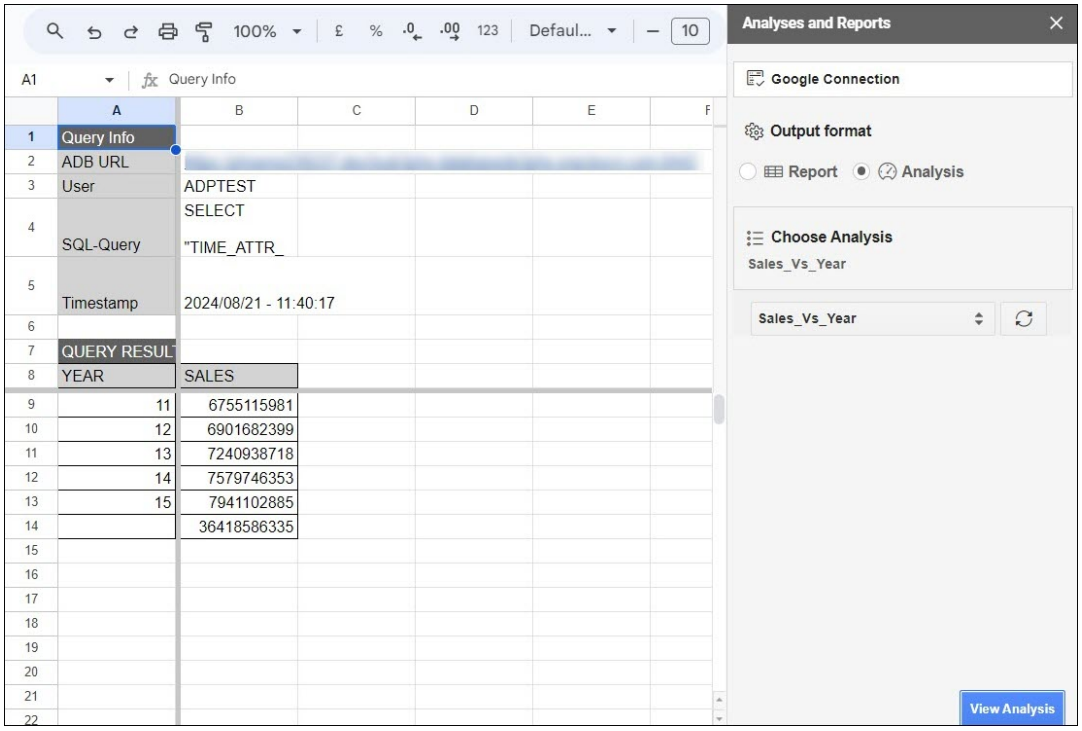
You can view Reports and Analytic Views or visualize data for analysis purposes.

The reports and charts can be viewed in various charts: Bar Charts, Area charts, Line Charts, and Pie Charts. Reports provide analytical insights that you create from the Analytic Views. An Analysis can contain multiple reports. The Analyses and Reports icon enables you to retrieve Analyses and Reports from the Autonomous Database.

View Analysis

To view Analysis and explore the Analyses and Reports menu:

1. Select **Analysis** under Output format.
2. Use the Select an Analysis drop-down to choose the Analysis you want to view.
3. Click **View Analysis** to view the analysis in the Google Sheet.

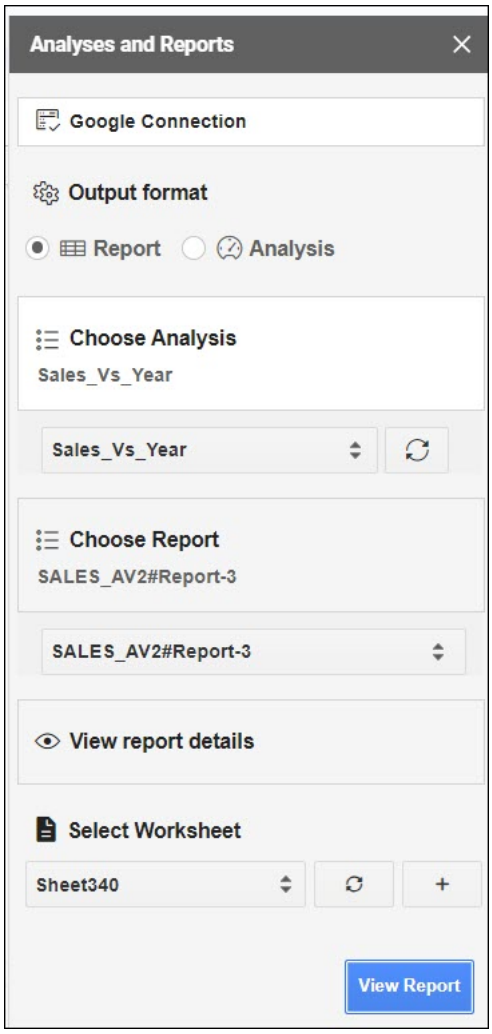


View Report

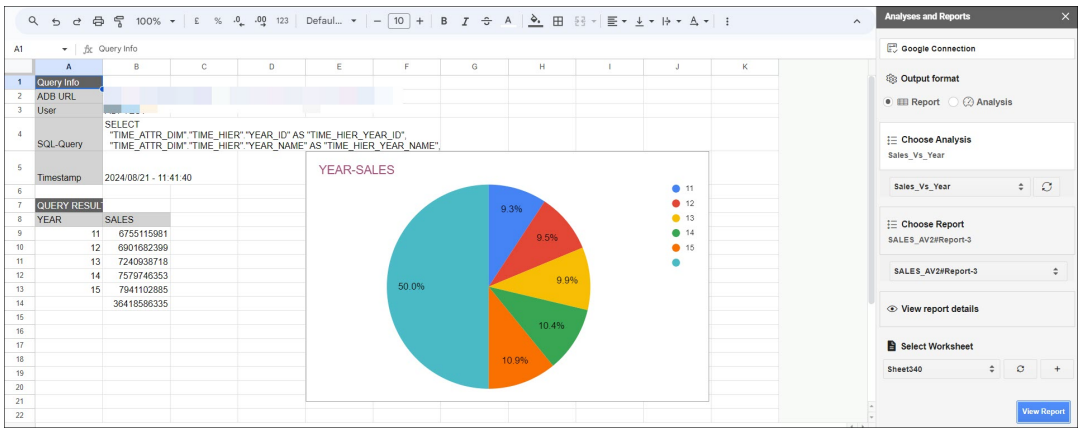
To view Reports :

1. Select the **Analyses and Reports** menu from the **Oracle Autonomous Database** menu. This opens the Analyses and Reports wizard.
2. Select **Report** under Output Format.
3. Use the **Select an Analysis** drop-down under **Choose Analysis** to choose the Analysis you want to view.
4. After you select the Analysis, to view the report present in the Analysis, click the **Select a report** drop-down and select the report you wish to view.

5. Click **View Report Detail** to view more information about the report: Analytic View Name, Type of visualization, and rows, columns, and values you select while creating the report.



6. Select the worksheet from the drop-down where you would want to view the report.
7. Click **View Report** to view the report in the selected sheet from the previous step. You can now view the report in the worksheet you select.



Clear Sheet

Once the add-on runs the query and retrieves the data into the worksheet, you can view the Timestamp, User, AV-query and SQL-query of the Analytic View in the automatically generated query results.

Once the add-on runs the query and retrieves the data into the worksheet, you can view the Timestamp, User, AV query, and SQL query of the Analytic View in the automatically generated query results.

The worksheet displays the result of the query in one go. Consider, for example, if you want to modify the query and generate the query result in the same sheet. You must clear the existing data in the sheet.

To clear query results in the Google sheet, click the menu item **Oracle Autonomous Database** and select **Clear Sheet**.

This option erases all data types in the selected sheet, including images and formatting.

Delete all sheets

Use this option to delete all the sheets existing in the spreadsheet.

Select **Delete All Sheets** from the **Oracle Autonomous Database** menu to delete all sheets from the spreadsheet.

About Oracle Autonomous Database menu

Use this option to view details about the add-in

The **About Oracle Autonomous Database** menu from **Oracle Autonomous Database** displays if the add-on is connected to server, the ORDS version, the Add-in version, the ORDS Schema version, the database major and minor version, the ADB URL and the Schema.

Share or Publish

Once you generate the query results in the Google Sheet, you can share it with other users. With sharing, creates a copy of the worksheet and sends it with the design tools hidden and worksheet protection turned on.

The recommended steps to take before you publish are:

1. Review and inspect to remove personal or sensitive information.
2. Save the source version of the worksheet. Consider adding a file name suffix of –src for the source worksheet. Then, remove the suffix in the distributed copy.
   Once you are ready to distribute to the users, click **Share**.
   - In the Share window that appears, add the user email IDs with whom you want to share the Sheets and to whom you want to provide permissions for accessing the Sheets.
   - You can select the permission of the users from the drop-down. Select **Editors** if you want the user to share the worksheet. **Viewers** and **commenters** can see the option to download, print and copy but not share the sheets.
   - Select **Notify people** check-box to notify the users of the share.

- Under General access, select **Restricted** from the drop-down to share it with people who have access to the link. You could also share it with people who do not have access by selecting **Anyone with the link** from the drop-down.

Oracle Autonomous Database for Google Sheets Privacy Policy Details

Effective Date: `10/4/2024`

Oracle Autonomous Database add-on for Google Sheets facilitates seamless data integration between Google Sheets and Oracle Autonomous Database. This Privacy Policy topic explains how we access, use, share, protect, retain, and delete your Google user data when you use our add-on.

Data use by **Oracle Autonomous Database add-on for Google Sheets** complies with Oracle's Privacy Policy.

1. **Google User Data We Access**
   - **Google Sheets Data**: The add-on accesses the content of your Google Sheets to import data from your Oracle Autonomous Database.
   - **User Profile Data**: User Profile Data, which includes personal information linked to a Google account, is not accessed or used by our add-on, as authentication is done with Oracle credentials. The data our application handles is limited to Google Sheets content.
2. **How We Use Google User Data**
   - **Data Integration**: Your Google Sheets data is used to enable functionalities like importing data from Oracle Autonomous Database into Google Sheets.
   - **Authentication**: Authentication is performed using your Oracle credentials. We do not access or use any Google authentication data or Basic Profile Information.
3. **Data Sharing and Disclosure**
   - **No Third-Party Sharing**: We do not share, sell, or disclose your Google user data to any third parties.
   - **Legal Obligations**: We may disclose your information if required by law or in response to valid legal processes.
4. **Compliance with Google API Services User Data Policy**
   - **Adherence to Limited Use Requirements**: To the extent the **Oracle Autonomous Database add-on for Google Sheets** uses and/or transfers information received solely from Google APIs to any other app, such use and transfer will adhere to Google API Services User Data Policy, including the Limited Use requirements.
5. **Data Protection Measures**
   - **Secure Transmission**: All data transferred between Google Sheets and Oracle Autonomous Database is encrypted using industry-standard protocols as detailed in our Security and Authentication for Autonomous Database.
   - **Access Controls**: Access to your data within the Add-on is restricted to authorized processes, ensuring that only necessary operations are performed.
   - **Oracle's Security Standards**: We adhere to Oracle's comprehensive security practices, including regular security assessments and compliance with global security standards.
6. **Data Retention and Deletion**

- **No Data Storage**: We do not store your Google Sheets data on our servers. Data is accessed in real-time solely for the purpose of facilitating the integration between Google Sheets and Oracle Autonomous Database.
- **User Control**: You can revoke the Add-on's access to your Google Sheets data at any time through your Google account settings.
- **Deletion Requests**: Since we do not retain your data, deletion requests are generally unnecessary. However, if you have concerns, please contact us at *adb_googlesheets_dev_ww_grp@oracle.com*.

7. **User Choices and Controls**
   - **Manage Permissions**: You can manage or revoke the add-on's permissions through your Google account settings at any time.
   - **Uninstallation**: To discontinue using the add-on, you can uninstall it from Google Sheets and revoke its access permissions.
8. **Changes to This Privacy Policy**
   We may update this Privacy Policy periodically. Changes will be reflected by the `Effective Date` at the top of this document. We encourage you to review this policy regularly to stay informed about how we protect your information.
9. **Contact Information**

   If you have any questions or concerns regarding this Privacy Policy, please contact us at:
   - **Email**: *adb_googlesheets_dev_ww_grp@oracle.com*
   - **Address**:
     Oracle Corporation

     500 Oracle Parkway

     Redwood Shores, CA 94065

     USA

Oracle Autonomous Database for Google Sheets Support

Welcome to the support page for the **Oracle Autonomous Database for Google Sheets**. This resource is designed to assist you with any issues or questions you may have while using the add-on.

Support for the Add-on

If you encounter any problems specifically related to the Oracle Autonomous Database Add-on, please reach out to our development team at `adb_googlesheets_dev_ww_grp@oracle.com`

Our team is dedicated to providing prompt assistance to ensure you have a seamless experience.

Support for Oracle Database Issues

For issues related to Oracle Database that are not specific to the Google Sheets add-on:

- **Contact Your Oracle Administrator**: Your organization's Oracle administrator can help with database access, permissions, and other database-related concerns.
- **Oracle Support Portal**: File a support ticket for further assistance at My Oracle Support.

The Catalog Tool

The Catalog Tool allows you browse, search and discover data in, and connected to, the Oracle Autonomous Database.

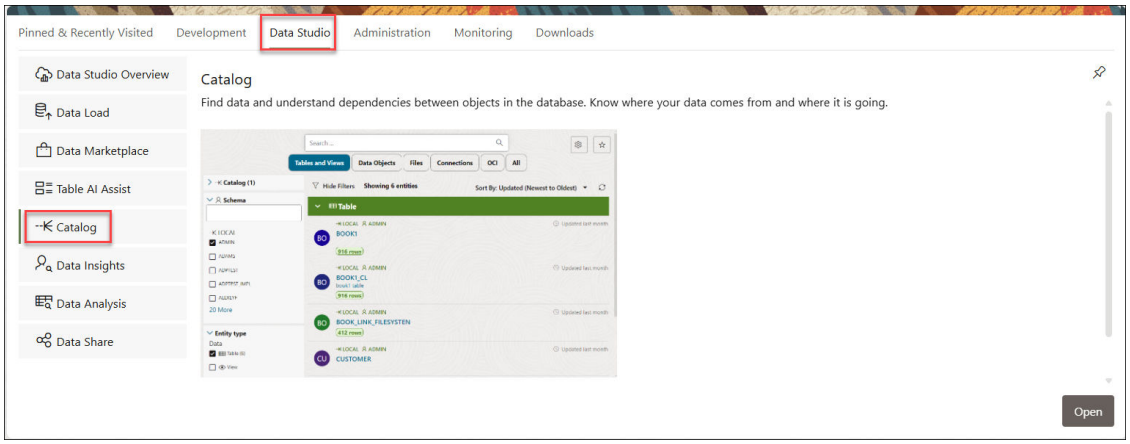
The Autonomous Database Catalog is a multi-catalog tool that provides a way to search for data and other objects in your currently connected Autonomous Database, and also in a wide range of other connected systems.

The Catalog tool enables you to search, find, load, or link connected data assets from anywhere in the cloud and beyond. It also enables you to mount new catalogs over other systems and search for data and other items in the connected Autonomous Database.

The Catalog tool can be used to mount new catalogs over:

- Other Autonomous Databases in your tenancy.
- Any other database that can be connected using a DB Link, for example an on-premises database that your Autonomous Database can connect to.
- Shared data, for example data shared from DataBricks using Delta Sharing.
- Existing external data catalogs such as AWS Glue, or the OCI Data Catalog.

To reach the Catalog tool, select the **Catalog** menu in the **Data Studio** tab of the Launchpad.



or click the Selector icon and select **Catalog** from the Data Studio menu in the navigation pane.

> **Note:**
>
> If you do not see the Catalog card then your database user is missing the required DWROLE role.
>
> Run the following command to grant `DWROLE` to the user:
>
> ```
> GRANT DWROLE TO ANALYST;
> ```

This chapter will take you through the features, capabilities, and technical architecture of the Catalog tool.

Enable the multi catalog feature in the tool

To enable the multi catalog feature in this tool, you need to have the `ORACLE_CATALOGS` role.

> **Note:**
>
> Until the user has `ORACLE_CATALOGS` role granted, they are limited to mounting only the local, connected Autonomous Database catalog.

In case the `ORACLE_CATALOGS` role is missing, run the following command as an **admin** to grant the `ORACLE_CATALOGS` role to the `user`:

```
CREATE ROLE ORACLE_CATALOGS;
    GRANT ORACLE_CATALOGS TO USER;
```

The following topics describe the Catalog tool and how to use it.

- About the Catalog Page
- Browse and Search Catalogs
- Sorting and Filtering Entities
- Filter Entities
- Display Entity Search
- About the Catalog Page
  Use the Catalog Tool to browse, search and discover data either in your Oracle Autonomous Database, or connected to it and get information about the entities in and available to your Oracle Autonomous Database. You can see the data in an entity, the sources of that data, the objects that are derived from the entity, and the impact on derived objects from changes in the sources.
- Browse and Search Catalogs
  The Catalog Tool aims to allow you to find data quickly and easily, whether or not the data is currently resident in the connected Autonomous Database.
- Sorting and Filtering Entities
  On the Catalog page, you can sort and filter the displayed search results.
- Filter Entities
  By selecting different quick filters, the faceted results of the entity types also vary.
- Display Entity Search
  If you do not select a quick filter, the **Tables and Views** filter is selected by default.
- Catalog Settings
  The Catalog Settings can manage the general settings, add, and view query scopes, create and view saved searches and change the look and feel of the Catalog page.
- Manage Catalogs
  You can now enable multiple catalogs using the Catalog Tool.

- Viewing Entity Details
  When you have found an entity you are interested in, you can click the entity to view its details, or click one of the other available actions from the menu that appears on the right hand side when you hover over that row.
- Registering Cloud Links to Access Data
  Cloud Links enable you to remotely access read only data on an Autonomous Database instance.
- Export Data to Cloud
  Use the **Export Data to Cloud** menu in the table actions of the Browse Catalog page to export data as text from an Autonomous Database to a cloud Object Store. The text format export options are CSV, JSON, Parquet, or XML.
- Gathering Statistics for Tables
  You can generate statistics that measure the data distribution and storage characteristics of tables.
- Editing Tables
  You can create and edit objects using Edit Table wizard available from the **Edit** menu in **Actions** (three vertical dots) besides the table entity.

About the Catalog Page

Use the Catalog Tool to browse, search and discover data either in your Oracle Autonomous Database, or connected to it and get information about the entities in and available to your Oracle Autonomous Database. You can see the data in an entity, the sources of that data, the objects that are derived from the entity, and the impact on derived objects from changes in the sources.

The Catalog page lists and displays details about:

- Database objects such as tables, columns, views, cloud objects, analytic views, packages, procedures, shares, share recipients, catalogs, catalog storage links, live table feed, share providers.
- Other types of object connected to the database, such as Cloud Storage Links, Cloud Storage Buckets, Cloud Objects (files on connected Cloud Storage), Compartments, Data Catalog Links, Catalog Storage Links, Autonomous Database.
- Database data dictionary objects such as tables, columns, views, database links, analytic views, packages, and procedures that have been created by the database tools or a database application such as SQL Developer.

The Catalog tool now provides a unified search and discovery of the following data assets that are connected to the Autonomous Database:

- Data in connected databases – for example, other Autonomous Databases in the same tenancy.
- Data in connected cloud storage systems – for example, in OCI, AWS S3, Azure, or Google Cloud Platform.
- Data in registered data catalogs – for example, in OCI Data Catalog, or AWS Glue.
- Data in registered data shares – for example, shared from Data Bricks.

Catalog Tool Terminology

The following are some major terms related to the Catalog Tool:

- **Catalog**: A catalog consists of one or many schemas, each with one or many tables. A catalog simply represents the set of data in that database as it is organized into schemas

and tables. The way you connect to the catalog determines the level of access to those schemas and tables. For other types of catalog, for example, catalogs that are mounted over external data catalogs or shares, the objects in the external system are still organized into schemas and tables but may not exist physically in such a form. For example, a catalog that is mounted over an AWS Glue data catalog may contain tables that actually exist as multiple files on AWS S3 cloud storage.

- **Mounting a Catalog**: This is the process of adding a new catalog connection to an external system so that the metadata in that system can be represented in the Autonomous Database catalog in a standard form.

A **Local** catalog is all the objects in or directly connected to your Autonomous Database as described in the above points. In addition to the local catalog, Catalog Explorer can add in additional catalogs so that you can discover data from other sources.

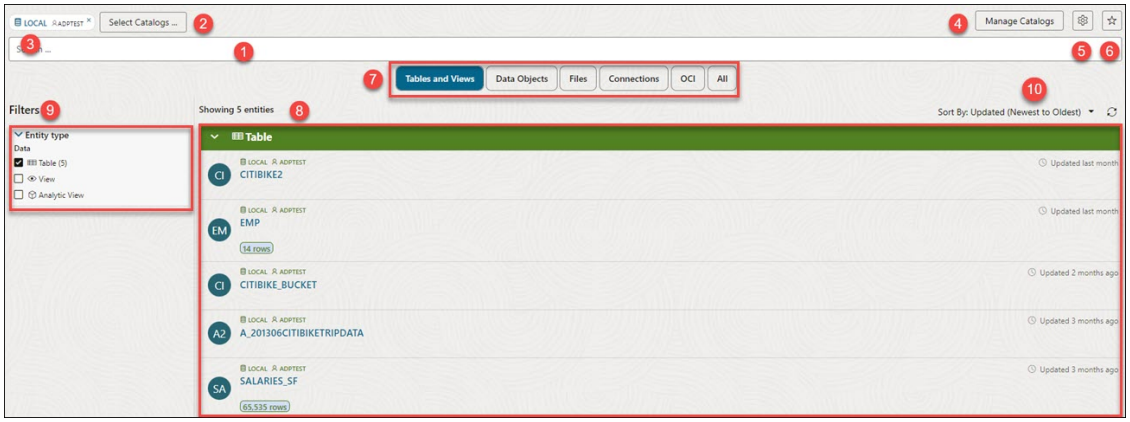
Additional catalogs can be mounted over:

- Mount Autonomous Database as Catalog: You can add a catalog to another autonomous database in your tenancy, which will allow you to search and discover all of the objects in that database based on the permissions for connection.
- Mount Database Link: The tool can mount an existing Database Link. Where a database link already exists, for example to an on-premises Oracle database, this can be mounted as a catalog. As with adding a catalog over an Autonomous Database, this option enables all the objects that are available to connection for search and discovery.
- Mount Data Share: The tool can mount registered live share or delta share as a catalog.
- Mount Amazon Glue: A catalog can be mounted over an AWS Glue Data Catalog database region.
- Mount OCI Data Catalog: The tool can mount data registered in OCI Data Catalog.

Once a new catalog has been mounted, you can add the catalog in the Catalog tool, and search and discover data from that catalog, or across many catalogs.

When you first open the Browse catalog page, it contains the **Search catalog** field, the **Catalog Settings** button, **Manage Catalogs** icon, a list of recently viewed objects, and several suggested searches. You can enter a search string, click on one of the recent objects to see its details, or click on **Show search suggestions** icon to view suggestions on the right side of the page.

As soon as you select Catalog menu from Data Studio menu bar, the page is displayed as below.



When you hover your mouse over a particular catalog entity, it will show a floating toolbar of common actions. The list is context-sensitive depending on the capabilities available for the particular entity. For example, tables in the current database offer more possibilities than tables in remote catalogs.

The Catalog page contains:

1. **Search** field

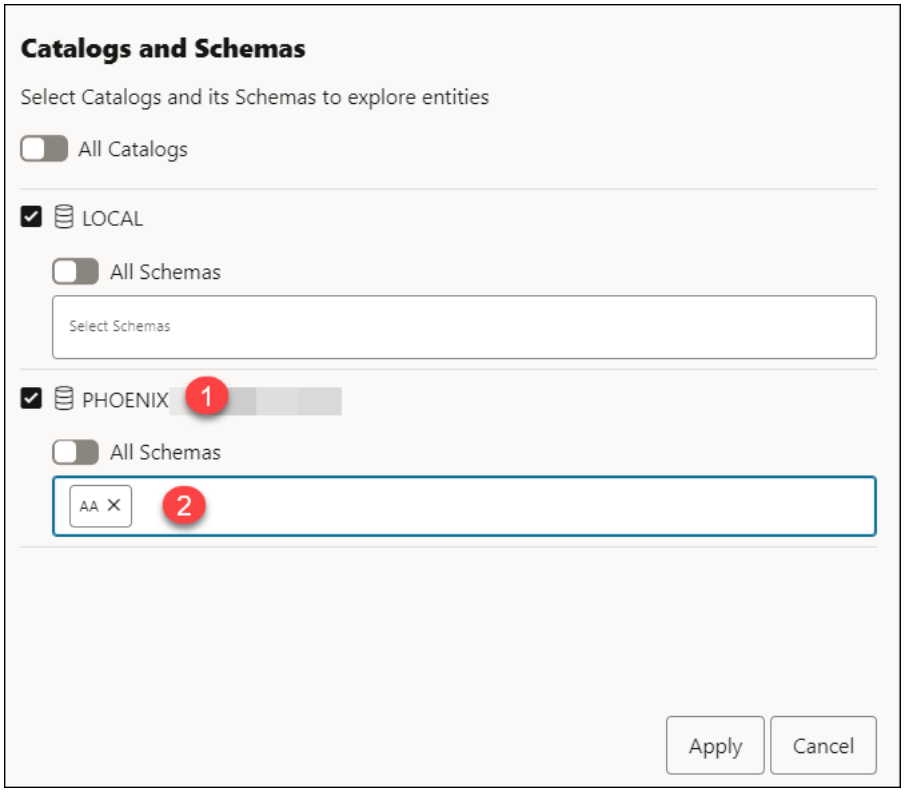
   You can search for the entities in the search field. For more details see Browse and Search Catalogs.

2. **Select Catalogs...** field
   Clicking this icon opens the **Catalogs and Schemas** dialog box.

   You can view a list of all mounted catalogs and schemas in this dialog box.

   Select specific schemas from a database of your choice to refine your search.

   - To show tables of only the **AA** schema from **PHOENIX** database, in addition to the default **local** schema:
     - On the **Catalogs and Schemas** dialog box, click the **PHOENIX** database and select **AA** from the **Select Schemas** search field.



3. **Default Database name and Schema name**
   This field displays the default database name along with the schema name.
4. **Manage Catalogs**
   Refer to Manage Catalogs for detailed information.
5. **Catalog Settings**
   Refer to Catalog Settings for detailed information.
6. **Saved Search Suggestions**

   Click to open or close the **Saved Search Suggestions** panel.
7. **Filters** option
   Click any of the filters icon to filter and refine the search results.

   Refer to Browse and Search Catalogs for detailed information.
8. **Display area**

   The area beneath the **Search catalog** field displays the entities returned by a search and that match the filter criteria set in the **Filters** panel. You can sort the entities by clicking the **Sort By** button and then setting sort values.

   Hover besides the name of the entity to view details about the entity.
9. **Faceted Filters** panel

   Select one or more filter values to limit the entities shown on the page. Only those entities that match the filter values are shown. That is, the items returned by a search are filtered by these filter settings. The filters also change depending on the quick filters you select. See Filter Entities.
10. **Toolbar**
    The toolbar appears after you run an initial search. It contains these buttons:

- **Sort By** 
  To select sorting values, click the **Sort By** button to open the list of options. Then click the **Ascending** or **Descending** icon next to **Name** or **Updated**. For example, if you select the **Ascending** icon next to **Name** the entities will be sorted in alphabetical order by entity name. If you select **Descending** icon next to **Updated**, the entities will be sorted in reverse of the latest updated entity..

  Click **Reload** to refresh the choices in the list.

Browse and Search Catalogs

The Catalog Tool aims to allow you to find data quickly and easily, whether or not the data is currently resident in the connected Autonomous Database.

Using the Catalog tool, you can discover data in connected systems, preview it, and choose whether or not to load, link or feed the data into the local database.

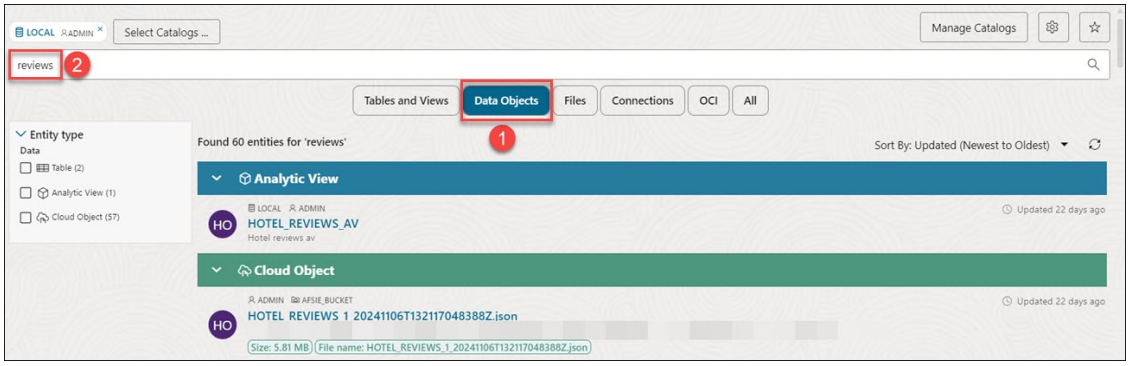
You can view the search bar on the Catalog's home page. To enter a search term, click on the search field located at the top. You can filter the search entry by selecting a quick filter displayed below the search field.

You must first select the type of assets you want to search from the filter buttons at the top of the screen, then search for objects by name.

Selecting the quick filters helps you display filtered searches in the display area. You can combine multiple filters. They are:

- **Tables and Views**
  This filter searches only for the database tables (both internal and external tables) and views (this includes both standard database views and analytic views)
- **Data Objects**
  This filter searches for data objects in the database and on connected cloud storage. This is a superset of the **Tables and Views** and **Files** scopes.
- **Files**
  This filter searches only for files in connected cloud storage.
- **OCI**
  This filter searches for other Oracle Cloud Infrastructure objects, such as other Autonomous Databases, buckets on OCI cloud storage, or a registered OCI Data Catalog. This field is available if you have an OCI credential. You can create an OCI credential from the Data Studio Settings icon.
- **Connections**
  This filter searches for connections that are registered in Data Studio, such as connections to external Data Catalogs or databases.
- **All**
  This filter searches for all objects in the catalog. Since there are many thousands of such objects, this scope may be slower to use.

For example, to find all tables, views or files that may contain data related to reviews, click **Data Objects** and search for *reviews*:



This displays all data objects that contain review data.

Sorting and Filtering Entities

On the Catalog page, you can sort and filter the displayed search results.

Sort Entities

To set a sort order for the entities on the page,

1. Click **Sort by** on the toolbar.
2. Find the value you want to use to sort, for example **Entity Name**.
3. Click the **Name (A - Z)** (Ascending) icon or the **Name (Z - A)** (Descending) icon next to that value.
4. You can set only one parameter. You can also set **Updated: (Oldest to Newest)** or **Updated: (Newest to Oldest)** based on the time you update the entity.

Filter Entities

Restrict which entities that are returned by a search are displayed on the page by setting filters in the **Filters** suggestions panel on the top of the Catalog page. Select one or more filter values. Only those entities that are returned by a search and that match the filter values are shown. Selecting all or none of the options shows all entities returned by the search.

By default, system tables and private tables are not displayed. To display them, click **Catalog Settings** in the toolbar and then click the **Show system tables** slider or the **Show private tables** slider, or both.

Filter Entities

By selecting different quick filters, the faceted results of the entity types also vary.

The faceted search displays various options in entity types based on different categories. You can select multiple entity types in various categories for more specific search results. It displays the count value in bracket.

The following table lists the entity types and filter condition subcategories with their description:

Table 3-6 Entity Types and Filter Condition

Field	Description
Filter for	

Table 3-6 (Cont.) Entity Types and Filter Condition

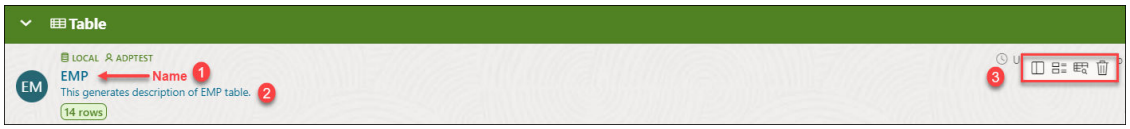
Field	Description
Entity Type	Specifies the name of the entity type under which you select entity filters
Filter condition subcategory	Data
Data Entity type values	• Table • View • Analytic View • Column • File • Cloud Object
Share Entity type values	• Share • Share Recipient • Cloud Link Namespace • Share Schema • Share Table
Connection Entity type values	• Catalog • Cloud Storage Link • Data Catalog Link • Live Table Feed • Share Provider • Cloud Link • Data Catalog Asset • Database Link • Share Link
Dictionary Entity Type Values	• Attribute • Attribute Dimensions • Directory • Credential • Function • Level • Mining Model • Procedure • Synonym • Schema
OCI	• Autonomous Database • Bucket • Compartment • Data Dictionary • Database Connection • Data Catalog • Vault • Vault Secret

Display Entity Search

If you do not select a quick filter, the **Tables and Views** filter is selected by default.

You can also view the Table after you enter the search term, a search is performed across **Tables and Views**.

Expand the Table header to view the Table name.



1. You can view the schema name. The icon color uniquely reflects schema or catalog. All entities within the same schema or catalog have the same entity color. If multiple catalogs are being searched, the catalog name appears next to the schema name.
2. **Auto-generate description**: You can also Auto generate a description by clicking the **Add description** link.
   On the **Add Description** wizard, click **Auto-Generate**. You need to set up an AI profile using the Data Studio Settings icon to configure the profile. Click **OK** on the **Add description** wizard. You can now view the auto generated description. Your profile must be AI enabled to generate auto description.
3. **Viewing Entity Details**
   You can view the entity details of the selected entity by just clicking it. You can view the menu of the available actions by hovering over the entity. The icons vary from entity to entity.

   For **Table and Views** type of entity, you can view the set of available actions of the entity:

   - **View Details**: Select **View Details** to view details about the table.
   - **Gather Statistics**: Select **Gather Statistics** to display new statistics after you modify the table's structure. Refer to the Gathering Statistics for Tables for more detailed information.
   - **Create Share**: Select **Create Share** to share from the associated table.
   - **Register to Cloud Link**: Select **Register to Cloud Link** to register the table for remote access for a selected audience you define. See Registering Cloud Links to Access Data section for more information.
   - **Create Analytic View:** Select **Create Analytic View** to create an Analytic View from the selected associated table. See Creating Analytic Views
   - **Query**: Selecting **Query** takes you to the Data Analysis page with the selected table.
   - **Export Data to Cloud Storage Location**: Select Export Data to Cloud to export data to a cloud object store.
   - **Edit**: Select **Edit** to edit the properties of the table. Refer to Editing Tables for more information.
   - **Drop**: Select **Drop** to delete the table.

Catalog Settings

The Catalog Settings can manage the general settings, add, and view query scopes, create and view saved searches and change the look and feel of the Catalog page.

You can alter the Catalog tool's user interface and page layout through themes and theme styles in the Catalog Settings.

Select **Show Settings** on the Catalog page to set the behavior of the Catalog. When you set these options, they take place immediately and are also saved as the default behavior for the

page. Clicking **Show Settings** opens the General tab where you can view the following options.

- **Show system tables**

  Select this option to include system tables in the search results.

- **Show private tables**

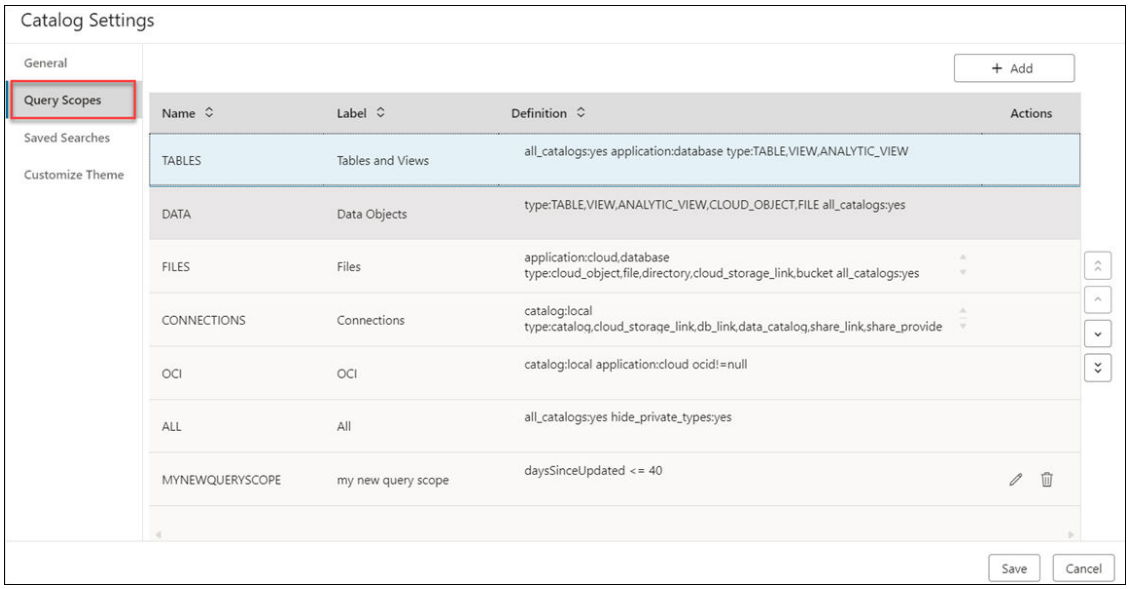
  Select this option to include private tables in the search results.

- **Page size**

  Select the number of entities to display on the page.

Gradually progress to use the **Query Scopes** tab to view, create, and delete query scopes. You can search for catalogs and save this search using query scopes.

Selecting Query Scope icon enables you to create new query scopes based on your preferences.



You can view, create, and edit the previously saved query scopes in this wizard. The query scopes are categorized based on by whom its created.

- Select **Custom** to view, create, edit, or delete the query scopes created by you.
- Select **Predefined** to view the query scopes which are already defined by the Database Actions. This option does not allow you to create, edit, or delete the query scopes.
- Select **All** to view all the query scopes. This includes Custom and Predefined query scopes.

Click **+Add** to create a Query Scope. Click **Cancel** to cancel its creation.

Specify the following fields in the Query Scope tab.

- **Name**: Enter the name of the Query Scope. This is a mandatory field.
- **Label**: This is a mandatory field. Enter a descriptive name here. You will use this field to refer to a query scope.

- **Definition**: Enter the Oracle Autonomous Database Data Definition Language (DDL) that creates the search entity. This is the same search criteria you enter in the Search Catalog field.

Once you have added the new query scope, it is visible in the list of query scopes in the Catalog Settings wizard.

Progress to the **Saved Searches** tab.

You can save your time from redefining the same search again in the future. You can diagnose problems faster since you are just few clicks away from accessing a saved search. Here is how you can create a saved search.

- Select this tab to save the five previous search queries that you entered into the **Search catalog** field. When the **Search catalog** field is empty and you click in the field, the last five search queries are listed in the drop-down list. (Any predefined searches selected from the **Suggestions** panel won't appear in this list, unless you edited them to make a new search.)

  The **Saved Searches** tab saves the current search query as per the criteria you specify or create a new saved search. Click **+Add** to create a new saved search.

- On the **Saved Searches** tab, click **+Add** to create a new search.
  - On the **Create New Search** dialog, specify the **Title**, **Scope**, **Definition** and **Description** (optional field) in their respective fields. For example, you want to search for a specific Entity type and a specific owner.
  - Select **Save**.

  After the creation of the saved search, it appears on the list of Saved Searches.

  You can change the columns displayed in the search results by clicking the pencil icon in the Actions column. Click the **delete** icon in the Actions column to delete the search you save. The saved searches you create are available for selection in the Saved Search panel in the right of the Catalog page.

- Progress to the **Customize Theme** tab to expand each entity type to select the properties and preview it.
  - On the **Customize Theme** tab, you can select the entity type whose appearance you want to define by editing the options in this tab.
    You can view the following menu options as you move from left to right.

Options	Description
Entity Type	This option describes the type of entity you want to edit. You can expand the entity type to select properties and to preview what the change looks like.
Is actions toolbar?	This option when enabled displays the actions menu items as floating toolbar on hover, else displays the actions menu.
Header background color	This option enables you to set the background color of the title of the entity header. This is the same as the text color for the properties of the entity listed.
Text color	This option enables you to set the text colour of the entity title.

Options	Description
Text highlighter	This option enables you to set the highlight colour of the box surrounding the properties of the entity.

Click **Save** in the Catalog Settings dialog to save all your preferences you set for the Catalog page.

Manage Catalogs

You can now enable multiple catalogs using the Catalog Tool.

You can mount additional catalogs from other Autonomous Databases in the same tenancy, so that you can search for data across multiple databases.

Mount Autonomous Database as Catalog

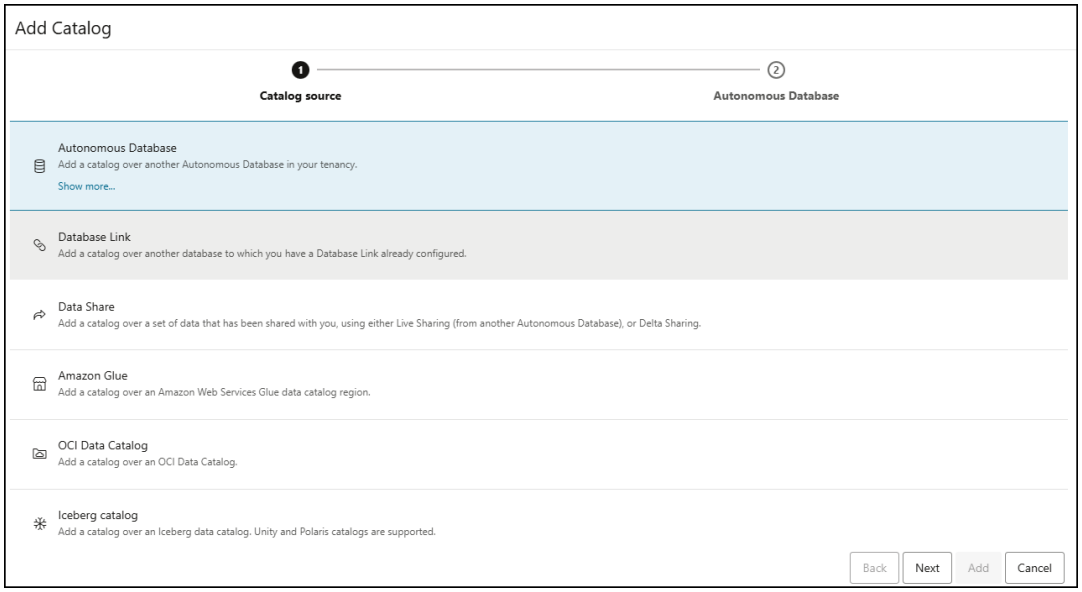
You will use an existing Autonomous Database to create a Database link and provide catalog name to mount it.

> **Note:**
>
> To mount an Autonomous Database as a Catalog, you must have the `CREATE DATABASE LINK` and `CREATE ANY DIRECTORY` system privileges. The ADMIN user is granted `CREATE DATABASE LINK` and `CREATE ANY DIRECTORY` system privileges. The ADMIN user can grant `CREATE DATABASE LINK` and `CREATE ANY DIRECTORY` system privileges to other users.

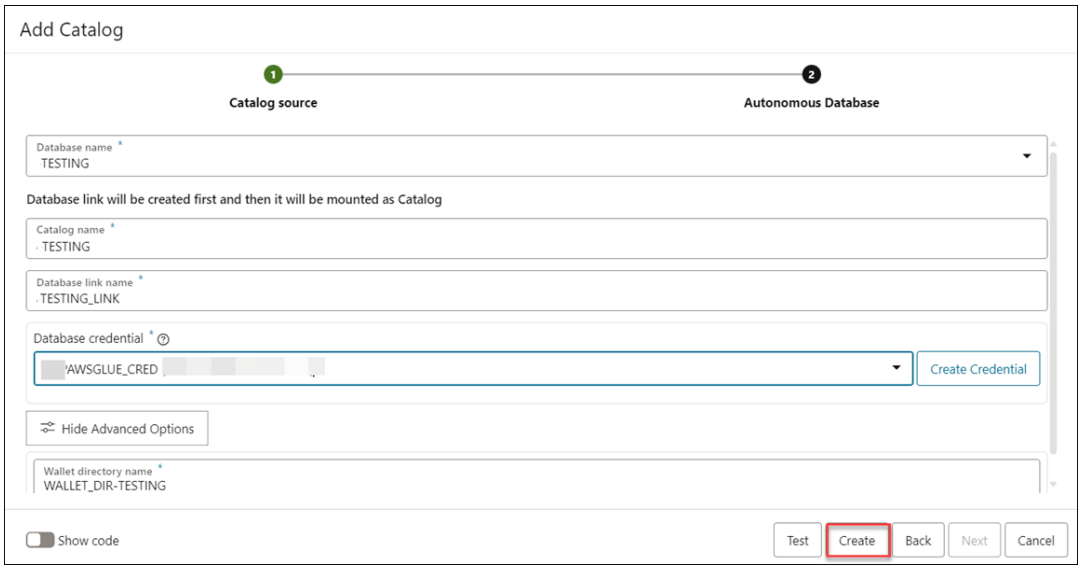
To add an autonomous database as a catalog, you need to perform the following operations:

- Store your object storage credentials in your Autonomous Database
- Create a database link or use an existing database link
- Mount the database link as a catalog

1. On the Catalog page, select **Manage Catalog**. Click **+Add**.
2. On the **Add Catalog** page, select **Autonomous Database** as Catalog Source.



3. Select the **Database name** from the drop-down. For example, *TESTING*.
4. You can view the following fields after you select the database name. Specify the following field values:



- **Catalog Name**: Enter the name of the catalog you want to mount the database link as. For example, *TESTING*.
- **Database link name**: Enter the name of the database link the tool creates using the existing database. For example, *TESTING_LINK*.
- **Database credential**: Select the credential from the drop-down which is required to create the database link. For example, *AWSGLUE_CRED*.
  Click **Create Credential** in case there is no existing credentials.
- Under **Show Advanced Options**, select the **Wallet Directory name** from the drop-down. You need to have permission to access the directory. For example, *WALLET_DIR-TESTING*.

> **Note:**
>
> The wallet file, along with the Database user ID and password provide access to data in the target Oracle Autonomous Database.

- Click **Test** to test the creation of the Database Link.

Click **Create** to create the autonomous database as Catalog.

After successful creation, you can view the Autonomous database listed under Manage Catalog.

Mount an existing Database Link as Catalog

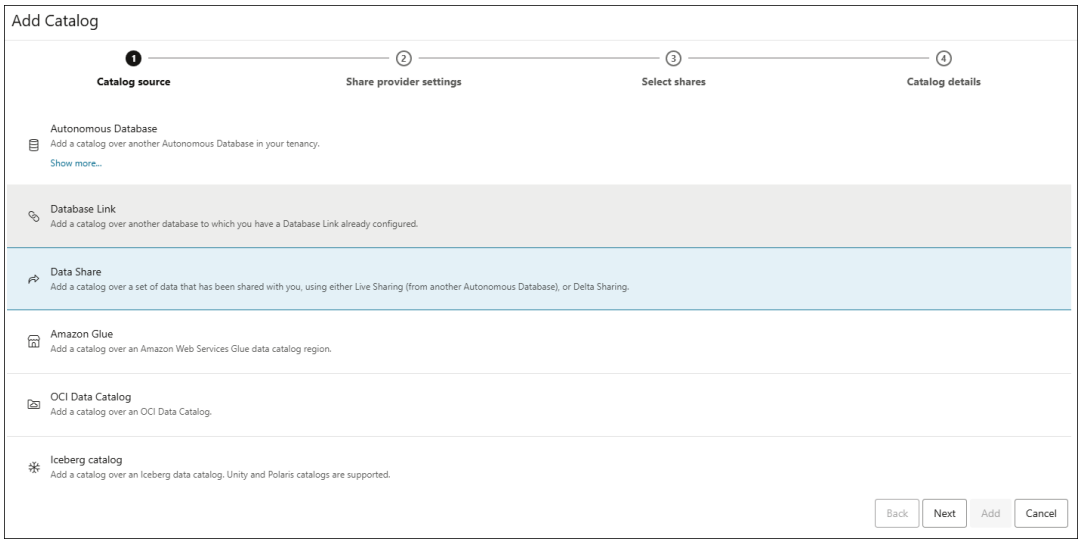
You can instantiate a catalog schema as a local database user. If a database link has already been set up, you can mount a catalog over the linked database in order to search and discover data sets in that database.

Mounting a catalog requires the following information:

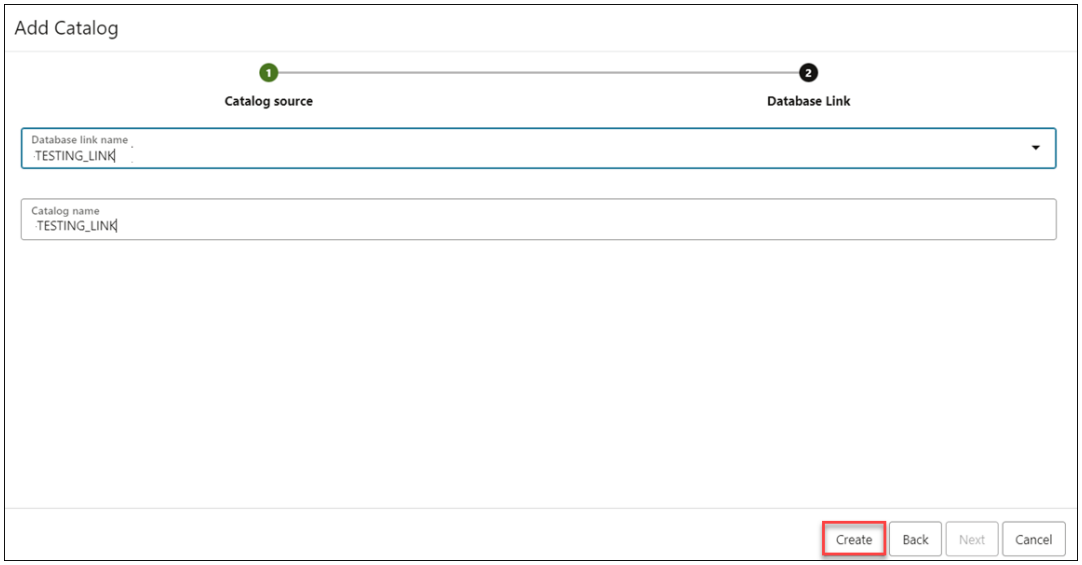
- Name of the database link
- Cloud credentials required to access the data

You can add a database link to one of the databases and mount its metadata as a new catalog.

1. On the Catalog page, select **Manage Catalog**.
2. Click **+Add**.
3. On the **Add Catalog** page, select **Database Link** from Catalog Source.



4. Select the **Database Link** tab.



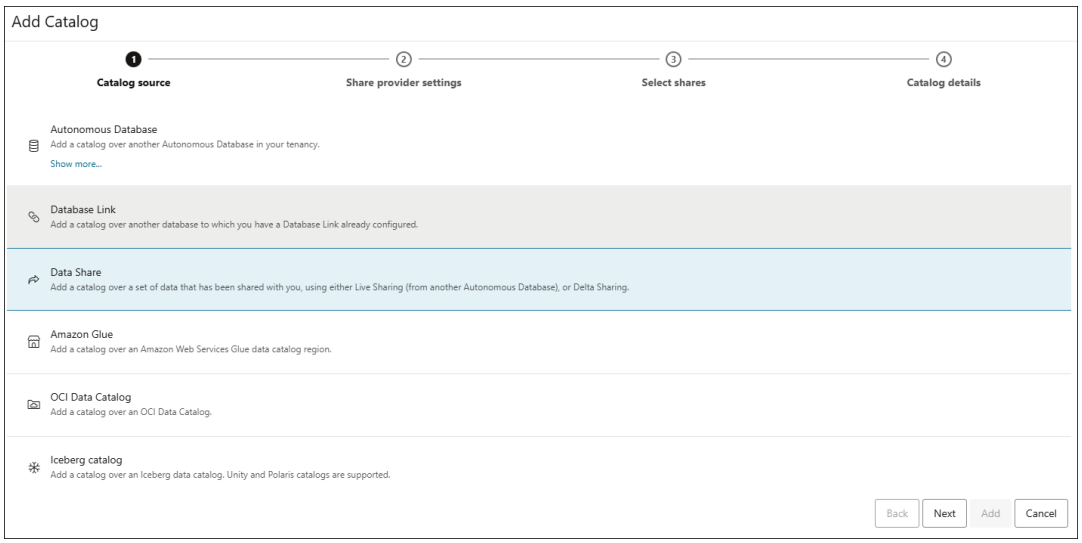
5. Select the **Database Link name** from the drop-down. For example, *AA-TESTING_LINK*.
6. Enter the name of the catalog in the **Catalog name** field. For example, *AA-TESTING_LINK*.
7. Click **Create**.
   You can view the newly mounted catalog in the **Manage Catalogs** dialog box.

   After you have successfully mounted a new catalog over a database connected using a Database link, you can select the catalog in Catalog Explorer and search for data in it.

Mount either Live Share or Delta Share Provider as Catalog

You can mount catalogs from registered data shares. This enables the consumers to access tables defined by other providers in other databases. The external tables need to be defined just once.

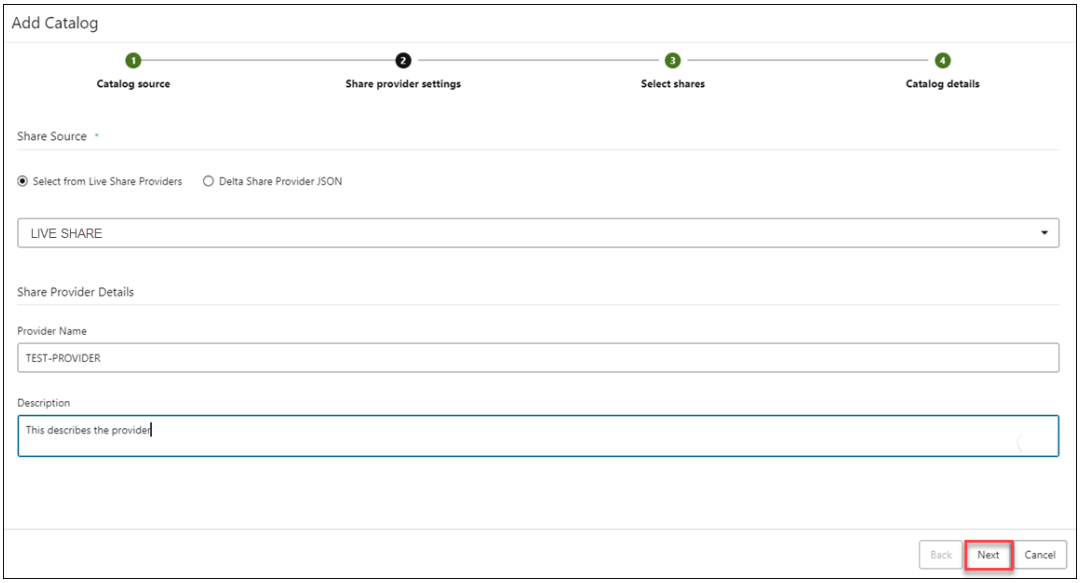
1. On the Catalog page, select **Manage Catalog**. Click **+Add**.
2. On the **Add Catalog** page, select **Data Share** from Catalog Source.



3. Click **Next** to progress to the **Share provider settings** tab.
   Under Share Source, select any of the available options:
   - **Select from Live Share Providers**
   - **Delta Share Provider JSON**

   In this example, you will select share source from Live Share Providers.

   Under **Share Provider Details**, specify the following details:
   - **Provider Name**: Enter the name of the share provider. For example, *TEST-PROVIDER*.
   - **Description**: Enter any description. This field is optional.



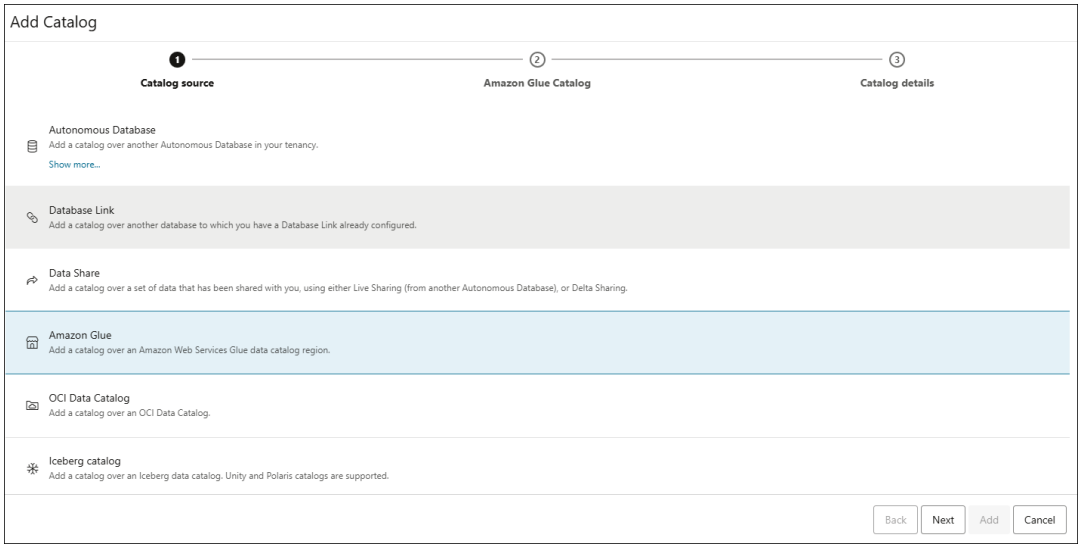
4. Click **Next** to progress to the **Select shares** tab.
5. On the Share provider settings tab, drag and drop the share you want to mount as a catalog from the Available Shares to the Selected Shares.
6. Click **Next** to progress to the Catalog details tab. On the Catalog details tab, specify the following details:
   - **Catalog name**: Enter a catalog name of your choice.
   - **Catalog description**: Enter a description.
7. Select **Create** to mount a Live Share or Delta Share as a catalog.

After you have successfully mounted a new catalog over a Share, you can select the catalog in Catalog Explorer and search for data in it.

Mount Amazon Glue as Catalog

You can mount catalogs from registered AWS Glue data connections.

1. On the Catalog page, select **Manage Catalog**.
2. Click **+Add**.
3. On the **Add Catalog** page, select **Amazon Glue** from Catalog Source.



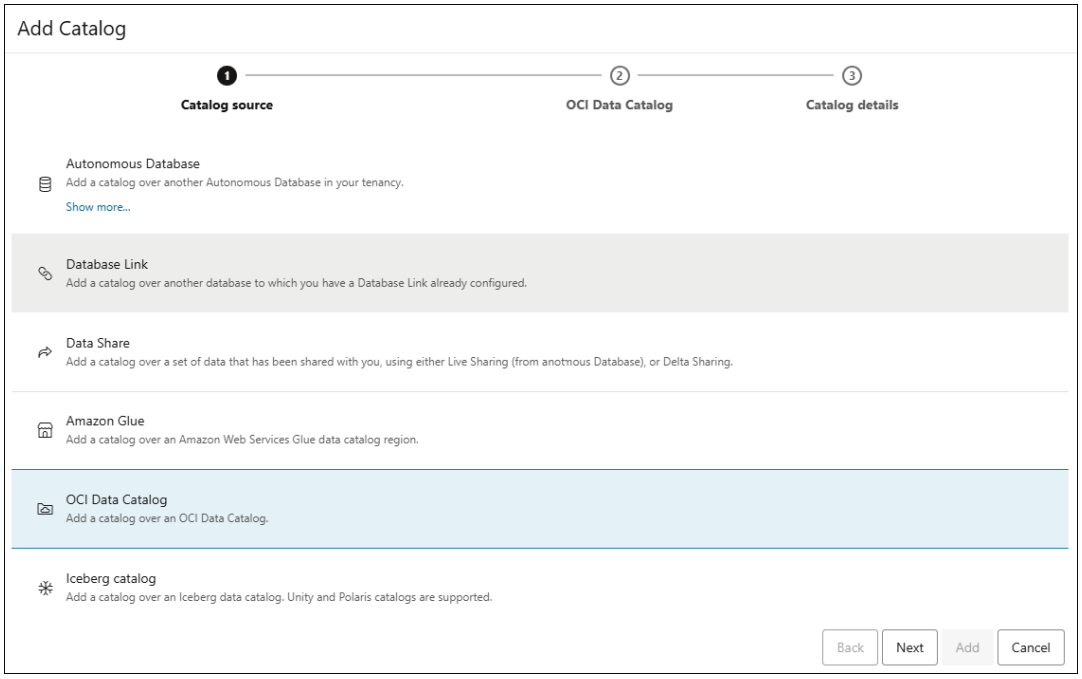
4. Click **Next** to proceed to the **Amazon Glue Catalog** tab.
5. On the **Amazon Glue Catalog** tab, specify the following details:
   - **Credential for Data Catalog Connection**: Select a credential from the drop-down.
   - **Region**: Select a region from the drop-down.
6. Click **Next** to progress to the **Catalog details** tab. Specify the following field values on the **Catalog details** tab:
   - **Catalog Name**: Enter the name that you want to use in Data Studio to refer to the catalog.
   - **Catalog Description**: Enter a description of the catalog.
7. Click **Create** to mount the AWS Glue Data Catalog region as a catalog.

After you have successfully mounted a new catalog over an AWS Glue Data Catalog region, you can select the catalog in Catalog Explorer and search for data in it.

Mount OCI Data Catalog as Catalog

You can mount catalogs from a registered OCI Data Catalog.

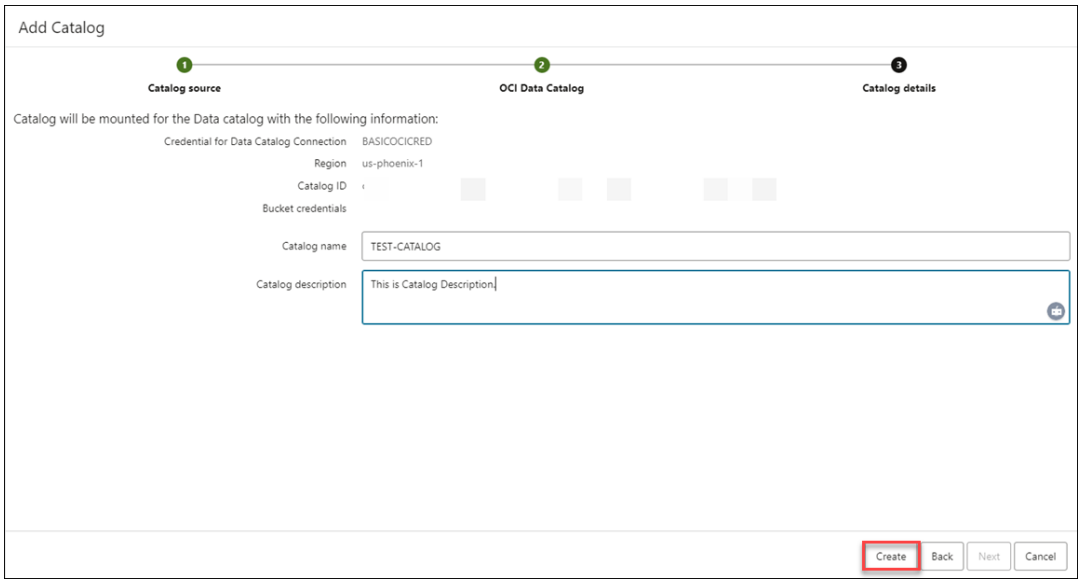
1. On the Catalog page, select **Manage Catalog**. Click **+Add**.
2. On the **Add Catalog** page, select **OCI Data Catalog** from Catalog Source.



3. Click **Next** to proceed to the **OCI Data Catalog** tab.
4. On the OCI Data Catalog tab, specify the following field values:
   - **Credential for Data Catalog Connection**: Select a credential from the drop-down. This field is mandatory. For example, *BASICOCICRED*.
   - **Region**: Select a region from the drop-down. This field is mandatory. For example, *us-phoenix-1*.
   - **Data Catalog ID**: Select a Data Catalog ID from the drop-down. A Data Catalog ID is the ID of the account to which the data catalog belongs. For example, *catalog1*.

     Select **Use separate credential for Object Storage** to use a different credential other than the selected one.

5. Click **Next** to progress to the **Catalog details** tab.
6. On the **Catalog details** tab, specify the following field values:
   - **Catalog Name**: Enter the name that you want to use in Data Studio to refer to the catalog. For example, *TEST_CATALOG*.
   - **Catalog Description**: Enter a description of the catalog.



7. Click **Create** to mount the OCI Data Catalog as catalog.

After you have successfully mounted a new catalog over an OCI Data Catalog, you can select the catalog in Catalog Explorer and search for data in it.

Mount a Catalog over an Iceberg Data Catalog

You can add a catalog over an Iceberg Data Catalog. Integrating a catalog with Iceberg data involves connecting with supported catalogs such as Unity and Polaris. To integrate Iceberg Data Catalogs via Data Studio, you need to ensure your Iceberg Catalogs are properly configured and accessible.

To configure and access your Iceberg Catalog, you must have the following:

1. **Iceberg Endpoint**: Set up Polaris or Unity Catalog using the Iceberg REST API. This involves specifying the catalog type, URI, and warehouse location. You will need the REST endpoint for your external Iceberg catalog. This is the URL that provides access to the Iceberg metadata.
   Example: *https://your-iceberg-catalog.com/api/v1/iceberg*
2. **Token Endpoint**: The */v1/oauth/tokens* endpoint is provided by Iceberg REST catalogs to issue **Bearer Token**.
3. **Client ID & Client Secret**: These are credentials provided by the OAuth server to identify your application (in this case, the Unity and Polaris Catalog integration). You will use these credentials to generate Bearer Token.
4. **Bearer Token**: To authenticate requests to the Iceberg REST endpoint, you will use OAuth with the Client Credentials. The Catalog tool calls the token endpoint to receive **Bearer Token**.

5. **Namespace**: A namespace is equivalent to a schema in a database. This location will serve as the repository for your Iceberg tables within the catalog. Iceberg catalogs group tables into namespaces, which can be nested within other namespaces. The Iceberg specification supports arbitrary levels of nesting.
   For example, a `SALES` table could be defined within a `STORES` namespace, which is defined in a `RETAIL` namespace, which is itself defined within a `CORPORATE` namespace. The Iceberg location of such a table would be `CORPORATE.RETAIL.STORES.SALES`.

The following is a sample configuration to create a REST Catalog integration that uses OAuth to connect to Apache Iceberg tables:

```
CREATE OR REPLACE CATALOG INTEGRATION tabular_catalog_int
  CATALOG_SOURCE = ICEBERG_REST
  TABLE_FORMAT = ICEBERG
  CATALOG_NAMESPACE = 'default'
  REST_CONFIG = (
    CATALOG_URI = 'https://api.tabular.io/ws'
    CATALOG_NAME = '<tabular_warehouse_name>'
  )
  REST_AUTHENTICATION = (
    TYPE = OAUTH
    OAUTH_TOKEN_URI = 'https://api.tabular.io/ws/v1/oauth/tokens'
    OAUTH_CLIENT_ID = '<oauth_client_id>'
    OAUTH_CLIENT_SECRET = '<oauth_secret>'
    OAUTH_ALLOWED_SCOPES = ('catalog')
  )
  ENABLED = TRUE;
```

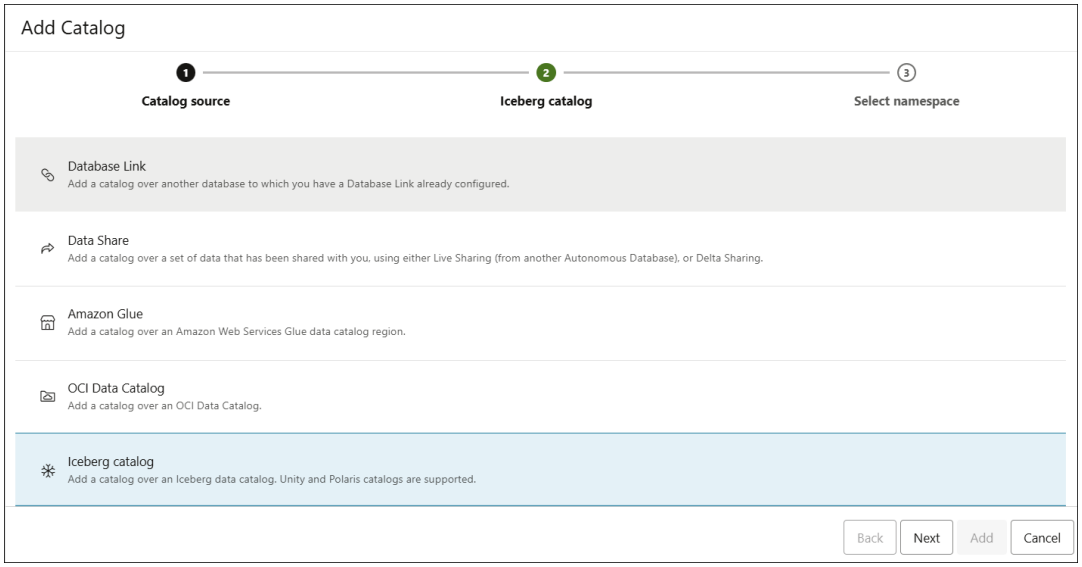
Here, `CATALOG_URI` is the REST end point to access the warehouse.

The `REST_AUTHENTICATION` procedure consists of all the parameters you need to create the `BEARER TOKEN` and use it to create the credential.

See Configure a catalog integration for Apache Iceberg™ REST catalogs for more information on this.

To mount a Polaris Catalog over an Iceberg Data Catalog:

1. On the Catalog page, select **Manage Catalog**. Click **+Add**.
2. On the **Add Catalog** dialog, select **Iceberg catalog** from the **Catalog source** tab.



Click **Next**.

3. Specify the following field values on the Catalog source tab of the Add Catalog dialog:

   - **Catalog name**: Enter the name of the Catalog you want to mount the Iceberg Catalog as.
     For example, *Polaris*.
   - **Iceberg catalog type**: Select *Polaris* from the drop-down field.
   - **Iceberg catalog endpoint**: It specifies your Polaris Catalog account URL. The endpoint for Snowflake's Polaris Catalog is usually in the format of *https://<account_locator>.snowflakecomputing.com/polaris/api/catalog*. For more information about account identifier formats, see the Snowflake documentation.
   - **Iceberg catalog credential**: Select a credential from the list of available credentials in the drop-down list. If you do not have a credential, you can create one. Select **Create Credential**. On the Create Credential dialog, specify the following field values:
     - Credential Name: Enter the name of your credential. For example, *POLARIS_CRED*.
       Under **Get New Bearer Token**,
       * **Access token end point**: Enter the Iceberg REST specification endpoint. This generates access token using OAuth2 defined as `/v1/oauth/tokens`. This endpoint was designed to facilitate authentication by exchanging client credentials (client ID and secret) for an access token.

         > **Note:**
         >
         > The `/v1/oauth/tokens` endpoint is deprecated in Iceberg version 1.6.0 and will be removed in version 2.0. You are encouraged to rely on external OAuth2 providers instead. See OAuth Authentication for more details.

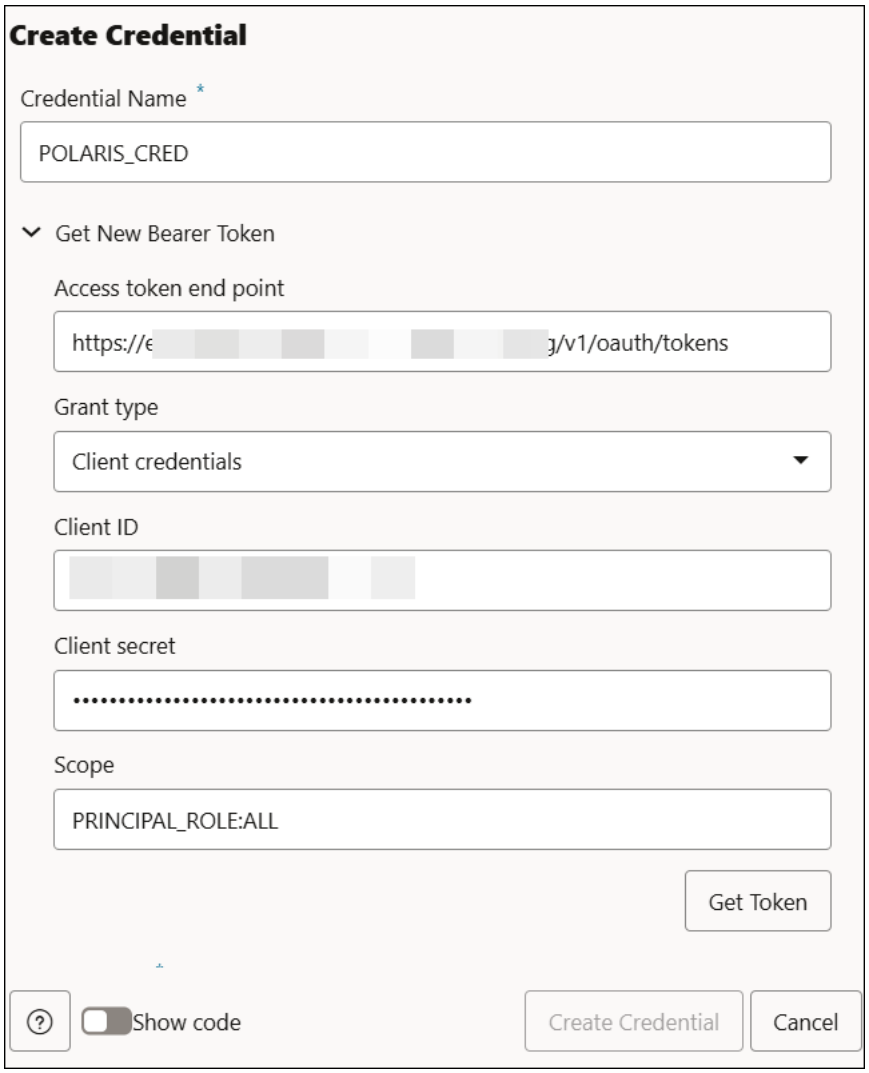
       * **Grant type**: Select *Client credentials*.
       * **Client ID**: Specify the Client ID.
       * **Client Secret**: Specify the Client Secret.

* **Scope**: *PRINCIPAL_ROLE:ALL*.
  Click **Get Token**.

  The **Bearer token** field gets populated.

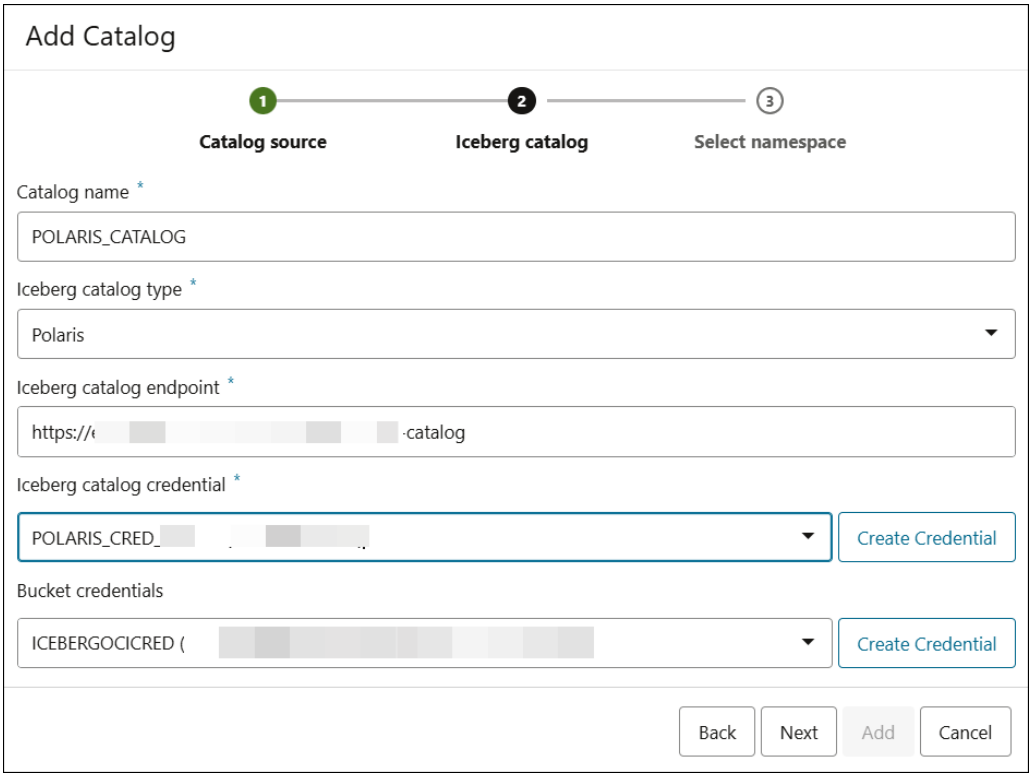
Click **Create Credential**.

POLARIS_CRED is displayed as Iceberg catalog credential.



> **Note:**
>
> The credentials are stored using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL` in the backend.
>
> For the sample example provided above, the procedure would be as follows:

```
BEGIN
  dbms_cloud.create_credential(
    credential_name  =>  'POLARIS_CRED',
    username         =>  'BEARER_TOKEN',
    password         =>  '<BEARER_TOKEN_VALUE This is
generated using token endpoint, client id, client secret>'
  );
END;
```



This credential allows the Oracle Autonomous Database to access the Iceberg table.

- **Bucket credentials**: This credential stores a cloud storage volume to store your Iceberg tables in Parquet format. This field is mandatory for Polaris catalogs.
  Click **Next** to proceed to the **Iceberg catalog** tab.

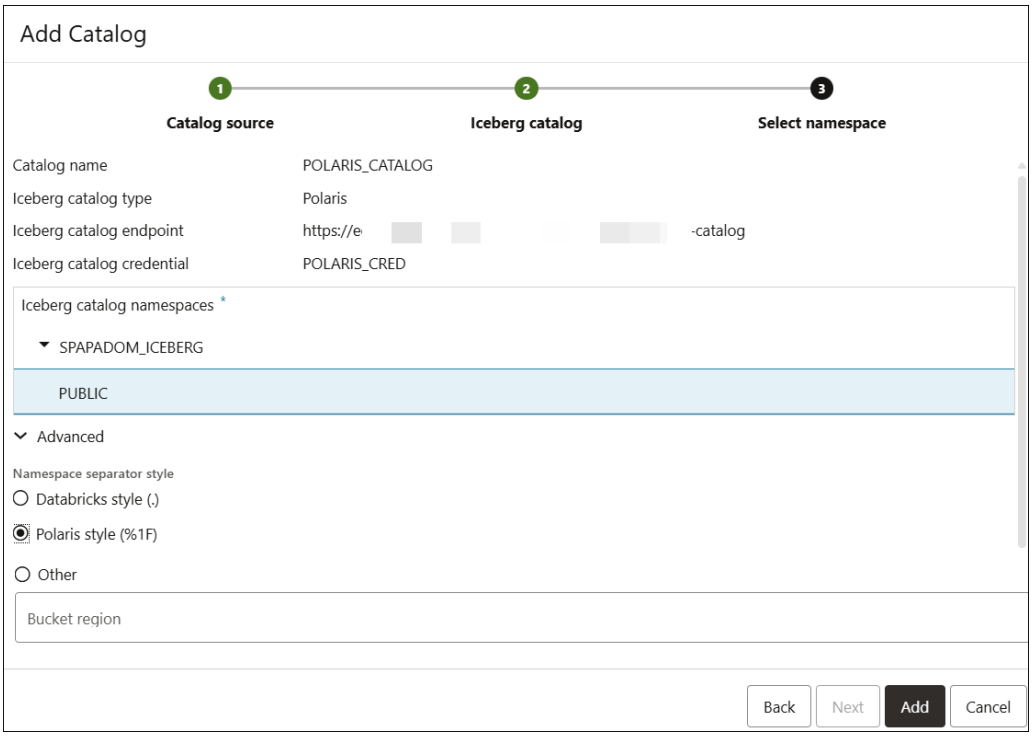
4. On the **Iceberg catalog** tab, you can specify the following field values:
   - **Iceberg catalog namespaces**: This field displays the hierarchical organization of tables. The **Iceberg catalog endpoint** consists of the root namespace. Select the namespace on which you want to have the catalog mounted.

- **Namespace separator style**: Select **Polaris style**. This is the default value. Select any value based on the way your catalog is configured.

  > **Note:**
  >
  > It is preferred that you retain the default value.

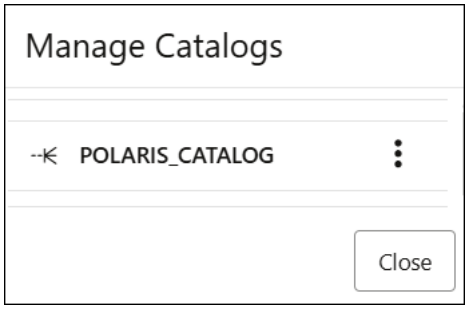
- **Bucket region**: Enter the bucket region. For example, *us-west-2*.
  Iceberg catalog endpoints, serve as interfaces for managing Iceberg tables stored in cloud storage like S3. The bucket region refers to the geographical location where the S3 bucket is hosted.

  This is mandatory field for Polaris catalogs.



Click **Add**.

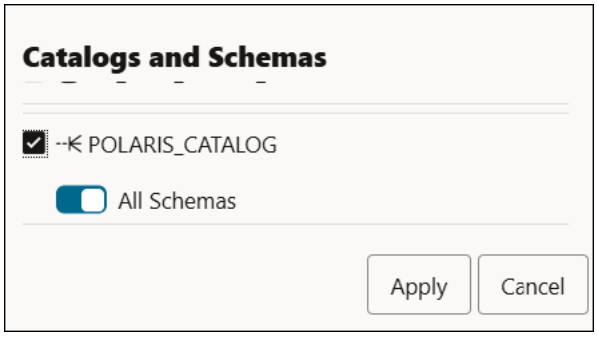
After you have successfully mounted a new catalog over an Iceberg Catalog, you can view the Polaris Catalog on the **Manage Catalogs** page. You can disable and delete the catalog from this page.



View the mounted Polaris Catalog on the Catalog Explorer

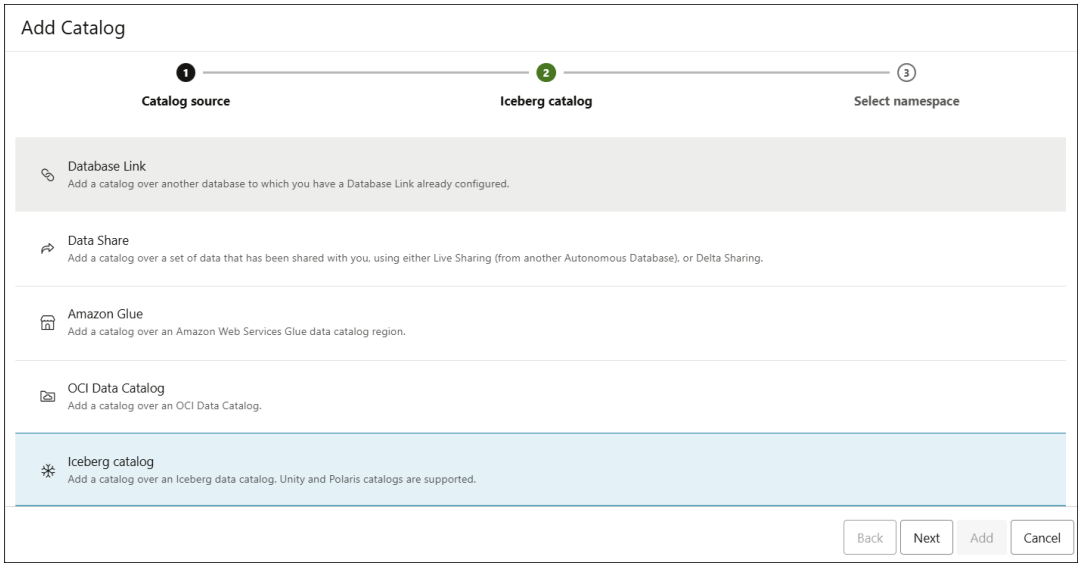
Once you have mounted the new catalog, you can load tables from the mounted catalog. To search for the catalog:

1. On the Catalog tool, click **Select Catalogs...**.
2. Click **POLARIS _CATALOG** filter on **Catalogs and Schemas** wizard to display the **POLARIS_CATALOG** catalogs.
3. Click **Apply** to view the results on the Catalog page.



To mount a Unity Catalog over an Iceberg Data Catalog:

1. On the Catalog page, select **Manage Catalog**. Click **+Add**.
2. On the Add Catalog dialog, select **Iceberg Catalog**.

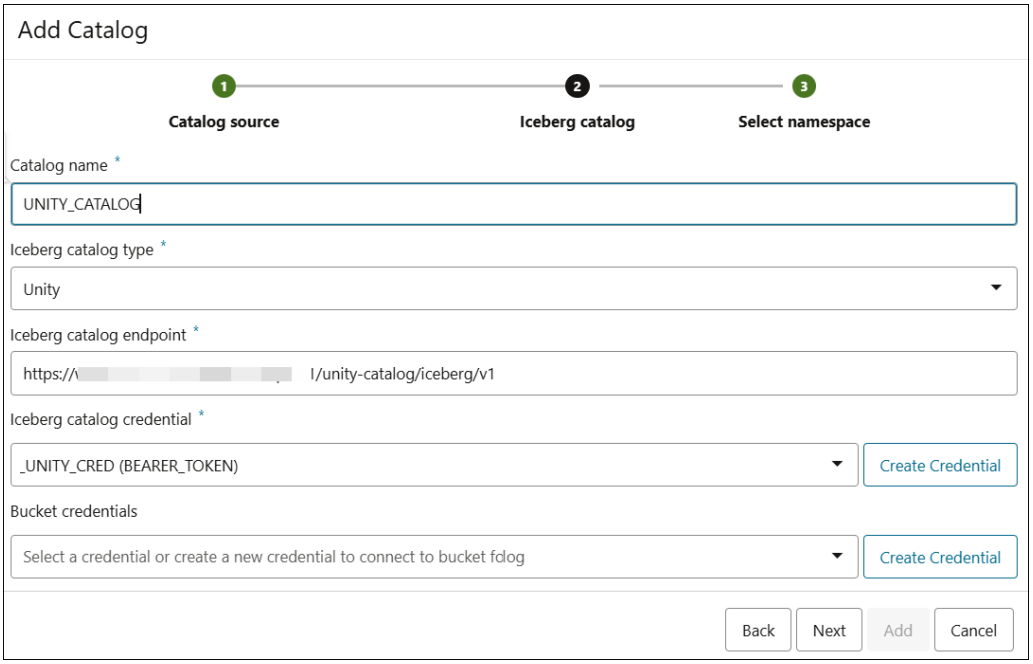


3. Click **Next**.
4. Specify the following field values on the Catalog source tab of the Add Catalog dialog:
   - **Catalog name**: Enter the name of the Catalog you want to mount the Iceberg Catalog as.
     For example, *Unity*.
   - **Iceberg catalog type**: Select *Unity* from the drop-down field.
   - **Iceberg catalog endpoint**:
     For Unity Catalog, you typically use the Databricks REST API. The endpoint for accessing Iceberg tables via Unity Catalog is usually in the format of *https://<databricks-instance-url>/api/2.1/unity-catalog/iceberg*.

     > **Note:**
     >
     > See https://docs.databricks.com/aws/en/external-access/iceberg for more information.

   - **Iceberg catalog credential**: Select a credential from the list of available credentials in the drop-down list. If you do not have a credential, you can create one. Select **Create Credential**.
     On the Create Credential dialog, specify the following values:
     – **Credential Name**: Enter the name of your credential. For example, *UNITY_CRED*.
     – **Bearer Token**: Paste the Bearer Token value.
       Select **Create Credential**.

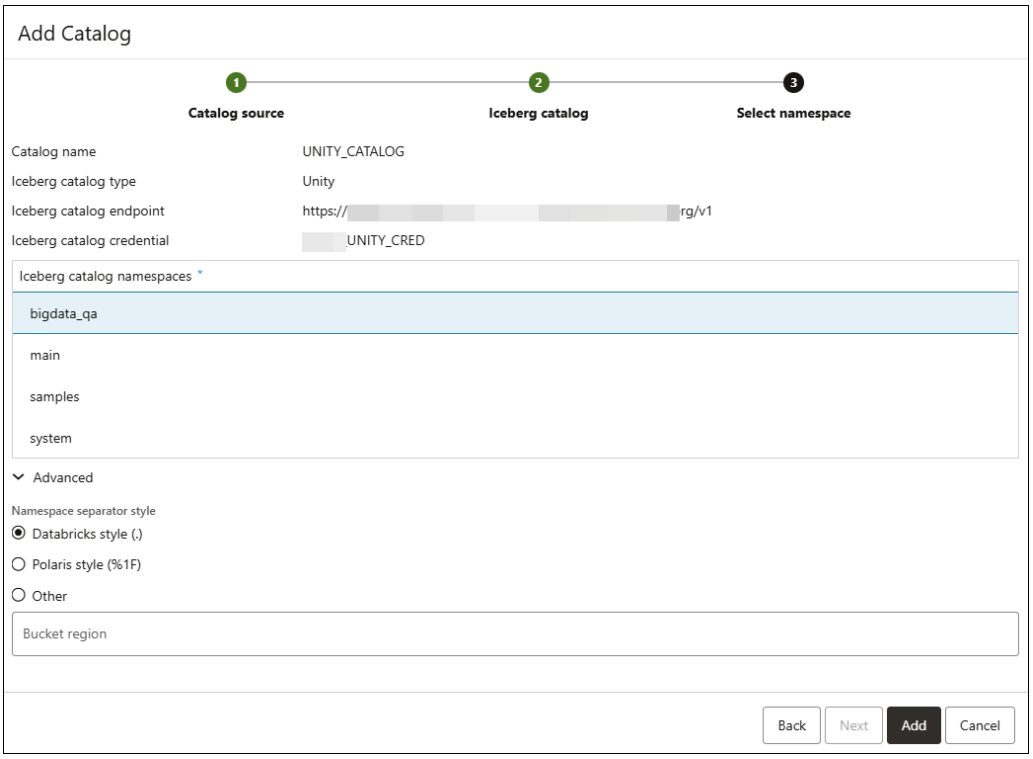
       UNITY_CRED is displayed as **Iceberg catalog credential**.



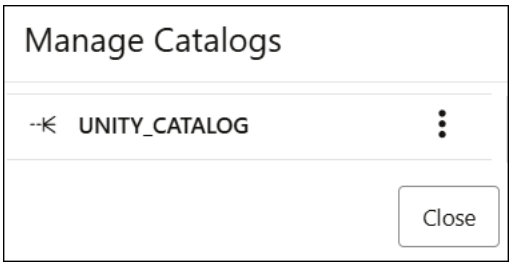
Click **Next** to proceed to **Iceberg catalog** tab.

On the **Iceberg catalog** tab, you can specify the following field values:

- **Iceberg catalog namespaces**: Select any one of the schemas you need access to.
- **Namespace separator style**: The namespace separator style typically refers to how namespaces are structured and separated within the catalog. By default, **Databricks style** is selected.
- **Bucket region**: This field is not mandatory.



Click **Add**.

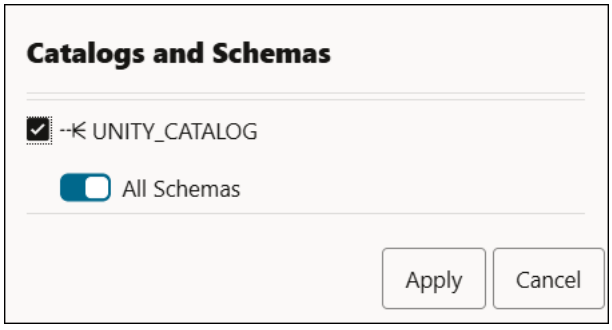


After you have successfully mounted a new catalog over an Iceberg Catalog, you can view the Unity Catalog on the **Manage Catalogs** page. You can disable and delete the catalog from this page.

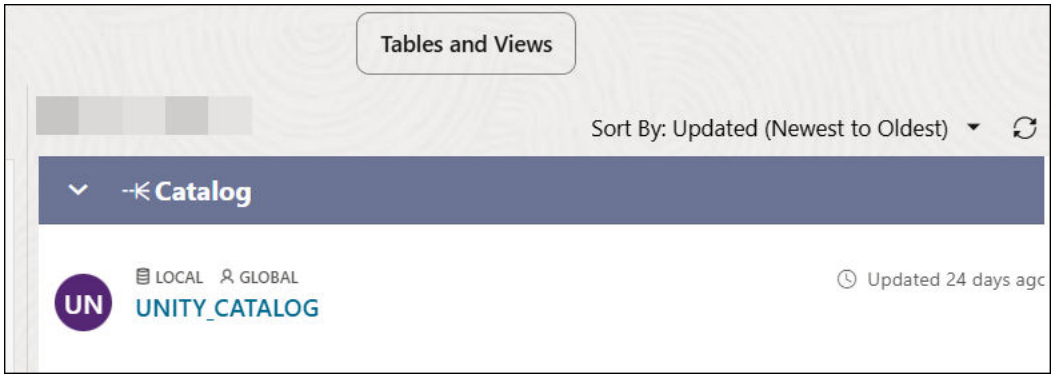
View the mounted Unity Catalog on the Catalog tool

Once you have mounted the new catalog, you can load tables from the mounted catalog. To search for the catalog:

1. On the Catalog tool, click **Select Catalogs…**.
2. Click **UNITY _CATALOG** filter on the **Catalogs and Schemas** wizard to display the **UNITY_CATALOG** catalogs.



3. Click **Apply** to view the results on the Catalog page.



- Inline Data Load of Delta Share from the Catalog Tool
  You can load a Delta Share from the Catalog tool without leaving the Catalog tool for loading.
- Query Remote Catalogs and Databases
  You can access and query external data by mounting catalogs. This feature uses a simple SQL syntax that is similar to how you query data using database links.

Inline Data Load of Delta Share from the Catalog Tool

You can load a Delta Share from the Catalog tool without leaving the Catalog tool for loading.

You need to first download your share profile to receive shares.

1. **Download your share profile**:
   For the data share you want to receive, download your profile sent from the share provider.
   - Open the invitation email you received from the data share provider, when the data share was published.
   - Copy the profile URL from the email.
   - Paste the URL into your browser and click **Get Profile Information**.
   - Your profile has been downloaded to your local machine. The Profile information downloaded message page is displayed.

   You can subscribe to the data share provider using the Catalog tool.

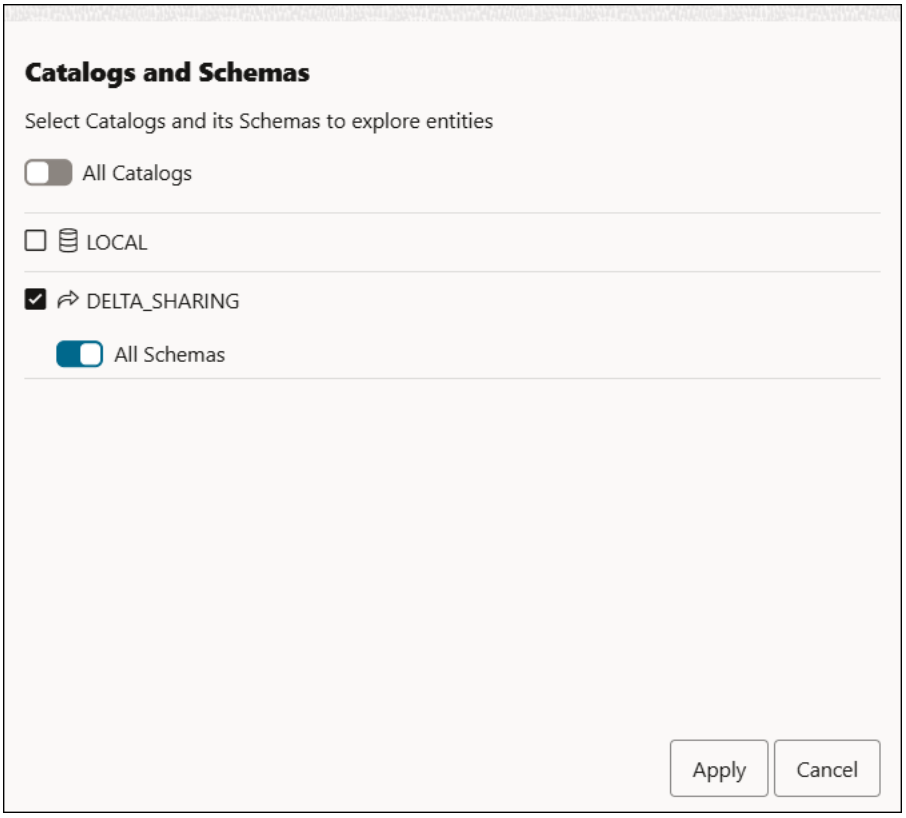
   To subscribe, you need to use the information contained in the uploaded JSON profile you received from the share provider.

From the **Manage Catalogs** feature of the Catalogs tool, you can upload the JSON profile and follow the Add Catalog wizard.

1. On the Data Studio menu of Database Actions, select the Catalog tool.
2. Select **Manage Catalogs**.
3. On the **Manage Catalogs** dialog, select **+Add**.
4. Mount Delta Share as catalog:

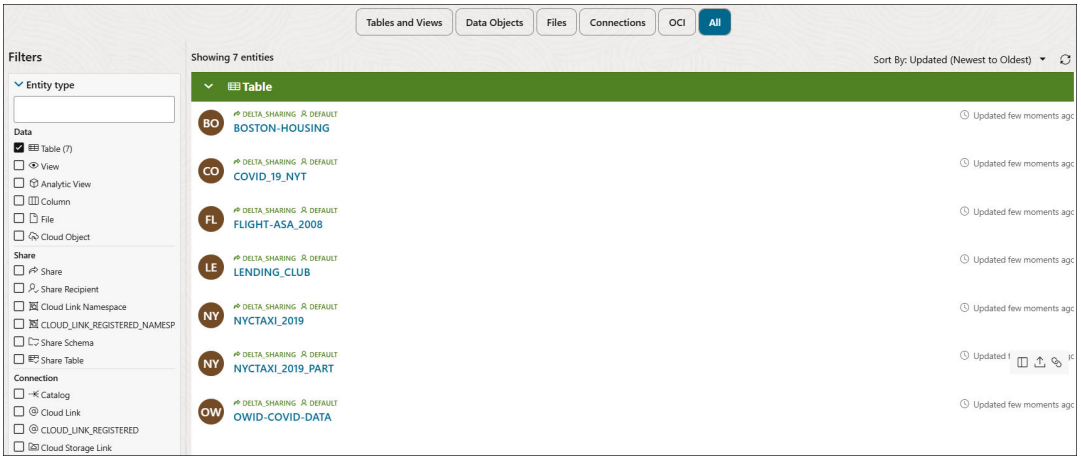
   Select **Data Share** as a Catalog Source on the Add Catalog dialog and click **Next**.
5. Select **Delta Share Provider JSON**, accept the **From File** default option, and click the **Delta Share Profile JSON** field.
   - Navigate to and select the **JSON profile** you downloaded in a previous step. Click **OPEN**.
   - Enter the **Provider Name**, under Share Provider Details and click **Next**.
6. Register shares made available to you.
   Move shares from **Available Shares** to **Selected Shares** and click **Next**.
7. Specify details of the Catalog:
   Enter the name of the Catalog and click **Create**.

   The Catalog page is displayed with a success message confirming that the Mounting Catalog for Shares was successful and that it has created the share provider.
8. View the newly created Delta share by filtering the results using the Select Catalogs…icon:
   - Click **Select Catalogs..**.
   - Select **Delta Sharing** from the **Catalogs and Schemas** wizard.

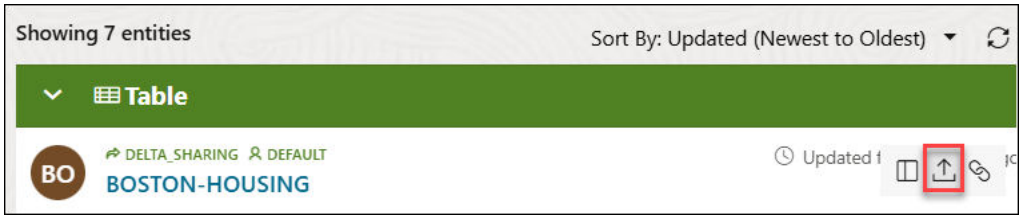


- Click **Apply** to apply the filter criteria in the search results.

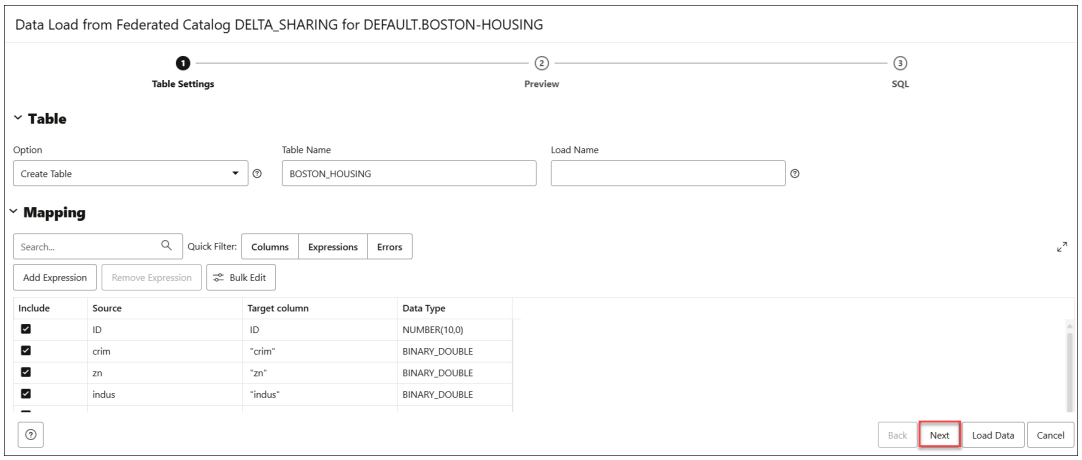
You will view all the tables listed from the Delta Share.



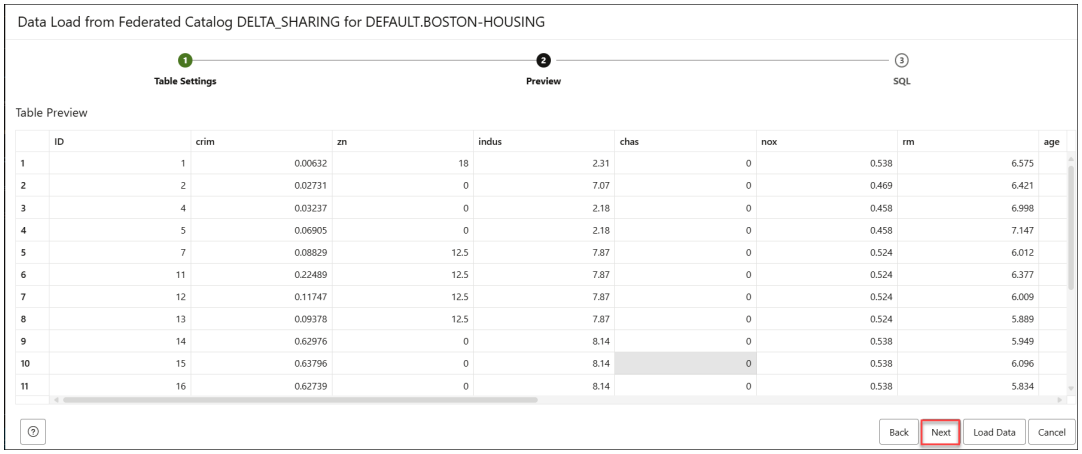
9. Select the table you want to load data from, then click **Load to table**.



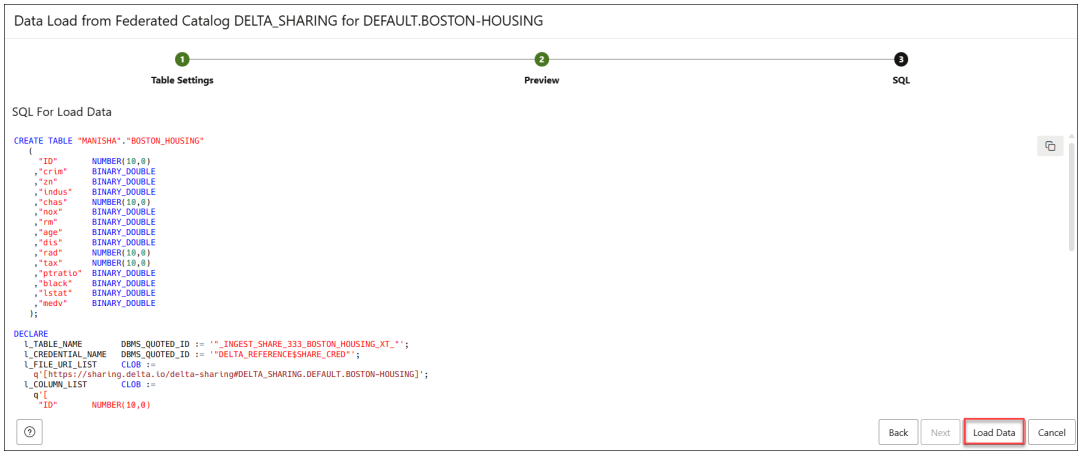
10. On the **Table Settings** of the Data Load dialog, you can specify processing options to specify settings for the data load job. You can also rename the newly created table from the catalog.



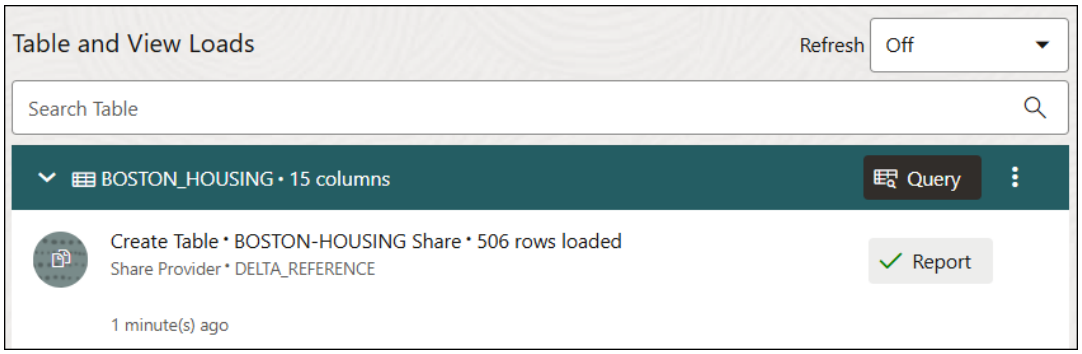
11. Click **Next** to view the data in the table.



12. Click **Next** to view the **Preview** tab to display the equivalent SQL code of the creating table job.



13. Select **Load Data**.
    A confirmation message is displayed that the data load job has started.
14. Navigate to the Data Load home page to view the progress of the data load job.



You have loaded data from Delta Share from the Catalog tool.

Query Remote Catalogs and Databases

You can access and query external data by mounting catalogs. This feature uses a simple SQL syntax that is similar to how you query data using database links.

The simplified SQL syntax makes it easy to discover and query external data without having to choose which external data to access, and without having to construct external tables or perform any other data integration tasks.

Refer to the Query External Data chapter for more information.

By querying remote catalogs and databases, you are accessing data directly from the external catalog in place, without having to move data into the Autonomous Database. This feature enables you to export data from the catalogs that the Autonomous Database can access without establishing multiple connections. You can query the Autonomous Database to see which external catalogs are available, what data is available for any given catalog, and you can query the data directly, from any SQL client. This involves providing a standard and simplified way to discover and query data sets connected to the Autonomous Database, leveraging the catalog's ability to present external data as standard Oracle schemas and tables.

Refer to the Manage Catalogs chapter for information on catalogs supported across various categories, including Databases, External Data Catalogs, Shares, and more.

Some of the key features are:

- **Discover External Data**: Using SQL, you can identify external catalogs along with the tables they contain. This will help you in understanding the available data structure.
- **Simplify Table Discovery**: Use existing query syntax and familiar views to easily list tables within an external catalog.
- **Integrate with data tools:** You can integrate the query data with Data Studio suite of tools to make informed decisions and gain deeper insights.

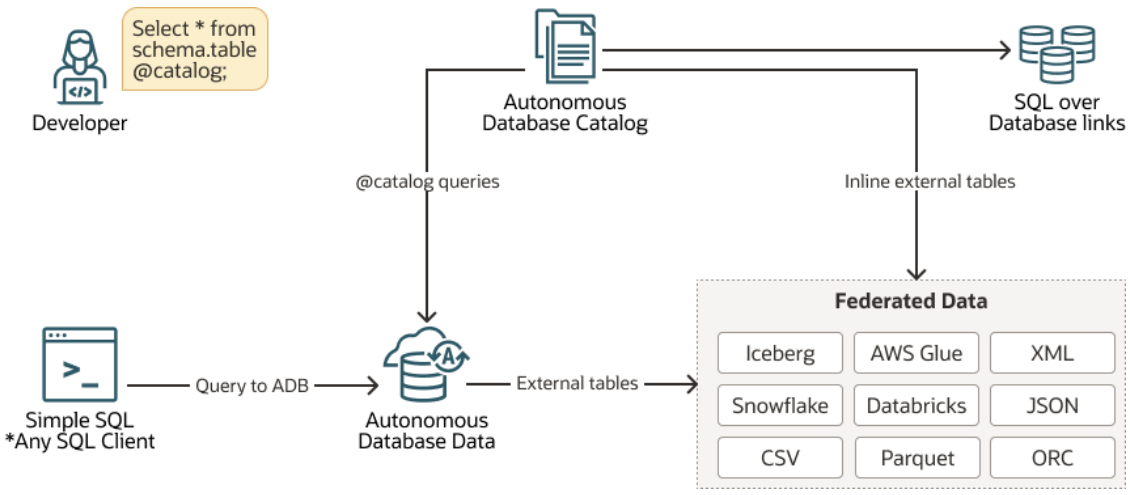
  This topic describes how to query external data using the catalog metadata using an SQL syntax of the form: `[schema].object@catalog_name`.
- Examples: List the Mounted Catalogs
  You will use this syntax in a SQL query.
- Examples: List the Tables in a Catalog, Including Their Owning Schemas
  To list all tables within a specific schema (catalog) from the enabled catalogs, you can use:
- Examples: Query Data from a Table in a Catalog
  To query data from a table in a specific catalog (schema), you must prepend the schema name to the table name.
- Examples: Query a Table from a Delta Share and Analyze the View
  Let's assume that we are working on an inventory database where we have data about the information collected by the U.S. Census Service concerning housing in the Boston area, and we need a query that returns the maximum value of the full-value property tax.

Conceptual Diagram of Querying Remote Catalogs

The following diagram displays the conceptual network diagram of querying remote catalogs using Autonomous Database:



Data from all types of external catalog can be queried this way including:

- **Database Links**: Data in other databases where a catalog is mounted over a database link.

  These catalogs are built using traditional database links, which are set up in advance by system administrators. The catalog tool autonomous database uses standard SQL queries on these links to discover tables and other objects.

  There are two types of database links: Oracle and Heterogeneous.

  For Oracle links, use queries like `SELECT table_name FROM all_tables@link`.

  For Heterogeneous links, similar queries are run, such as `SELECT table_name FROM all_tables@link`.
- **Glue Catalogs**: Data made available through AWS Glue, where a catalog is mounted over an AWS Glue region.
- **OCI Data Catalogs**: Data made available via OCI Data Catalogs. These catalogs use customer-defined credential objects to securely connect to OCI endpoints protected by ACLs.
- **Delta Share Catalogs**: Data that has been shared using the Delta Sharing standard from any system that can use this standard to share data, where a catalog is mounted over the share. These catalogs leverage External Table Delta Sharing support, which employs customer-defined credential objects to access delta sharing endpoints. The credential includes a bearer token for authentication.
- **Iceberg Catalogs**: Data made available through an Iceberg Data Catalog, such as Databricks Unity Iceberg Catalog, or Snowflake Polaris.

Concepts Related to Querying Remote Catalogs and Databases

An understanding of the following concepts is necessary for querying with Remote Catalogs:

- **Catalog**: A catalog is a metadata layer that organizes and describes data assets such as schemas and tables. It acts as a bridge between the database and external data sources. A catalog contains one or more schemas, and each schema can have multiple tables. These schemas and tables represent the logical organization of data.
- **External Catalogs**: they are catalogs that stores metadata for systems other than the locally connected ADB, including other ADBs, remote databases, shares, external data catalogs.
- **DB Links**: DB Links are a mechanism to connect to a remote database from an Oracle database. They allow you to access tables, views, and other objects in a remote database as if they were local objects. They enable querying data in remote databases. This feature aims to treat DB Links as a type of "catalog." The data dictionary of a remote database connected via a DB Link can be considered a catalog.
- **Mounting a Catalog**: A **mounted catalog** is one where the Autonomous Database has an active connection to the catalog, allowing the database to access and query its datasets. Oracle Autonomous Database supports mounting catalogs from external data sources like AWS Glue or Databricks.

About Querying Remote Catalogs and Databases

This topic describes how to query external data using the catalog metadata using an SQL syntax of the form: `[schema].object@catalog_name`.

Here the syntax `[schema].object@catalog_name` refers to a representation of accessing database objects

The table describes the parameters and their descriptions used in the syntax:

Parameters	Description
Schema	This field is optional, and it defaults to the current user. A schema is a namespace within a catalog that organizes related database objects such as tables, views, procedures, or functions. It acts as a logical container for these objects.
Object	This field refers to any database object contained within a schema, such as tables, views, procedures, or functions.
Catalog	The catalog field displays the name of the catalog with the referenced table. You can create and manage catalogs using the `DBMS_CATALOG` package or the Catalog Tool of the Data Studio suite of tools.

> **Note:**
>
> You can replace catalogs with **dbLinks** as well.

Accessing Remote Tables

To access a table from a remote schema using a catalog, you must follow these steps:

1. **Mount a Catalog**: Begin by mounting a catalog over any supported type of data store (e.g., Iceberg, Delta Lake, etc.). Mounting a catalog standardizes the metadata, enabling SQL access to external data as if it were tables within a schema in the catalog. Refer to Manage Catalogs for detailed steps on mounting catalogs. Once the catalog is mounted and metadata is standardized, you can directly query external data using SQL. Even if the external data does not physically exist as traditional tables, the catalog abstracts it into a tabular format for easy querying.
2. **Reference the table**: Once mounted, you can reference the remote table by specifying the schema and catalog (if applicable) followed by the table name using the following syntax: `[remote_schema].table@catalog`.

Here the `schema` in this identifier is the remote schema that contains the remote table. `Table`, in this case, is the table name in the remote catalog.

> **Note:**
>
> The user must have the appropriate credentials to access the specific table and catalog.

Key Points to Consider

- The feature is designed using the `DBMS_CATALOG` package installed in an ADB-S environment.
- DDL operations (e.g., `CREATE, ALTER, DROP`) are not allowed on remote databases via catalogs. If you do so, you may encounter an *"ORA-02021: DDL operations are not allowed on a remote database"* error.
- **Same name Restriction**: This feature enforces that for a given user, there cannot exist a DB link and a catalog with the same name.

In the subsequent chapters, you will learn how to:

- Display the list of Mounted Catalogs
- Display the list of tables in a Catalog, Including Their Owning Schemas
- Query data from a Table in a Catalog
- Query data using DBLinks

You will use SQL Worksheet Editor of Database Actions to run SQL queries. You must first connect to your Database Actions instance and select **SQL** under **Development** menu.

Prerequisites:

You will require an OCI account.

How are DBlinks different from Catalogs?

DBLinks: They are primarily used to connect and query another database directly using a syntax.

For example:

```
SELECT * FROM <schema_name>.<table_name>@<dblink_name>;
```

When a catalog is mounted over another database via a DBLink, there is no need to separately define metadata in the catalog because the DBLink syntax directly accesses the remote database objects. Essentially, the DBLink acts as a transparent connection to the remote database, allowing queries to run as if the data were local.

Catalogs: They serve as a metadata layer that can be mounted over different types of data stores, not only databases connected via DBLinks but also external data catalogs or data shares like Delta Share or Live Share providers. When a catalog is mounted over a non-database store, the `@catalog` syntax adapts queries to generate inline external tables, enabling access to external data without requiring a DBLink. This means catalogs abstract the metadata management and provide a unified interface for querying diverse data sources, including external ones.

Examples: List the Mounted Catalogs

You will use this syntax in a SQL query.

For example, to list the catalogs you mount, you could run the following command:

```
SELECT CATALOG_NAME,CATALOG_TYPE,IS_ENABLED FROM USER_MOUNTED_CATALOGS;
```

The output of the query lists the catalogs that you connect with.

After the connection, you can query the catalogs using the syntax mentioned above:

```
SELECT * FROM "DEFAULT"."BOSTON-HOUSING"@CATALOGNAME;
```

In the above example, *Catalogname* is a catalog you have mounted, and *BOSTON-HOUSING* is a table in that catalog.

Examples: List the Tables in a Catalog, Including Their Owning Schemas

To list all tables within a specific schema (catalog) from the enabled catalogs, you can use:

```
SELECT OWNER, TABLE_NAME FROM ALL_TABLES@CATALOGNAME;
WHERE OWNER = '<SCHEMA_NAME>';
```

Here, *ALL_TABLES* is the table name.

For example, to list tables in the `SH` schema (a sample schema available in Oracle Autonomous Database):

```
SELECT OWNER, TABLE_NAME FROM ALL_TABLES@CATALOGNAME;
WHERE OWNER = 'SH';
```

This query returns all tables owned by the specified schema.

> **Note:**
>
> In this example, you are listing tables in the `SH` schema of an external database.

Examples: Query Data from a Table in a Catalog

To query data from a table in a specific catalog (schema), you must prepend the schema name to the table name.

For example, querying data from the `SALES` table in the SH schema:

```
SELECT * FROM "SH"."SALES"@catalogname;
```

> **Note:**
>
> In this example, you are querying data in the `SH` schema of an external database.

If you are working with other schemas like `SSB`, you can similarly query their tables by specifying the schema name:

```
SELECT * FROM "SSB"."SALES"@catalogname;
```

> **Note:**
>
> In this example, you are querying data in the `SSB` schema of an external database.

Examples: Query a Table from a Delta Share and Analyze the View

Let's assume that we are working on an inventory database where we have data about the information collected by the U.S. Census Service concerning housing in the Boston area, and we need a query that returns the maximum value of the full-value property tax.

1. **Create an Oracle Delta Share provider and credential**:
   For creating a Delta Share provider, you typically need to interact with the Delta Sharing platform, which involves creating a credential suitable for use with delta share providers. In this example, you can create `DATABRICKS_PROVIDER`.

```
BEGIN
      dbms_share.create_or_replace_share_provider(
            provider_name=>   'DATABRICKS_PROVIDER',
            endpoint=>        'https://sharing.delta.io/delta-sharing');
      dbms_cloud.create_credential(
            credential_name => 'CREDENTIAL_NAME',
            username =>        'BEARER_TOKEN',
            password =>        '*********************************');
      dbms_share.set_share_provider_credential(
            'DATABRICKS_PROVIDER', 'CREDENTIAL_NAME');
   END;
   //
```

   The output of this procedure successfully creates a delta share provider.

2. **Mount a DB Share Catalog**:
   After creating credentials, you can mount the registered share provider from step 1 as a catalog to enable the catalog users to search and discover data from the share, and to query that data using SQL.

```
BEGIN
      dbms_catalog.mount_share(
                              catalog_name=>'databricks',
                              share_provider=>'databricks_provider',
                              share_name=>'delta_sharing');
      END;
    /
```

   The output of this procedure successfully creates a catalog integration that enables the Catalog tool to query tables stored in Databricks.

3. **Run a simple query**:
   You can now run a simple query on the table:

```
select max(tax) from "DEFAULT"."BOSTON-HOUSING"@catalogname;
```

   The output returns the maximum value of the full value of the property tax rate present in the table.

```
MAX(TAX)
----------
711
```

Viewing Entity Details

When you have found an entity you are interested in, you can click the entity to view its details, or click one of the other available actions from the menu that appears on the right hand side when you hover over that row.

The way you select the entity details can be set using the **Customize Themes** tab in the Catalog Settings menu.

To view details about an entity, click the **Actions** icon at the top right of the Table and View Loads header entry, then click **Table** and select **View Details**.

For all entities, the details include Lineage and Impact sections. The inclusion of other details, such as Preview and Statistics, varies by entity type.

Preview

Preview displays the data of the entity. For a table, the Preview displays the columns of the table and the data in those columns. You can sort the data in the column into ascending or descending order by clicking the up or down arrow to the right of the column name.

Describe

For an analytic view, the Describe tab has information about the entity, and displays the hierarchies, levels, level depth, dimension tables, level columns, and number of distinct values for a level.

Lineage

Lineage displays all known information about the upstream dependencies of the entity, and therefore how the entity was created and how it is linked to other entities.

For example, for a table that you created in your database, the lineage is just the table. For a table that you created by loading a CSV file from cloud storage, the lineage includes the ingest directive for the data load and the CSV file that is the source of the data.

Pointing to the name of an item in the lineage displays the table name, the application that created it, the type of entity, the path to it, and the schema it is in.

Arrows point from an entity to the entity that it derives from. For example, for a table created in a data load job, an arrow points from the table to the ingest job and an arrow points from the ingest job to the CSV file. If you point to an arrow, then a Links Information box appears that shows information about the relationship between the two entities.

To view more details about an item, click the Actions icon for the item, then click **Expand**. For a table, the columns of the table are displayed. Pointing to the name of the table or of a column displays the name, application, type, path, and schema of the table or column. To collapse the display, click the Actions icon, then click **Collapse**.

You can increase or decrease the size of the displayed objects by using the + (plus) and - (minus) keys. You can reposition the objects by grabbing a blank spot in the display and dragging vertically or horizontally.

The lineage for some entities, such as analytic views, is more complex. An analytic view entity deployed for a business model has links to columns in a fact table and to hierarchies. The fact table has links to attribute dimensions and, for a data load job, to an ingest directive for the job. The ingest directive has a link to the source file. The attribute dimensions have links to tables for the dimensions. Those tables have links to ingest directives that have link to source files.

Impact

Impact shows all known information about the downstream use of an entity, and therefore how a change in the definition of an entity may affect other entities that depend on it. For example, if a table is used in an analytic view, a change to one of the column definitions in the table may affect the mapping from that column to the analytic view.

Classifications

For an analytic view and its attribute dimensions, hierarchies, and measures, the Classifications tab displays classifications and their values. Classifications are metadata that applications can use to present information about analytic views. When creating a business model, you may specify the values for the Caption and Description classifications.

Optimize

For an analytic view, the Optimize tab has information about caches created for the analytic view. A cache may exist if the advanced option Enable Autonomous Aggregate Cache was selected for the business model for which the analytic view is deployed.

Statistics

Statistics display information about the entity. For example, the statistics for a table include the size of the table and the numbers of rows and columns. They also include the names of the columns, their data types, the number of distinct values and null values, the maximum and minimum values, and other information.

The data is represented in the form of histogram which is column statistic which provides more detailed information about data distribution in a table's columns.

The histograms in the statistics pane can be representative of the following types:

- Frequency: In a frequency histogram, each distinct column value corresponds to a single bucket of the histogram. Since each value has its own dedicated bucket, some buckets may have many values, whereas others have few.
- Top-frequency: A top frequency histogram is a variation on a frequency histogram that ignores non-popular values that are statistically insignificant
- Height-Balanced: In this histogram, column values are divided into buckets so that each bucket contains approximately the same number of rows.
- Hybrid: A hybrid histogram combines characteristics of both height-based histograms and frequency histograms. This approach enables the optimizer to obtain better selectivity estimates in some situations.

Refer to Gathering Statistics for Tables section for more details.

Job Report

Displays a report of the total rows loaded and failed for a specific table.

The report displays of the total rows loaded and failed.

You can view the name of the table, the time the table was loaded and the time taken to process the load.

Data Definition

Data Definition displays the Oracle Autonomous Database DDL that created the entity.

You can view the following **Entity Types** from the drop-down:

- All
- Table
- View
- Analytic View
- Table,View,Analytic View
- Analytic Dashboard
- Attribute (Attribute Dimension)
- Attribute (Hierarchy)
- Attribute Dimension
- Cloud Link (Cloud Link Namespace)
- Cloud Link Namespace
- Cloud Object (Cloud Storage Link)
- Cloud Object (Data Catalog Asset)
- Cloud Object (Share Link)
- Cloud Storage Link
- Cloud Virtual Object (Cloud Storage Link)
- Column (Table)
- Column (View)
- Data Catalog Asset
- Data Catalog Link
- Database Link
- Directory
- External Location
- File (Directory)
- Function
- Hierarchy
- Ingest Job
- Level (Attribute Dimension)
- Level (Hierarchy)
- Live Table Feed
- Measure (Analytic View)
- Mining Model
- Package
- Procedure
- Schema
- Share
- Share Link

- Share Provider
- Share Recipient
- Share Schema (Share)
- Share Table (Share Schema)

Table Entity Details
Click the **Actions** icon next to **Table** entity to perform the following operations:

- Select **View Details** to view details about the table.
- Select Gather Statistics to display new statistics after you modify the table's structure. Refer to the Gathering Statistics for Tables for more detailed information. You can also gather statistics using the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Add to Share** to share the table. Refer to Provide Share for detailed information. You can also share the selected table using the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Register to Cloud Link** to register the table for remote access for a selected audience you define. See Registering Cloud Links to Access Data section for more information. You can also register the selected table using the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Create Analytic View** to create an Analytic View from the selected associated table. See Creating Analytic Views. You can also create an Analytic View from selected table using the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Query** to analyze the selected table in the Data Analysis tool. Refer to The Data Analysis Tool for more information. You can also analyze the selected table using the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select Export Data to Cloud to export data to a cloud object store. You can also export data from the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Edit** to edit the properties of the table. Refer to Editing Tables for more information. You can also edit properties of the selected table from the **Actions** drop-down field while viewing the table details in the Table Entity wizard.
- Select **Drop** to delete the table.

View Entity Details

Click the **Actions** icon next to **View** entity to perform the following operations:

- Select **View Details** to view details about the view.
- Select **Add to Share** to share the table. Refer to Provide Share for detailed information.
- Select **Create Analytic View** to create an Analytic View from the selected associated table. See Creating Analytic Views.
- Select **Query** to analyze the selected table in the Data Analysis tool. Refer to The Data Analysis Tool for more information.

Share Entity Details

Click the **Actions** icon next to **Share** entity to perform the following operations:

- Select **View Details** to view details about the share.

- Select **Objects** to view the **Select Tables** dialog of the specific share where you can remove tables from the list of Shared Tables list or add tables from the list of Available Tables list to the list of Shared Tables.
- Select **Recipients and Profiles** to view the **Recipients and Profiles** dialog which enables you to create a new share recipient. You can also revoke the recipient right from the share by clicking X next to the recipient name. The Recipients and Profiles dialog enables you to update the list of recipients, copy profile activation link, send an activation mail to the selected recipient.
- Select **Manage Versions** to
- Select **Jobs** to view the **Jobs** table and see information related to it. A job is created whenever something needs to happen to a share. This includes the following:
  - PUBLISH VERSIONED SHARE
  - PUBLISH LIVE SHARE
  - DROP SHARE VERSIONS
- Select **Scheduling** to
- Select **Publish**
- Select **Unpublish**
- Select **Delete**

Share Recipient Entity Details

Click the **Actions** icon next to the **Share Recipient** entity to view the share recipient entity details.

- Select **Granted Shares** to open **Manage Granted Shares** dialog where you can grant access to a share from list of available shares or you can revoke access from the current selection of share..
- Select **Get Bearer Token** to open an Auth Token dialog to authenticate the recipient. Use this option when your token expires. This enables you to generate a new token. A Bearer Token is part of the JSON file.
- Select **Copy Profile Activation Link** to copy the JSON profile activation link to clipboard.
- Select **Rename** to rename the Recipient.
- Select **Delete** to delete the recipient you created entirely. By doing so, access to all shares will end instantly and any existing delta credentials will become invalid.

Cloud Storage Link Entity Details

Click the **Actions** icon next to **Cloud Storage Link** entity to perform the following operations:

- Select **View Details** to view details about the table.
- Select **Objects** to view objects available in the selected storage link. You can click a file on the navigator pane to view it on the display area.
- Selecting **Link Tables** opens the Link Data page on the Data Load tool with the selected cloud storage link on the Cloud Location URL field. You can link data present in the cloud storage to the Autonomous Database. See Linking to Objects in Cloud Storage.
- Selecting **Load Tables** opens the Load Data page on the Data Load tool with the selected cloud storage link on the Cloud Location URL field. You can load data present in the cloud storage to the Autonomous Database. See Loading Data from Cloud Storage.

- Selecting **Create Live Table Feed** opens the Create Live Table feed wizard with he selected cloud storage link on the Cloud Location URL field. See Feeding Data to view more details.
- Select **Edit** to update any details on the cloud storage location. See Managing Connections to view details on creation of cloud storage location.
- Select **Rename** to rename the cloud store location to a different name.
- Select **Delete** to delete the cloud store location.

Catalog Entity Details

Click the **Actions** icon next to **Catalog** entity to perform the following operations:

- Select **View Details** to view more details about the catalog.
- Select **Disable** to disable the catalog.
- Select **Delete** to delete the catalog.

Data Catalog Link Entity Details

Click the **Actions** icon next to **Data Catalog Link** entity to perform the following operations:

- Select **View Details** to view more details about the data catalog link.
- Select **Edit** to edit the data catalog.
- Select **Rename** to rename the data catalog.
- Select **Delete** to delete the data catalog.

Database Link Entity Details

Click the **Actions** icon next to **Database Link** entity to perform the following operations:

- Select **View Details** to view more details about the database link.
- Select **Load to table** to load the database link to a table.
- Select **Link to table** to link the database link to a table.
- Select **Mount as catalog** to mount the database link as catalog.
- Select **Delete** to delete the database link entity.

Live Table Feed Entity Details

Click the **Actions** icon next to **Live Table Feed** entity to perform the following operations:

- Select **View Details** to view more details about the live table feed.
- Select **Edit Live Table Feed** to view the Edit Live Table Feed wizard where you can edit the live table.
- Select **Delete Live Table Feed** to delete the Live Table Feed.
- Select **Run Live Table Feed Immediately(Once)** to run the live table feed.

Share Provider Entity Details

Click the **Actions** icon next to **Share Provider** entity to perform the following operations:

- Select **View Details** to view the share provider entity details..
- Select **Manage Shares** for Share provider dialog box. This lists the shares you select to share with the recipient. You can edit the list of shares you wish to share with the recipient.

- Select **Rename** to renames the Provider Name.
- Select **Delete** to remove the Share Provider Entity.
- Select **Load to table** to view the Load Data page with the Share tab selected.
- Select **Link to table** to view the Link Data page with the Share tab selected to view and run the related link object. Drag and drop the shared data to add it to the data link job.
- Select **Copy Endpoint** to copy the share endpoint.

Bucket Entity Details

Click the **Actions** icon next to **Bucket** entity to perform the following operations:

- Select **View Details** to view details of the bucket entity.
- Select **Create Cloud Storage Link** to create cloud storage link.

Compartment Entity Details

Click the **Actions** icon next to **Compartment** entity to perform the following operations:

- Select **View Details** to view details of the compartment entity.
- Select **Create Share Recipient** to create a share recipient.

> **Note:**
>
> **Some catalog entity types do not have details screens**
>
> There are certain items in the catalog that do not have detail screens yet, thus clicking on them might not provide more details.

- Autonomous Database Entity Details
  You can mount additional catalogs from other Autonomous Databases in the same tenancy.

Autonomous Database Entity Details

You can mount additional catalogs from other Autonomous Databases in the same tenancy.

Before selecting whether or not to mount a catalog, you can browse the databases using the catalog to get additional information about each one.

Click **All** filter from the top and select **Autonomous Database** from OCI faceted filter panel in the left.

Selecting the above options lists all the autonomous databases in your tenancy.

You can view details about the database and launch the following applications from the **Database actions** drop-down field in the **Autonomous Database Entity** dialog box:

- Database Transforms
- Graph Studio
- APEX
- Machine learning notebook

- Machine learning user management
- Mongo Database
- ORDS
- SQL Developer

You can hover over the autonomous database whose details you want to view.

Click **Actions** next to the Autonomous Database entity and select **View Details** to view the following details:

General

The General tab displays the tenancy details, backup and recovery information, and network and maintenance details of the selected autonomous database.

Under **General Information**, you can view:

- **Database Name**: You set the database name when you provision a database or when you rename a database.
- **Workload Type**: The Autonomous Database supports different workload types, including: Data Warehouse, Transaction Processing, JSON Database, and APEX Service.
- **Compartment**: When creating a compartment, you must provide a name for it (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores) that is unique within its parent compartment. Oracle will also assign the compartment a unique ID called an Oracle Cloud ID.
- **OCID**: It displays the Oracle Cloud ID. See Resource Identifiers for more information.
- **Created**: Displays the date when the autonomous database was created.
- **License type**: The License type field shows on the Autonomous Database Information tab when you enable the Bring Your Own License (BYOL) option. This field shows your license and Oracle Database Edition.
- **Database Version**: Specifies the version of the Database.
- **Lifecycle State**: You can view availability information for an autonomous database instance in this field.
- **Instance type**: You can view the instance details of the autonomous database.
- **Character Set**: The Autonomous Database default database character set is Unicode `AL32UTF8` and the default national character set is `AL16UTF16`. When you provision a database, depending on the workload type, you can select a database character set and a national character set.
- **Mode**: You can select any of the following autonomous database operation modes:
  - Read/Write
  - Read-Only
  - Restricted

  The default mode is Read/Write.

Under **Resources** you can view:

- **Compute**: This field displays the autonomous database instance ECPU count (OCPU count if your database uses OCPUs).

Under **APEX** you can view, **instance name** that displays the autonomous database instance you use to create an APEX Service instance using an OCI.

Under **Data Safe** you can view, **Status** field that displays if you have registered the autonomous database with Oracle Data Safe. Oracle Data Safe, which is included with Autonomous Database, provides a unified control center that helps you manage the day-to-day security and compliance requirements of Oracle Databases.

Under **Disaster Recovery**, you can view:

- **Role**: Each autonomous database has a designated role: primary, standby, or snapshot standby.
- **Local**: If there is a local peer database, Autonomous Data Guard standby, this field shows the local standby's availability domain. See Use Standby Databases with Autonomous Data Guard for Disaster Recovery for more information.
- **Cross-region**: Displays if cross-region Autonomous Data Guard is enabled by provisioning a remote standby instance.

Under **Backup**, you can view:

- **Automatic backup retention period**: The backup retention period specifies how many days automatic backups are retained and the period for which you are billed for the automatic backups that are retained. If you change the backup retention period to a shorter period and automatic backups exist that are older, you are no longer billed for the automatic backups with timestamps beyond the specified retention period.
- **Total backup storage**: Displays the total storage being billed, including for automatic backups and if there are long-term backups, this also includes the long term backup storage.
- **Last Automatic backup**: Shows the timestamp of the last automatic backup.
- **Next long term backup**: When you configure scheduled long-term backups, this field displays the timestamp for the next long-term backup.
- **Long term backup schedule**: Displays the long-term backup schedule, with links to edit or delete a long-term backup schedule.

Under **Network**, you can view:

- **Access type**: Displays the specified access type for the Autonomous Database instance.
- **Access control list**: This field displays if Access Control Lists (ACLs) of an Autonomous Database Instance are defined. It can display the following two values:
  - **Enabled**: The field displays Enabled when ACLs of the Autonomous Database Instance are defined.
  - **Disabled**: The field displays Disabled when ACLs of the Autonomous Database Instance are not defined.
- **Mutual TLS(mTLS) authentication**: Displays if your Autonomous Database instance is configured to only allow mTLS connections.

Under **Maintenance**, you can view:

- **Patch level**:You can view Autonomous Database patch information.
- **Next maintenance**: This field in the Oracle Cloud Infrastructure Console reflects a maintenance window date and time based on the patch level.

- **Customer contacts**: When customer contacts are set, Oracle sends notifications to the specified email addresses for Autonomous Database service-related issues.

Under **Encryption**, you can view the **Encryption key** field that displays the master encryption key the Oracle Autonomous Database creates.

Lineage

Lineage displays all known information about the upstream dependencies of the entity, and therefore how the entity was created and how it is linked to other entities.

For example, for an autonomous database that you create, the lineage is just the cloud. For an autonomous database you create from cloud storage, the lineage includes the ingest directive for the load and the cloud object store path that is the source of the database.

Pointing to the name of an item in the lineage displays the database name, the application that created it, the type of entity, the path to it, and the schema it is in.

Arrows point from an entity to the entity that it derives from.

You can increase or decrease the size of the displayed objects by using the + (plus) and - (minus) keys. You can reposition the objects by grabbing a blank spot in the display and dragging vertically or horizontally.

Impact

Impact shows all known information about the downstream use of an entity, and therefore how a change in the definition of an entity may affect other entities that depend on it.

Click **Actions** next to the Autonomous Database entity and select **+ Create Database Link** to create database links from the Autonomous Database. See Load Data from Oracle and Non-Oracle Databases using Database Links.

Click **Actions** next to the Autonomous Database entity and select **Create Share Recipient** to create share recipient from the Autonomous Database. See Create Share Recipient to create a share recipient from the Autonomous Database.

Registering Cloud Links to Access Data

Cloud Links enable you to remotely access read only data on an Autonomous Database instance.

You can register a table for remote access for a selected audience. Scope indicates who can remotely access the data. Scope can be set to various levels, including to the region where the database resides, to individual tenancies, or to compartments. You can provide a namespace and a name other than the original schema and object names. For example, you can register a table under the namespace FOREST and for security purposes or for naming convenience, you can provide a namespace and a name other than the original schema and object names.

To register a table to cloud link, click Actions next to the Table entity and select **Register to Cloud Link**.

Specify the following field values:

- **Cloud Link Namespace**: Enter a namespace to register the table. For example, ADMIN.
- **Cloud Link Name**: Enter a name for the cloud link. For example, Sales.
- **Description**: Specify the description of your cloud link.
- **Scope**: Specifies who and from where a user is allowed to access the registered table.

You can choose from any of the following available options:

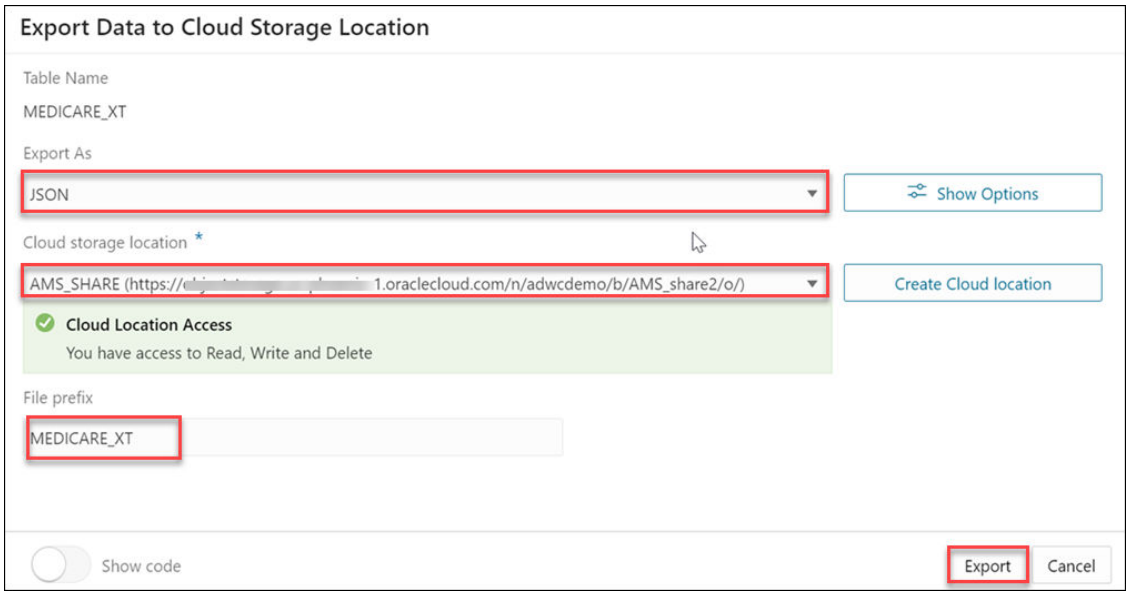
- **MY$REGION**: You can grant remote data access to other tenancies in the region of the Autonomous Database instance that is registering the data set. This is the least restrictive scope.
- **MY$TENANCY**: You can grant remote data access to any resource, tenancy, compartment, or database in the tenancy of the Autonomous Database instance that is registering the data set. This scope is more restrictive than MY$REGION scope.
- **MY$COMPARTMENT**: You can grant remote data access to any resource, compartment, or database in the compartment of the Autonomous Database instance that is registering the data set.
- **OCID**: Access to the data set is allowed for the specific Autonomous Database instances identified by OCID.

Click **OK** to finish the registration of the selected table with the cloud link.

Export Data to Cloud

Use the **Export Data to Cloud** menu in the table actions of the Browse Catalog page to export data as text from an Autonomous Database to a cloud Object Store. The text format export options are CSV, JSON, Parquet, or XML.

To export data to a cloud storage location, click **Actions** next to the Table entity on the Browse Catalog page and select **Export Data to Cloud**.



The Export Data to Cloud Storage Location displays the following fields:

- **Table Name**: This field displays the table name.
- **Export As**: This drop-down displays the list of format options you wish to export the data. You can select CSV, JSON, Parquet, or XML. When you export the data as **CSV**, and click **Show Options**, you can:
  - Set the maximum file size value using the slider. The maximum file size you can export is from 10MB to 1GB.
  - Select the **header** option to write column names as the first line in output files.

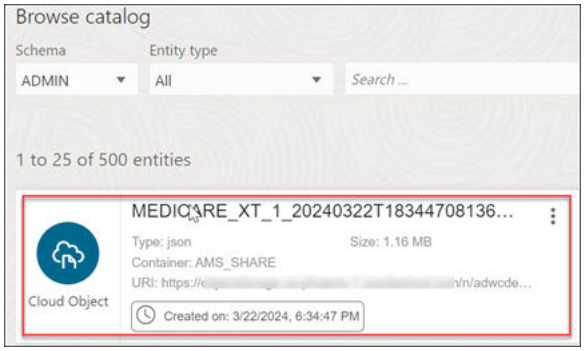
  - Select the **Escape** option to specify the occurrence of the quote character in the field value using the “\” character.
  - **Text Enclosure and Field delimiter**: These options are visible only when the selected file is in CSV format. Select or enter the character used in the source file for text enclosure and field delimiter.
  - **Compression**: Select **No Compression** to disable compression or **GZIP** to enable GZIP compression for selected file.
- **Cloud storage Location**: Select the uri value to the URL for an existing bucket on your Cloud Object Storage from the drop-down. If you do not have a cloud storage location, select **Create Cloud Location** to create a cloud storage location to export your data. For more details, see Create Credentials.

> **Note:**
>
> The Cloud storage location is highlighted in red if the tool doesn’t accept the selected cloud location. In this case, you will receive a Cloud Location Access Error that says “`You do not have access to Read, Write and Delete`”.

- **File prefix**: Specify the File prefix. This will be the prefix of the file you export.

Click **Export**.

After the file export is complete, you will view the newly created cloud object in the entity list of the Browse Catalog page.



Gathering Statistics for Tables

You can generate statistics that measure the data distribution and storage characteristics of tables.

You must gather statistics periodically for tables where the statistics become stale over time because of changing data volumes or changes in column values. The Gather Statistics icon gathers new statistics after the table’s structure are modified in ways that make the previous statistics inaccurate. For example, after loading a significant number of rows into a table, collect new statistics on the number of rows. After updating data in a table, you do not need to collect new statistics on the number of rows, but you might need new statistics on the average row length.

Table Statistics also include column statistics. The statistics you generate include the following:

Table statistics:

- **Table Size**: Specifies the size of the table in bytes.
- **Number of rows**: Displays the number of rows in the table.
- **Number of columns**: Displays the number of columns in the table
- **Compressed size**: Displays the size of compressed table in bytes.
- **Statistics gathered on**: Displays date and time of last statistics gathered.

Column Statistics

- Number of distinct values (NDV) in column
- Number of nulls in column
- Data distribution (histogram)

The above information is displayed in the statistics details of tables.

Editing Tables

You can create and edit objects using Edit Table wizard available from the **Edit** menu in **Actions** (three vertical dots) besides the table entity.

Clicking **Edit** from the Actions menu opens the **Edit Table** wizard. You can visit the panes in any order to edit a table. The table properties are grouped in several panes.

- **Schema**: Database schema in which the table exists.
- **Name**: Name of the table.

The different panes in the dialog are described in the following sections:

- Columns Pane
- Primary Key Pane
- Unique Keys Pane
- Indexes Pane
- Foreign Keys Pane
- Table Constraints Pane
- Comments Pane
- Storage Pane
- External Table Properties Pane
- Materialized View Pane
- DDL Pane
- Output Pane

- Columns Pane
  Specifies properties for each column in the table.
- Primary Key Pane
  Specifies the primary key for the table.
- Unique Keys Pane
  Specifies one or more unique constraints for the table.
- Indexes Pane
  Lists the indexes defined for the table.

- Foreign Keys Pane
  Specifies one or more foreign keys for the table.
- Table Constraints Pane
  Specifies one or more check constraints for the table.
- Comments Pane
  Enter descriptive comments in this pane.
- Storage Pane
  Enables you to specify storage options for the table.
- External Table Properties Pane
  Specifies options for an external table.
- Materialized View Pane
  Specifies options for a materialized view.
- DDL Pane
  You can review and save the SQL statements that are generated when creating or editing the object. If you want to make any changes, go back to the relevant panes and make the changes there.
- Output Pane
  Displays the results of the DDL commands.

Columns Pane

Specifies properties for each column in the table.

General tab

Lists the columns available in the table.To add a column, click **Add Column (+)**. A new row is added to the table below. Select the row and enter the details for the column. To delete a column, select the row and click **Remove Column (-)**. To move a column up or down in the table, select it and use the up-arrow and down-arrow icons.

- **Name**: Name for the column.
- **Datatype**: Data type for the column.
- **Default**: If no value is specified, the default value is null.
- **Default on NULL**: Applicable for Oracle Database 12c and later releases. If this option is selected, when a row is inserted into the table and the value specified for the column is NULL, the default value is inserted into the column.
- **Expression**: Expression for computing the value in the column.
- **Comments**: Optional descriptive comments about the column. Use this field to provide descriptions for the attributes.

In the table:

- **PK**: If this option is selected, the column becomes the primary key.
- **Identity Column** : If this option is selected, the column becomes an identity column. This is applicable only for Oracle Database 12c and later releases. For more details, see the Identity Column tab.

Constraints tab

Displays the Not Null and Check Constraints for a column. A check constraint requires values in a column to comply with a specified condition.

- **Not Null Constraint: Name**: Name for the Not Null constraint.

- **Not Null Constraint: Not Null**: If this option is selected, the column must contain data. You cannot specify no value or an explicit null value for this column when you insert a row. If this option is not checked, the column can contain either data or no data. A primary key column cannot be null.
- **Check Constraint: Name**: Name for the check constraint definition.
- **Check Constraint: Constraint**: Condition that must be met for a column to fulfill the check constraint. You can use any valid CHECK clause (without the CHECK keyword). For example, to indicate that the value in a numeric column named RATING must be from 1 to 10, you can specify: rating >=1 and rating <= 10.
- **Enabled**: If this option is selected, the constraint is checked when data is entered or updated in the column.
- **Deferrable**: If this option is selected, you can defer checking the validity of the constraint until the end of a transaction.
- **Initially Immediate**: If this option is selected, the constraint is checked whenever you add, update, or delete data from the column.
- **Validate**: If this option is selected, the existing data is checked to see if it conforms to the constraint.

Primary Key Pane

Specifies the primary key for the table.

The primary key is the column, or set of columns, that uniquely identifies each row in the table. If the Primary Key checkbox is selected for a column in the General tab, the corresponding fields are automatically populated in the Primary Key pane. You can make changes to the properties as required.

An index is automatically created on the primary key.

- **Name**: Name of the constraint to be associated with the primary key definition.
- **Enabled**: If this option is checked, the primary key constraint is enforced: that is, the data in the primary key column (or set of columns) must be unique and not null.
- **Index**: Name of the index to which the primary key refers.Tablespace: Name of the tablespace associated with the index.
- **Available Columns**: Lists the columns that are available to be added to the primary key definition. You can select multiple attributes, if required, for the primary key.
- **Selected Columns**: Lists the columns that are included in the primary key definition. To add a column to the primary key definition, select it in Available Columns and click the Add (>) icon; to remove a column from the primary key definition, select it in Selected Columns and click the Remove (<) icon. To move all columns from available to selected (or the reverse), use the Add All (>>) or Remove All (<<) icon. To move a column up or down in the primary key definition, select it in Selected Columns and use the arrow buttons.

Unique Keys Pane

Specifies one or more unique constraints for the table.

A unique constraint specifies a column, or set of columns, whose data values must be unique: each data value must not be null, and it must not be the same as any other value in the column.

To add a unique constraint, click the Add button; to delete a unique constraint, select it and click the Remove button.

- **Name**: Name of the unique constraint.
- **Enabled**: If this option is selected, the unique constraint is enforced.
- **Rely**: If this option is selected, the constraint in NOVALIDATE mode is taken into account during query rewrite.
- **Deferrable**: If this option is selected, in subsequent transactions, constraint checking can be deferred until the end of the transaction using the SET CONSTRAINT(S) statement.
- **Initially Immediate**: If this option is selected, the constraint is checked at the end of each subsequent SQL statement.
- **Validate**: If the option is selected, the existing data is checked to see if it conforms to the constraint.
- **Index**: Name of the index to which the unique key refers.
- **Tablespace**: Name of the tablespace associated with the index.
- **Available Columns**: Lists the columns that are available to be added to the unique constraint definition.
- **Selected Columns**: Lists the columns that are included in the unique constraint definition. To add a column to the unique constraint definition, select it in Available Columns and click the Add (>) icon; to remove a column from the unique constraint definition, select it in Selected Columns and click the Remove (<) icon. To move all columns from available to selected (or the reverse), use the Add All (>>) or Remove All (<<) icon. To move a column up or down in the unique constraint definition, select it in Selected Columns and use the arrow buttons.

Indexes Pane

Lists the indexes defined for the table.

To add an index, click Add Index (+); to delete an index, select it and click Remove Index (-).

- **Name**: Name of the index.
- **Type**: The type of Oracle index. Non-unique means that the index can contain multiple identical values; Unique means that no duplicate values are permitted; Bitmap stores rowids associated with a key value as a bitmap.
- **Tablespace**: Name of the tablespace for the index.
- **Expression**: A column expression is an expression built from columns, constants, SQL functions, and user-defined functions. When you specify a column expression, you create a function-based index.
- **Available Columns** and **Selected Columns**: Columns selected for the index. To select a column, click the column in the Available Columns box, and then click the click the Add Selected Columns icon to move it to the Selected Columns box.

Foreign Keys Pane

Specifies one or more foreign keys for the table.

A foreign key specifies a column ("local column"), whose data values match values in the primary key or unique constraint of another table.

- **Name**: Name of the foreign key definition.
- **Enabled**: If this option is checked, the foreign key is enforced.

- **Rely**, **Deferrable**, **Initially Immediate**, **Validate**: See the description of these fields in the Unique Keys pane.
- **Referenced Constraint: Schema**: Name of the schema containing the table with the primary key or unique constraint to which this foreign key refers.
- **Referenced Constraint: Table**: Name of the table with the primary key or unique constraint to which this foreign key refers.
- **Referenced Constraint: Constraint**: Name of the primary key or unique constraint to which this foreign key refers.
- **Referenced Constraint: On Delete**: Action to take automatically when a row in the referenced table is deleted and rows with that value exist in the table containing this foreign key: NO ACTION (shown by a crossing line in diagrams) performs no action on these rows; CASCADE (shown by an "X") deletes these rows; SET NULL (shown by a small circle) sets null all columns in those rows that can be set to a null value.
- **Associations: Local Column**: Lists the column in the currently selected (local) table that is included in the foreign key definition. For each referenced column in the foreign key definition, select the name of a column in the edited table.
- **Associations: Referenced Column**: For each local column, identifies the column in the other (foreign) table that must have a value matching the value in the local column.

Table Constraints Pane

Specifies one or more check constraints for the table.

A check constraint specifies a condition that must be met when a row is inserted into the table or when an existing row is modified.

- **Name**: Name of the check constraint definition.
- **Check Condition**: Condition that must be met for a row to fulfil the check constraint. You can use any valid CHECK clause (without the CHECK keyword). For example, to indicate that the value in a numeric column named RATING must be from 1 to 10, you can specify rating >=1 and rating <= 10.
- **Enabled**: If this option is checked, the check constraint is enforced.

Comments Pane

Enter descriptive comments in this pane.

This is optional.

Storage Pane

Enables you to specify storage options for the table.

When you create or edit a table or an index, you can override the default storage options.

- **Organization**: Specifies that the table is stored and organized with (Index) or without an index (Heap) or as an external table (External).
- **Tablespace**: Name of the tablespace for the table or index.
- **Logging**: ON means that the table creation and any subsequent INSERT operations against the table are logged in the redo log file. OFF means that these operations are not logged in the redo log file.

- **Row Archival**: YES enables in-database archiving, which allows you to archive rows within the table by marking them as invisible.

External Table Properties Pane

Specifies options for an external table.

An external table is a read-only table whose metadata is stored in the database but whose data in stored outside the database.

External Table

- **Access Driver Type**: Specifies the type of external table.
  - **ORACLE_LOADER**: Extracts data from text data files. This is the default access driver, which loads data from external tables to internal tables.
  - **– ORACLE_DATAPUMP**: Extracts data from binary dump files. This access driver can perform both loads and unloads.
  - **– ORACLE_BIGDATA**: Extracts data from Oracle Big Data Appliance.
  - **– ORACLE_HDFS**: Extracts data stored in a Hadoop Distributed File System (HDFS).
  - **– ORACLE_HIVE**: Extracts data stored in Apache HIVE.
- **Default Directory**: Specifies the default directory to use for all input and output files that do not explicitly name a directory object. The location is specified with a directory object, not a directory path.
- **Access Params**: Assigns values to the parameters of the specific access driver for the external table. Access parameters are optional.
  - **OPAQUE_FORMAT_SPEC**: The opaque_format_spec specifies all access parameters for the ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access drivers. For descriptions of the access parameters, see *Oracle Database Utilities*. Field names specified in the opaque_format_spec must match columns in the table definition, else Oracle Database ignores them.
  - **USING CLOB**: Enables you to derive the parameters and their values through a subquery. The subquery cannot contain any set operators or an ORDER BY clause. It must return one row containing a single item of data type CLOB.
- **Reject Limit**: The number of conversion errors that can occur during a query of the external data before an Oracle Database error is returned and the query is aborted.
- **Project Column**: Determines how the access driver validates the rows of an external table in subsequent queries.
  - **ALL**: Processes all column values, regardless of which columns are selected, and validates only those rows with fully valid column entries. If any column value raises an error, such as a data type conversion error, the row is rejected even if that column was not referenced in the select list of the query.
  - **REFERENCED**: Processes only those columns in the select list of the query. The ALL setting guarantees consistent result sets. The REFERENCED setting can result in different numbers of rows returned, depending on the columns referenced in subsequent queries, but is faster than the ALL setting. If a subsequent query selects all columns of the external table, then the settings behave identically.
- **Location**: Specifies the data files for the external table. Use the Add (+) icon to add each location specification.
  - ORACLE_LOADER and ORACLE_DATAPUMP, the files are named in the form directory:file. The directory portion is optional. If it is missing, then the default directory

is used as the directory for the file. If you are using the ORACLE_LOADER access driver, then you can use wildcards in the file name. An asterisk (*) signifies multiple characters and a question mark (?) signifies a single character.

- For ORACLE_HDFS, LOCATION is a list of Uniform Resource Identifiers (URIs) for a directory or for a file. There is no directory object associated with a URI.
- For ORACLE_HIVE, LOCATION is not used. Instead, the Hadoop HCatalog table is read to obtain information about the location of the data source (which could be a file or another database).

Opaque Format Spec

Specifies all access parameters for the ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access drivers.

CLOB Subquery

Type or copy and paste the query.

Materialized View Pane

Specifies options for a materialized view.

Query: Contains the SQL code for the query part of the view definition. Type or copy and paste the query.

General

- **On Pre-built Table**: If **Yes**, an existing table is registered as a preinitialized materialized view. This option is particularly useful for registering large materialized views in a data warehousing environment. The table must have the same name and be in the same schema as the resulting materialized view, and the table should reflect the materialization of a subquery.
- **Reduced Precision**: **Yes** authorizes the loss of precision that will result if the precision of the table or materialized view columns do not exactly match the precision returned by the subquery. If **No**, the precision of the table or materialized view columns must exactly match the precision returned by the subquery, or the create operation will fail.
- **For Update**: Select **Yes** to allow a subquery, primary key, object, or rowid materialized view to be updated. When used in conjunction with Advanced Replication, these updates will be propagated to the master.
- **Real Time MV**: Select **Yes** to create a real-time materialized view or a regular view. A real-time materialized view provides fresh data to user queries even when the materialized view is not in sync with its base tables due to data changes. Instead of modifying the materialized view, the optimizer writes a query that combines the existing rows in the materialized view with changes recorded in log files (either materialized view logs or the direct loader logs). This is called on-query computation.
- **Query Rewrite**: If **Enable**, the materialized view is enabled for query rewrite, which transforms a user request written in terms of master tables into a semantically equivalent request that includes one or more materialized views.
- **Build**: Specifies when to populate the materialized view. **Immediate**indicates that the materialized view is to be populated immediately. **Deferred** indicates that the materialized view is to be populated by the next refresh operation. If you specify Deferred, the first (deferred) refresh must always be a complete refresh; until then, the materialized view has a staleness value of unusable, so it cannot be used for query rewrite.
- **Use Index**: If **Yes**, a default index is created and used to speed up incremental (fast) refresh of the materialized view. If **No**, this default index is not created. (For example, you

might choose to suppress the index creation now and to create such an index explicitly later.)

- **Index Tablespace**: Specifies the tablespace in which the materialized view is to be created. If a tablespace is not selected, the materialized view is created in the default tablespace of the schema containing the materialized view.
- **Cache**: If **Yes**, the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This setting is useful for small lookup tables. If **No**, the blocks are placed at the least recently used end of the LRU list.

Refresh Clause

- **Refresh**: Select **Yes** to enable refresh operations.
- **Refresh Type**: The method of refresh operation to be performed:
  - Complete Refresh: Executes the defining query of the materialized view, even if a fast refresh is possible.
  - Fast Refresh: Uses the incremental refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes for conventional DML changes are stored in the materialized view log associated with the master table. The changes for direct-path INSERT operations are stored in the direct loader log.
  - Force Refresh: Performs a fast refresh if one is possible; otherwise, performs a complete refresh.
- **Action**: The type of refresh operation to be performed:
  - On Demand: Performs a refresh when one of the DBMS_MVIEW refresh procedures are called.
  - On Commit: Performs a fast refresh whenever the database commits a transaction that operates on a master table of the materialized view. This may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.
  - Specify: Performs refresh operations according to what you specify in the Start on and Next fields.
- **Start Date**: Starting date and time for the first automatic refresh operation. Must be in the future.
- **Next Date**: Time for the next automatic refresh operation. The interval between the Start on and Next times establishes the interval for subsequent automatic refresh operations. If you do not specify a value, the refresh operation is performed only once at the time specified for Start on.
- **With**: Refresh type, which determines the type of materialized view:
  - Primary Key: Creates a primary key materialized view, which allows materialized view master tables to be reorganized without affecting the eligibility of the materialized view for fast refresh.
  - Row ID: Creates a rowid materialized view, which is useful if the materialized view does not include all primary key columns of the master tables.
- **Default Storage**: If Yes, DEFAULT specifies that Oracle Database will choose automatically which rollback segment to use. If you specify DEFAULT, you cannot specify the `rollback_segment`. DEFAULT is most useful when modifying, rather than creating, a materialized view.

- **Storage Type**: MASTER specifies the remote rollback segment to be used at the remote master site for the individual materialized view. LOCAL specifies the remote rollback segment to be used for the local refresh group that contains the materialized view. This is the default.
- **Rollback Segment**: Enter the name of the rollback segment.
- **Using Constraint**: If this option is checked, more rewrite alternatives can be used during the refresh operation, resulting in more efficient refresh execution. The behavior of this option is affected by whether you select Enforced or Trusted.
  - Enforced: Causes only enforced constraints to be used during the refresh operation.
  - Trusted: Enables the use of dimension and constraint information that has been declared trustworthy by the database administrator but that has not been validated by the database. If the dimension and constraint information is valid, performance may improve. However, if this information is invalid, then the refresh procedure may corrupt the materialized view even though it returns a success status.

DDL Pane

You can review and save the SQL statements that are generated when creating or editing the object. If you want to make any changes, go back to the relevant panes and make the changes there.

For a new table, click **CREATE** to view the generated DDL statements.

When you edit table properties, click **UPDATE** to view the generated ALTER statements.

For a new table, the UPDATE tab will not be available. When you are finished, click **Apply**.

Output Pane

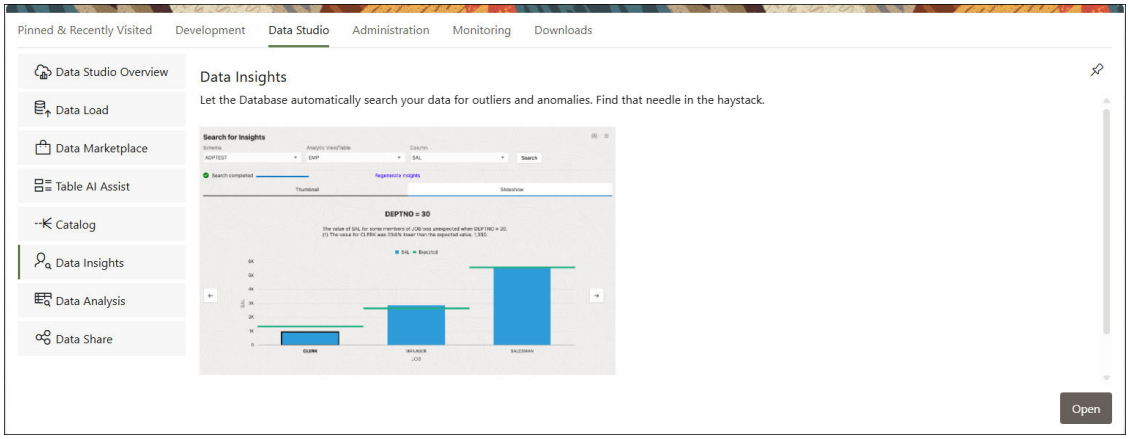
Displays the results of the DDL commands.

If there are any errors, go to the appropriate pane, fix the errors, and run the commands again. You can save to a text file or clear the output.

The Data Insights Page

The Data Insights page displays information about patterns and anomalies in the data of entities in your Oracle Autonomous Database.

To reach the Data Insights page, click the **Data Studio** tab in the Database Actions page, and select the **Data Insights** menu



or click the Selector icon and select **Data Insights** from the Data Tools menu in the navigation pane.

The following topics describe insights and how to generate and use them.

- About Insights
  You can generate insights for a table or for the analytic view deployed for data analysis.
- Generate Insights and View Reports
  Use these procedures to generate Insights and view reports about them.

About Insights

You can generate insights for a table or for the analytic view deployed for data analysis.

The insights that Data Insights generates for the analytic view of a business model can be more useful than those for a table because of the additional metadata that an analytic view provides.

Insights highlight data points as potentially anomalous if the actual value for a measure when filtering on pairs of analytic view hierarchy values or table column values is considerably higher or lower than the expected value, calculated across all hierarchy or column values. Insights highlight unexpected patterns, which you may want to investigate.

Insights are automatically generated by various analytic functions built into the database. The results of the insight analysis appear as a series of bar charts in the Data Insights dashboard.

Data Insights uses the following steps to generate insights:

1. Finds the values of a measure, for example Sales, across all of the distinct pairs of the hierarchy or column values for the measure. If Sales has the hierarchies or columns Marital Status, Age Band, Income Level, and Gender, then the pairs would be the values of each distinct value of each hierarchy or column paired to each distinct value of each of the other hierarchies or columns. For example, if the values of Marital Status are Married and Single, and the values of Age Band are A, B, and C, then the pairs would be Married and A, Married and B, Married and C, Single and A, Single and B, and Single and C. Each distinct value of Marital Status would also be paired with each distinct value of Income Level and Gender, and so on.
2. Estimates an expected value for the measure for each hierarchy or column pair.
3. Calculates the actual value for the measure for each hierarchy or column pair, for example Marital Status = S, Age Band = C, and then the difference between the actual value and the expected value.

4. Scores all of the differences and selects the largest variations between the actual and expected values to highlight as potential insights.

The resulting insights highlight cases where the measure value is significantly larger or smaller for a given hierarchy or column value pair than expected, for example much higher Sales where Marital Status = S and Age Band = C.

Insights for analytic views tend to use the higher levels of a hierarchy because the differences between the estimated and actual values are generally larger than they are for lower level attributes. For example, the difference in dollars between the estimated and actual sales for the entire USA are generally larger than the difference between the estimated and actual sales for a town with a population under 1000. The difference is calculated in absolute values, not percentages.

Insights for tables categorize columns as dimension columns or measure columns based on their data types and cardinality. A VARCHAR2 column is always categorized as a dimension, but a NUMBER column may be either a dimension or a measure. For example, a NUMBER column for YEAR values that has only 10 distinct values in a table with 1 million rows is assumed to be a dimension.

Generate Insights and View Reports

Use these procedures to generate Insights and view reports about them.

Generate Insights

To generate insights for a table or business model, do the following:

1. In the **Schema** field, select a schema.
2. In the **Analytic View/Table** field, select an analytic view or a table.
3. In the **Column** field, select a column that contains data about which you want gain insights.
4. Click **Search**.

A confirmation notice announces that the request for insights has been successfully submitted. Dismiss the notice by clicking the Close (X) icon in the notice.

A progress bar indicates that the search is in progress and when it has completed. The insights appear in the Data Insights dashboard as a series of bar charts.

To refresh the display of the insights, click **Refresh**. To have refreshes occur automatically, click **Enable Auto Refresh**.

Click **Recent Searches** to view the list of previous insights search.

Select **View Errors** to see any log of error that occurs while its creation. The results appear in a new browser tab.

View the Report

The charts in the Data Insights dashboard show the data that contain anomalous results. The bars in a chart show the actual values. The expected values are indicated by green horizontal lines. The bars that are outlined in black contain the most significant differences between the expected and the actual values.

For example, if the fact table for the insights records values about an insurance program, and the measures of the fact table are AGE_CODE, GENDER_CODE, INCOME_CODE, NUM_INSURED, NUM_UNINSURED, and YEAR, then insights might be generated for the NUM_INSURED measure. In that case, the dashboard would have a series of charts labeled

YEAR and INCOME_CODE. Each chart would have a value of the related dimension in the upper left corner. For example, an INCOME_CODE chart that has a related AGE_CODE might have the AGE_CODE value 2 in the upper left corner.

Clicking a chart displays more details about it. At the top of the expanded view of the chart is the dimension name and value and a short textual analysis of notable insights. Below the analysis is the chart showing the values and insights about them.

For example, a chart for INCOME_CODE might have at AGE_CODE = 2 at the top, plus the textual analysis. In the chart, the INCOME_CODE values would be on the x-axis and the NUM_INSURED values would be on the y-axis. Pointing to a bar on the expanded chart displays the actual and the expected NUM_INSURED value for that INCOME_CODE and AGE_CODE.

Click the **Back** button to return to the Data Insights dashboard.

View Previous Reports

To see the results of a previous search, click the Recent Searches icon at the upper right. In the Recent Searches panel, click anywhere in the box for the insights search that you want to see.

To filter the previous searches, enter a value in the search field at the top of the Recent Searches panel.

To close the Recent Searches panel without selecting a search, click the X at the upper right of the panel.

Use Oracle OLAP with Autonomous Database

Oracle OLAP is available on Autonomous Database. Oracle OLAP supports uses such as planning, forecasting, budgeting, and analysis.

- Enable Oracle OLAP on Autonomous Database
  Describes the steps to use Oracle OLAP on Autonomous Database.

Enable Oracle OLAP on Autonomous Database

Describes the steps to use Oracle OLAP on Autonomous Database.

1. Run `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` to enable Oracle OLAP.

   ```
   EXEC DBMS_CLOUD_ADMIN.ENABLE_FEATURE('OLAP');
   ```

   Running this command also enables Java, if it is not already enabled.

   See ENABLE_FEATURE Procedure for more information.
2. Restart the Autonomous Database instance.

   See Restart Autonomous Database for more information.
3. After the restart operation completes, wait for about 20 minutes to allow the Oracle OLAP installation jobs to complete.
4. Verify that Oracle OLAP is installed.

For example:

```
SELECT comp_name, version, status FROM dba_registry
             WHERE comp_id IN ('APS','XOQ','JAVAVM');

COMP_NAME                      VERSION    STATUS
------------------------------ ---------- ------
JServer JAVA Virtual Machine 19.0.0.0.0 VALID
OLAP Analytic Workspace      19.0.0.0.0 VALID
Oracle OLAP API              19.0.0.0.0 VALID
```

5. Verify that Oracle OLAP is working.

```
set serveroutput on
EXEC dbms_aw.execute('show eversion');
```

This should show results like:

```
Oracle OLAP Release 19.23.0.1.0
```

For more information, see the following:

- Getting Started with Oracle OLAP
- Oracle OLAP

Manage the Service

Describes basic tasks for managing an Autonomous Database instance.

- Lifecycle Operations
  You can start, stop, restart, rename, and terminate an Autonomous Database instance.
- Update Compute and storage limits
  Autonomous Database has the ability to increase its storage or CPU cores. You can also activate auto scaling.
- Update Billing Model, Choose Bring Your Own License, or Update Instance to a Paid Instance
  Describes how to choose to bring your own license to your Autonomous Database instance. Also shows how to update the billing model to the ECPU compute model and shows how to update your instance from free (Always Free) to a paid instance.
- Clone, Move, or Upgrade an Autonomous Database Instance
  Autonomous Database provides cloning where you can choose to create a full clone, create a metadata clone, or create a refreshable clone. You can also move a database to a different compartment. By creating a clone you can upgrade an instance with Oracle Database 19c to create an Oracle Database 23ai clone (either a full clone or a refreshable clone).
- Use Refreshable Clones with Autonomous Database
  Autonomous Database provides cloning where you can choose to create a full clone of the active instance, create a metadata clone, or create a refreshable clone. With a refreshable clone the system creates a clone that can be easily updated with changes from the source database.

- Manage Autonomous Database Built-in Tools
  Autonomous Database includes built-in tools that you can enable and disable when you provision or clone a database, or at any time for an existing database.
- Use Autonomous Database Events
- Manage Time Zone File Updates on Autonomous Database
- Monitor Autonomous Database Availability
  Shows you the steps to view availability information for an Autonomous Database instance.
- Monitor Regional Availability of Autonomous Databases
  The regional availability is represented as a list of daily uptime percentages of Autonomous Databases across a set of services in each available region.
- Manage Resource Availability with Compartment Quotas
  Autonomous Database supports the compartment quotas feature of Oracle Cloud Infrastructure.

Lifecycle Operations

You can start, stop, restart, rename, and terminate an Autonomous Database instance.

- Provision an Autonomous Database Instance
  Follow these steps to provision a new Autonomous Database instance using the Oracle Cloud Infrastructure Console.
- Start Autonomous Database
  Describes the steps to start an Autonomous Database instance.
- Stop Autonomous Database
  Describes the steps to stop an Autonomous Database instance.
- Restart Autonomous Database
  Describes the steps to restart an Autonomous Database instance.
- Rename Autonomous Database
  Shows you the steps to change the database name for an Autonomous Database instance.
- Update the Display Name for an Autonomous Database Instance
  Shows you the steps to change the display name for an Autonomous Database instance.
- Terminate an Autonomous Database Instance
  Describes the steps to terminate an Autonomous Database instance.
- Undelete a Terminated Autonomous Database Instance
  Describes the steps to undelete a terminated Autonomous Database instance.
- Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted
  You can select an Autonomous Database operation mode: Read/Write, Read-Only, or Restricted. The default mode is Read/Write.
- Schedule Start and Stop Times for an Autonomous Database Instance
  Describes the steps to schedule daily start and stop times for an Autonomous Database instance.
- Concurrent Operations on Autonomous Database
  Describes the actions that cause Oracle Cloud Infrastructure Console to ask you to confirm pausing or canceling a concurrent operation.

Provision an Autonomous Database Instance

Follow these steps to provision a new Autonomous Database instance using the Oracle Cloud Infrastructure Console.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- Choose your region. See Switching Regions for information on switching regions and working in multiple regions.
- Choose your **Compartment**. See Compartments for information on using and managing compartments.

On the Autonomous Databases page, perform the following steps:

1. Click **Create Autonomous Database**.
2. Provide basic information for the Autonomous Database.
   - **Compartment**. See Compartments for information on using and managing compartments.
   - **Display name** Specify a user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique.

     The default display name is a generated 16-character string that matches the default database name.
   - **Database name** Specify the database name; it must consist of letters and numbers only. The maximum length is 30 characters. The same database name cannot be used for multiple Autonomous Databases in the same tenancy in the same region.

     The default database name is a generated 16-character string that matches the default display name.
3. Choose a workload type. Select the workload type for your database from the choices:
   - **Data Warehouse**
   - **Transaction Processing**
   - **JSON**
   - **APEX**
4. Configure the database (ECPU billing model)
   - **Always Free**: Select to show Always Free options.

     You can only create a free instance in the tenancy's Home region.
   - **Developer**: Select to show Autonomous Database for Developers options.

     An Autonomous Database for Developers instance is a fixed shape database that is suited for development and testing use cases.

     Selecting this option sets the **Compute** resources to a fixed value of 4 ECPUs and the **Storage** to 20 GB.
   - **Choose database version**: Select the database version. The available database versions are Oracle Database 23ai and Oracle Database 19c.

> **Note:**
>
> - In regions where Oracle Database 23ai is not available, Oracle Database 19c is the only choice.
> - Autonomous Database with Oracle Database 23ai in the Paid tier is available in all commercial public cloud regions.
> - Always Free Autonomous Database with Oracle Database 23ai is available in all commercial public cloud regions *except* the following regions: Colombia Central: Bogota (BOG), Saudi Arabia Central (RUH), Singapore West: Singapore (XSP)

- **ECPU count**: Specify the number of CPUs for your database. The minimum value is 2.
- **Compute auto scaling**: By default compute auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. If you do not want to use compute auto scaling then deselect this option.

  See Use Auto Scaling for more information.
- **Storage**: Specify the storage you wish to make available to your database. Depending on your workload type you have these options:
  - **Data Warehouse**: Specify your storage in Terabytes (TB).
  - **Transaction Processing** or **JSON**: Specify your storage in Gigabytes (GB) or Terabytes (TB). Enter the size in the **Storage** field. Select **GB** or **TB** for the **Storage unit size**.
- By default, the IO capacity of your database depends on the number of ECPUs you provision. When you provision 384 TB of storage, your database is entitled to the full IO capacity of the Exadata infrastructure, independent of the number of ECPUs you provision.

  Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

  If you want to provision more than 384 TB of storage, file a Service Request at Oracle Cloud Support.
- **Storage auto scaling**: By default storage auto scaling is disabled. Select if you want to enable storage auto scaling to allow the system to automatically expand to use up to three times more storage.

  With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

  With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

  See Use Auto Scaling for more information.
- **Show advanced options**: Click to show additional options
  - **Enable elastic pool:**

See Create or Join an Elastic Pool While Provisioning or Cloning an Instance for more information.

- **Compute model**: Shows the selected billing model.
  - **ECPU**
    Use the ECPU billing model for Autonomous Database. ECPUs are based on the number of cores elastically allocated from a pool of compute and storage servers.
  - **OCPU**
    Use the legacy OCPU billing model if your tenancy is using the OCPU model and you want to continue using OCPUs. The OCPU billing model is based on physical core of a processor with hyper threading enabled.

> **Note:**
>
> OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

Click **Change compute model** to change the billing model. After you select a different billing model, click **Save**.

See Compute Models in Autonomous Database for more information.

- **Bring your own license**: If you want to Bring Your Own License to the database, click **Enable** to show the **Update license and Oracle Database Edition** page.

  See Choose Bring Your Own License Option While Provisioning or Cloning for more information.

5. Backup retention

   Automatic backup retention period in days You have the option to select the automatic backup retention period, in a range from 1 to 60 days. You can restore and recover your database to any point-in-time in this retention period.

   Select **Immutable backup retention** to lock the backup retention period.

   After setting the immutable backup retention option, you cannot disable this option or change the retention period. To disable immutable backup retention or to change the backup retention period, file a Service Request at Oracle Cloud Support.

   See About Backup and Recovery on Autonomous Database for more information.

6. Create administrator credentials. Set the password for the Autonomous Database Admin user.

   - **Username** This is a read only field.
   - **Password** Set the password for the Autonomous Database Admin user.
   - **Confirm password** Enter the same password again to confirm your new password.

   The password must meet the strong password complexity criteria based on Oracle Cloud security standards. For more information on the password complexity rules, see About User Passwords on Autonomous Database.

7. Choose network access

> **Note:**
>
> After you provision your Autonomous Database you can change the network access option you select for the instance.

- **Secure access from everywhere**

  By default, secure connections are allowed from everywhere.

- **Secure access from allowed IPs and VCNs only**

  This option restricts connections to the database according to the access control lists (ACLs) you specify. To add multiple ACLs for the Autonomous Database, click **Add access control rule**.

  See Configure Access Control Lists When You Provision or Clone an Instance for more information.

- **Private endpoint access only**

  This option assigns a private endpoint, private IP, and hostname to your database. Specifying this option allows traffic only from the VCN you specify; access to the database from all public IPs or VCNs is blocked. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your Autonomous Database.

  See Configure Private Endpoints When You Provision or Clone an Instance for more information.

See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.

8. (Optional) Provide contacts for operational notifications and announcements

   Click **Add contact** and in the **Contact email** field, enter a valid email address. To enter multiple **Contact email** addresses, repeat the process to add up to 10 customer contact emails.

   See View and Manage Customer Contacts for Operational Issues and Announcements for more information.

9. (Optional) Click Show advanced options to select advanced options.

   - **Encryption key**
     Encrypt using an Oracle-managed key: By default Autonomous Database uses Oracle-managed encryption keys. Using Oracle-managed keys, Autonomous Database creates and manages the encryption keys that protect your data and Oracle handles rotation of the TDE master key.

     Encrypt using a customer-managed key in this tenancy: If you select this option, a master encryption key from a Oracle Cloud Infrastructure Vault in the same tenancy is used to generate the TDE master key on Autonomous Database.

     Encrypt using a customer-managed key located in a remote tenancy: If you select this option, a master encryption key in the Oracle Cloud Infrastructure Vault located in a remote tenancy is used to generate the TDE master key on Autonomous Database.

     See Use Customer-Managed Encryption Keys on Autonomous Database for more information.

   - **Maintenance**

Patch level By default the patch level is **Regular**. Select **Early** to configure the instance with the early patch level.

See Set the Patch Level for more information.

- **Management**
  Choose a character set and a national character set for your database.

  See Choose a Character Set for Autonomous Database for more information.

- **Tools**
  If you want to view or customize the tools configuration, select the tools tab.

  See Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance for more information.

- **Security attributes**
  Add a security attribute to control access for your resources using Zero Trust Packet Routing (ZPR) policies. To enter security attributes during provisioning you must already have set up security attributes with Zero Trust Packet Routing. You also can add security attributes after provisioning.

  > **Note:**
  >
  > You can apply Oracle Zero Trust Packet Routing (ZPR) policies to a private endpoint.

  Specify a **Namespace**, **Key**, and **Value** security attribute.

  Click **Add security attribute** to add additional security attributes.

  See Overview of Zero Trust Packet Routing for more information.

- **Tags**
  If you want to use Tags, enter the **Tag key** and **Tag value**. Tagging is a metadata system that allows you to organize and track resources within your tenancy. Tags are composed of keys and values which can be attached to resources.

  See Tagging Overview for more information.

10. Optionally, you can save the resource configuration as a stack by clicking **Save as Stack**. You can then use the stack to create the resource through the Resource Manager service.

    Enter the following details on the **Save as Stack** dialog, and click **Save**.

    - **Name:** Optionally, enter a name for the stack.
    - **Description:** Optionally, enter a description for this stack.
    - **Save in compartment:** Select a compartment where this Stack will reside.
    - **Tag namespace**, **Tag key**, and **Tag value**: Optionally, apply tags to the stack.

    For requirements and recommendations for Terraform configurations used with Resource Manager, see Terraform Configurations for Resource Manager. To provision the resources defined in your stack, apply the configuration.

11. Click **Create Autonomous Database**.

On the Oracle Cloud Infrastructure console the Lifecycle state shows **Provisioning** until the new database is available.

Start Autonomous Database

Describes the steps to start an Autonomous Database instance.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To start Autonomous Database:

1. On the **More actions** drop-down list menu on the Autonomous Database instance, select **Start**.

   Start is only shown for a stopped instance.
2. Click **Start** to confirm.

Notes for starting a stopped Autonomous Database instance:

- When an Autonomous Database instance is started, Autonomous Database CPU billing is initiated, billed by the second with a minimum usage period of one minute.
- When an Autonomous Database remains stopped for over 7 days it may take a few minutes or longer to start up, depending on the size of the database. To avoid this extra startup time, Oracle recommends starting your Autonomous Database instance once every 7 days.

Stop Autonomous Database

Describes the steps to stop an Autonomous Database instance.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To start Autonomous Database:

1. On the **More actions** drop-down list menu on the Autonomous Database instance, select **Stop**.
2. Click **Stop** to confirm.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

Notes for a stopped Autonomous Database instance:

- Autonomous Database Tools are no longer able to connect to a stopped instance.
- Autonomous Database in-flight transactions and queries are stopped.

- Autonomous Database CPU billing is halted.
- When an Autonomous Database remains stopped for over 7 days it may take a few minutes or longer to start up, depending on the size of the database. To avoid this extra startup time, Oracle recommends starting your Autonomous Database instance once every 7 days.

Restart Autonomous Database

Describes the steps to restart an Autonomous Database instance.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To restart Autonomous Database:

1. On the **More actions** drop-down menu, select **Restart**.
2. In the confirmation dialog, select **Restart** to confirm.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

The Autonomous Database instance state changes to "Restarting". After the restart is successful, Autonomous Database instance state is "Available".

> **Note:**
>
> When an Autonomous Database instance is restarted, Autonomous Database CPU billing is initiated, billed by the second with a minimum usage period of one minute.

Rename Autonomous Database

Shows you the steps to change the database name for an Autonomous Database instance.

Before you rename your database, note the following:

- A single tenancy in the same region cannot contain two Autonomous Databases with the same name.
- The database rename operation changes the connection strings required to connect to the database. Thus, after you rename a database you must download a new wallet for any existing instance wallets that you use to connect to the database (and any applications also must be updated to use the new connection string and the new wallet to connect to the database).

  If you are using a regional wallet, you can continue to use the existing wallet to connect to any databases that were not renamed. However, if you want to connect to a renamed database, you must download a new regional wallet.

  See Download Client Credentials (Wallets) for more information.

> **Note:**
>
> The rename operation terminates all connections to the database. After the rename operation completes, you can reconnect to the database.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To rename an Autonomous Database instance, do the following:

1. On the **More actions** drop-down list menu on the Autonomous Database instance, select **Rename Database**.

   This shows the Rename Database dialog.
2. On the Rename Database dialog, provide values for the fields:
   - New database name: the name you enter must consist of letters and numbers only. The maximum length is 30 characters.
3. Click **Rename**.

After validating the fields, while the system renames the database the lifecycle state changes to **Updating**. You can start using the database after the rename operation completes and the lifecycle state shows **Available**.

Notes for Autonomous Database rename:

- Renaming your database does not change global references to your database from existing database links on remote databases. Changing such references is the responsibility of the administrator of the remote databases.
- When you rename a database, the Autonomous Database OCID does not change.
- If your database has Autonomous Data Guard enabled, the rename operation is not available.
- You cannot use the rename operation on a refreshable clone instance or on a database that is the source for a refreshable clone.
- The rename operation restarts the database.
- You can rename your Autonomous Database using the API. See UpdateAutonomousDatabase for more information.

Update the Display Name for an Autonomous Database Instance

Shows you the steps to change the display name for an Autonomous Database instance.

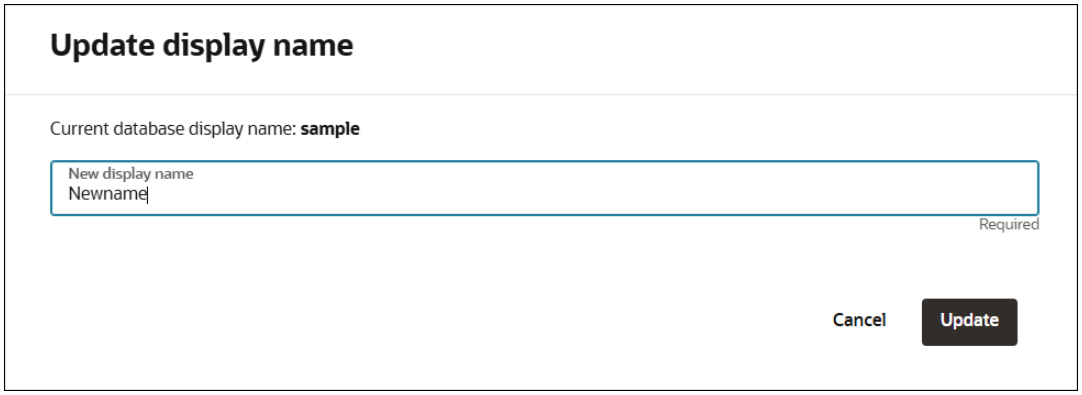
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To update the display name on an Autonomous Database instance:

1. On the **More actions** drop-down list menu on the OCI console, select **Update display name**.



2. Enter a display name in the **New display name** field.
   - The display name minimum length is 1 character and maximum length is 255 characters.
   - The display name must include only letters, numbers, underscores "_", and hyphens "-".
   - The display name must start with a letter or an underscore "_", and cannot contain two successive hyphens "-".
3. Enter the current display name to confirm the change.
4. Click **Update**.

You can see the updated display name on the Oracle Cloud Infrastructure Console.

Terminate an Autonomous Database Instance

Describes the steps to terminate an Autonomous Database instance.

> **Note:**
>
> Terminating an Autonomous Database deletes the instance and it will no longer be available to use. You may undelete a terminated database instance and its retained backups using the Undelete database option. See Undelete a Terminated Autonomous Database Instance for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To terminate an Autonomous Database instance:

1. On the **More actions** drop-down list menu on the Autonomous Database instance, select, select **Terminate**.
2. On the **Terminate Autonomous Database** page enter the database name to confirm that you want to terminate the database.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.
3. Click **Terminate**.

Notes for terminating a database:

- There are limitations for terminating a database when Autonomous Data Guard is enabled with a cross-region standby database. See Terminate a Cross-Region Standby Database for more information.
- You must first terminate the alastic pool before you terminate a database that is an elastic pool leader. See Terminate an Elastic Pool for more information.
- After a database is terminated, you can list the terminated databases. To show terminated databases, on the Autonomous Databases list page, in the Search box enter **Terminated databases**, select **Include**, and click **Apply filter**.

Undelete a Terminated Autonomous Database Instance

Describes the steps to undelete a terminated Autonomous Database instance.

You can undelete a database up to 72 hours after the database was terminated, or up to the backup retention period, whichever is lower. Using undelete is not possible after more than three days (72 hours) from the time you terminated the database.

Before you undelete your database, note the following:

- To undelete an Autonomous Database instance the instance must use the ECPU compute model.

  See Compute Models in Autonomous Database for more information.
- If a different database with the same name exists in the same region, you must first rename or terminate the existing database before you can successfully undelete the database.
- If a database was configured with a Private Endpoint within a Virtual Cloud Network (VCN), a VCN must exist before you can undelete the database. If VCN is not available, use Oracle Cloud Support to file a Service Request to recover the VCN.
- The undelete operation is not available when the terminated database is an Autonomous Database for Developers instance.

Perform the following prerequisite steps as necessary:

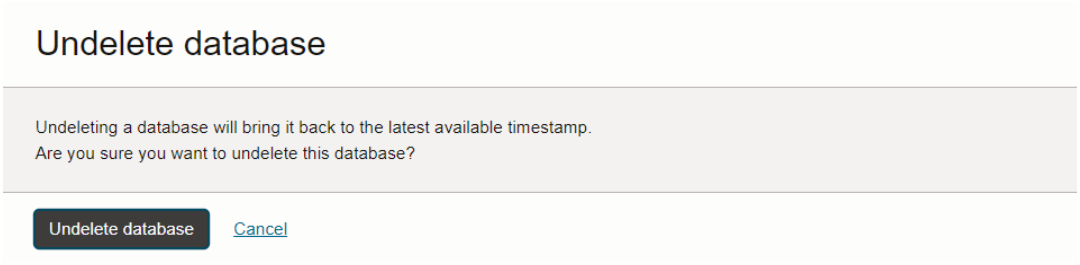
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

To undelete an Autonomous Database instance:

1. On the Autonomous Databases page in the search and filter box enter **Terminated databases** and select **Include**.

2. Click **Apply filter**.

3. In the row that shows the terminated database, click at the end of the row and in the menu select **Undelete**. This shows the Undelete database dialog.



4. Click **Undelete**.

   The Autonomous Database lifecycle state badge changes to **Provisioning**.

While the system undeletes the database, the Lifecycle state changes from **Provisioning** to **Updating**, and then to **Available**.

You can start using the database after the undelete operation completes and the lifecycle state shows **Available**.

Notes for Autonomous Database undelete:

- If you are unable to undelete a database instance within 72 hours, file a service request at Oracle Cloud Support or contact your support representative for assistance.
- When an Autonomous Database instance is undeleted, it will be billed as a running database for the time-period that it was terminated. See Oracle Autonomous Database Serverless Features Billing for more information.
- If you were using a wallet to connect to your database, you must download the wallet again after you undelete the database.

  See Download Client Credentials (Wallets) for more information.
- Any additional features enabled after the initial creation of the database must be re-enabled after you undelete a database. For example, you need to re-enable Data Safe registration, Autonomous Data Guard, or Flashback Time Travel after you undelete.
- When you undelete your database, the following are automatically restored:
  - All the backups before the restore timestamp, including automatic backups and if there are any long-term backups.
  - The most recent Network Access options that were specified before the database was deleted.

    See About Network Access Options for more information.
  - The most recent Backup retention period specified for automatic backups and long-term backups before the database was deleted.
- You cannot perform the undelete operation if the terminated database is:
  - A refreshable clone
  - A Backup-Based Disaster Recovery peer
  - An Autonomous Data Guard standby database

However, if you delete one of these, you can provision them again from the source database.

Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted

You can select an Autonomous Database operation mode: Read/Write, Read-Only, or Restricted. The default mode is Read/Write.

- Change Autonomous Database Operation Mode for a Session
  You can set the Autonomous Database operation mode for a session to Read-Only. When you set the session mode to Read-Only users in the session can only run queries.
- Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted
  From the Oracle Cloud Infrastructure Console you can select an Autonomous Database operation mode: Read/Write, Read-Only, or Restricted. The default mode is Read/Write.
- Autonomous Database Operation in Read-Only Mode
  When the database is in Read-Only mode, each of the following is disabled:

Change Autonomous Database Operation Mode for a Session

You can set the Autonomous Database operation mode for a session to Read-Only. When you set the session mode to Read-Only users in the session can only run queries.

To enable Read-Only mode for a session:

1. Connect to Autonomous Database.

   You can connect as the ADMIN user or as the user whose session you want to set to Read-only mode.
2. Run the following SQL statement:

```
ALTER SESSION SET READ_ONLY = TRUE;
```

To disable Read-Only mode for a session:

```
ALTER SESSION SET READ_ONLY = FALSE;
```

> **Note:**
>
> The `READ_ONLY` session parameter applies when the database is in Read/Write mode. If the database is in Read-Only mode, setting the session parameter value to `TRUE` or to `FALSE` does not change the operation mode for the session.

Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted

From the Oracle Cloud Infrastructure Console you can select an Autonomous Database operation mode: Read/Write, Read-Only, or Restricted. The default mode is Read/Write.

If you select Read-Only mode users can only run queries. In addition, for Read-Only or Read/Write mode, you can restrict access to only allow users with the `RESTRICTED SESSION` privilege to connect to the database. The ADMIN user has this privilege. You can use the restricted

access mode to perform administrative tasks such as indexing, data loads, or other planned activities.

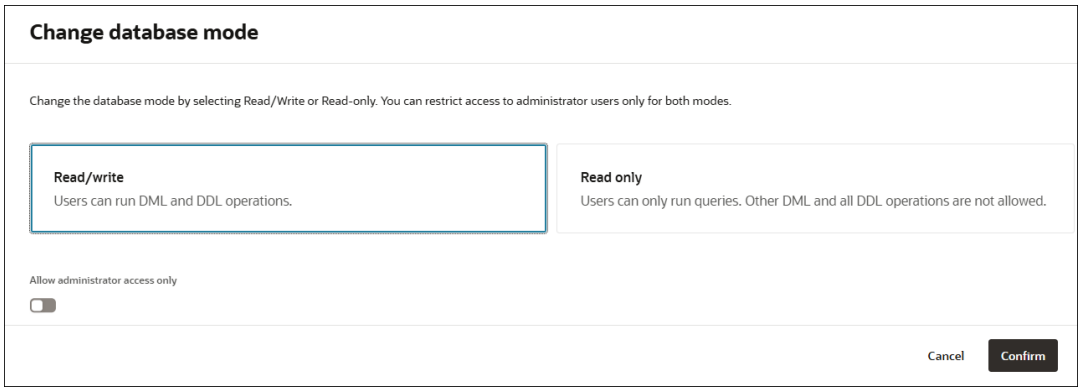
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To change the Autonomous Database operation mode, do the following:

1. On the **Details** page, in the **Mode** field under General Information, click **Edit**.

   This shows the Change database mode panel.



2. Select a mode, either **Read/write** or **Read only**.
3. If you want to restrict access to only allow the ADMIN or privileged users, then select **Allow administrator access only**.
4. Click **Confirm**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

   While the mode changes, the Lifecycle state field shows **Updating**. After the mode change completes, the Lifecycle state field shows **Available**.

Notes for changing the database mode:

- The database must be available with the **Lifecycle state** field showing **Available** to change the database mode.
- When you change the database mode to restricted mode or when you change from restricted mode to unrestricted mode, the database terminates existing database connections as follows:
  - When the mode is restricted, that is the Mode field shows **(Admin-only access)**, if you deselect **Allow administrator access only** and click **Confirm**, then users and applications need to reestablish database connections after the mode change completes.
  - When the mode is unrestricted, that is the Mode field does not show **(Admin-only access)**, if you select **Allow administrator access only** and click **Confirm**, then

users and applications need to reestablish database connections after the mode change completes.

Autonomous Database Operation in Read-Only Mode

When the database is in Read-Only mode, each of the following is disabled:

- On the Oracle Cloud Infrastructure Console, the **Administrator Password** action is not allowed. Also, in Database Actions, under Administration, the **Database Users** card is disabled.
- Oracle APEX URLs are not available:
  - In Database Actions, under Development, the APEX link is disabled.
  - On the Oracle Cloud Infrastructure Console Tools tab, the **Open APEX** link is disabled.
- Oracle Machine Learning User Administration is disabled:
  - In Database Actions, under Development, the Oracle Machine Learning link is disabled.
  - On the Oracle Cloud Infrastructure Console Tools tab, the **Open Oracle ML User Administration** link is disabled.
- Setting resource management rules is disabled. In Database Actions, under Administration, the **Set Resource Management Rules** link is disabled.
- Upgrading the database is disabled when the database is in Read-Only mode.

Schedule Start and Stop Times for an Autonomous Database Instance

Describes the steps to schedule daily start and stop times for an Autonomous Database instance.

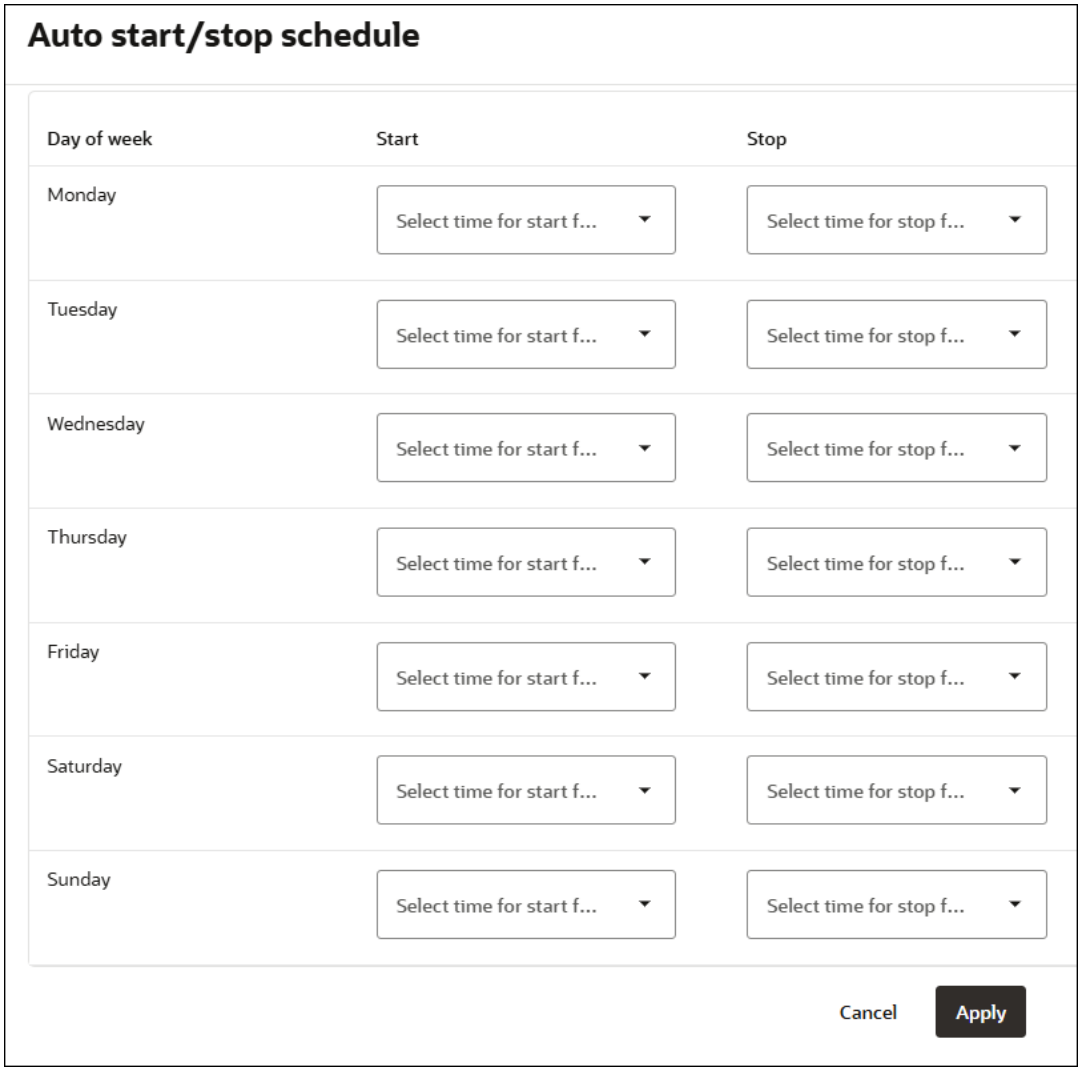
When you enable Auto Start/Stop Schedule on an Autonomous Database instance, the instance automatically starts and stops according to the schedule you specify. This allows you to reduce costs by scheduling shutdown periods for times when a system is not in use.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To set the Auto Start/Stop Schedule, do the following:

1. On the **Details** page, from the **More actions** drop-down list, select **Auto start/stop schedule**.
2. For each day you want to schedule, select a start time and a stop time.



The drop-down list allows you to schedule start times and stop times hourly, on the hour, specified in Coordinated Universal Time (UTC).

Selecting both a start time and a stop time is not required. You can select just a start time or just a stop time.

3. Click **Apply** to apply the schedule.
4. In the schedule confirmation, click **Apply**.

   While the system applies the Auto Start/Stop Schedule, the lifecycle state changes to **Updating**. When the operation completes the lifecycle state shows **Available**.

   The **Auto start/stop schedule** field under **General Information** on the Autonomous Database details page lists the days with an Auto Start/Stop Schedule enabled, and includes an **Edit** link that you can click to view the details or make changes.

To remove start and stop times for a day from an Auto Start/Stop Schedule, edit the schedule and choose the Select time (UTC) value for either the start or the stop time for that day.

Notes for Autonomous Database Auto Start/Stop Schedule:

- A scheduled stop works the same way as a manual stop; when the scheduled stop occurs, any running database sessions are stopped.

- You can perform a manual start for a database, if necessary, after a database has stopped due to a scheduled stop.

  See Start Autonomous Database for more information.

- You can perform a manual stop for a database, if necessary, after a database has started due to a scheduled start.

  See Stop Autonomous Database for more information.

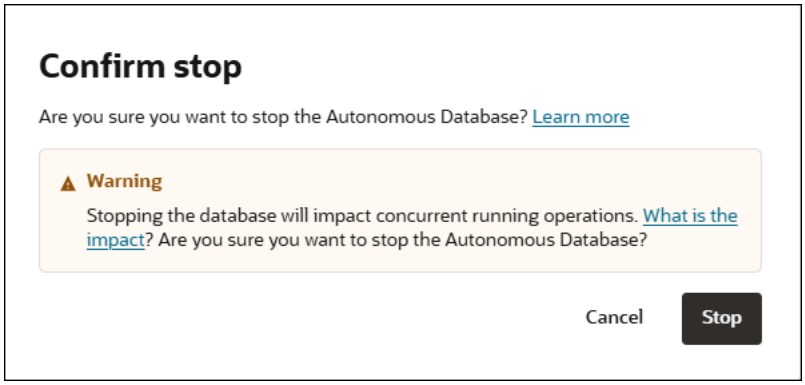
- The Lifecycle state must be **Available** to view or to edit the Auto Start/Stop Schedule.
- Always Free Autonomous Database does not support Auto Start/Stop Scheduling.
- A database that has been scheduled stopped, remains stopped until the next scheduled start time or until you start the database. Likewise, a database that has been scheduled started, remains running until the next scheduled stop time or until you stop the database.
- When an Autonomous Database remains stopped for over 7 days it may take a few minutes or longer to start up, depending on the size of the database. To avoid this extra startup time, Oracle recommends starting your Autonomous Database instance once every 7 days.

Concurrent Operations on Autonomous Database

Describes the actions that cause Oracle Cloud Infrastructure Console to ask you to confirm pausing or canceling a concurrent operation.

When you initiate certain operations that take some time to complete, including scaling the system, these operations do not prevent you from performing other operations. For example, database connections, database operations, and most Autonomous Database actions proceed normally while you scale the system. However, certain database lifecycle management actions such as stopping the database have an impact on concurrent long-running operations.

For some actions a confirmation dialog displays to let you know when a concurrent operation is active. This allows you to proceed or to cancel the operation. For example, while stopping Autonomous Database you see a message such as the following:



- Manage Scaling with Concurrent Operations
  Describes the impact on scaling operations when you initiate certain actions during an ongoing scaling request.
- Long-Term Backup with Concurrent Operations
  Describes the impact on a long-term backup operation when you initiate certain actions during an ongoing long-term backup.

Manage Scaling with Concurrent Operations

Describes the impact on scaling operations when you initiate certain actions during an ongoing scaling request.

Action	Description
Stop	Stop pauses scaling. The scaling restarts when the database starts.
Restart	Restart pauses scaling. The scaling restarts when the database starts.
Restore	Restore pauses scaling. The scaling restarts when the restore completes if resources allow.
Switchover	Switchover pauses scaling. The scaling restarts when the switchover completes. The scaling also occurs on the standby database after the switchover.
Failover	Failover pauses scaling. The scaling restarts when the failover completes. The scaling also occurs on the standby database if it is available after the failover.
Terminate	Scaling stops and the database is terminated.
Change Database Mode Read-Write or Read-Only	A mode change pauses scaling. The scaling restarts when the database starts after the mode change completes.

Long-Term Backup with Concurrent Operations

Describes the impact on a long-term backup operation when you initiate certain actions during an ongoing long-term backup.

Action	Description
Stop	Stop cancels an ongoing long-term backup. The long-term backup does not restart when the database starts.
Restart	Restart cancels an ongoing long-term backup. The long-term backup does not restart when the database starts.
Restore	Restore cancels an ongoing long-term backup.
Switchover	Switchover cancels an ongoing long-term backup. The long-term backup does not restart after the switchover completes.
Failover	Failover cancels an ongoing long-term backup. The long-term backup does not restart after the failover completes.
Terminate	Terminate cancels an ongoing long-term backup.

Update Compute and storage limits

Autonomous Database has the ability to increase its storage or CPU cores. You can also activate auto scaling.

- Add CPU or Storage Resources or Enable Auto Scaling
  Describes how to scale your Autonomous Database on demand by adding CPU cores or storage. Also describes how to enable auto scaling.
- Remove CPU or Storage Resources or Disable Auto Scaling
  Describes how to scale your Autonomous Database on demand by removing CPU cores or storage. Also describes how to disable auto scaling.

- Use Auto Scaling
  When you create an Autonomous Database instance, by default compute auto scaling is enabled and storage auto scaling is disabled. You can manage auto scaling from the Oracle Cloud Infrastructure Console to enable or disable compute auto scaling or storage auto scaling.

Add CPU or Storage Resources or Enable Auto Scaling

Describes how to scale your Autonomous Database on demand by adding CPU cores or storage. Also describes how to enable auto scaling.

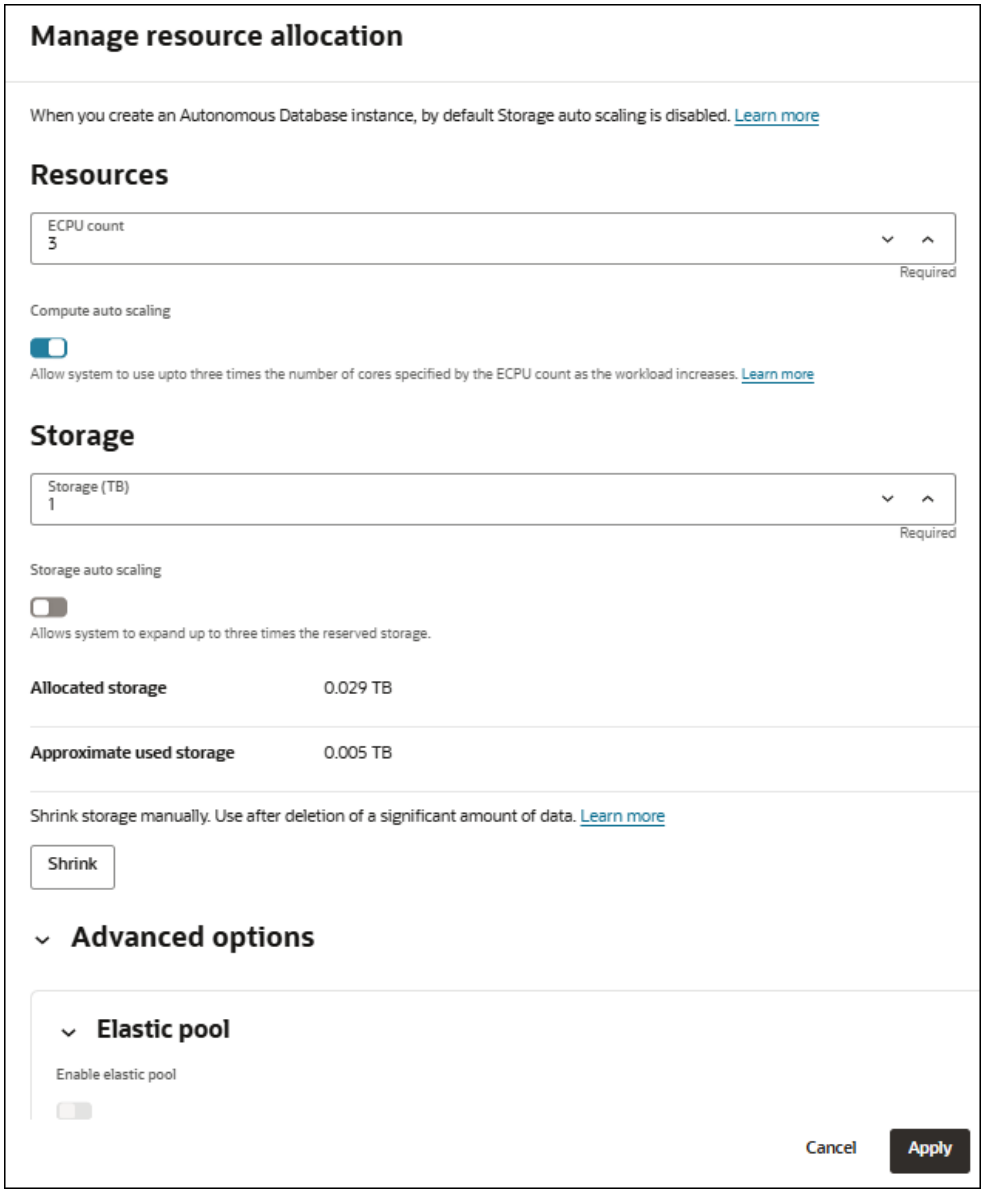
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To add resources to an Autonomous Database instance:

1. On the **More Actions** menu, click **Manage resource allocation**.
2. In the **Manage resource allocation** area, add resources for your scale request.
   - Enter a value or click the up arrow to select a value for **ECPU count** (**OCPU count** if your database uses OCPUs). The default is no change.
   - **Storage**: Specify the storage you wish to make available to your database. Depending on your workload type and your compute model, you have these options:
     - **Data Warehouse**: Specify your storage in Terabytes (TB).
     - **Transaction Processing** or **JSON**: Specify your storage in Gigabytes (GB) or Terabytes (TB). Enter the size in the **Storage** field. Select **GB** or **TB** for the **Storage unit size**. GB units are only available when the Workload type is Transaction Processing and the Compute model is **ECPU**.

     The default is no change.



3. Enable compute auto scaling.

   Select **Compute auto scaling** to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand, compared to the database operating with compute auto scaling disabled. The additional resources are available until you disable compute auto scaling.

   If compute auto scaling is disabled while more CPUs are in use than the specified **ECPU count** (**OCPU count** if your database uses OCPUs), then Autonomous Database scales the number of CPUs in use down to the **ECPU count** (**OCPU count**).

   See Use Auto Scaling for more information.

4. To enable Storage auto scaling, select **Storage auto scaling**.

   When you select **Storage auto scaling** the database can expand to use up to three times the reserved base storage.

   If you disable **Storage auto scaling** and the used storage is greater than the reserved base storage, as specified by the storage shown in the **Storage** field on the Oracle Cloud Infrastructure Console, Autonomous Database shows a warning on the disable storage

auto scaling confirmation dialog. The warning lets you know that the reserved base storage value will be increased to the nearest TB greater than the actual storage usage on a Data Warehouse workload instance, or to the nearest GB greater than the actual storage usage on a Transaction Processing workload instance, and shows the new reserved base storage value.

See Use Auto Scaling for more information.

> **Note:**
>
> Clicking **Shrink** initiates the Shrink storage operation. See Shrink Storage for more information.

5. Click **Enable elastic pool** to join an elastic pool.

> **Note:**
>
> To enable an elastic pool the instance must use the ECPU compute model and the workload type you select must be **Transaction Processing**.

6. Click **Apply** to change your resources.

When you click **Apply** with a resource change, the Lifecycle state changes to **Scaling in Progress...**. After the Lifecycle state changes to **Available** the changes apply immediately.

Note the following for adding storage resources or changing the **Storage auto scaling** value:

- Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

  With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

  With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

Remove CPU or Storage Resources or Disable Auto Scaling

Describes how to scale your Autonomous Database on demand by removing CPU cores or storage. Also describes how to disable auto scaling.

Perform the following prerequisite steps as necessary:

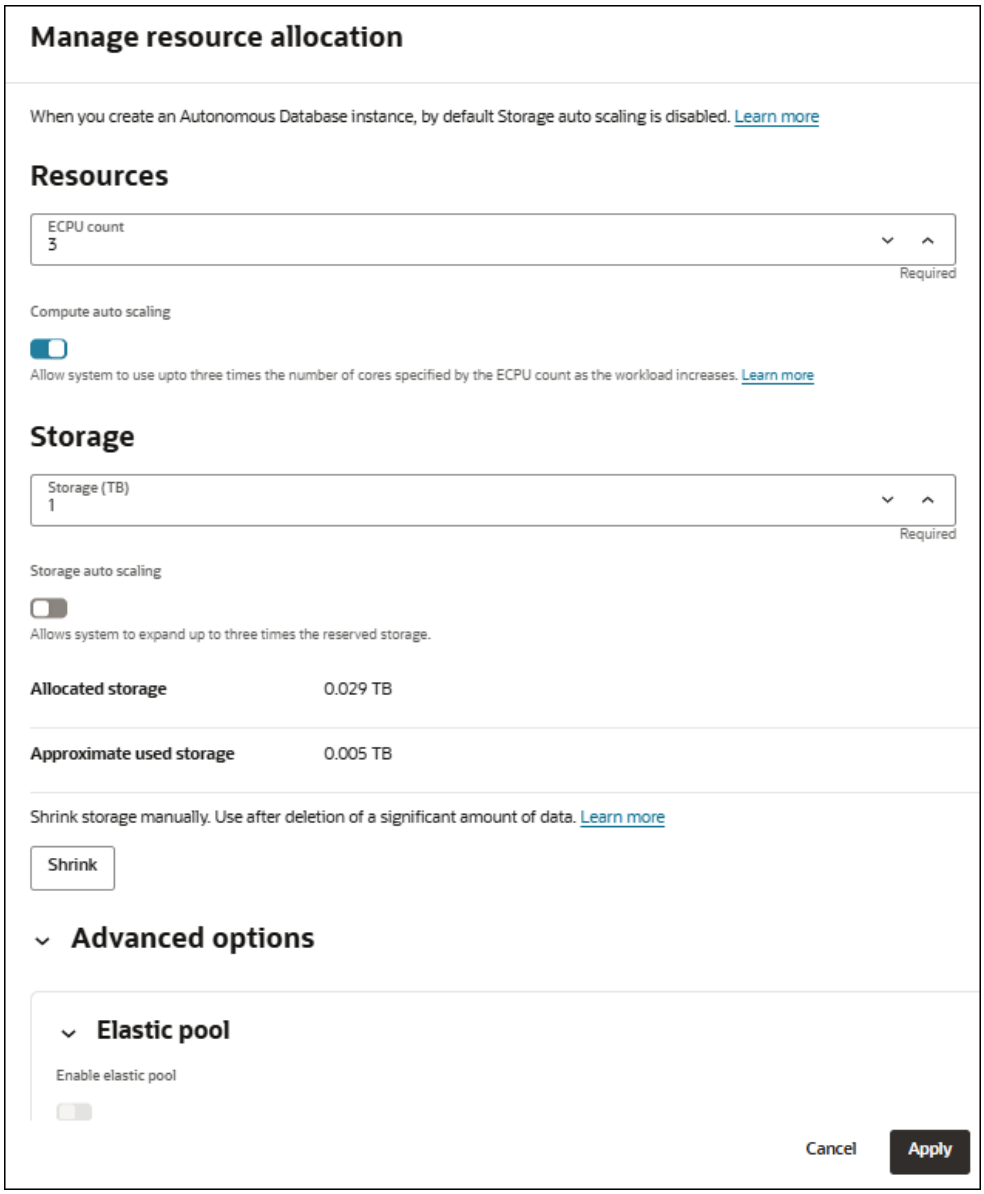
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To remove resources from an Autonomous Database instance:

1. On the **More Actions** drop-down menu of the OCI console, click **Manage resource allocation**.

2. In the **Manage resource allocation** area, select the change in resources for your scale request:
   - Enter a value or click the down arrow to select a value for the **ECPU count** (**OCPU count** if your database uses OCPUs). The default is no change.
   - **Storage**: Specify the storage you wish to make available to your database. Depending on your workload type and your compute model, you have these options:
     - **Data Warehouse**: Specify your storage in Terabytes (TB).
     - **JSON**: Specify your storage in Terabytes (TB).
     - **Transaction Processing**: Specify your storage in Gigabytes (GB) or Terabytes (TB). Enter the size in the **Storage** field. Select **GB** or **TB** for the **Storage unit size**. GB units are only available when the Workload type is Transaction Processing and the Compute model is **ECPU**.

     The default is no change.



3. When compute auto scaling is enabled, deselect **Compute auto scaling** to disable compute auto scaling.

   If compute auto scaling is disabled while more CPUs are in use than the specified **ECPU count** (**OCPU count** if your database uses OCPUs), then Autonomous Database scales the number of CPUs in use down to the **ECPU count** (**OCPU count** if your database uses OCPUs).

   See Use Auto Scaling for more information.

4. When Storage auto scaling is enabled, deselect **Storage auto scaling** to disable storage auto scaling.

   If you disable **Storage auto scaling** and the used storage is greater than the reserved base storage, as specified by the storage shown in the **Storage** field on the Oracle Cloud Infrastructure Console, Autonomous Database shows a warning on the disable storage auto scaling confirmation dialog. The warning lets you know that the reserved base storage value will be increased to the nearest TB greater than the actual storage usage on a Data Warehouse workload instance, or to the nearest GB greater than the actual storage usage on a Transaction Processing workload instance, and shows the new reserved base storage value.

   See Use Auto Scaling for more information.

   > **Note:**
   >
   > Clicking **Shrink** initiates the Shrink storage operation. See Shrink Storage for more information.

5. Select **Enable elastic pool** to join an elastic pool.
6. Click **Apply** to change your resources.

When you click **Apply** with a resource change, the Lifecycle state changes to **Scaling in Progress...**. After the Lifecycle state changes to **Available** the changes apply immediately.

Note the following when you scale down storage or change the **Storage auto scaling** value:

- Scaling down storage is not allowed if the Autonomous Database instance contains the following:
  - `MEMOPTIMIZE FOR WRITE` tables
- If you have columns with the `ROWID` data type, the `ROWID`s that these column values point to may change during the scale down storage operation.
- Tables that contain the following may be moved offline during a scale down operation. DML operations on these tables may be blocked for the duration of the move and the table indexes for these tables may become unusable until the scale down operation completes:
  - Tables with bitmap join indexes
  - Nested tables
  - Object tables
  - Partitioned tables with domain indexes
- Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

Use Auto Scaling

When you create an Autonomous Database instance, by default compute auto scaling is enabled and storage auto scaling is disabled. You can manage auto scaling from the Oracle Cloud Infrastructure Console to enable or disable compute auto scaling or storage auto scaling.

- Compute Auto Scaling
- Storage Auto Scaling
  When you create an Autonomous Database instance, by default **Storage auto scaling** is disabled. You can manage scaling and enable storage auto scaling from the Oracle Cloud Infrastructure Console or using the API.
- Shrink Storage
  When the storage used in the database is significantly lower than the allocated storage, the shrink operation reduces the allocated storage.

Compute Auto Scaling

With compute auto scaling enabled the database can use up to three times more CPU and IO resources than specified by the number of ECPUs (OCPUs if your database uses OCPUs) as shown in the **ECPU count** or **OCPU count** field on the Oracle Cloud Infrastructure Console.

When auto scaling is enabled, if your workload requires additional CPU and IO resources, the database automatically uses the resources without any manual intervention required. For example:

- In the ECPU compute model, when the **ECPU count** is 512, this allows the database to use up to 512 x 3 ECPUs (1536 ECPUs) when auto scaling is enabled.

  To see the average number of ECPUs used during an hour you can use the "Number of ECPUs allocated" graph on the Overview tab on the **Database Dashboard** card in Database Actions. See Database Dashboard Overview for more information.
- In the OCPU compute model, when the **OCPU count** is 128, this allows the database to use up to 128 x 3 OCPUs (384 OCPUs) when auto scaling enabled.

  To see the average number of OCPUs used during an hour you can use the "Number of OCPUs allocated" graph on the Overview tab on the **Database Dashboard** card in Database Actions. See Database Dashboard Overview for more information.

Enabling compute auto scaling does not change the concurrency and parallelism settings for the predefined services. See Manage Concurrency and Priorities on Autonomous Database for more information.

> **Note:**
>
> Your license type determines the **ECPU count** maximum. For example, if your license type is Bring your own license (BYOL) with Oracle Database Standard Edition (SE), the **ECPU count** maximum is 32.For this license type the maximum allowed value for **ECPU count** is 32. With compute auto scaling enabled you can use up to **ECPU count** x 3 ECPUs. This license restricts the number of ECPUs you can use to a maximum of 32 ECPUs, with or without compute auto scaling enabled.

When compute auto scaling is enabled your database may use and you may be billed for additional CPU consumption as needed by your workload, up to three times (3x) the number of base CPUs (as shown in the **ECPU count** or **OCPU count** field on the Oracle Cloud Infrastructure Console). See Oracle Autonomous Database Serverless Features Billing for details on compute auto scaling billing.

See Add CPU or Storage Resources or Enable Auto Scaling for the steps to enable compute auto scaling.

Storage Auto Scaling

When you create an Autonomous Database instance, by default **Storage auto scaling** is disabled. You can manage scaling and enable storage auto scaling from the Oracle Cloud Infrastructure Console or using the API.

With **Storage auto scaling** enabled, the Autonomous Database can expand to use up to three times the reserved base storage, as specified by the storage shown in the **Storage** field on the Oracle Cloud Infrastructure Console. If you need additional storage, the database automatically uses the reserved storage without any manual intervention required.

You specify the base storage when you provision or clone your database, or you can change the storage at any time by clicking **Manage resource allocation** under **More Actions** in the OCI console and changing the storage size. Depending on your workload type and the compute model selection, you have these options to specify the reserved base storage units:

- **Data Warehouse**: Specify your storage in Terabytes (TB).
- **Transaction Processing**: Specify your storage in Gigabytes (GB) or Terabytes (TB). GB units are only available when the Workload type is Transaction Processing and the Compute model is ECPU.

Using the Oracle Cloud Infrastructure Console or the APIs you can provision or auto-scale an Autonomous Database instance's storage up to 384 TB. For storage requirements larger than 384 TB, Oracle recommends that you file a Service Request at Oracle Cloud Support.

For example, if your storage is 100 TB and storage auto scaling is enabled, you have access to a maximum of 300 TB of storage and if your storage is 200 TB, you have access to a maximum of 384 TB (if you requested a larger maximum by filing a service request, then the maximum would be your custom maximum size).

As data flows in, depending on your workload type, you are billed as follows:

- For storage usage below your reserved base storage, you are billed based on your base storage.
- After your allocated storage exceeds your reserved base storage, storage usage is billed based on your allocated storage rounded up to the nearest TB for workload type Data Warehouse and to the nearest GB for workload types Transaction Processing, APEX, or JSON, in a given hour.

For example, when the Workload type is Data Warehouse, if your reserved base storage is 4 TB, until your allocated storage exceeds 4TB of storage, you are billed based on your base storage (4 TB). After you exceed 4 TB, storage is billed based on the allocated storage rounded up to the nearest TB, in a given hour. In this example, if the allocated storage grows over 4 TB in a given hour, say to 4.9 TB, you are billed for 5 TB of storage from that hour onward.

If you then delete 1 TB of data, your allocated storage remains at 4.9 TB and you are billed for 5 TB until you perform a shrink operation. When you perform a shrink operation, Autonomous Database may be able to reduce your allocated storage back to 3.9TB (shrinking the data and undo tablespaces). After the shrink operation completes and your allocated storage (3.9TB) is once again below your reserved base storage (4 TB), you will once again be billed for your reserved base storage of 4 TB. See Shrink Storage for more information.

> **Note:**
>
> Reducing temp tablespace requires a database restart.

If you disable **Storage auto scaling** and the used storage is greater than the reserved base storage, as specified by the storage shown in the **Storage** field on the Oracle Cloud Infrastructure Console, Autonomous Database shows a warning on the disable storage auto scaling confirmation dialog. The warning lets you know that the reserved base storage value will be increased to the nearest TB greater than the actual storage usage on a Data Warehouse workload instance, or to the nearest GB greater than the actual storage usage on a Transaction Processing workload instance, and shows the new reserved base storage value.

To see the Autonomous Database instance storage usage, you can view the "Storage allocated" and "Storage used" graphs on the Overview tab by clicking the **Database Dashboard** card in Database Actions. See Database Dashboard Overview for more information.

See Add CPU or Storage Resources or Enable Auto Scaling for the steps to enable storage auto scaling.

Note the following when you enable **Storage auto scaling**:

- Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

  With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

  With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

Shrink Storage

When the storage used in the database is significantly lower than the allocated storage, the shrink operation reduces the allocated storage.

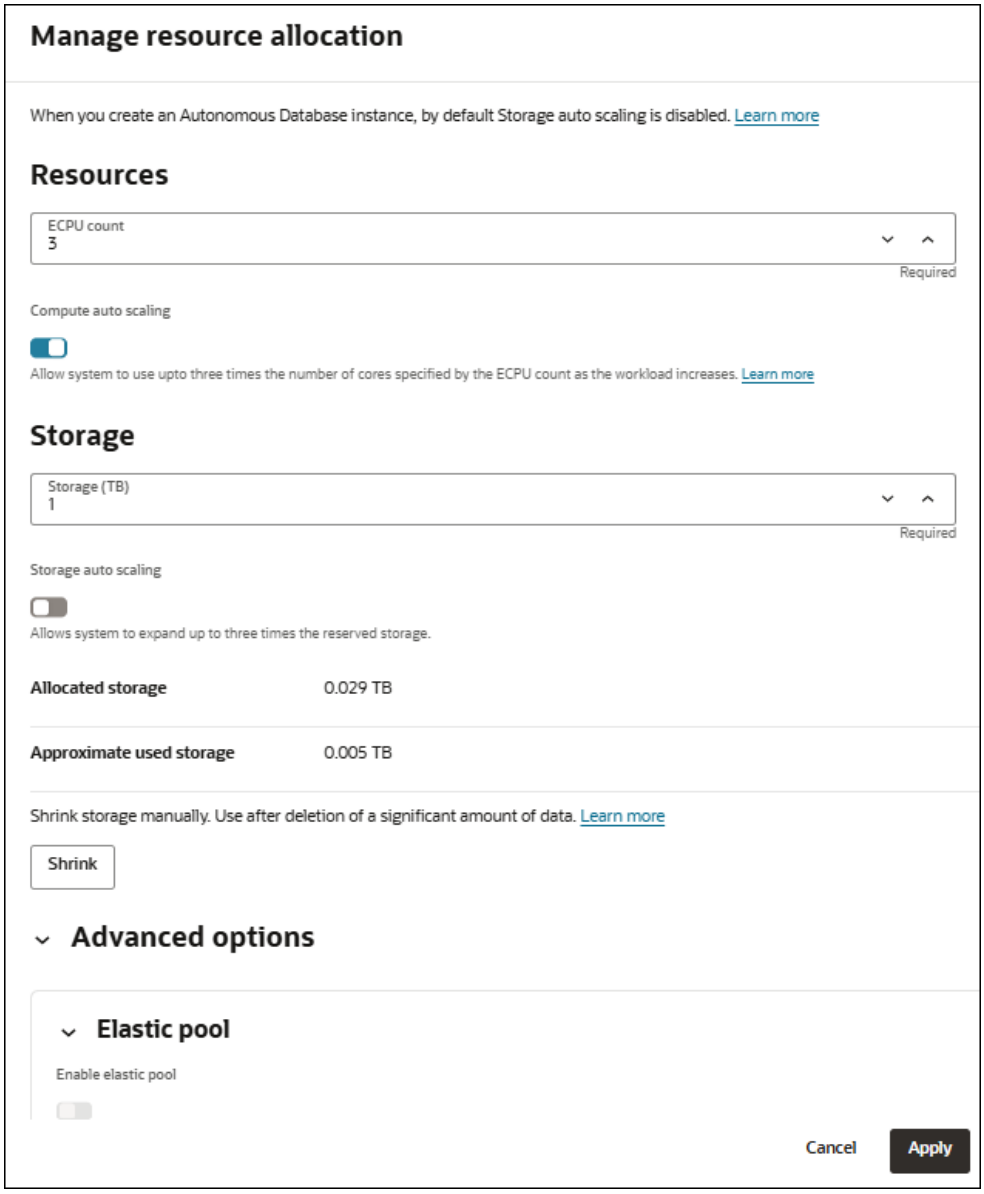
To understand storage allocation and the shrink operation, note the following:

- Reserved base storage: is the base amount of storage you select for the database when you provision or scale the database, excluding any auto-scaled value. The reserved base storage is shown in the **Storage** field on the Oracle Cloud Infrastructure Console.
- Allocated storage: is the amount of storage physically reserved for all database tablespaces (excluding sample schema tablespaces). This number also includes the free space in these tablespaces.
- Used storage: is the amount of storage actually used in all tablespaces (excluding the sample schema tablespaces). The used storage excludes the free space in these tablespaces. Used storage is the storage actually used by database objects, tables, indexes, and so on, including internally used temp space.
- Maximum storage: is the maximum storage reserved. When storage auto scaling is disabled, the maximum storage equals the reserved base storage. When storage auto scaling is enabled, the maximum storage is three times the base storage (maximum = reserved base x 3).

> **Note:**
>
> The **Shrink** operation is not available with Always Free Autonomous Database.

To shrink storage:

1. On the **More Actions** drop-down list of the OCI console, click **Manage resource allocation**.
2. In the **Manage resource allocation** area, select **Shrink**.



3. Click **Confirm** in the Shrink Database dialog.

> **Note:**
>
> The **Shrink** operation is a long running operation.

The **Shrink** operation requires that all of the following apply:

- **Storage auto scaling** must be enabled.
- The allocated storage must be greater than the reserved base storage.
- The allocated storage, rounded up to the nearest 1TB, can be reduced by 1TB or more.
- The following must be true:

  Allocated storage - Used storage > 100 GB

When you click **Shrink** and these conditions are not met, Autonomous Database shows the **Action unavailable** dialog.

Note the following for the Shrink operation:

- The shrink operation runs an `alter table... move online` operation which uses the database's CPUs. In cases where the shrink operation is running slow or taking a very long time, Oracle recommends that you scale up the number of CPUs. See Add CPU or Storage Resources or Enable Auto Scaling for more information.
- The shrink operation is not allowed if the Autonomous Database instance contains the following:
  - Vector indexes
  - Advanced Queuing tables
  - `MEMOPTIMIZE FOR WRITE` tables
- If you have columns with the `ROWID` data type, the `ROWID`s that these column values point to may change during the shrink operation.
- Tables that contain the following may be moved offline during the shrink operation. DML operations on these tables may be blocked for the duration of the move and the table indexes for these tables may become unusable until the shrink operation completes:
  - Tables with bitmap join indexes
  - Nested tables
  - Object tables
  - Immutable tables
  - Blockchain tables
  - Partitioned tables with domain indexes
- If you perform a **Shrink** operation very soon after a data deletion operation, the **Shrink** operation may fail. This can be due to the delay required for Autonomous Database to recalculate storage values. In this case, Oracle recommends that you retry the **Shrink** operation (that is, wait for several minutes for the storage deletion and any associated storage usage updates to complete and perform the **Shrink** operation again).

Update Billing Model, Choose Bring Your Own License, or Update Instance to a Paid Instance

Describes how to choose to bring your own license to your Autonomous Database instance. Also shows how to update the billing model to the ECPU compute model and shows how to update your instance from free (Always Free) to a paid instance.

- Choose Bring Your Own License Option While Provisioning or Cloning
  Describes how to select the option to Bring Your Own License (BYOL) while provisioning or cloning an Autonomous Database instance.
- Choose Bring Your Own License on Autonomous Database (ECPU Compute Model)
- Choose Bring Your Own License on Autonomous Database (OCPU Compute Model)
  Describes how to Bring Your Own License (BYOL) to your Autonomous Database instance.
- Update to ECPU Billing Model on Autonomous Database
  Describes how to update an Autonomous Database instance from the OCPU billing model to the ECPU billing model.

- Update Always Free Instance to Paid with Autonomous Database
  Describes how to update your instance to paid from free with Autonomous Database.
- Upgrade Autonomous JSON Database to Autonomous Transaction Processing
  You can promote an Autonomous JSON Database to an Autonomous Transaction Processing database at any time.
- Upgrade APEX Service to Autonomous Transaction Processing
  Easily upgrade APEX Service to Autonomous Transaction Processing.

Choose Bring Your Own License Option While Provisioning or Cloning

Describes how to select the option to Bring Your Own License (BYOL) while provisioning or cloning an Autonomous Database instance.

> **Note:**
>
> The Bring Your Own License (BYOL) option is only available for Autonomous Database instances with the Transaction Processing or Data Warehouse workload types.

During provisioning or cloning you can select **Bring Your Own License (BYOL)** to bring existing database software licenses to the database cloud service when your organization already owns Oracle Database software licenses:

1. During provisioning, in the Database configuration area, under **Advanced options**, enable the **Bring your own license** field.

   This shows the Update license and Oracle Database Edition pane.

2. On the Update license and Oracle Database Edition pane, select **Bring Your Own License (BYOL)**.

   Selecting **Bring Your Own License (BYOL)** displays the Update license and Oracle Database Edition pane.

3. On the Update license and Oracle Database Edition pane, choose an Oracle Database Edition, one of: **Oracle Database Enterprise Edition (EE)** or **Oracle Database Standard Edition (SE).**

   When you select **Bring your own license (BYOL)** you also specify the Oracle Database Edition. The Oracle Database Edition you specify is based on the licenses you bring to Autonomous Database and determines the values that you can select for the **ECPU count**.

Oracle Database Edition	Description
Oracle Database Enterprise Edition (EE)	With this option you can select the **Enable the BYOL ECPU limit and set the number of ECPUs to be covered by BYOL** (we call this the **BYOL ECPU limit** option). • **BYOL ECPU limit** selected: When you select this option you set a **BYOL ECPU limit** for your BYOL licenses.When you select this option you set a **BYOL ECPU limit** for your BYOL licenses. • **BYOL ECPU limit** deselected: For this license type the maximum allowed value for **ECPU count** is 512, however you may contact your Oracle account team to request more ECPUs. With compute auto scaling enabled you can use up to **ECPU count** x 3 ECPUs. For example, if you set the **ECPU count** to 512, you can use up to 1,536 ECPUs.
Oracle Database Standard Edition (SE)	For this license type the maximum allowed value for **ECPU count** is 32. With compute auto scaling enabled you can use up to **ECPU count** x 3 ECPUs. This license restricts the number of ECPUs you can use to a maximum of 32 ECPUs, with or without compute auto scaling enabled.

4. Click **Save**.
5. Continue with any remaining provisioning or cloning steps.

   See Provision an Autonomous Database Instance and Clone an Autonomous Database Instance for more information.

Notes for when you Bring Your Own License (BYOL):

- See Elastic Pool Notes for information on BYOL usage with an instance that is in an elastic pool.
- The **BYOL ECPU limit** you set on an Autonomous Data Guard Primary database does not apply to a cross-region or cross-tenancy Autonomous Data Guard Standby database. On a cross-region or cross-tenancy Standby you can independently set the **BYOL ECPU limit**, as required.
- For information on Bring Your Own License (BYOL) licensing options for Oracle Cloud Infrastructure, see the following:
  - Lower your TCO for Oracle Database Standard Edition with the Bring Your Own License (BYOL) program
  - For Bring Your Own License (BYOL) policies, see Oracle Cloud Services contracts. BYOL policies are described in the **Oracle PaaS and IaaS Universal Credits Service Descriptions** document under **Cloud Service Descriptions**.
  - Frequently asked questions: Oracle Bring Your Own License (BYOL)
  - Cloud pricing

Choose Bring Your Own License on Autonomous Database (ECPU Compute Model)

Describes how to choose Bring Your Own License to your Autonomous Database instance.

> **Note:**
>
> See Choose Bring Your Own License on Autonomous Database (OCPU Compute Model) if you are using the OCPU compute model.

The **License type** field on the Oracle Cloud Infrastructure Console Autonomous Database Information tab shows when you enable the Bring Your Own License (BYOL) option. This field shows your license type and Oracle Database Edition. For example:

License type: Bring Your Own License (BYOL), Enterprise Edition

The Bring Your Own License (BYOL) option is only available for Autonomous Database instances with the Transaction Processing or Data Warehouse workload types.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To choose Bring Your Own License for your Autonomous Database instance:

1. On the **Details** page, from the **More actions** drop-down list, select **Update license and Oracle Database edition**.
2. On the **Update license Oracle Database edition** page enable or disable Bring Your Own License (BYOL) option from the choices:

   Enable **Bring Your Own License (BYOL)** to bring existing database software licenses to the database cloud service when your organization already owns Oracle database software licenses.

   When you select **Bring your own license (BYOL)** you also specify the Oracle Database Edition. The Oracle Database Edition you specify is based on the licenses you bring to Autonomous Database and determines the values that you can select for the **ECPU count**.

   Choose one of: **Oracle Database Enterprise Edition (EE)** or **Oracle Database Standard Edition (SE)**.

Oracle Database Edition	Description
Oracle Database Enterprise Edition (EE)	You have two options, depending on whether you select **Enable BYOL ECPU limit and set the number of ECPUs to be covered by BYOL** (we call this the **BYOL ECPU limit** option and this option is either selected or deselected): • **BYOL ECPU limit** selected: When you select this option you set a **BYOL ECPU limit** for your BYOL licenses. The value you specify indicates how many licenses to use from your existing Enterprise Edition licenses. That is, the **BYOL ECPU limit** indicates how many of your existing licenses you are bringing to the Autonomous Database instance. The **BYOL ECPU limit** you specify indicates how many ECPUs will be covered by the Enterprise Edition licenses you bring. Any ECPU usage beyond the **BYOL ECPU limit** will not by covered by BYOL licenses. • **BYOL ECPU limit** deselected: For this license type the maximum allowed value for **ECPU count** is 512, however you may contact your Oracle account team to request more ECPUs. With compute auto scaling enabled you can use up to **ECPU count** x 3 ECPUs. For example, if you set the **ECPU count** to 512, you can use up to 1,536 ECPUs.
Oracle Database Standard Edition (SE)	For this license type the maximum allowed value for **ECPU count** is 32. With compute auto scaling enabled you can use up to **ECPU count** x 3 ECPUs. This license restricts the number of ECPUs you can use to a maximum of 32 ECPUs, with or without compute auto scaling enabled.

3. Click **Save**.

While the system applies the changes, the lifecycle state changes to **Updating**. The database remains up and accessible, there is no downtime while the license type updates. When the operation completes the lifecycle state shows **Available**.

For information on Bring Your Own License (BYOL) licensing options for Oracle Cloud Infrastructure, see the following:

- Lower your TCO for Oracle Database Standard Edition with the Bring Your Own License (BYOL) program
- For BYOL policies, see Oracle Cloud Services contracts. BYOL policies are described in the **Oracle PaaS and IaaS Universal Credits Service Descriptions** document under **Cloud Service Descriptions**.
- Frequently asked questions: Oracle Bring Your Own License (BYOL)
- Cloud pricing

Notes Update license and Oracle Database edition:

- If you try to switch to Bring Your Own License (BYOL) Standard Edition when the base ECPU count is above 32, you see the following message:
  ```
  You cannot select Oracle Database Standard Edition unless your ECPU count is a total of sixteen (32) or less ECPUs. Use the Manage Scaling option to adjust your ECPU count before changing to Standard Edition.
  ```
  In this case, lower your ECPU count before you enable Bring Your Own License (BYOL). See Remove CPU or Storage Resources or Disable Auto Scaling for more information.
- If you enable **Bring Your Own License (BYOL)** field and select Standard Edition when the base ECPU count is 32 and compute auto scaling is enabled, you see the following message:

```
Compute auto scaling will be disabled with a base ECPU count of 32, under an
Oracle Database Standard Edition license.
```

In this case, **Compute auto scaling** is disabled and the **ECPU count** is set to 32.

- If you select **Enable Bring Your Own License (BYOL)** and Standard Edition when the base ECPU count is below 32 and above 8, with compute auto scaling enabled, you see the following message:
  ```
  Your compute auto scaling maximum will be set to 32 ECPUs, under an Oracle
  Database Standard Edition license.
  ```

  In this case, the maximum number of ECPUs with compute auto scaling is 32.
- See Elastic Pool Notes for information on BYOL usage with an instance that is in an elastic pool.
- The **BYOL ECPU limit** you set on an Autonomous Data Guard Primary database does not apply to a cross-region or cross-tenancy Autonomous Data Guard Standby database. On a cross-region or cross-tenancy Standby you can independently set the **BYOL ECPU limit**, as required.

  See Autonomous Data Guard Notes for information on BYOL usage with Autonomous Data Guard.
- For information on Bring Your Own License (BYOL) licensing options for Oracle Cloud Infrastructure, see the following:
  - Lower your TCO for Oracle Database Standard Edition with the Bring Your Own License (BYOL) program
  - For BYOL policies, see Oracle Cloud Services contracts. BYOL policies are described in the **Oracle PaaS and IaaS Universal Credits Service Descriptions** document under **Cloud Service Descriptions**.
  - Frequently asked questions: Oracle Bring Your Own License (BYOL)
  - Cloud pricing

Choose Bring Your Own License on Autonomous Database (OCPU Compute Model)

Describes how to Bring Your Own License (BYOL) to your Autonomous Database instance.

> **Note:**
>
> See Choose Bring Your Own License on Autonomous Database (ECPU Compute Model) if you are using the ECPU compute model.

The **License type** field shows on the Autonomous Database Information tab when you enable the Bring Your Own License (BYOL) option. This field shows your license and Oracle Database Edition. For example:

License type: Bring Your Own License (BYOL), Enterprise Edition

The Bring Your Own License (BYOL) option is only available for Autonomous Database instances with the Transaction Processing or Data Warehouse workload types.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.

- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To enable or disable Bring Your Own License (BYOL):

1. On the **Details** page, from the **More actions** drop-down list, select **Update license and Oracle Database edition**.
2. On the **Update license and Oracle Database edition** page enable or disable the Bring Your Own License (BYOL) option and select an Oracle Database Edition:

   When you enable **Bring Your Own License (BYOL)**, you also choose an Oracle Database Edition. The choices are:

   Oracle Database Enterprise Edition (EE): For this license type the maximum allowed value for **OCPU count** is 128, however you may contact your Oracle account team to request more than 128 OCPUs. With auto scaling enabled you can use up to **OCPU count** x 3 OCPUs. For example, if you set the **OCPU count** to 128, you can use up to 384 OCPUs.

   Oracle Database Standard Edition (SE): For this license type the maximum allowed value for **OCPU count** is 8. With auto scaling enabled you can use up to **OCPU count** x 3 OCPUs. This license restricts the number of OCPUs you can use to a maximum of 8 OCPUs, with or without auto scaling enabled.

   The edition you select is based on the licenses you bring to Autonomous Database and changes the maximum value that you can select for the **OCPU count**.

   See Use Auto Scaling for more information.
3. Click **Save**.

While the system applies the changes, the lifecycle state changes to **Updating**. The database remains up and accessible, there is no downtime while the license type updates. When the operation completes the lifecycle state shows **Available**.

For information on Bring Your Own License (BYOL) licensing options for Oracle Cloud Infrastructure, see the following:

- Lower your TCO for Oracle Database Standard Edition with the Bring Your Own License (BYOL) program
- For BYOL policies, see Oracle Cloud Services contracts. BYOL policies are described in the **Oracle PaaS and IaaS Universal Credits Service Descriptions** document under **Cloud Service Descriptions**.
- Frequently asked questions: Oracle Bring Your Own License (BYOL)
- Cloud pricing

Notes for Update license and Oracle Database Edition:

- If you enable **Bring Your Own License (BYOL)** with Standard Edition when the base OCPU count is above 8, you see the following message:
  ```
  You cannot select Oracle Database Standard Edition unless your OCPU count is a total of eight (8) or less OCPUs. Use the Manage Scaling option to adjust your OCPU count before changing to Standard Edition.
  ```
  In this case, lower your OCPU count before you enable Bring Your Own License (BYOL). See Remove CPU or Storage Resources or Disable Auto Scaling for more information.

- If you enable **Bring Your Own License (BYOL)** with Standard Edition when the base OCPU count is 8 and **Compute auto scaling** is enabled, you see the following message:
  `Compute auto scaling will be disabled with a base OCPU count of 8, under an Oracle Database Standard Edition license.`

  In this case, **Compute auto scaling** is disabled and the OCPU count is set to 8.
- If you select **Enable Bring Your Own License (BYOL)** with Standard Edition when the base OCPU count is below 8 and above 2, with **Compute auto scaling** enabled, you see the following message:
  `Your compute auto scaling maximum will be set to 8 OCPUs, under an Oracle Database Standard Edition license.`

  In this case, the maximum number of OCPUs with **Compute auto scaling** enabled is 8.

Update to ECPU Billing Model on Autonomous Database

Describes how to update an Autonomous Database instance from the OCPU billing model to the ECPU billing model.

> **Note:**
>
> If you update an Autonomous Database instance to use the ECPU billing model, you cannot revert back to the OCPU billing model.

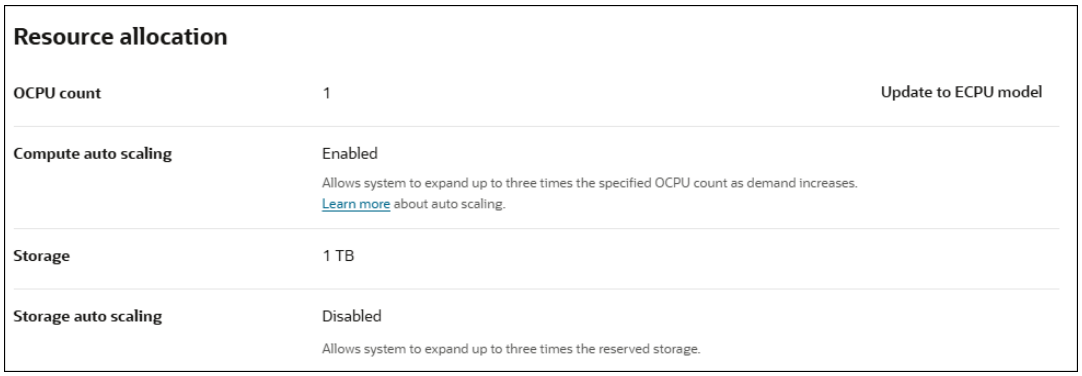
See Compute Models in Autonomous Database for details on the Autonomous Database billing models.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To update to the ECPU billing model:

1. On the **Autonomous Database information** page, under **Resource allocation**, in the **OCPU count** field, click **Update to ECPU model**.



2. In the **Update compute model** area.

- **Compute**: For the billing options **ECPU count** and **Compute auto scaling**, the values are read only and you must accept the defaults. You can change the values after you update to ECPU billing model.

  See Use Auto Scaling for more information.

- **Current automatic backup storage**: The default backup retention is 60 days.

  To change the default specify a value for **Automatic backup retention period in days**.

  See Edit Automatic Backup Retention Period on Autonomous Database for more information.

3. Click **Save**.

While the system applies the changes, the Lifecycle state changes to **Updating**.

The database remains up and accessible, there is no downtime when you update the billing model. When the operation completes the Lifecycle state shows **Available** and on the details page under **Resource allocation**, the fields show **ECPU count** and **Compute auto scaling**.

Notes for Updating to the ECPU billing model:

- Your current storage selection is retained. You may scale up or down your storage after updating the billing model. See Add CPU or Storage Resources or Enable Auto Scaling for more information.
- Updating to the ECPU billing model impacts the cost of your compute, storage, and backups. See Compute Models in Autonomous Database for details on the ECPU billing model.
- Peer databases connected to an Autonomous Database instance that is updated to the ECPU billing model are also updated to the ECPU billing model.

  See Use Standby Databases with Autonomous Data Guard for Disaster Recovery and Use Backup-Based Disaster Recovery for more information on the Autonomous Database disaster recovery options.
- Updating a refreshable clone's source database to the ECPU billing model does not automatically update the refreshable clone's billing model to ECPUs. You must update the ECPU billing model on the refreshable clone separately as well. See Use Refreshable Clones with Autonomous Database for more information.

Update Always Free Instance to Paid with Autonomous Database

Describes how to update your instance to paid from free with Autonomous Database.

You can upgrade from an Always Free Autonomous Database account to a paid account at any time. If you have a free Oracle Cloud Infrastructure account this is a two step process:

First, upgrade to a paid Oracle Cloud Infrastructure account.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Always Free Autonomous Database instance from the links under the **Display Name** column.

> **Note:**
>
> Promotion of Always Free to a paid Autonomous Database is supported when the database version for the Always Free Autonomous Database is Oracle Database 19c or Oracle Database 23ai.

Upgrade your Always Free Autonomous Database instance as follows:

1. On the **Details** page, from the **More actions** drop-down list, select **Update instance to paid**.
2. On the **Update Instance** page confirm and proceed with the upgrade.

When you upgrade from an Always Free instance to a paid instance you get a paid instance of the same workload type with the minimum CPU and minimum storage available for that workload type. After you upgrade you can scale up CPU and storage resources to fit your needs.

For example:

- **Data Warehouse** workload type: When you upgrade to paid from an Always Free instance, the upgrade process provides a paid Autonomous Database instance with workload type **Data Warehouse**, with 2 ECPUs and 1 TB of database storage (if your instance is not enabled to use ECPUs you get 1 OCPU and 1 TB of database storage).
- **Transaction Processing** workload type: When you upgrade to paid from an Always Free instance, the upgrade process provides a paid Autonomous Database instance with workload type **Transaction Processing**, with 2 ECPUs and 1 TB of database storage (if your instance is not enabled to use ECPUs you get 1 OCPU and 1 TB of database storage).

Upgrade Autonomous JSON Database to Autonomous Transaction Processing

You can promote an Autonomous JSON Database to an Autonomous Transaction Processing database at any time.

An Autonomous JSON Database is the same as an Autonomous Transaction Processing database, except that an Autonomous JSON Database is limited in these respects:

- You can store only up to 20 GB of data other than JSON document collections.[1]

  (All Autonomous Databases, including , limit the storage of JSON data to 128 TB.)
- Collections cannot be **heterogeneous**. That is, they can only contain JSON documents. For example, you cannot have a collection of image documents or a collection that contains both JSON documents and image documents.

These limitations are appropriate if your use is primarily development of applications that use JSON documents. If you have a greater need to use data other than JSON data then follow these steps to promote your database to an Autonomous Transaction Processing database:

1. Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
2. From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database**, and then click Autonomous JSON Database.

[1] You can subscribe to information event AJDNonJsonStorageExceeded, to be informed when the 20 GB limit is exceeded. See About Information Events on Autonomous Database.

3. Choose your JSON Database from those listed in the compartment, by clicking its name in column **Display name**.
4. Do one of the following:
   - From the **More actions** drop-down list, select **Change workload type**.
   - In tab Autonomous Database information, under heading **General information**, item **Workload type**, click **Edit**.
5. Click **Convert** to confirm that you want to convert this database to Autonomous Transaction Processing.
6. If you were using the refreshable clone feature with your Autonomous JSON Database then re-create the clone after promotion to Autonomous Transaction Processing. See Using Refreshable Clones with Autonomous Database.

See Autonomous Database Billing Summary for more information.

Upgrade APEX Service to Autonomous Transaction Processing

Easily upgrade APEX Service to Autonomous Transaction Processing.

If you want to expand your capabilities to include the full features of Oracle Autonomous Database with APEX, you can easily upgrade an APEX Service instance to a full Oracle Autonomous Transaction Processing instance. You can upgrade from either the APEX Instances Details page or the Autonomous Database Details page.

To upgrade to Oracle Autonomous Transaction Processing:

1. From the Oracle Cloud Infrastructure left navigation list, select **Developer Services** and then click **APEX Application Development** or **APEX Instances**.

   The APEX Instances page appears.
2. Under **Filters**, narrow the display by selecting **APEX** from the Type list.
3. On the APEX Instances page, click the APEX instance name.

   The APEX Instance Details page appears.
4. You can upgrade in two ways:
   - On the APEX Instance Details page:
     - Under **APEX instance information**, find **Database type** and click **Edit**.
   - Navigate to the Autonomous Database Details page:
     - Under **APEX instance information**, click the Database name.
     - Under **General information**, find **Workload type** and click **Edit**.

     A dialog appears.
5. Review the information in the dialog and then click **Convert** to convert the database to Autonomous Transaction Processing.

See Autonomous Database Billing Summary for more information.

Clone, Move, or Upgrade an Autonomous Database Instance

Autonomous Database provides cloning where you can choose to create a full clone, create a metadata clone, or create a refreshable clone. You can also move a database to a different compartment. By creating a clone you can upgrade an instance with Oracle Database 19c to create an Oracle Database 23ai clone (either a full clone or a refreshable clone).

- About Cloning on Autonomous Database
  When you create a clone for an Autonomous Database instance, you have the option to select the clone type: a full clone, a metadata clone, or a refreshable clone:
- Prerequisites for Cloning
  Describes prerequisites for cloning an Autonomous Database instance.
- Clone an Autonomous Database Instance
  Shows you the steps to clone an Autonomous Database from the Oracle Cloud Infrastructure Console.
- Clone an Autonomous Database from a Backup
  Shows the options to select a backup as the clone source for cloning Autonomous Database.
- Cross Tenancy and Cross-Region Cloning
  You can clone an Autonomous Database instance from one tenancy, source tenancy, to a different tenancy (destination tenancy).
- Clone Autonomous Database to Change Workload Type
  When you create an Autonomous Database clone, by default the clone is of the same workload type. Optionally, you can select that the clone is of a different workload type than the source database.
- Notes for Cloning Autonomous Database
  Provides information about the cloning operation and the resulting cloned database.
- Move an Autonomous Database to a Different Compartment
  Shows you the steps to move a database to a different Oracle Cloud Infrastructure compartment.
- Upgrade an Autonomous Database Instance to Oracle Database 23ai
  When you clone an Autonomous Database instance and the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.

About Cloning on Autonomous Database

When you create a clone for an Autonomous Database instance, you have the option to select the clone type: a full clone, a metadata clone, or a refreshable clone:

- **Full Clone**: creates a new database with the source database's data and metadata.
- **Refreshable Clone**: creates a read-only full clone that can be easily refreshed with the data from the source database.

  See Use Refreshable Clones with Autonomous Database for more information.
- **Metadata Clone**: creates a new database that includes all of the source database schema metadata, but not the source database data.

For a Full Clone or a Metadata Clone, you have the option to select the clone source:

- **Clone from a database instance**. This creates a clone of a running database.
- **Clone from a backup**. This creates a clone when you select a backup from a list of backups, or when you enter a backup point-in-time to clone.
- **Clone from the latest backup**. This creates a clone where Autonomous Database uses the most recent backup data that is available to create the clone.

> **Note:**
>
> Depending on the cloning options you choose, cloning an Autonomous Database instance copies your database files to a new instance. Depending on the size of your database and where you are cloning your database, expect the cloning operation to take significantly longer than provisioning a new Autonomous Database instance. There is no downtime associated with cloning and the cloning operation has no impact on applications running on the source.

Additional Cloning Options: Cross-Region, Unavailable Instance, Preview Version, and Cross-Tenancy

There are additional cloning options that allow you to clone to a different region or tenancy:

- You can clone a database where the source and the cloned database are in different regions (cross-region cloning). This allows you to clone an existing database or clone a backup to create a database in a different region.
- You can clone a database when the source Autonomous Database instance is in the **Unavailable** state. This allows you to create a new database from a backup and use the new database in place of the unavailable database.
- When an upcoming release is available for preview with Autonomous Database, you can clone your existing database to use the preview version. A preview version is only available when there is an upcoming major version to release. At times no preview version will be available.
- You can also move an Autonomous Database to a different Oracle Cloud Infrastructure Compartment. See Move an Autonomous Database to a Different Compartment for more information.
- You can clone a database where the source and the cloned database are in different tenancies (cross-tenancy cloning). This allows you to clone an existing database or clone a backup to create a database in a different tenancy, where the clone is either in a different tenancy in the same region or in a different tenancy in a different region.

> **Note:**
>
> The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

See Cross Tenancy and Cross-Region Cloning for more information.

Prerequisites for Cloning

Describes prerequisites for cloning an Autonomous Database instance.

To clone an Autonomous Database instance you must define the required access using OCI Identity and Access Management policy statements written by an administrator, whether you're using the Console, the REST API, the CLI, or another tool.

The following policies allow you to create a clone:

```
Allow group Group_Name to read autonomous-databases in compartment
Compartment_Name
      where target.id = 'oc1.autonomousdatabase.oc1..unique_ID'

Allow group Group_Name to manage autonomous-databases in compartment
Compartment_Name
```

The where clause is optional and provides a more fine grained way to grant access to a specific database.

You can limit cloning permissions so that the group can only clone Autonomous Databases but cannot create Autonomous Databases, or further limit permission to only create a particular type of clone: Full Clone, Metadata Clone, or Refreshable Clone. See IAM Permissions and API Operations for Autonomous Database for more information and examples.

This shows the policies for cloning within a tenancy. See Prerequisites for Cross Tenancy Cloning for cross tenancy cloning policies.

See IAM Policies for Autonomous Database and Getting Started with Policies for more information.

Clone an Autonomous Database Instance

Shows you the steps to clone an Autonomous Database from the Oracle Cloud Infrastructure Console.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- Choose your region. See Switching Regions for information on switching regions and working in multiple regions.
- Choose your **Compartment**. See Compartments for information on using and managing compartments.
- Select an Autonomous Database instance from the list in your compartment.

To clone the Autonomous Database instance:

1. On the **Autonomous Database Details** page, from the **More actions** drop-down list, select **Create clone**.
2. On the **Create Autonomous Database clone** page, choose the clone type from the choices:
   - **Full clone**: creates a new database with the source database's data and metadata.
   - **Refreshable clone**: creates a read-only full clone that can be easily refreshed with the source database's data.
     See Use Refreshable Clones with Autonomous Database for more information.
   - **Metadata clone**: creates a new database with the source database's metadata without the data.

3. In the **Clone source** area, select one of:
   - **Clone from database instance**: This creates a clone from a running database.
   - **Clone from a backup**: This creates a database clone from a selected backup, from a point-in-time timestamp, or from the latest backup data that is available. See Clone an Autonomous Database from a Backup for more information.
4. Provide basic information for the Autonomous Database clone.
   - **Choose your preferred region**: from the list, select the region where you want to create the clone.

     Note: the list only shows the regions that you are subscribed to.

     For the clone type **Clone from database instance** as the clone source, when you choose another region other than the current region for your clone target, using either the Oracle Cloud Infrastructure CLI or Terraform you can only perform such a cross-region clone from the remote region. That is, call the create clone API from the remote region to which you want to clone, with the source database OCID as that of the source that you want to clone from.
   - **Create in Compartment**: See Compartments for information on using and managing compartments.

     Note: the list only shows the compartments that you are subscribed to.
   - **Display name**: Specify a user-friendly description or other information that helps you easily identify the resource.

     You can use the name provided, of the form: **Clone-of-***DBname* or change this to the name you want to use to identify the database. The supplied *DBname* is the name of the source database that you are cloning.
   - **Database name**: Specify the database name; it must consist of letters and numbers only. The maximum length is 30 characters. The same database name cannot be used for multiple Autonomous Databases in the same tenancy in the same region.

     The default database name is a generated 16-character string.
5. Select a value for **Choose a workload type** from the following options.
   - **Data Warehouse**: This creates an Autonomous Data Warehouse type clone.
   - **Transaction Processing**: This creates an Autonomous Transaction Processing type clone.
   - **JSON**: This creates an Autonomous JSON Database type clone.
   - **APEX**: This creates an APEX type clone.

   > **Note:**
   >
   > The unavailable cloning options are grayed out. See Clone Autonomous Database to Change Workload Type for more information on cross workload cloning.
6. Configure the database (ECPU compute model)
   - **Always Free**: Select to show Always Free options.

     You can only create a free instance in the tenancy's Home region.
   - **Developer**: Select to show Autonomous Database for Developers options.

This option is only available when the source is an Autonomous Database for Developers instance.

An Autonomous Database for Developers instance is a fixed shape database that is suited for development and testing use cases.

Selecting this option sets the **Compute** resources to a fixed value of 4 ECPUs and the **Storage** to 20 GB.

- **Choose database version**: Select the database version. The available database versions are Oracle Database 23ai and Oracle Database 19c.

  Notes for selecting a database version:

  - In regions where Oracle Database 23ai is not available, Oracle Database 19c is the only choice.
  - Autonomous Database with Oracle Database 23ai in the Paid tier is available in all commercial public cloud regions.
  - Always Free Autonomous Database with Oracle Database 23ai is available in all commercial public cloud regions *except* the following regions: Colombia Central: Bogota (BOG), Saudi Arabia Central (RUH), Singapore West: Singapore (XSP)
  - If the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.
  - If the source database version is Oracle Database 23ai, you can select Oracle Database 23ai for the clone.
- **ECPU count**: Specify the number of CPUs for your database. The minimum value for the number of ECPUs is 2.
- **Compute auto scaling**: By default compute auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. If you do not want to use compute auto scaling then deselect this option.

  See Use Auto Scaling for more information.
- **Storage**: Specify the storage you wish to make available to your database. Depending on your workload type you have these options:

  - **Data Warehouse**: Specify your storage in Terabytes (TB).

    For a Full Clone, the minimum storage that you can specify is the source database's actual used space rounded to the next TB.
  - **Transaction Processing** or **JSON**: Specify your storage in Gigabytes (GB) or Terabytes (TB). Enter the size in the **Storage** field. Select **GB** or **TB** for the **Storage unit size**.

    For a Full Clone, the minimum storage that you can specify is the source database's actual used space rounded to the next GB.
- By default, the IO capacity of your database depends on the number of ECPUs you provision. When you provision 384 TB of storage, your database is entitled to the full IO capacity of the Exadata infrastructure, independent of the number of ECPUs you provision.

  Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

If you want to provision more than 384 TB of storage, file a Service Request at Oracle Cloud Support.

- **Storage auto scaling**: By default storage auto scaling is disabled. Select if you want to enable storage auto scaling to allow the system to automatically expand to use up to three times more storage.

  With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

  With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

  See Use Auto Scaling for more information.

- **Show advanced options**: Click to show additional options:

  – **Enable elastic pool**:

    See Create an Elastic Pool While Provisioning or Cloning an Instance for more information.

  – **Compute model**: Shows the selected compute model.

    See Compute Models in Autonomous Database for more information.

  – **Bring your own license**: If you want to Bring Your Own License to the database, click **Enable** to show the **Update license and Oracle Database Edition** page.

    See Choose Bring Your Own License Option While Provisioning or Cloning for more information.

7. Backup retention

   By default the automatic backup retention is 60 days.

   Automatic backup retention period in days: You have the option to select an automatic backup retention period, in a range from 1 to 60 days. You can restore and recover your database to any point-in-time in this retention period.

   Select **Immutable backup retention** to lock the backup retention period.

   After setting the immutable backup retention option, you cannot disable this option or change the retention period. To disable immutable backup retention or to change the backup retention period, file a Service Request at Oracle Cloud Support.

   See About Backup and Recovery on Autonomous Database for more information.

8. Create administrator credentials

   - **Username** This is a read-only field.
   - **Password** Set the password for the Autonomous Database Admin user. The password must meet the strong password complexity criteria based on Oracle Cloud security standards. For more information on the password complexity rules see Create Users on Autonomous Database - Connecting with a Client Tool.
   - **Confirm password** Specify a value to confirm the password.

9. Choose network access

> **Note:**
>
> After you clone your Autonomous Database you can change the network access option you select for the cloned instance.

- **Secure access from everywhere**

  By default all secure connections are allowed from everywhere.

- **Secure access from allowed IPs and VCNs only**

  This option restricts connections to the database according to the access control rules (ACLs) you specify. To add multiple ACLs for the Autonomous Database, click **Add access control rule**.

  See Configure Access Control Lists When You Provision or Clone an Instance for more information.

- **Private endpoint access only**

  This option assigns a private endpoint, private IP, and hostname to your database. Specifying this option allows traffic only from the VCN you specify; access to the database from all public IPs or VCNs is blocked. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your Autonomous Database.

  See Configure Private Endpoints When You Provision or Clone an Instance for more information.

See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.

10. (Optional) Provide contacts for operational notifications and announcements

    Click **Add contact** and in the **Contact email** field, enter a valid email address. If the database you are cloning has a customer contact list, the list is copied. To enter multiple **Contact email** addresses, repeat the process to add up to 10 customer contact emails.

    See View and Manage Customer Contacts for Operational Issues and Announcements for more information.

11. (Optional) Click Show advanced options to select advanced options.

    - **Encryption key**
      Encrypt using an Oracle-managed key: By default Autonomous Database uses Oracle-managed encryption keys. Using Oracle-managed keys, Autonomous Database creates and manages the encryption keys that protect your data and Oracle handles rotation of the TDE master key.

      Encrypt using a customer-managed key in this tenancy: If you this option, a master encryption key from a Oracle Cloud Infrastructure Vault in the same tenancy is used to generate the TDE master key on Autonomous Database.

      Encrypt using a customer-managed key located in a remote tenancy: If you this option, a master encryption key in the Oracle Cloud Infrastructure Vault located in a remote tenancy is used to generate the TDE master key on Autonomous Database.

      See Use Customer-Managed Encryption Keys on Autonomous Database for more information.

    - **Maintenance**

Patch level By default the patch level is the patch level of the source database. Select **Early** to configure the instance with the early patch level. Select **Regular** to configure the instance with the regular patch level.

See Set the Patch Level for more information.

- **Management**
  Shows the character set and national character set for your database.

  See Choose a Character Set for Autonomous Database for more information.

- **Tools**
  If you want to view or customize the tools configuration, select the tools tab.

  See Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance for more information.

- **Security attributes**
  Add a security attribute to control access for your resources using Zero Trust Packet Routing (ZPR) policies. To enter security attributes during provisioning you must already have set up security attributes with Zero Trust Packet Routing. You also can add security attributes after provisioning.

  > **Note:**
  >
  > You can apply Oracle Zero Trust Packet Routing (ZPR) policies to a private endpoint.

  Specify a **Namespace**, **Key**, and **Value** security attribute.

  Click **Add security attribute** to add additional security attributes.

  See Overview of Zero Trust Packet Routing for more information.

- **Tags**
  If you want to use Tags, enter the **Tag key** and **Tag value**. Tagging is a metadata system that allows you to organize and track resources within your tenancy. Tags are composed of keys and values which can be attached to resources.

  See Tagging Overview for more information.

12. Click **Create Autonomous Database clone**.

On the Oracle Cloud Infrastructure console the **State** shows Provisioning... until the new database is available.

If you created a cross-region clone, a new tab shows the newly provisioned clone's Oracle Cloud Infrastructure Console and the region shown is the region you selected when you created the clone.

See Notes for Cloning Autonomous Database for additional information on cloning.

See Cloning an Autonomous Database for information on using the API.

Clone an Autonomous Database from a Backup

Shows the options to select a backup as the clone source for cloning Autonomous Database.

Perform the following prerequisite steps as necessary:

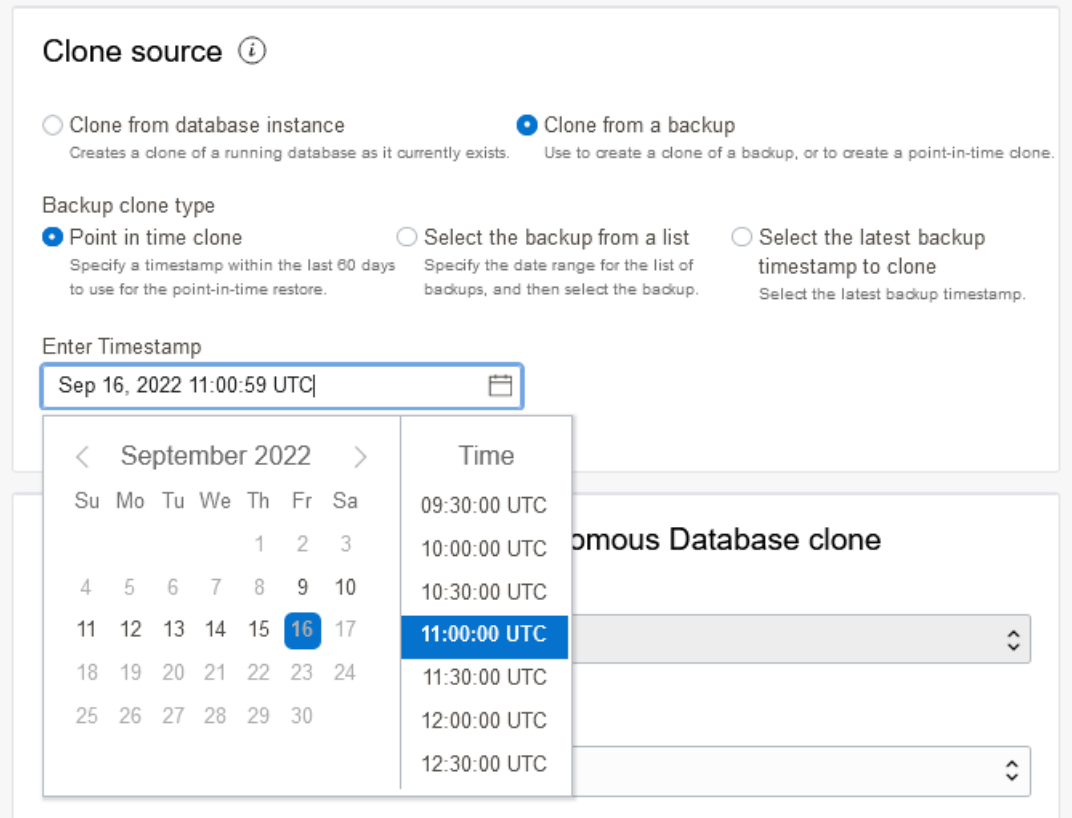
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.

- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

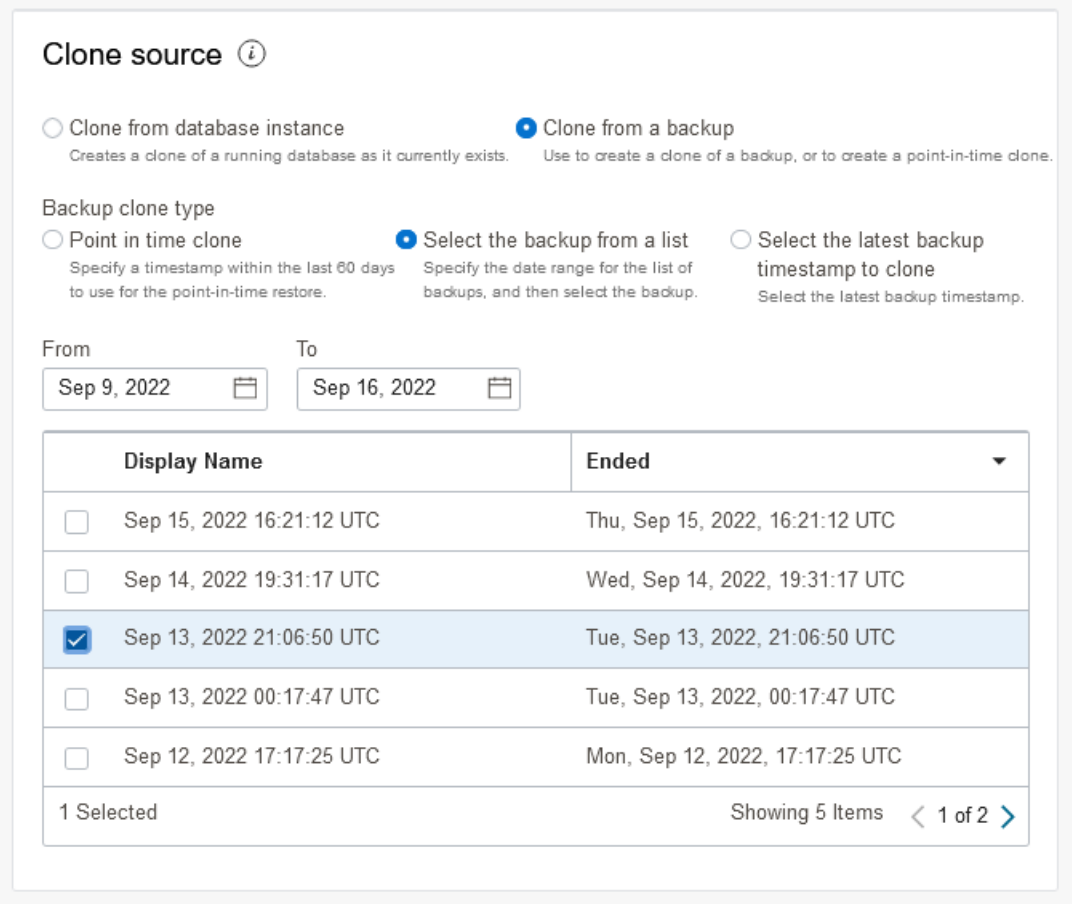
To clone an Autonomous Database instance from a backup:

1. Choose your region. See Switching Regions for information on switching regions and working in multiple regions.
2. Choose your **Compartment**. See Compartments for information on using and managing compartments.
3. Select an Autonomous Database instance from the list in your compartment.
4. On the **Details** page, from the **More actions** drop-down list, select **Create clone**.
5. On the **Create Autonomous Database clone** page, choose the clone type from the choices:
   - **Full clone**: creates a new database with the source database's data and metadata.
   - **Refreshable clone**: creates a read-only full clone that can be easily refreshed with the source database's data.
     See Use Refreshable Clones with Autonomous Database for more information.
   - **Metadata clone**: creates a new database with the source database's metadata without the data.
6. In the **Configure clone source** area, select the **Clone source** option:
   - **Clone from database instance**: This creates a clone from a running database. See Clone an Autonomous Database Instance for details and steps with this selection.
   - **Clone from a backup**: This selection creates a database clone using a backup. Select this option.
7. In the **Configure clone source** area, select the **Backup clone type**:
   - **Point in time clone**: Enter a timestamp to clone in the **Enter Timestamp** field.
   - **Select the backup from a list**: Enter **From** and **To** dates to narrow the list of backups then select a backup to use for the clone source.
   - **Latest backup timestamp**: See Clone an Autonomous Database from Latest Backup for information on this clone option.

   Point in time clone



Select the backup from a list



8. Provide basic information for the Autonomous Database.
   - **Choose your preferred region**: from the list, select the region where you want to create the clone.

     Note: the list only shows the regions that you are subscribed to.

     For the clone type **Clone from a backup** as the clone source, when you choose another region other than the current region for your clone target, using either the Oracle Cloud Infrastructure CLI or Terraform you can only perform such a cross-region clone from the remote region. That is, call the create clone API from the remote region to which you want to clone, with the source database OCID as that of the source that you want to clone from.
   - **Create in Compartment**: See Compartments for information on using and managing compartments.
   - **Display name**: Specify a user-friendly description or other information that helps you easily identify the resource.

     You can use the name provided, of the form: **Clone-of-***DBname* or change this to the name you want to use to identify the database. The supplied *DBname* is the name of the source database that you are cloning.
   - **Database Name**: Specify the database name; it must consist of letters and numbers only. The maximum length is 30 characters. The same database name cannot be used for multiple Autonomous Databases in the same tenancy in the same region.

     The default database name is a generated 16-character string.

9. Select a value for **Choose a workload type** from the following options.
   - **Data Warehouse**: This creates an Autonomous Data Warehouse type clone.
   - **Transaction Processing**: This creates an Autonomous Transaction Processing type clone.
   - **JSON**: This creates an Autonomous JSON Database type clone.
   - **APEX**: This creates an APEX type clone.

   > **Note:**
   >
   > The unavailable cloning options are grayed out. See Clone Autonomous Database to Change Workload Type for more information on cross workload cloning.

10. Configure the database (ECPU compute model)
    - **Always Free**: Select to show Always Free options.

      You can only create a free instance in the tenancy's Home region.
    - **Choose database version**: Select the database version. The available database versions are Oracle Database 23ai and Oracle Database 19c.

      Notes for selecting a database version:
      - In regions where Oracle Database 23ai is not available, Oracle Database 19c is the only choice.
      - Autonomous Database with Oracle Database 23ai in the Paid tier is available in all commercial public cloud regions.
      - Always Free Autonomous Database with Oracle Database 23ai is available in all commercial public cloud regions *except* the following regions: Colombia Central: Bogota (BOG), Saudi Arabia Central (RUH), Singapore West: Singapore (XSP)
      - If the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.
      - If the source database version is Oracle Database 23ai, you can select Oracle Database 23ai for the clone.
    - **ECPU count**: Specify the number of CPUs for your database. The minimum value for the number of ECPUs is 2.
    - **Compute auto scaling**: By default compute auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. If you do not want to use compute auto scaling then deselect this option.

      See Use Auto Scaling for more information.
    - **Storage**: Specify the storage you wish to make available to your database. Depending on your workload type you have these options:
      - **Data Warehouse**: Specify your storage in Terabytes (TB).

        For a Full Clone, the minimum storage that you can specify is the source database's actual used space rounded to the next TB.

  - **Transaction Processing** or **JSON**: Specify your storage in Gigabytes (GB) or Terabytes (TB). Enter the size in the **Storage** field. Select **GB** or **TB** for the **Storage unit size**.

    For a Full Clone, the minimum storage that you can specify is the source database's actual used space rounded to the next GB.

- By default, the IO capacity of your database depends on the number of ECPUs you provision. When you provision 384 TB of storage, your database is entitled to the full IO capacity of the Exadata infrastructure, independent of the number of ECPUs you provision.

  Autonomous Database uses Exadata Smart Flash Cache to automatically cache frequently accessed data, delivering the high I/O rates and fast response times of flash. The amount of flash cache for your database depends on the amount of storage you provision, or the amount of allocated storage if you enable storage auto scaling.

  If you want to provision more than 384 TB of storage, file a Service Request at Oracle Cloud Support.

- **Storage auto scaling**: By default storage auto scaling is disabled. Select if you want to enable storage auto scaling to allow the system to automatically expand to use up to three times more storage.

  With storage auto scaling disabled, the guaranteed minimum flash cache size is 10% of your database's provisioned storage size.

  With storage auto scaling enabled, the guaranteed minimum flash cache size is 10% of your database's provisioned base storage size or its allocated storage size, whichever is higher.

  See Use Auto Scaling for more information.

- **Show advanced options**: Click to show the compute model options or if you want to create or join an elastic pool:

  - **Enable elastic pool**:

    See Create an Elastic Pool While Provisioning or Cloning an Instance for more information.

  - **Compute model**: Shows the selected compute model.

    See Compute Models in Autonomous Database for more information.

  - **Bring your own license**: If you want to Bring Your Own License to the database, click **Enable** to show the **Update license and Oracle Database Edition** page.

    See Choose Bring Your Own License Option While Provisioning or Cloning for more information.

11. Backup retention

    By default the automatic backup retention is 60 days.

    Automatic backup retention period in days You have the option to select the automatic backup retention period, in a range from 1 to 60 days. You can restore and recover your database to any point-in-time in this retention period.

    Select **Immutable backup retention** to lock the backup retention period.

    After setting the immutable backup retention option, you cannot disable this option or change the retention period. To disable immutable backup retention or to change the backup retention period, file a Service Request at Oracle Cloud Support.

    See About Backup and Recovery on Autonomous Database for more information.

12. Create administrator credentials.
    - **Username** This is a read-only field.
    - **Password** Set the password for the Autonomous Database Admin user. The password must meet the strong password complexity criteria based on Oracle Cloud security standards. For more information on the password complexity rules see Create Users on Autonomous Database - Connecting with a Client Tool.
    - **Confirm password** Specify a value to confirm the password.
13. Choose network access

    > **Note:**
    >
    > After you clone your Autonomous Database you can change the network access option you select for the cloned instance.

    - **Secure access from everywhere**

      By default all secure connections are allowed from everywhere.
    - **Secure access from allowed IPs and VCNs only**

      This option restricts connections to the database according to the access control rules (ACLs) you specify. To add multiple ACLs for the Autonomous Database, select this option and click **Add access control rule**.

      See Configure Access Control Lists When You Provision or Clone an Instance for more information.
    - **Private endpoint access only**

      This option assigns a private endpoint, private IP, and hostname to your database. Specifying this option allows traffic only from the VCN you specify; access to the database from all public IPs or VCNs is blocked. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your Autonomous Database.

      See Configure Private Endpoints When You Provision or Clone an Instance for more information.

    See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.
14. (Optional) Provide contacts for operational notifications and announcements

    Click **Add contact** and in the **Contact email** field, enter a valid email address. If the database you are cloning has a customer contact list, the list is copied. To enter multiple **Contact email** addresses, repeat the process to add up to 10 customer contact emails.

    See View and Manage Customer Contacts for Operational Issues and Announcements for more information.
15. (Optional) Click Show advanced options to select advanced options.
    - **Encryption Key**
      Encrypt using an Oracle-managed key: By default Autonomous Database uses Oracle-managed encryption keys. Using Oracle-managed keys, Autonomous Database creates and manages the encryption keys that protect your data and Oracle handles rotation of the TDE master key.

Encrypt using a customer-managed key in this tenancy: If you this option, a master encryption key from a Oracle Cloud Infrastructure Vault in the same tenancy is used to generate the TDE master key on Autonomous Database.

Encrypt using a customer-managed key located in a remote tenancy: If you this option, a master encryption key in the Oracle Cloud Infrastructure Vault located in a remote tenancy is used to generate the TDE master key on Autonomous Database.

See Use Customer-Managed Encryption Keys on Autonomous Database for more information.

- **Maintenance**
  Patch level By default the patch level is the patch level of the source database. Select **Early** to configure the instance with the early patch level. Select **Regular** to configure the instance with the regular patch level.

  See Set the Patch Level for more information.

- **Management**
  Shows the character set and national character set for your database.

  See Choose a Character Set for Autonomous Database for more information.

- **Tools**
  If you want to view or customize the tools configuration, select the tools tab.

  See Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance for more information.

- **Security attributes**
  Add a security attribute to control access for your resources using Zero Trust Packet Routing (ZPR) policies. To enter security attributes during provisioning you must already have set up security attributes with Zero Trust Packet Routing. You also can add security attributes after provisioning.

  > **Note:**
  >
  > You can apply Oracle Zero Trust Packet Routing (ZPR) policies to a private endpoint.

  Specify a **Namespace**, **Key**, and **Value** security attribute.

  Click **Add security attribute** to add additional security attributes.

  See Overview of Zero Trust Packet Routing for more information.

- **Tags**
  If you want to use Tags, enter the **Tag key** and **Tag value**. Tagging is a metadata system that allows you to organize and track resources within your tenancy. Tags are composed of keys and values which can be attached to resources.

  See Tagging Overview for more information.

16. Click **Create Autonomous Database Clone**.

On the Oracle Cloud Infrastructure console the **State** shows Provisioning... until the new database is available.

See Notes for Cloning an Autonomous Database from a Backup for additional information on cloning.

See Cloning an Autonomous Database for information on using the API.

- Clone an Autonomous Database from Latest Backup
  When you choose to clone from latest backup, this selects the latest backup as the clone source. You can choose this option if a database becomes unavailable or for any reason when you want to create a clone based on the most recent backup.

Clone an Autonomous Database from Latest Backup

When you choose to clone from latest backup, this selects the latest backup as the clone source. You can choose this option if a database becomes unavailable or for any reason when you want to create a clone based on the most recent backup.

Follow the steps in Clone an Autonomous Database from a Backup and in the Clone source area, select **Clone from a backup** and **Select the latest backup timestamp to clone** to create a clone that recovers the most recent backup data that is available for the Autonomous Database instance (the clone source) from the database backup and logs backup.

After Autonomous Database has finished provisioning the clone, query the view `dba_pdbs` to see the `last_recover_time` and `last_recover_scn` columns. These columns provide the saved timestamp and the saved SCN of the data from which the cloned database was created.

For example:

```
SELECT last_recover_time, last_recover_scn FROM dba_pdbs;
```

Cross Tenancy and Cross-Region Cloning

You can clone an Autonomous Database instance from one tenancy, source tenancy, to a different tenancy (destination tenancy).

- About Cross Tenancy Cloning
  When you create a cross tenancy clone you can either select that the clone is created in the same region as the source tenancy or in a different region than the source tenancy (cross-region).
- Prerequisites for Cross Tenancy Cloning
  Describes prerequisites for creating a cross tenancy clone where the source database is in one tenancy and the cloned database is in a different tenancy.
- Create a Cross Tenancy or Cross-Region Clone
  Shows the steps to create a cross tenancy clone when the source database and the cloned database are in the same region, or when the source database and the cloned database are in different regions (cross-region).
- Create a Cross Tenancy Clone from a Backup
  Shows the steps to create a cross tenancy clone from a backup.

About Cross Tenancy Cloning

When you create a cross tenancy clone you can either select that the clone is created in the same region as the source tenancy or in a different region than the source tenancy (cross-region).

> **Note:**
>
> The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

Note the following for cross tenancy cloning:

- All clone types are supported: the cloned database can be a Full clone, a Metadata clone, or a Refreshable clone.
- A clone can be created from a source Autonomous Database instance or from a backup (using the latest backup, a specified backup, or by selecting a long-term backup).
- The source Autonomous Database instance can use either the ECPU or OCPU compute model. Depending on your workload type, you can clone from a source that uses the OCPU compute model to a clone that uses the ECPU compute model (this is allowed for the Data Warehouse and the Transaction Processing workload types).
- The cloned database can be in the same region or in a different region (cross-region).
- The cross tenancy cloning option does not support cloning with customer managed keys on the source. See Manage Encryption Keys on Autonomous Database for more information on customer managed keys.

Prerequisites for Cross Tenancy Cloning

Describes prerequisites for creating a cross tenancy clone where the source database is in one tenancy and the cloned database is in a different tenancy.

You must run the commands to create a cross tenancy clone on the destination tenancy. Before you create a cross tenancy clone you need to define OCI Identity and Access Management groups and policies on the source tenancy, the tenancy that contains the instance you are cloning, and on the destination tenancy. The groups and policies you define allow you to run commands to create the clone on the destination tenancy and allow the destination tenancy to contact the source tenancy where the source Autonomous Database instance resides.

The OCI Identity and Access Management groups and policies you add support the following:

- A member of a group in the source tenancy allows a group in the destination tenancy to access (read) the source Autonomous Database instance on the source tenancy.

  You do not need to allow other actions on the source Autonomous Database instance (for example, start, stop terminate, or any write operations).
- A member of a group in the destination tenancy is allowed to create a clone in the destination tenancy using the Autonomous Database instance in the source tenancy as the clone source.

  On the destination tenancy you also add a policy that allows a group to manage the Autonomous Database instance on the source tenancy. For example, this policy allows the group to create the clone database, and allows a refreshable clone to run commands that contact the source tenancy, such as **Refresh** and **Disconnect**.

To create a cross tenancy clone use OCI Identity and Access Management to create the required groups and to define the policies that authorize cross tenancy cloning:

1. Create a group on the destination tenancy that contains the user that will be allowed to create a clone.

a. On the destination tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.

b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).

c. Under **Identity domain**, click **Groups**.

d. To add a group, click **Create group**.

e. On the Create group page, enter a Name and a Description.

   For example, enter the Name: **DestinationGroup**.

f. On the Create group page, click **Create**.

g. Click **Create** to save the group.

h. On the **Group** page, click **Assign user to groups** and select the users you want to add to the group.

i. Click **Add**.

j. On the **Group** page, from the **Group information** tab copy the OCID for use in Step 2.

2. On the source tenancy, define OCI Identity and Access Management policies for the source Autonomous Database instance.

   a. On the source tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.

   b. Under **Identity**, click **Policies**.

   c. To write a policy, click **Create Policy**.

   d. On the Create Policy page enter a Name and a Description.

   e. On the Create Policy page, select **Show manual editor**.

   f. In the policy builder, add policies so that the group in the destination tenancy is allowed to create a clone using an Autonomous Database instance on the source tenancy as the clone source.

      For example, define the following generic policies:

```
define tenancy DestinationTenancy as ocid1.tenancy.oc1..unique_ID
define group DestinationGroup as ocid1.group.region1..unique_ID
admit group DestinationGroup of tenancy DestinationTenancy to read
autonomous-database-family
       in compartment ocid1.compartment.region1..unique_ID
       where target.id = 'oc1.autonomousdatabase.oc1..unique_ID'
```

      This policy specifies the following:

      - Line 1: the OCID is the OCID of the destination tenancy. This is the tenancy where you are going to create the clone.
      - Line 2: the OCID is the OCID of the group to which the user who will create the clone belongs. This is the OCID you created in Step 1.
      - Line 3: The first OCID is the OCID of the compartment where the source database resides. The second OCID, after the `where` clause, is the OCID of the source Autonomous Database instance.

> **Note:**
>
> The where clause is optional and provides a more fine grained way to grant access to a specific database.

For example, set these policies on the source tenancy to allow cross tenancy cloning:

```
define tenancy DestinationTenancy as
ocid1.tenancy.oc1..aaa_example_rcyx2a
define group DestinationGroup as ocid1.group.oc1..aaa_example_6vctn6xsaq
admit group DestinationGroup of tenancy DestinationTenancy to read
autonomous-database-family in compartment
   ocid1.compartment.region1..bbb_example_rcyx2b where target.id =
'oc1.autonomousdatabase.oc1.aaaabbbbcccc'
```

This policy specifies a user in the `DestinationGroup` of the `DestinationTenancy` can read from a specific Autonomous Database instance in the specified compartment (on the source tenancy). To create a cross tenancy clone the policy only needs to allow read on the source Autonomous Database instance.

g. Click **Create** to save the policy.

3. Define policies on the destination tenancy.

   a. On the destination tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.

   b. Under **Identity**, click **Policies**.

   c. To write a policy, click **Create Policy**.

   d. On the Create Policy page enter a Name and a Description.

   e. On the Create Policy page, select **Show manual editor**.

   f. In the policy builder, add policies so that a group is endorsed to manage Autonomous Databases on the source tenancy.

   For example:

   ```
   Define tenancy SourceTenancy as ocid1.tenancy.oc1..unique_ID
   Endorse group DestinationGroup to manage autonomous-database-family in
   tenancy SourceTenancy
   ```

   This policy specifies the following:

   - Line 1: The OCID is the source tenancy OCID. This is the tenancy where the source Autonomous Database instance resides.
   - Line 2: Specifies that the DestinationGroup group can manage Autonomous Databases in the source tenancy.

   Notes for defining policies on the destination tenancy:

   - For the following policy:

     ```
     Endorse group DestinationGroup to manage autonomous-database-family in
     tenancy SourceTenancy
     ```

This policy allows the group `DestinationGroup` to create Autonomous Databases and Autonomous Database clones in the source tenancy. You can limit cloning permissions so that the group can only clone Autonomous Databases but cannot create Autonomous Databases, or further limit permission to only create a particular type of clone: Full Clone, Metadata Clone, or Refreshable Clone. See IAM Permissions and API Operations for Autonomous Database for more information and examples.

- If these polices are revoked, cross tenancy cloning is no longer allowed.

See Getting Started with Policies for more information.

Create a Cross Tenancy or Cross-Region Clone

Shows the steps to create a cross tenancy clone when the source database and the cloned database are in the same region, or when the source database and the cloned database are in different regions (cross-region).

Cross-region cloning is not supported in the free tier or for Autonomous Database for Developers instances.

These steps cover creating a Full clone or a Metadata clone. See Create a Cross Tenancy or Cross-Region Refreshable Clone for details on creating a cross tenancy refreshable clone.

> **Note:**
>
> The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

To create a cross tenancy clone:

1. Perform the prerequisite steps to define the OCI Identity and Access Management policies to authorize cross tenancy cloning.

   See Prerequisites for Cross Tenancy Cloning for details.

2. On the tenancy where you want to create the clone, on the destination tenancy in the destination region, use the CLI or call the REST API with a valid clone type FULL or METADATA and provide the OCID of the source database, where the source database resides in a different tenancy (the source tenancy).

   For example, with the CLI:

   ```
   oci db autonomous-database create-from-clone
         --clone-type metadata
         --compartment-id ocid1.tenancy.oc1..unique_ID
         --source-id ocid1.autonomousdatabase.oc1.iad.unique_ID
         --db-name dbnameclone
         --admin-password password
         --data-storage-size-in-tbs 1
         --compute-model ECPU
         --compute-count 4
   ```

   See create-from-clone for more information.

   Use the `CreateAutonomousDatabase` API to create a cross tenancy clone.

   See the following for additional information on the REST API:

- CreateAutonomousDatabase
- CreateAutonomousDatabaseCloneDetails

- See Notes for Cross Tenancy and Cross-Region Cloning for more information.
- For information about using the API and signing requests, see REST APIs and Security Credentials.
- For information about SDKs, see Software Development Kits and Command Line Interface.

Create a Cross Tenancy Clone from a Backup

Shows the steps to create a cross tenancy clone from a backup.

These steps cover creating a Full clone or a Metadata clone. See Create a Cross Tenancy or Cross-Region Refreshable Clone for details on creating a cross tenancy refreshable clone.

> **Note:**
>
> The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

To create a cross tenancy clone from a backup:

1. Perform the prerequisite steps to define the OCI Identity and Access Management policies to authorize cross tenancy cloning.

   See Prerequisites for Cross Tenancy Cloning for details.

2. On the tenancy where you want to create the clone, on the destination tenancy in the destination region, use the CLI or call the REST API with a valid clone type FULL or METADATA and provide the OCID of the backup (on the source tenancy), where the source database resides in a different tenancy (the source tenancy).

   > **Note:**
   >
   > See Create a Cross Tenancy or Cross-Region Refreshable Clone to create a cross tenancy refreshable clone.

   For example, with the CLI:

```
oci db autonomous-database create-from-backup-timestamp
     --autonomous-database-id ocid1.autonomousdatabase.oc1.iad.anuw_example
     --clone-type full
     --compartment-id ocid1.tenancy.oc1..fcue4_example
     --admin-password password
     --compute-model ECPU
     --compute-count 2
     --db-name ExampleTest1
     --timestamp 2023-12-15T19:30:00Z
     --data-storage-size-in-tbs 1
```

See create-from-backup-timestamp and create-from-backup-id for more information.

Use the `CreateAutonomousDatabase` API to create a cross tenancy clone by cloning from a backup of an existing Autonomous Database.

See the following for information on the REST API:

- CreateAutonomousDatabase
- CreateAutonomousDatabaseFromBackupDetails Reference
- CreateAutonomousDatabaseFromBackupTimestampDetails Reference

- For information about using the API and signing requests, see REST APIs and Security Credentials.
- For information about SDKs, see Software Development Kits and Command Line Interface.

Clone Autonomous Database to Change Workload Type

When you create an Autonomous Database clone, by default the clone is of the same workload type. Optionally, you can select that the clone is of a different workload type than the source database.

Cloning a database to a different workload type is useful when:

- You have provisioned a database of an incorrect workload type and now need to clone the database to the appropriate workload type.
- You need a copy of your database of a different workload type to branch out to run new types of workloads on your data.

Note the following when you clone to a different workload type:

- You can clone between the following workload types:
  - Autonomous Data Warehouse to Autonomous Transaction Processing
  - Autonomous Transaction Processing to Autonomous Data Warehouse
  - Autonomous JSON Database to Autonomous Transaction Processing or Autonomous Data Warehouse or APEX Service
  - APEX Service to Autonomous JSON Database or Autonomous Transaction Processing or Autonomous Data Warehouse
- You may also clone from a backup, when choosing to clone a database to a different workload type.
- The cloned database can be in the same region or in a different region (cross-region).
- Cloning a database to a different workload type does not affect the database's existing data dictionary, optimizer statistics, and object compression. New objects that are created after cloning are created using the cloned database's workload type parameters (for example compression and statistics).
- When you clone from Autonomous Data Warehouse to Autonomous Transaction Processing, the cloned database has the additional services TP and TPURGENT.
- When you clone from one of the following to Autonomous Data Warehouse the cloned database does not have the services TP or TPURGENT:
  - Autonomous Transaction Processing
  - Autonomous JSON Database

  - APEX Service

The following are not allowed when you clone and select a different workload type:

- Creating a cross workload refreshable clone.
- Cloning to a more restrictive workload type, such as from Autonomous Transaction Processing or Autonomous Data Warehouse database to Autonomous JSON Database or APEX Service.

See the following for steps to create an Autonomous Database clone:

- Clone an Autonomous Database Instance
- Clone an Autonomous Database from a Backup

Notes for Cloning Autonomous Database

Provides information about the cloning operation and the resulting cloned database.

- General Notes for Cloning on Autonomous Database
  Provides general information about the cloning operation and the resulting cloned database.
- Notes for Cloning an Autonomous Database from a Backup
- Notes for Cross Tenancy and Cross-Region Cloning
  Provides information about cross tenancy and cross-region cloning.
- Resource Management Rules and Performance Data for a Cloned Database
  Provides notes for resource management rules and performance data for a cloned database.
- Optimizer Statistics for a Cloned Database
  During the provisioning for either a Full Clone or a Metadata Clone, the optimizer statistics are copied from the source database to the cloned database.
- Disable Oracle Scheduler Jobs for a Cloned Database
  Oracle Scheduler jobs from a source database are copied to the clone when you perform a clone operation. You can assure that cloned Oracle Scheduler jobs are disabled on the clone.

General Notes for Cloning on Autonomous Database

Provides general information about the cloning operation and the resulting cloned database.

- If the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.
- If the source database version is Oracle Database 23ai, you can select Oracle Database 23ai for the clone.
- If there is an ongoing scaling operation on a source database, you cannot initiate a clone operation until the ongoing operation completes. If you attempt such an operation you will see message such as the following:

  ```
  The operation cannot be performed because the Autonomous Database with Id
  **** is in the SCALE_IN_PROGRESS state.
  ```

- If you define a network Access Control List (ACL) on the source database, the currently set network ACL is cloned to the new database. If a database is cloned from a backup, the

current source database's ACL is applied (not the ACL that was valid at the time of the backup).

- If you create a clone and the source database has an access control list (ACL) and you specify the private endpoint network access option, **Virtual cloud network** for the target database, the ACL is not cloned to the new database. In this case, you must define security rules within your Network Security Group (or groups) to control traffic to and from your target database (instead of using the access control rules that were specified in the ACL on the clone source). See Configure Private Endpoints When You Provision or Clone an Instance for more information.
- Cloning an Autonomous Database instance copies your database files to a new instance. There is no downtime associated with cloning and the cloning operation has no impact on applications running on the source.
- For a **Metadata Clone**, the APEX Apps and the OML Projects and Notebooks are copied to the clone. For a **Metadata Clone**, the underlying database data of the APEX App or OML Notebook is not cloned.
- The Autonomous Database Details page for an Autonomous Database instance that was created by cloning includes the **Cloned From** field. This displays the name of the database where the clone was created.
- The value of the `DBA_SERVICES.FAILOVER_TYPE` column is not copied to a cloned Autonomous Database instance.

Notes for Cloning an Autonomous Database from a Backup

Provides Notes for cloning an Autonomous Database from a backup:

- If there is an ongoing clone from backup operation on a source database, you cannot initiate a new clone operation on the same backup being cloned until the ongoing operation completes. Thus, you cannot clone from backup twice concurrently from a specific backup (for example, a specific timestamp or a specific selected backup from the list of backups).
- For external tables, partitioned external tables, and the external partitions of hybrid partitioned tables a backup does not include the external files that reside on your Object Store. Thus, for the clone from backup operation, it is your responsibility to backup, and restore if necessary, the external files associated with external tables, external partitioned tables, or the external files for a hybrid partitioned table
- With clone from backup, the Oracle Machine Learning workspaces, projects, and notebooks of the source database are not cloned to the new database.
- After Autonomous Database has finished provisioning the clone, query the view `dba_pdbs` to see the `last_recover_time` and `last_recover_scn` columns. These columns provide the saved timestamp and the saved SCN of the data from which the cloned database was created.

  For example:

```
SELECT last_recover_time, last_recover_scn FROM dba_pdbs;
```

Notes for Cross Tenancy and Cross-Region Cloning

Provides information about cross tenancy and cross-region cloning.

- For cloning, when you choose a region other than the current region for your clone target, using either the Oracle Cloud Infrastructure CLI or Terraform you can only perform such a cross-region clone from the remote region. That is, call the create clone API from the

remote region to which you want to clone, with the source database OCID as that of the source that you want to clone from.

- The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. Cross tenancy cloning is not available using the Oracle Cloud Infrastructure Console.

  See Cross Tenancy and Cross-Region Cloning for more information.

- The cross tenancy cloning option does not support cloning with customer managed keys on the source. See Manage Encryption Keys on Autonomous Database for more information on customer managed keys.

Resource Management Rules and Performance Data for a Cloned Database

Provides notes for resource management rules and performance data for a cloned database.

The following applies for resource management rules and performance data in a cloned database:

- During the provisioning for either a Full Clone or a Metadata Clone, any resource management rule changed by the user in the source database is carried over to the cloned database.
- For a cloned database, performance data for the time prior to the clone operation is not visible in the **Database Dashboard** card (under Monitor in Database Actions).

For more information on setting resource management rules, see Manage Runaway SQL Statements on Autonomous Database.

Optimizer Statistics for a Cloned Database

During the provisioning for either a Full Clone or a Metadata Clone, the optimizer statistics are copied from the source database to the cloned database.

The following applies for optimizer statistics for tables in a cloned database:

- Full Clone: loads into tables behave the same as loading into a table with statistics already in place.
- Metadata Clone: the first load into a table after the database is cloned clears the statistics for that table and updates the statistics with the new load.

For more information on Optimizer Statistics, see Optimizer Statistics Concepts.

Disable Oracle Scheduler Jobs for a Cloned Database

Oracle Scheduler jobs from a source database are copied to the clone when you perform a clone operation. You can assure that cloned Oracle Scheduler jobs are disabled on the clone.

To disable Oracle Scheduler jobs on Autonomous Database instances that are cloned, you can define a trigger using the `AFTER CLONE` clause. To use the `AFTER CLONE` clause, define the trigger on the source database before you perform the clone operation.

For example:

```
CREATE OR REPLACE TRIGGER after_clone_instance
     AFTER CLONE
     ON PLUGGABLE DATABASE
BEGIN
-- Disable specific jobs or use a cursor to grab all scheduled jobs and
```

```
disable them
     DBMS_SCHEDULER.DISABLE(name=> job_name);
END;
/
```

See CREATE TRIGGER Statement for more information.

Note the following:

- The value for the `DBA_SCHEDULER_WINDOWS.REPEAT_INTERVAL` column is not copied to a cloned Autonomous Database instance.

Move an Autonomous Database to a Different Compartment

Shows you the steps to move a database to a different Oracle Cloud Infrastructure compartment.

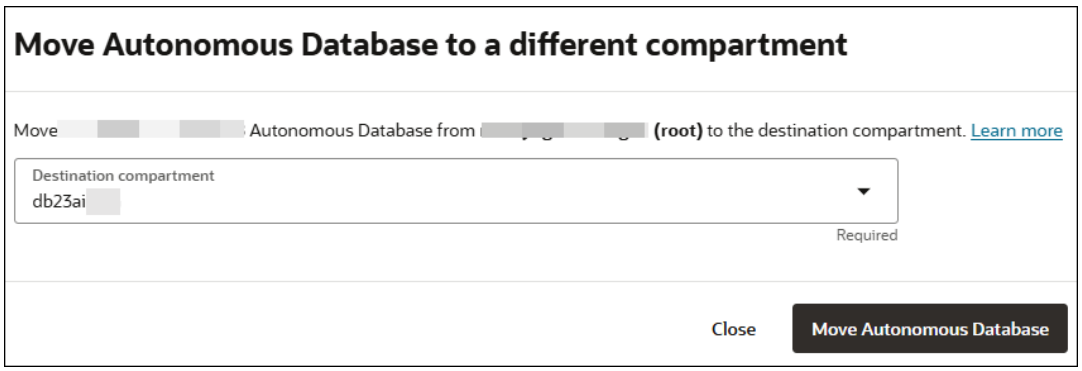
- To move a database you must have the right to manage Autonomous Databases in the database's current compartment and in the compartment you are moving it to.
- As soon as you move a database to a different compartment, the policies that govern the new compartment apply immediately and affect access to the database. Therefore, your access to the database may change, depending on the policies governing your Oracle Cloud user account's access to resources.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

To move a database to a different compartment:

1. Choose your region. See Switching Regions for information on switching regions and working in multiple regions.
2. Choose your **Compartment**. See Compartments for information on using and managing compartments.
3. Select an Autonomous Database instance from the list in your compartment.
4. On the **Details** page, from the **More actions** drop-down list, select **Move resource**.
5. In the **Move Autonomous Database to a different compartment** page, select the new compartment.



6. Click **Move Autonomous Database**.

See Moving Database Resources to a Different Compartment for more information.

Upgrade an Autonomous Database Instance to Oracle Database 23ai

When you clone an Autonomous Database instance and the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.

- Upgrade to Oracle Database 23ai by Creating a Full Clone
  If your Autonomous Database instance is using Oracle Database 19c, in regions where Oracle Database 23ai is available, you can upgrade to Oracle Database 23ai by creating a full clone.
- Upgrade to Oracle Database 23ai by Creating a Refreshable Clone
  You can create a refreshable clone where the source database version is Oracle Database 19c and the cloned database version is Oracle Database 23ai.

Upgrade to Oracle Database 23ai by Creating a Full Clone

If your Autonomous Database instance is using Oracle Database 19c, in regions where Oracle Database 23ai is available, you can upgrade to Oracle Database 23ai by creating a full clone.

To upgrade your Autonomous Database by creating a full clone, do the following:

1. Verify the Oracle Database version for your Autonomous Database instance is Oracle Database 19c.

   On the Oracle Cloud Infrastructure Console, the Autonomous Database details page includes the **Database version** field showing your database version.
2. During the cloning operation, in the Clone type area select **Full clone**, and in the Clone source area, select **Clone from database instance**.
3. During the cloning operation, in the cloning step where you configure the database, select Oracle Database 23ai in the **Choose database version** selection.

   Oracle Database 23ai only shows in regions where Oracle Database 23ai is available.

See Clone an Autonomous Database Instance for the detailed steps for this type of clone.

> **Note:**
>
> The clone has its own wallet and you cannot use the wallet of the source database to connect to the clone. All users must obtain a new wallet and use the new wallet to access the upgraded database. See Download Client Credentials (Wallets) for more information.

Upgrade to Oracle Database 23ai by Creating a Refreshable Clone

You can create a refreshable clone where the source database version is Oracle Database 19c and the cloned database version is Oracle Database 23ai.

Creating a refreshable clone with an Oracle Database 19c source and an Oracle Database 23ai refreshable clone allows you to test your workload with Oracle Database 23ai, or you can use the refreshable clone to upgrade to Oracle Database 23ai.

To create this type of refreshable clone, start with an Autonomous Database Database version 19c instance and follow the steps to create a refreshable clone, and select Database version 23ai for the clone. See Create a Refreshable Clone for an Autonomous Database Instance for more information.

> **Note:**
>
> An Oracle Database 19c source with an Oracle Database 23ai refreshable clone is especially useful when you want to use Capture-Replay to test your workloads running on Oracle Database 19c before you upgrade to Oracle Database 23ai. See Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay for more information.

Note the following when the refreshable clone source Autonomous Database Database version is 19c and the cloned Autonomous Database Database version is 23ai:

- After you create the refreshable clone, the clone will be in the stopped state and is not available for read-only operations. The only operations available for this type of refreshable clone are refresh (either manual or automatic), and disconnect.

  See Refresh a Refreshable Clone on Autonomous Database and Disconnect a Refreshable Clone from the Source Database for more information.

- This type of refreshable clone only allows a refresh when the database is in the "Stopped" state. The stopped refresh applies only for refreshable clones that have a source Oracle Database 19c and the cloned database is Oracle Database 23ai.

- To use the refreshable clone you must disconnect the clone from the source database and start the database.

  See Start Autonomous Database and Disconnect a Refreshable Clone from the Source Database for more information.

- You can reconnect a disconnected refreshable within 24 hours. When the source Oracle Database 19c and the refreshable clone Oracle Database 23ai, the clone reverts to the stopped state when you reconnect and you may refresh data from the source again.

  See Reconnect a Refreshable Clone to the Source Database for more information.

- While the refreshable clone is connected to the source database, if no refresh is performed within 7 days, the refreshable clone can no longer be refreshed. In this case you have the following option:

  – You can disconnect the refreshable clone from the source database. After the disconnect operation completes you can use the database as a standalone database and the data reflects the state of the source database at the time of the last successful refresh.

    See Disconnect a Refreshable Clone from the Source Database for more information.

- Creating a cross-region refreshable clone with an Oracle Database 19c source and an Oracle Database 23ai refreshable clone is not supported.

- Creating a cross tenancy refreshable clone with an Oracle Database 19c source and an Oracle Database 23ai refreshable clone is not supported in either the same region or cross-region.

Use Refreshable Clones with Autonomous Database

Autonomous Database provides cloning where you can choose to create a full clone of the active instance, create a metadata clone, or create a refreshable clone. With a refreshable clone the system creates a clone that can be easily updated with changes from the source database.

For details on creating a clone that is a full clone or a metadata clone, see Cloning and Moving an Autonomous Database.

- About Refreshable Clones on Autonomous Database
  When you create a refreshable clone for an Autonomous Database instance the system clones the source database to a database that can be refreshed from the source.
- Prerequisites for Creating a Refreshable Clone
  Describes prerequisites for creating a refreshable clone.
- Create and Manage Refreshable Clones
  When you create a refreshable clone the system creates a clone that can be easily updated with changes from the source database.
- View Refreshable Clones for an Autonomous Database Instance
- Use the API
  Provides details for using the APIs to create, refresh, list, disconnect, and reconnect a refreshable clone.
- Refreshable Clone Notes
  Lists limitations and notes for Autonomous Database refreshable clones.

About Refreshable Clones on Autonomous Database

When you create a refreshable clone for an Autonomous Database instance the system clones the source database to a database that can be refreshed from the source.

Using Cloud Links you can specify that access to a data set from one or more databases is offloaded to a refreshable clone. When a consumer Autonomous Database is listed in a data set's offload list, access to the data set is directed to the refreshable clone. See Register a Data Set with Offload Targets for Data Set Access for more information.

You can create a Refreshable Clone with a Oracle Database 19c source where the Refreshable Clone is Oracle Database 23ai. This type of Refreshable Clone is especially useful when you want test workloads running on Oracle Database 19c and run the workload on Oracle Database 23ai before you upgrade to Oracle Database 23ai. See Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay for more information.

- Refreshable Clone Features
  Describes refreshable clone features.
- About Refreshable Clone Billing
  Provides information about refreshable clone billing.
- Refreshable Clone Operations
  You can create a refreshable clone from an Autonomous Database instance. After you create a refreshable clone you can perform several operations on the refreshable clone, including: refresh, stop, start, restart, disconnect from source, and terminate.
- Refreshable Clone with Automatic Refresh Enabled
  By default you manually refresh a refreshable clone with changes from the source database. When you enable the automatic refresh option, Autonomous Database

automatically refreshes a refreshable clone with data from the source database at given time intervals.

- Refreshable Clone Lifecycle States
  After you create a refreshable clone, the clone indicates its state on the Autonomous Database Information page in the Lifecycle state field. In addition, the Mode field indicates that a refreshable clone is **Read-Only**.
- Refreshable Clone Refresh Timing and Disconnecting from the Source Database
  A refreshable clone with **Automatic refresh** disabled has a one week refresh age limit and a banner on the Oracle Cloud Infrastructure console displays the date and time up to which you can refresh the refreshable clone. The banner also includes a **Refresh clone** button.
- Refreshable Clone Reconnect to the Source Database
  After you perform a **Disconnect refreshable clone** operation, a banner displays the date and time up to which you can reconnect the database to the source. The banner also includes a **Reconnect refreshable clone** button.
- Operations on an Autonomous Database with an Attached Refreshable Clone
  Describes details for using a source Autonomous Database instance that has one or more attached refreshable clones.

Refreshable Clone Features

Describes refreshable clone features.

A refreshable clone allows you to do the following:

- Maintain one or more copies of the source database for use as read-only databases. A clone database is available when you need it, and when you want to update the data you can refresh the clone from the source database.
- Create one or more clones in regions other than the region of your primary (source) database. Clones in remote regions can be refreshed from the source database.
- You can enable the refreshable clone automatic refresh option. With automatic refresh enabled Autonomous Database automatically refreshes the clone with data from the source. See Refreshable Clone with Automatic Refresh Enabled for more information.
- Share copies of a production database with multiple business units. For example, one business unit might use the source database for ongoing transactions and another business unit could at the same time use the refreshable clone database for read-only operations.

  This option also allows you to spread the cost of database usage across multiple business units. You can bill the different units separately, based on their usage of one or more refreshable clone databases.
- Use a refreshable clone as a test database. You can disconnect a refreshable clone from its source and perform DML operations or calculations as needed, in addition to querying data. This allows you to run DML and make changes while the database is disconnected. When you are done with your testing you can reconnect to the source database, which refreshes the clone to the point where it was when you disconnected.

  The reconnect operation is only available for 24 hours after the disconnect time. If you do not reconnect within the reconnect period, the clone is disconnected from the source database and refreshing and reconnecting are not possible.

> **Note:**
>
> Refreshable clones have a one week refresh age limit. If you do not perform a refresh within a week (7 days), the refreshable clone automatically disconnects from its source database. The refresh by date is shown in the Oracle Cloud Infrastructure Console banner. See Disconnect a Refreshable Clone from the Source Database for more information.
> See Upgrade to Oracle Database 23ai by Creating a Refreshable Clone for additional restrictions for the case when the source is Database version 19c and the refreshable clone is Database version 23ai.

About Refreshable Clone Billing

Provides information about refreshable clone billing.

See Oracle Autonomous Database Serverless Features Billing for information on refreshable clone billing.

Refreshable Clone Operations

You can create a refreshable clone from an Autonomous Database instance. After you create a refreshable clone you can perform several operations on the refreshable clone, including: refresh, stop, start, restart, disconnect from source, and terminate.

Operation	Description
Create	You can create a refreshable clone from an Autonomous Database instance. You can create more than one refreshable clone using the same Autonomous Database instance as a source. See Create a Refreshable Clone for an Autonomous Database Instance for the steps to create a refreshable clone.
View	You view a refreshable clone from the Oracle Cloud Infrastructure console Autonomous Database Details page. See View Refreshable Clones for an Autonomous Database Instance for more information.
Start or Restart	When a refreshable clone is stopped as indicated by the Lifecycle state **Stopped**, you can start the database. When a refreshable clone is available as indicated by the Lifecycle state **Available**, you can restart the database. Start and Restart are not allowed when a refreshable clone source is Database version 19c and the refreshable clone is Database version 23ai. See Upgrade to Oracle Database 23ai by Creating a Refreshable Clone for more information.
Refresh	For a refreshable clone, you can refresh the clone with data from the source database. See Refresh a Refreshable Clone on Autonomous Database for more information.
Edit Automatic Refresh Policy	When you enable the automatic refresh option a refreshable clone automatically refreshes from the source database at regular intervals. By default, automatic refresh is disabled and you must manually refresh at least once every 7 days. See Edit Automatic Refresh Policy for Refreshable Clone for more information.
Disconnect Clone from Source	You can disconnect a refreshable clone from the source database to make the clone a standard read/write database. See Disconnect a Refreshable Clone from the Source Database for more information.

Operation	Description
Reconnect Refreshable Clone	When a clone database is disconnected, you can use the clone as a standard read/write database. There is a 24 hour reconnect period where you can reconnect the clone to its source database. After the reconnect period the refreshable clone is disassociated from the source database and reconnecting to the source database is not allowed. See Reconnect a Refreshable Clone to the Source Database for more information.
Stop	When a refreshable clone is stopped, database operations are not available and charging for OCPU usage on the refreshable clone stops.
Terminate	If you want to terminate a refreshable clone, select **More actions** and **Terminate**. Terminating a refreshable clone disassociates the clone database from the source database.

Refreshable Clone with Automatic Refresh Enabled

By default you manually refresh a refreshable clone with changes from the source database. When you enable the automatic refresh option, Autonomous Database automatically refreshes a refreshable clone with data from the source database at given time intervals.

> **Note:**
>
> The automatic refresh option is only available when the source database uses the ECPU compute model.

Note the following for a refreshable clone with automatic refresh enabled:

- You can manually refresh a refreshable clone between automatic refreshes. If you manually refresh to a refresh point later than the next refresh point specified for an automatic refresh, the automatic refresh may fail. Following refreshes, after the failed refresh, are attempted at the next scheduled automatic refresh.
- If a refreshable clone is stopped, disconnected, or already at a later timestamp than the specified automatic refresh point, the automatic refresh fails.
- If a scheduled refresh is missed due to the source database being stopped, or the refreshable clone being disconnected, or when the refreshable clone was manually refreshed to later point, the missed refresh is skipped. The refreshable clone refreshes at the next scheduled interval.
- When an automatic refresh is missed, Autonomous Database does the following:
  - Shows a banner on the Oracle Cloud Infrastructure Console.

    For example:

    
  - Generates the automatic refresh failed event. See Autonomous Database Lifecycle Events for more information.

- If no refresh is performed within 7 days, the refreshable clone automatically disconnects from its source database.

  See Disconnect a Refreshable Clone from the Source Database for more information.

- See Upgrade to Oracle Database 23ai by Creating a Refreshable Clone for additional restrictions for the case when the source is Database version 19c and the refreshable clone is Database version 23ai.

Refreshable Clone Lifecycle States

After you create a refreshable clone, the clone indicates its state on the Autonomous Database Information page in the Lifecycle state field. In addition, the Mode field indicates that a refreshable clone is **Read-Only**.

A refreshable clone indicates its state as follows:

- **Updating**: When a refreshable clone is refreshing or reconnecting, the Lifecycle state field shows **Updating**. While the database is refreshing connections and queries wait until the refresh completes. After the refresh completes the state is set to **Available**, and connections and queries resume.

  See Refresh a Refreshable Clone on Autonomous Database for more information.

- **Stopped**: When a refreshable clone is stopped, database operations are not available and charging for compute usage on the refreshable clone stops.

- **Available**: When the refreshable clone is available, database operations are available and you are charged for compute usage on the refreshable clone.

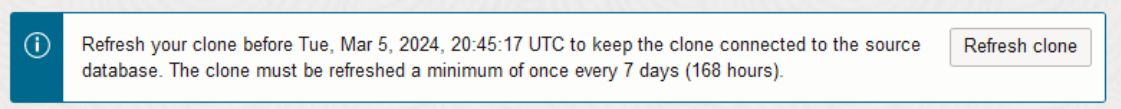
The Autonomous Database Information page Mode field indicates the database mode, as follows:

Read-Only: No data can be inserted into or updated in a refreshable clone as it is a read-only database. You can use a refreshable clone for read-only queries and for reporting.

See Disconnect a Refreshable Clone from the Source Database to change the database to Read/Write mode. In this case the refreshable clone is disconnected from the source database.

Refreshable Clone Refresh Timing and Disconnecting from the Source Database

A refreshable clone with **Automatic refresh** disabled has a one week refresh age limit and a banner on the Oracle Cloud Infrastructure console displays the date and time up to which you can refresh the refreshable clone. The banner also includes a **Refresh clone** button.



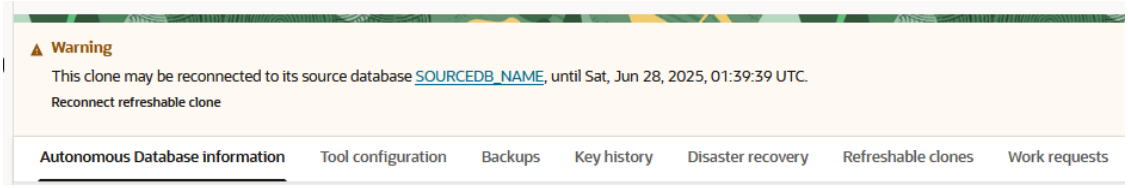
Refreshable clones have a one week refresh age limit. If you do not perform a refresh within a week (7 days), the refreshable clone automatically disconnects from its source database. The refresh by date is shown in the Oracle Cloud Infrastructure Console banner. See Disconnect a Refreshable Clone from the Source Database for more information.

When a refreshable clone has exceeded the maximum refresh time and is automatically disconnected, if you want to use a refreshable clone that can be refreshed from the source database, you must create a new refreshable clone.

See Upgrade to Oracle Database 23ai by Creating a Refreshable Clone for additional restrictions for the case when the source is Database version 19c and the refreshable clone is Database version 23ai.

Refreshable Clone Reconnect to the Source Database

After you perform a **Disconnect refreshable clone** operation, a banner displays the date and time up to which you can reconnect the database to the source. The banner also includes a **Reconnect refreshable clone** button.



When a disconnected database is not reconnected within 24 hours from the disconnect time, the Oracle Cloud Infrastructure Console removes the reconnect refreshable clone banner.

When a disconnected refreshable clone has exceeded the reconnect period, you have the following options:

- You can use the database as a standard Autonomous Database; there is no longer an option to reconnect the database to the source database.
- If you want to use a refreshable clone that can be refreshed from the source database, then you must create a new refreshable clone. If you create a new refreshable clone, then you might want to terminate the disconnected clone that is no longer able to refresh from the source database.

Operations on an Autonomous Database with an Attached Refreshable Clone

Describes details for using a source Autonomous Database instance that has one or more attached refreshable clones.

When you make certain changes on a source Autonomous Database instance that has one or more refreshable clones attached to it, the changes are applied to both the source database and to the refreshable clones as follows:

- Storage: The storage value you set on the source database applies to both the source database and to any attached refreshable clones.
- ADMIN password: The ADMIN password value you set on the source database applies to both the source database and to any attached refreshable clones.

To view the refreshable clones for a source database, on the Autonomous Database Details page, select the **Refreshable clones** tab.

The list on the **Refreshable clones** tab provides a link to each refreshable clone in the **Display name** colmn, and includes the **Last refresh** field with a timestamp and the **Refresh point** column with a timestamp. The refresh point specifies the timestamp for the source database data to which the refreshable clone data is refreshed.

If you want to terminate a source database that has one or more attached refreshable clones, then before you terminate the source database you must do the following until there are no longer any attached refreshable clones.

For each attached refreshable clone, do one of the following:

- Disconnect the refreshable clone from the source database. See Disconnect a Refreshable Clone from the Source Database for more information.

- Terminate the refreshable clone to disassociate the refreshable clone from the source database. You can terminate a refreshable clone by selecting **More actions** and **Terminate**.

Prerequisites for Creating a Refreshable Clone

Describes prerequisites for creating a refreshable clone.

To create a refreshable clone you must define the required access using OCI Identity and Access Management policy statements written by an administrator, whether you're using the Console, the REST API, the CLI, or another tool.

The following policies allow you to create a refreshable clone:

```
Allow group Group_Name to read autonomous-databases in compartment
Compartment_Name
      where target.id = 'oc1.autonomousdatabase.oc1..unique_ID'

Allow group Group_Name to manage autonomous-databases in compartment
Compartment_Name
```

The `where` clause is optional and provides a more fine grained way to grant access to a specific database.

You can limit cloning permissions so that the group can only clone Autonomous Databases but cannot create Autonomous Databases, or further limit permission to only create a particular type of clone: Full Clone, Metadata Clone, or Refreshable Clone. See IAM Permissions and API Operations for Autonomous Database for more information and examples.

This shows the policies for cloning within a tenancy. See Prerequisites for Cross Tenancy Cloning for cross tenancy cloning policies.

See IAM Policies for Autonomous Database and Getting Started with Policies for more information.

Create and Manage Refreshable Clones

When you create a refreshable clone the system creates a clone that can be easily updated with changes from the source database.

- Create a Refreshable Clone for an Autonomous Database Instance
  Shows you the steps to create an Autonomous Database refreshable clone from the Oracle Cloud Infrastructure Console.
- Edit Automatic Refresh Policy for Refreshable Clone
  When you enable the automatic refresh option a refreshable clone automatically refreshes from the source database at regular intervals. By default, automatic refresh is disabled and you must manually refresh at least once every 7 days.
- Refresh a Refreshable Clone on Autonomous Database
  Shows you the steps to refresh a refreshable clone from the Oracle Cloud Infrastructure Console.
- Disconnect a Refreshable Clone from the Source Database
- Reconnect a Refreshable Clone to the Source Database
- Create a Cross Tenancy or Cross-Region Refreshable Clone

Create a Refreshable Clone for an Autonomous Database Instance

Shows you the steps to create an Autonomous Database refreshable clone from the Oracle Cloud Infrastructure Console.

See Prerequisites for Creating a Refreshable Clone for required refreshable clone prerequisites.

Perform the following steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To create a refreshable clone do the following:

1. On the **Details** page, from the **More actions** drop-down list, select **Create clone**.
2. On the **Create Autonomous Database clone** page, choose the clone type **Refreshable clone** from the choices:
   - **Full clone**: creates a new database with the source database's data and metadata.
   - **Refreshable clone** To create a refreshable clone, select this clone type.
   - **Metadata clone**: creates a new database with the source database's metadata without the data.
3. Provide basic information for the Autonomous Database clone.
   - **Choose your preferred region**. Use the current region or select a different region. When you create a refreshable clone, the preferred region list only shows a remote region if your tenancy is subscribed to the remote region (you must be subscribed to the remote region where you create a refreshable clone).

     The list of available regions only shows a remote region if your tenancy is subscribed to the remote region (you must be subscribed to the paired remote region for the target region where you are cloning your database). See Autonomous Database Cross-Region Paired Regions for more information.
   - **Create in compartment**. See Compartments for information on using and managing compartments.
   - **Source database name** This field is read-only and shows the name of the source database.
   - **Display name** Specify a user-friendly description or other information that helps you easily identify the database.

     You can use the name provided, of the form: **Clone-of-***DBname* or change this to the name you want to use to identify the database. The supplied *DBname* is the name of the source database that you are cloning.
   - **Database name**: Specify the database name; it must consist of letters and numbers only. The maximum length is 30 characters. The same database name cannot be used for multiple Autonomous Databases in the same tenancy in the same region.

     The default database name is a generated 16-character string.
4. Configure the database (with ECPU compute model)

- **Choose database version**: Select the database version. The available database versions are Oracle Database 23ai and Oracle Database 19c.

  Notes for selecting a database version:

  – If the source database version is Oracle Database 23ai, you can select Oracle Database 23ai for the clone.

  – If the source database version is Oracle Database 19c, in regions where Oracle Database 23ai is available, you can choose either Oracle Database 19c or Oracle Database 23ai for the clone.

  – Autonomous Database with Oracle Database 23ai in the Paid tier is available in all commercial public cloud regions.

  – An Oracle Database 19c source with an Oracle Database 23ai refreshable clone is especially useful when you want to use Capture-Replay to test your workloads running on Oracle Database 19c before you upgrade to Oracle Database 23ai. See Test 19c Workloads on a on 23ai Refreshable Clone with Capture-Replay for more information.

- **ECPU count**: Specify the number of ECPUs for your database. The minimum value for the number of ECPUs is 2.
- **Compute auto scaling**: By default compute auto scaling is enabled to allow the system to automatically use up to three times more CPU and IO resources to meet workload demand. If you do not want to use compute auto scaling then deselect this option.

  See Use Auto Scaling for more information.
- **Show advanced options**: Click to show the compute model options or if you want to create or join an elastic pool:

  – **Enable elastic pool**:

    See Create an Elastic Pool While Provisioning or Cloning an Instance for more information.

  – **Compute model**: Shows the selected compute model.

    See Compute Models in Autonomous Database for more information.

  – **Bring your own license**: If you want to Bring Your Own License to the database, click **Enable** to show the **Update license and Oracle Database Edition** page.

    See Choose Bring Your Own License Option While Provisioning or Cloning for more information.

> **Note:**
>
> The storage for a refreshable clone is set to the same size as on the source database. To change the storage size for a refreshable clone, you must change the storage value on the source database.

5. Select **Enable automatic refresh** to specify that the refreshable clone automatically refreshes. By default, **Enable automatic refresh** is deselected and you must manually refresh at least once every 7 days. When you select **Enable automatic refresh**, the dialog shows two fields:

   - **Frequency of refresh**: specifies the refresh frequency in hours or days. The minimum is one hour and the maximum is 7 days. The default **Frequency of refresh** value is 1 hour.

- **Data lag**: specifies the data lag in minutes, hours, or days, the minimum is 0 minutes and the maximum is 7 days. This is the value that specifies the amount of time behind the source that the data refresh is, where a value of 0 specifies that the refreshable clone refreshes to the latest available timestamp. The default **Data lag** value is 0.

6. Choose network access

> **Note:**
>
> After you clone your Autonomous Database you can change the network access option you select for the cloned instance.

- **Secure access from everywhere**

  By default all secure connections are allowed from everywhere.

- **Secure access from allowed IPs and VCNs only**

  This option restricts connections to the database according to the access control rules (ACLs) you specify. To add multiple ACLs for the Autonomous Database, select this option and click **Add access control rule**.
  See Configure Access Control Lists When You Provision or Clone an Instance for more information.

- **Private endpoint access only**

  This option assigns a private endpoint, private IP, and hostname to your database. Specifying this option allows traffic only from the VCN you specify; access to the database from all public IPs or VCNs is blocked. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your Autonomous Database.

  See Configure Private Endpoints When You Provision or Clone an Instance for more information.

See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.

7. (Optional) Provide contacts for operational notifications and announcements

   Click **Add contact** and in the **Contact email** field, enter a valid email address. If the database you are cloning has a customer contact list, the list is copied. To enter multiple **Contact email** addresses, repeat the process to add up to 10 customer contact emails.

   See View and Manage Customer Contacts for Operational Issues and Announcements for more information.

8. (Optional) Click Show advanced options to select advanced options.

   - **Encryption key**
     A refreshable clone uses the encryption key of the source Autonomous Database.

     See Use Customer-Managed Encryption Keys on Autonomous Database for more information.

   - **Maintenance**
     Patch level By default the patch level is the patch level of the source database. Select **Early** to configure the instance with the early patch level. Select **Regular** to configure the instance with the regular patch level.

     See Set the Patch Level for more information.

- **Management**
  Shows the character set and national character set for your database.

  See Choose a Character Set for Autonomous Database for more information.

- **Tools**
  Refreshable clones inherit their tool status for each built-in tool from the refreshable clone's source database. If the source of a refreshable clone changes its tool configuration, the change is reflected in the refreshable clone after the next refresh.

  See Configure Autonomous Database Built-in Tools for more information.

- **Tags**
  If you want to use Tags, enter the **Tag key** and **Value**. Tagging is a metadata system that allows you to organize and track resources within your tenancy. Tags are composed of keys and values which can be attached to resources.

  See Tagging Overview for more information.

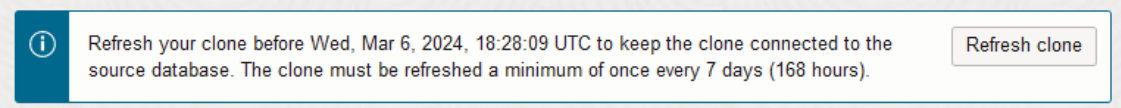
9. Click **Create Autonomous Database clone**.

On the Oracle Cloud Infrastructure console the **State** shows **Provisioning...** until the refreshable clone is available.

After the provisioning completes the Lifecycle state shows **Available** and the Mode is **Read-only**.

After you download the wallet for the refreshable clone and connect to the database, you can begin using the database to perform read-only operations such as running queries or building reports and notebooks.

When **automatic refresh** is disabled, after you create a refreshable clone, the Oracle Cloud Infrastructure console shows a banner similar to the following with a message indicating the date prior to which the next refresh must be completed (the banner shows the 7 day refresh limit).



See Refresh a Refreshable Clone on Autonomous Database for details on refreshing a refreshable clone.

Edit Automatic Refresh Policy for Refreshable Clone

When you enable the automatic refresh option a refreshable clone automatically refreshes from the source database at regular intervals. By default, automatic refresh is disabled and you must manually refresh at least once every 7 days.

The edit auto refresh settings dialog allows you to enable or disable automatic refresh for a refreshable clone. When automatic refresh is enabled you can change the automatic refresh options.

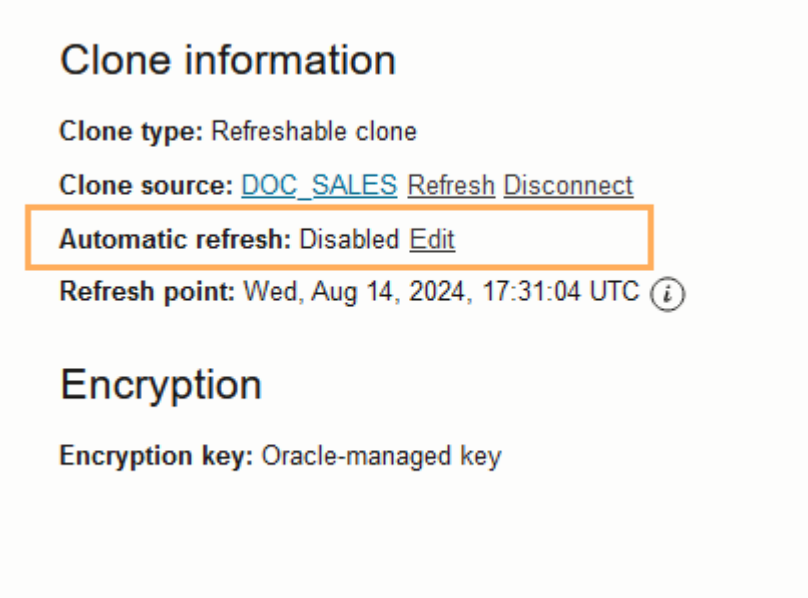
> **Note:**
>
> The automatic refresh option is only available when the source database uses the ECPU compute model.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To edit auto refresh options:

1. On the clone source, on the **Details** page, select the **Refreshable clones** tab.
2. In the Refreshable clones list, under **Display name**, select a refreshable clone.
3. On the refreshable clone, in the **Clone information** area, in the **Automatic refresh** field click **Edit**.



This shows the Edit automatic refresh policy pane.

4. Select or deselect **Enable automatic refresh** to enable or disable automatic refresh for the refreshable clone. When **Enable automatic refresh** is selected, you can modify the options:
   - **Frequency of refresh**: specifies the refresh frequency in hours or days. The minimum is one hour and the maximum is 7 days. The default **Frequency of refresh** value is 1 hour.
   - **Data lag**: specifies the data lag in minutes, hours, or days, the minimum is 0 minutes and the maximum is 7 days. This is the value that specifies the amount of time behind the source that the data refresh is, where a value of 0 specifies that the refreshable clone refreshes to the latest available timestamp. The default **Data lag** value is 0.
5. Click **Save**.

Subscribe to the Information event `com.oraclecloud.databaseservice.autonomous.database.information` to be notified about the completion or failure of a scheduled Automatic Refresh. See Information Events on Autonomous Database for more information.

Refresh a Refreshable Clone on Autonomous Database

Shows you the steps to refresh a refreshable clone from the Oracle Cloud Infrastructure Console.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

You can refresh a refreshable clone as follows:

1. On the Details page, under Clone information, in the **Clone source** field click the **Refresh** link.

   This shows the Refresh clone dialog.

2. In the Refresh clone dialog, specify the **Refresh point timestamp**.

   The refresh point specifies the timestamp of the source database data to which the refreshable clone is refreshed.

   The timestamp can be a minimum of 1 minute in the past and a maximum of 7 days in the past. The timestamp must be later than, that is after, the last refresh point. Thus, if you create a refreshable clone, then you would need to wait some time before you refresh the clone.

3. Click **Refresh clone**.

On the Oracle Cloud Infrastructure console the Lifecycle state shows **Updating** until the refresh operation completes. While the database is updating connections and queries wait until the refresh completes.

You can check the status of the refresh operation by selecting the **Work requests** tab on the Autonomous Database details page.

On the Oracle Cloud Infrastructure Console, under Clone Information the **Refresh point** shows the timestamp of the source database's data that the clone was refreshed to.

> **Note:**
>
> Refreshable clones have a one week refresh age limit. If you do not perform a refresh within a week (7 days), the refreshable clone automatically disconnects from its source database. The refresh by date is shown in the Oracle Cloud Infrastructure Console banner. See Disconnect a Refreshable Clone from the Source Database for more information.

Disconnect a Refreshable Clone from the Source Database

Shows you the steps to disconnect a refreshable clone from the source database.

When you disconnect a refreshable clone the refreshable clone is disassociated from the source database. This converts the database from a refreshable clone to a regular database. Following the disconnect operation you are allowed to reconnect the disconnected database to the source database. The reconnect operation is limited to a 24 hour period.

There are several ways to find refreshable clones. See View Refreshable Clones for an Autonomous Database Instance for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

Starting from the Source Database Console Disconnect a refreshable clone from the source database and convert the refreshable clone to a read/write database:

1. On the Autonomous Database **Details** page select the **Refreshable clones** tab.

   This shows the list of refreshable clones.

2. In the row for the refreshable clone you want to disconnect, click ⋯ at the end of the row and select **Disconnect clone from source database**.
3. In the Disconnect refreshable clone dialog enter the source database name to confirm disconnecting the clone.
4. Click **Disconnect refreshable clone**.

Starting from the Clone Database Console Disconnect a refreshable clone from the source database and convert the refreshable clone to a read/write database:

1. On the Autonomous Database Details page, under Clone information, in the **Clone source** field click click ... at the end of the row and select **Disconnect**.
2. In the Disconnect refreshable clone dialog enter the source database name to confirm disconnecting the clone.
3. Click **Disconnect refreshable clone**.

The Autonomous Database Lifecycle state of the cloned database changes to **Updating**. When the disconnect operation completes the Lifecycle state changes to **Available** and the Mode shows **Read/Write**.

After you disconnect a refreshable clone, the Oracle Cloud Infrastructure Console updates with the following changes:

- The **Display name** on the Autonomous Databases page updates and does not show the **Refreshable clone** indicator for the cloned instance.
- On the disconnected instance, the Autonomous Database Details page updates and does not show the **Refreshable clone** indicator, and the **Clone information** area is removed.
- On the disconnected instance the Autonomous Database details page displays a banner indicating the date and time up to which you can reconnect the database to the source. The banner also includes a **Reconnect refreshable clone** link. For example:

  See Reconnect a Refreshable Clone to the Source Database for more information.
- On the source database, on the **Autonomous Database Details** page, when you select the **Refreshable clones** tab, the list of refreshable clones no longer shows an entry for the disconnected clone.

Notes for disconnecting a refreshable clone.

- Disconnecting a refreshable clone from the source may fail if the source database has scaled down its storage and the refreshable clone has a larger amount of data than the source. In this case, you have the following options:
  - You may scale up the storage on the source database temporarily before disconnecting, and then scale the source back down after disconnecting.
  - Refresh the clone to a point where the scale down of storage occurred.
- After you disconnect a refreshable clone you have 24 hours to reconnect. After the reconnect period is over, the reconnect operation is not available. If you do not reconnect a disconnected refreshable clone, the clone is a standard Autonomous Database and there is no longer an option to reconnect the database to the source database.
- A disconnected refreshable clone is no longer associated with the source database. To use the database or to initiate the reconnect operation, you must know the name of the refreshable clone database that was disconnected from the source database. You must initiate the reconnect operation from the disconnected clone database. You cannot reconnect a disconnected clone from the source database.

Reconnect a Refreshable Clone to the Source Database

Shows you the steps to reconnect a disconnected clone to the source database.

After you disconnect a refreshable clone, during the following 24 hour reconnect period you can reconnect to the source database. The reconnect operation restores all the data back to that time when the clone was disconnected.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

Reconnect a database and restore all the data back to that time when the refreshable clone was disconnected from the source database as follows:

1. On the **Details** page, from the **More actions** drop-down list, select **Reconnect refreshable clone**.

   This shows the Reconnect Refreshable Clone dialog.
2. In the Reconnect Refreshable Clone dialog, enter the source database name to confirm.

> **Note:**
>
> All data and metadata inserted, updated, or deleted from the database where you run the reconnect operation will be lost when the database is reconnected to the source database.

3. Click **Reconnect refreshable clone**.

The Autonomous Database Lifecycle state changes to **Updating**.

When the reconnect refreshable clone operation completes, the Oracle Cloud Infrastructure Console on the clone indicates the change as follows:

- The Mode shows **Read Only**.
- If the clone was available when you initiated the reconnect operation, the Lifecycle state changes to **Available**.
- If the clone was stopped when you initiated the reconnect operation, the Lifecycle state shows **Stopped**.
- On the Autonomous Database Details page, the Clone Information area is updated. The **Clone type** shows Refreshable Clone, the **Clone source** shows the source database link, the **Refresh** link, **Disconnect** link, and the **Refresh point** shows the last refresh timestamp.

Notes for reconnecting a disconnected clone to the source database:

- If you disconnect a refreshable clone, you have 24 hours to use the reconnect operation. After the reconnect period is over, the reconnect operation is not available. If you do not reconnect a disconnected refreshable clone, the Autonomous Database is a standard read/write database and there is no longer an option to reconnect the database to the source database.
- Network ACLs and Private Endpoint network configuration options on a refreshable clone can be changed when the clone is disconnected from the source database. When you reconnect a refreshable clone to its source database, the reconnect operation does not

restore the network ACLs or Private Endpoint network configuration options on the refreshable clone.

Create a Cross Tenancy or Cross-Region Refreshable Clone

You can create a refreshable clone in a different tenancy (destination tenancy). When you create a cross tenancy refreshable clone, the refreshable clone in the destination tenancy can be in the same region or in a different region (cross-region).

The cross tenancy cloning option is only available using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

These steps cover creating a Refreshable clone. See Create a Cross Tenancy or Cross-Region Clone for details on creating a cross tenancy Full clone or Metadata clone.

To create a cross tenancy refreshable clone:

1. Perform the prerequisite steps to define the OCI Identity and Access Management policies to authorize cross tenancy cloning.

   See Prerequisites for Cross Tenancy Cloning for details.

   > **Note:**
   >
   > If the polices you specify to allow cross tenancy cloning are subsequently revoked, cross-tenancy cloning is no longer allowed. In addition, for a refreshable clone, when the policies are revoked actions on the remote tenancy that require contact with the source tenancy, such as disconnect and refresh will fail.

2. On the tenancy where you want to create the refreshable clone, use the CLI or call the REST API.

   You run the CLI or call the REST API on the destination tenancy in the destination region where you want to create the refreshable clone. The source database resides in a different tenancy, and if specified in a different region. This creates either a cross-tenancy refreshable clone in the same region, or a cross-tenancy refreshable clone in a different region (cross-region).

   For example, with the CLI:

   ```
   oci db autonomous-database create-refreshable-clone
       --compartment-id ocid1.tenancy.oc1..aaaaaaaafcue47pqmrf4vigne_example
       --source-id ocid1.autonomousdatabase.oc1.iad.anuwcljs4bv3yyiae2_example
       --db-name adatabasedb1
       --data-storage-size-in-tbs 1
       --compute-model ECPU
       --compute-count 2
       --refreshable-mode MANUAL
   ```

   See create-refreshable-clone for more information.

   Use the `CreateAutonomousDatabase` API to create a cross tenancy refreshable clone. When you call this API, to create a refreshable clone you set the `source` value to `CLONE_TO_REFRESHABLE` and the `sourceID` to the OCID of the source database.

   See the following for information on the REST API:

   - CreateAutonomousDatabase

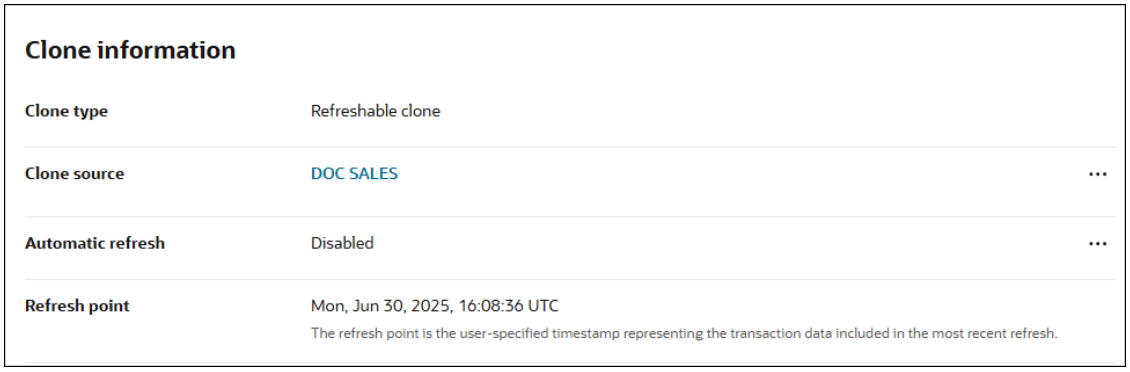
- CreateRefreshableAutonomousDatabaseCloneDetails
- For information about using the API and signing requests, see REST APIs and Security Credentials.
- For information about SDKs, see Software Development Kits and Command Line Interface.

View Refreshable Clones for an Autonomous Database Instance

If you know a refreshable clone's display name, you can view the instance by selecting from the list of Autonomous Databases on the Oracle Cloud Infrastructure Console.

On the Oracle Cloud Infrastructure Console, the details page for a refreshable clone shows a **Refreshable clone** badge to indicate the instance is a refreshable clone.

The **Clone information** area shows details for a refreshable clone. You can access the source database by clicking the link in the **Clone source** field.



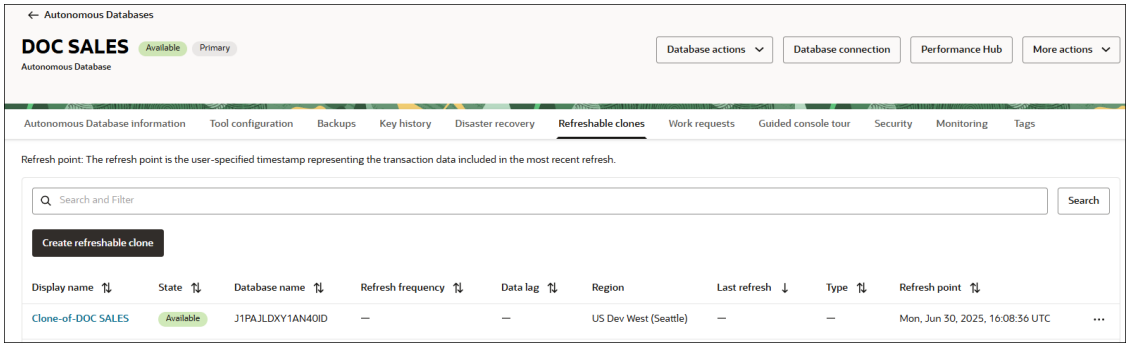
Under **Clone information** the console shows the **Last refresh point**, indicating the timestamp of the source database's data that the clone was last refreshed with.

When an Autonomous Database instance has attached refreshable clones, you can view the refreshable clones as follows:

1. Choose your region. See Switching Regions for information on switching regions and working in multiple regions.
2. Choose your **Compartment**. See Compartments for information on using and managing compartments.
3. Select an Autonomous Database instance from the list on the Autonomous Databases page.
4. On the **Autonomous Database** details page, select the **Refreshable clones** tab.

This shows the list of refreshable clones for the Autonomous Database instance.

If you click ... at the end of a row in the list, you can select an action to perform for the refreshable clone.



Use the API

Provides details for using the APIs to create, refresh, list, disconnect, and reconnect a refreshable clone.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage a refreshable clone:

- To create a refreshable clone, use CreateAutonomousDatabase.
- To refresh a refreshable clone, use AutonomousDatabaseManualRefresh.
- To list the attached refreshable clones for a database, use ListAutonomousDatabaseClones.
- To disconnect a refreshable clone from the source database, use UpdateAutonomousDatabase.

Refreshable Clone Notes

Lists limitations and notes for Autonomous Database refreshable clones.

- See Upgrade to Oracle Database 23ai by Creating a Refreshable Clone for additional notes when you select a refreshable clone source with Database version 19c and a cloned Autonomous Database Database version 23ai.
- Always Free Autonomous Databases do not support refreshable clones.
- Autonomous Database does not support using customer-managed encryption keys with a refreshable clone. You cannot create a refreshable clone from a source database that uses customer-managed encryption keys. Additionally, you cannot switch to a customer-managed encryption key on a source database that has one or more refreshable clones.
- You cannot create a cascading series of refreshable clones. Thus, a refreshable clone cannot be created from another refreshable clone.
- You cannot backup or restore a refreshable clone.
- The ADMIN password for a refreshable clone is inherited from the source database. If you want to change the ADMIN password for a refreshable clone you must change the ADMIN password on the source database, and then refresh the clone for the ADMIN password on the clone to come into effect.
- Oracle APEX URLs do not work in a refreshable clone read-only database and the APEX URLs are disabled in the Oracle Cloud Infrastructure Console and in the Database Actions APEX and APEX Workspaces cards. APEX URLs are enabled for a read/write database when a refreshable clone is disconnected from the source.

- Oracle Machine Learning is disabled in a refreshable clone read-only database. The OML User Administration URLs are disabled in the Oracle Cloud Infrastructure Console and on the Database Actions Launchpad.
- Oracle Data Safe is not supported for a refreshable clone instance. The Data Safe data in the refreshable clone's source database, for example user registration, data masking, and so on are available and Data Safe can be enabled when a refreshable clone is disconnected from the source.
- When you scale up or scale down the storage on the source Autonomous Database instance for a refreshable clone, the change is immediately reflected in the database console and in the billing for the refreshable clone. When the refreshable clone is refreshed to a refresh point after the scale up or down operation, the system makes a corresponding change to the refreshable clone storage (scaling up or scaling down the refreshable clone storage to match the source database).
- You cannot use the rename operation on a refreshable clone instance or on a database that is the source for a refreshable clone.
- When the patch level of a source Autonomous Database instance is **Regular**, in regions that support the **Early** patch level you can set the patch level of a clone to **Early**. See Set the Patch Level for more information.
- Automatic Workload Repository (AWR) data and reports are not available for refreshable clones. In addition, the graphs that rely on AWR data are not available, including the following graphs:
  - The Running SQL statements graph on the Overview tab shown on the **Database Dashboard** card in Database Actions.
  - The SQL statement response time graph on the Overview tab shown on the **Database Dashboard** card in Database Actions.
  - The Time period graphs on the Monitor tab shown on the **Database Dashboard** card in Database Actions.
  - The Performance Hub graph data older than one hour is not available.
- Creating a cross-region refreshable clone with an Oracle Database 19c source and an Oracle Database 23ai refreshable clone is not supported.
- Creating a cross tenancy refreshable clone with an Oracle Database 19c source and an Oracle Database 23ai refreshable clone is not supported in either the same region or cross-region.
- For an Oracle Autonomous JSON Database (workload type **JSON Database**), note the following when reconnecting to the source database:
  - If, after you disconnect the refreshable clone, you promote both the clone and the source to Oracle Autonomous Transaction Processing (workload type **Transaction Processing**), you can reconnect the database to the source.
  - If after you disconnect the refreshable clone, you promote the source database to Oracle Autonomous Transaction Processing (workload type **Transaction Processing**) and do not promote the disconnected clone, the disconnected clone must also be promoted to Oracle Autonomous Transaction Processing (workload type **Transaction Processing**) before you perform the reconnect operation.
  - If after you disconnect the refreshable clone, you promote the disconnected database to Oracle Autonomous Transaction Processing (workload type **Transaction Processing**), you can still reconnect to the source but the reconnected database remains in the promoted state.

  See Promote to Autonomous Transaction Processing for more information.

Manage Autonomous Database Built-in Tools

Autonomous Database includes built-in tools that you can enable and disable when you provision or clone a database, or at any time for an existing database.

- About Autonomous Database Built-in Tools
  Provides a complete list of Autonomous Database built-in tools and a description of each tool.
- About Configuring Built-in Tools Compute Resources and Limits
- View Autonomous Database Built-in Tools Status
  Describes the steps to view the status of built-in tools on your Autonomous Database instance.
- Configure Autonomous Database Built-in Tools
  You can enable or disable Autonomous Database built-in tools for an existing Autonomous Database instance. In addition, with the ECPU compute model you can configure the number of ECPUs and the idle time allowed for several of the built-in tools.
- Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance
  During provisioning or when you clone an instance, you can enable or disable Autonomous Database built-in tools.
- Notes for Autonomous Database Built-in Tools
  Provides additional Autonomous Database built-in tools notes and lists differences that apply depending on the workload type of your Autonomous Database instance.

About Autonomous Database Built-in Tools

Provides a complete list of Autonomous Database built-in tools and a description of each tool.

Tool	Description
Oracle APEX	Oracle APEX is a low-code development platform that you can use to build scalable, secure enterprise applications that can be deployed anywhere. See Create Applications with Oracle APEX in Autonomous Database for more information.
Database Actions	Oracle Database Actions is a web-based interface that uses Oracle REST Data Services to provide development, data tools, administration and monitoring features for Oracle Autonomous Database. See Connect with Built-In Oracle Database Actions for more information.
Graph Studio	Graph Studio automates the creation of knowledge (RDF) and property graphs and includes interactive tooling for query, analysis, and visualization of these graphs in the Autonomous Database. You must log in as a graph-enabled user to access Graph Studio. Create this user in Database Actions. See Using Oracle Graph with Autonomous Database for more information.

Tool	Description
Oracle ML User Interface	Oracle Machine Learning User Interface provides immediate access to the Oracle Machine Learning components and functionality on Autonomous Database, including OML Notebooks, OML AutoML UI, OML Models, and template example notebook. This includes: • OML Notebooks • OML AutoML UI • OML for Python • OML for R • OML Services
Data Transforms	Oracle Data Transforms allows you to design graphical data transformations in the form of data flows and workflows. The data flows define how the data is moved and transformed between different systems, while the workflows define the sequence in which the data flows run.
Web Access (ORDS)	Oracle REST Data Services (ORDS) provides HTTPS interfaces for working with the contents of your Oracle Database in one or more REST enabled schema See Develop with Oracle REST Data Services on Autonomous Database for more information.
MongoDB API	Oracle Database API for MongoDB enables MongoDB-compatible clients and drivers to connect directly to Autonomous Database. See Using Oracle Database API for MongoDB for more information.
Data Lake Accelerator	Data Lake Accelerator enhances the performance and scalability of external data processing on Oracle Autonomous Database. It automatically allocates additional CPU resources to speed up external data scans from Object Stores based on query needs. This integration enables efficient resource utilization, faster query responses, and easy scaling for large data volumes. **Note:** Only Oracle Database 19c supports Data Lake Accelerator. See About Data Lake Accelerator for more information.
SODA Drivers	Simple Oracle Document Access (SODA) is a set of APIs that let you work with JSON documents managed by the Oracle Database without needing to use SQL. SODA drivers are available for REST, Java, Node.js, Python, PL/SQL, and C. See Use SODA for REST with Autonomous Database for more information.

About Configuring Built-in Tools Compute Resources and Limits

When your Autonomous Database instance is using the ECPU compute model, the built-in tools that use a VM have default compute resource limits. Optionally you can configure the compute resource limits for these tools.
For the built-in tools that use a VM, the **ECPU count** and **Maximum idle time** specify resources and configuration options for the VMs that run the associated built-in tool, and mean the following in terms of resource usage and billing:

- You do not pay for a tool's ECPU allocation if you do not use the tool.
- The VMs associated with a tool are provisioned when you start using a tool. For example, if Graph Studio is disabled, billing does not begin when you enable the tool. Billing begins when you start using Graph Studio.
- The **ECPU count** specifies the number of ECPUs that are dedicated to the tool. The built-in tools **ECPU count** value applies in addition to the database **ECPU count** you specify for the instance.
- After you start using a tool you are billed per ECPU hour reserved from the time the built-in Tool is launched. ECPU usage is measured each second, in units of whole ECPUs and averaged across an hour. If your database is running for less than an hour or you change the number of ECPUs for only part of an hour, your built-in Tool ECPU usage is billed per second for the average ECPU consumption during that hour. The minimum ECPU consumption is one minute.
- Billing stops for a built-in tool's allocated ECPUs when the built-in tool is disabled, the instance stops or is terminated, or when the built-in tool is idle for more than the specified **Maximum idle time**.

See Oracle Autonomous Database Serverless Billing for Database Tools for more information.

View Autonomous Database Built-in Tools Status

Describes the steps to view the status of built-in tools on your Autonomous Database instance.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To view built-in tools status:

1. Navigate to the Autonomous Database details page.
2. Select the **Tool configuration** tab.

   This displays the tools configuration details and status.

Autonomous Database information | Tool configuration | Monitoring | Backups | Key history | Disaster recovery | Refreshable clones

Oracle APEX

Oracle APEX is a low-code development platform that you can use to build scalable, secure enterprise applications that can be deployed anywhere. Learn more.

Status	Enabled	Edit

MongoDB API

Oracle Database API for MongoDB enables MongoDB-compatible clients and drivers to connect directly to Autonomous Database. Learn more.

Status	Disabled	Edit

If your Autonomous Database instance is on a private endpoint and you enable the **Allow public access** option, the tools tab shows both a **Private access URL** and a **Public access URL**. The Private access URL provides the URL to access a tool from within the VCN where the database resides. The Public access URL provides the URL to access a tool from the public internet, to provide access from allowed public IPs or from allowed public VCNs. See Use a Private Endpoint with Public Access Allowed for more information.

Configure Autonomous Database Built-in Tools

You can enable or disable Autonomous Database built-in tools for an existing Autonomous Database instance. In addition, with the ECPU compute model you can configure the number of ECPUs and the idle time allowed for several of the built-in tools.

- Configure Autonomous Database Built-in Tools (ECPU compute model)
- Configure Autonomous Database Built-in Tools (OCPU compute model)

Configure Autonomous Database Built-in Tools (ECPU compute model)

Describes how to enable or disable Autonomous Database built-in tools for an existing Autonomous Database instance.

Tool status is retained across starts and restarts for an Autonomous Database instance. For example, if a tool is disabled before you stop or restart an instance, the tool maintains the same status (disabled) after a start or restart.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To configure Autonomous Database built-in tools:

1. On the Autonomous Database details page, select the **Tool configuration** tab.
2. Click **Edit** and on the Configure tools pane switch the **Status** toggle on to enable a tool.
3. (Optional) When enabled, Graph Studio, Oracle Machine Learning User Interface, Data Lake Accelerator, and Data Transforms provide default **ECPU count** and **Max idle time** values and you can configure these values.

   Change the **ECPU count** value if you want to provide more or less resources for a built-in tool.

   Change the **Max idle time** value to specify the time, in minutes, after which an idle Graph Studio, Data Transforms, or Oracle Machine Learning VM is terminated.

   See About Configuring Built-in Tools Compute Resources and Limits for more information.
4. Click **Apply** to apply your changes.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

> **Note:**
>
> Only Oracle Database 19c supports Data Lake Accelerator.

See About Data Lake Accelerator for more information.

Configure Autonomous Database Built-in Tools (OCPU compute model)

Describes how to enable or disable Autonomous Database built-in tools for an existing Autonomous Database instance.

Tool status is retained across starts and restarts for an Autonomous Database instance. For example, if a tool is disabled before you stop or restart an instance, the tool maintains the same status (disabled) after a start or restart.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To configure Autonomous Database built-in tools:

1. On the Autonomous Database details page, select the **Tool configuration** tab.
2. Click **Edit**.
3. On the Configure tools pane, switch the Status toggle on or off to enable or disable a tool.
4. Click **Apply** to apply your changes.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance

During provisioning or when you clone an instance, you can enable or disable Autonomous Database built-in tools.

- Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance (ECPU compute model)
- Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance (OCPU compute model)

Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance (ECPU compute model)

Describes how to enable or disable Autonomous Database built-in tools when you provision or clone an instance.

When you are cloning, note the following:

- When you are cloning and you select **Full Clone** or **Metadata Clone**, the built-in tools default settings are based on the defaults for the workload type of the clone. In this case, the defaults are not based on source database built-in tools settings.
- When you are cloning and you select **Refreshable Clone**, the refreshable clone inherits the built-in tool status from the source database. Editing the built-in tool status for refreshable clone is not be possible during or after provisioning. If the source database of refreshable clone changes its tool configuration, this is reflected in the refreshable clone after the next refresh.

Perform the steps to provision or clone an instance:

- Provision an Autonomous Database Instance
- Clone an Autonomous Database Instance

1. Click **Show advanced options** to select advanced options.
2. In advanced options, select the **Tools** tab.
3. Click **Edit tool configuration**.
4. Select or deselect a tool in the **Status** field to enable or disable the tool.
5. (Optional) When enabled, Graph Studio, Oracle Machine Learning User Interface, and Data Transforms provide default **ECPU count** and **Maximum idle count** values and let you configure these values.

   Change the **ECPU count** value if you want to provide more or less resources for a built-in tool.

   Change the **Maximum idle time value** to specify the time, in minutes, after which an idle Graph Studio, Data Transforms, or Oracle Machine Learning VM is terminated.

   See About Configuring Built-in Tools Compute Resources and Limits for more information.
6. (Optional) When enabled, Data Lake Accelerator provides the following default values for **ECPU count** and **Max idle time** and lets you configure **ECPU count**.

   Change the **ECPU count** value to specify the number of user requested allocated ECPUs.

   Max idle time value is 10 minutes and specifies the time after which a VM is terminated. This value can not be changed.

   See About Data Lake Accelerator for more information.

   > **Note:**
   >
   > Only Oracle Database 19c supports Data Lake Accelerator.
7. Click **Apply** to apply the configuration changes and return to the provision or clone steps.

Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance (OCPU compute model)

Describes how to enable or disable Autonomous Database built-in tools when you provision or clone an instance

When you are cloning, note the following:

- When you are cloning and you select **Full Clone** or **Metadata Clone**, the built-in tools default settings are based on the defaults for the workload type of the clone. In this case, the defaults are not based on source database built-in tools settings.
- When you are cloning and you select **Refreshable Clone**, the refreshable clone inherits the built-in tool status from the source database. Editing the built-in tool status for refreshable clone is not be possible during or after provisioning. If the source database of refreshable clone changes its tool configuration, this is reflected in the refreshable clone after the next refresh.

Perform the steps to provision or clone an instance:

- Provision an Autonomous Database Instance
- Clone an Autonomous Database Instance

1. Click **Show advanced options** to select advanced options.
2. In advanced options, select the **Tools** tab.
3. Click **Edit tool configuration**.
4. Select or deselect a tool in the **Status** field to enable or disable the tool.
5. Click **Apply** to apply the configuration changes and return to the provision or clone steps.

Notes for Autonomous Database Built-in Tools

Provides additional Autonomous Database built-in tools notes and lists differences that apply depending on the workload type of your Autonomous Database instance.

- Disabling ORDS affects built-in tools such as Database Actions, APEX, and MongoDB API. Therefore, if you disable ORDS, this also disables APEX, Database Actions, and MongoDB API.
- When ORDS is disabled, Database Actions, APEX, and MongoDB API are disabled. If you subsequently enable ORDS this does not automatically enable APEX, Database Actions, or the MongoDb APIs. You must manually enable each built-in tool that is dependent on ORDS. Enable ORDS first, then you can enable APEX, Database Actions, or the MongoDB APIs
- Always Free Autonomous Database does not provide configuration options for Autonomous Database tools and does not allow you to enable or disable Autonomous Database tools.
- By default when you provision an Autonomous Database with Autonomous Data Warehouse or Autonomous Transaction Processing workload types, the MongoDB API is disabled. If MongoDB API is disabled, you can enable it during provisioning or cloning, or in an existing database.

  You can enable MongoDB API only if you have an ACL or if you are on a private endpoint. See Configure Access for MongoDB for more information.
- For JSON Database, Graph Studio is not supported and enabling or disabling Graph Studio for JSON Database is not possible.

  For JSON Database, MongoDB API is enabled by default and you can disable it during the provisioning or cloning, or in an existing database.
- When you are cloning and you select **Full Clone** or **Metadata Clone**, the built-in tools default settings are based on the defaults for the workload type of the clone. In this case, the defaults are not based on source database built-in tools settings.

- When you are cloning and you select **Refreshable Clone**, the refreshable clone inherits the built-in tool status from the source database. Editing the built-in tool status for refreshable clone is not be possible during or after provisioning. If the source database of refreshable clone changes its tool configuration, this is reflected in the refreshable clone after the next refresh.
- When you provision or clone an Autonomous Database with the APEX workload type (APEX service), the only supported built-in tools are Oracle APEX, Web Access (ORDS), and Database Actions. In the APEX service, you can only disable Database Actions.
- All existing sessions end after you disable a built-in tool. In addition, disabling Oracle APEX or Web Access (ORDS) also affects the existing applications that are based on these tools. For example, a user application based on ORDS does not continue to work after you disable ORDS.

Use Autonomous Database Events

Oracle Cloud Infrastructure Events enable you to create automation based on state changes for your Autonomous Database.

You can use Oracle Cloud Infrastructure Events to subscribe to and be notified of Autonomous Database events. The Oracle Cloud Infrastructure Events allow you to create automation and to receive notifications based on state changes for resources.

- About Events Based Notification and Automation on Autonomous Database
- Critical Events on Autonomous Database
  Critical events on Autonomous Database are issues that cause disruption to the database.
- Information Events on Autonomous Database
  Information events provide important details about database lifecycle events, workload capture and reply events, and some other non-critical events on Autonomous Database.
- Autonomous Database Lifecycle Events
  Provides a list of Autonomous Database lifecycle events.
- Get Notified of Autonomous Database Events
  Using Oracle Cloud Infrastructure Events you can subscribe to Autonomous Database events individually or in two categories, Critical and Information events.

About Events Based Notification and Automation on Autonomous Database

You can subscribe to Oracle Cloud Infrastructure Events.

An event could be a resource life cycle state change or a system event impacting a resource. For example, an event is emitted on Autonomous Database when maintenance begins and ends. Subscribing to events allows you to receive notifications or to perform other types of automation for events.

You can subscribe to Autonomous Database events as follows:

- Critical Events: See Critical Events on Autonomous Database for details on the events in the Critical event category.
- Information Events: See Information Events on Autonomous Database for details on the events in the Information event category.
- Lifecycle Management Events. See Autonomous Database Lifecycle Events for the list of Autonomous Database events.
- Autonomous Data Guard Events. See Events and Notifications for a Standby Database for the list of Autonomous Data Guard events.

Critical events and Information events include an event category attribute (in the `eventCategory` field). Optionally you can subscribe to events and add an event category to receive notifications about events in a category, or to perform other types of automation for events by event type and event category.

The event categories are:

- **Incident**: Database incident events
- **Maintenance**: Database maintenance events
- **Performance**: Database performance events
- **Security**: Database security events
- **Other**: Other events

See Overview of Events for complete information on Oracle Cloud Infrastructure Events.

See Get Notified of Autonomous Database Events for information on creating event rules.

Critical Events on Autonomous Database

Critical events on Autonomous Database are issues that cause disruption to the database.

Event	Event Category	Description
`AdminPasswordWarning`	Security	Provides a message that the Autonomous Database ADMIN password is expiring within 30 days or is expired. • If the ADMIN password is within 30 days of being unusable, you receive a warning indicating the date when the ADMIN password can no longer be used. • If the ADMIN password expires and is no longer usable, Autonomous Database reports an event that specifies that the ADMIN user password has expired and must be reset.
`AutomaticFailoverBegin`	Incident	When an automatic failover begins for the Autonomous Database and the database is unavailable an `AutonomousDatabase-AutomaticFailoverBegin` event is generated. The event will only be triggered if you are using Autonomous Data Guard.
`AutomaticFailoverEnd`	Incident	When an automatic failover that was triggered is complete and the database is now available an `AutonomousDatabase-AutomaticFailoverEnd` event is generated. The event will only be triggered if you are using Autonomous Data Guard.

Event	Event Category	Description
`DatabaseDownBegin`	Incident	The Autonomous Database instance cannot be opened, or the services such as high, low, medium, tp, or tpurgent are not started or available. The following conditions do not trigger `DatabaseDownBegin`: • Operations performed during the maintenance window • Load balancer, network, or backup related issues • A user stopping the instance This event will not be triggered if you are using Autonomous Data Guard and the standby database is not available due to any of these conditions.
`DatabaseDownEnd`	Incident	The database is recovered from the down state, meaning the Autonomous Database instance is opened with its services, following a `DatabaseDownBegin` event. `DatabaseDownEnd` is triggered only if there was a preceding `DatabaseDownBegin` event. The following conditions do not trigger `DatabaseDownEnd`: • Operations performed during the maintenance window • A user starting the instance If you are using Autonomous Data Guard and the primary database goes down, this triggers a `DatabaseDownBegin` event. If the system fails over to the standby database, this triggers a `DatabaseDownEnd` event.
`DatabaseInaccessibleBegin`	Incident	The Autonomous Database instance is using customer-managed keys and the database becomes inaccessible (state shows **Inaccessible**). The following conditions trigger `DatabaseInaccessibleBegin`: • Oracle Cloud Infrastructure Vault master encryption key is deleted. • Oracle Cloud Infrastructure Vault master encryption key is disabled. • Autonomous Database instance is not able to reach the Oracle Cloud Infrastructure Vault.
`DatabaseInaccessibleEnd`	Incident	If the Autonomous Database instance recovers from the **Inaccessible** state that generated a `DatabaseInaccessibleBegin` event, when the database state changes to **Available**, the database triggers a `DatabaseInaccessibleEnd` event.

Event	Event Category	Description
`DatabaseUserPasswordWarning`	Security	Provides a message that the Autonomous Database user password is expiring within the specified grace period (default 30 days) or has already expired. • If an Autonomous Database user password is within the specified grace period of being unusable, you receive a warning indicating the date when the password can no longer be used. • If an Autonomous Database user password expires and is no longer usable, Autonomous Database reports an event that specifies that the password has expired and must be reset. The `DatabaseUserPasswordWarning` event is generated once per day.
`FailedLoginWarning`	Security	If the number of failed login attempts reaches 3 * *number of total users* in the last three (3) hours, the database triggers a `FailedLoginWarning` event. Failed login attempts could be due to a user entering an invalid username or password, or due to a connection timeout. The event is triggered when the failed login attempts threshold is exceeded within the monitored time period (the last three hours).
`InstanceRelocateBegin`	Incident	If an Autonomous Database is relocated to another Exadata infrastructure due to server maintenance, hardware refresh, a hardware issue, or as part of a resource scale up, the `InstanceRelocateBegin` event is triggered at the start of the relocation process.
`InstanceRelocateEnd`	Incident	If an Autonomous Database is relocated to another Exadata infrastructure due to server maintenance, hardware refresh, a hardware issue, or as part of a resource scale up, the `InstanceRelocateEnd` event is triggered at the end of the relocation process.
`WalletExpirationWarning`	Security	This event is generated when Autonomous Database determines that a wallet is due to expire in less than six (6) weeks. This event is reported at most once per week. This event is triggered when there is a connection that uses the wallet that is due to expire.

Use the event type **Autonomous Database - Critical** to specify critical events in Event rules.

Information Events on Autonomous Database

Information events provide important details about database lifecycle events, workload capture and reply events, and some other non-critical events on Autonomous Database.

The times shown with information events are in UTC.

Event	Event Category	Description
AJDNonJsonStorageExceeded	Performance	This event is generated when an Autonomous JSON Database has exceeded the maximum storage limit of 20GB of data stored outside of SODA collections. This limit does not apply to data stored in SODA collections or objects associated with SODA collections, such as indexes or materialized views. In addition to this event, an email is sent to the account owner. You must either reduce your usage of non-SODA-related data to below the 20GB limit or promote the Autonomous JSON Database to Autonomous Transaction Processing. See Promote to Autonomous Transaction Processing for more information.
APEXUpgradeAvailable	Incident	This event is generated when you are using Oracle APEX and a new release becomes available.
APEXUpgradeBegin	Incident	This event is generated when you are using Oracle APEX and your Autonomous Database instance begins an upgrade to a new Oracle APEX release or begins to apply an Oracle APEX Patch Set Bundle.
APEXUpgradeEnd	Incident	This event is generated when you are using Oracle APEX and your Autonomous Database instance completes an upgrade to a new Oracle APEX release or completes the installation of an Oracle APEX Patch Set Bundle.
AutomaticRefreshEnd	Incident	This event is generated when the scheduled Automatic Refresh completes. See Edit Automatic Refresh Policy for Refreshable Clone for more information.
AutomaticRefreshFailed	Incident	This event is generated when the scheduled Automatic Refresh fails. See Edit Automatic Refresh Policy for Refreshable Clone for more information.
DatabaseConnection	Security	This event is generated if a connection is made to database from a new IP address (the connection has not been made from the specified IP address in the last 30 days).

Event	Event Category	Description
`InactiveConnectionsDetected`	Security	This event is generated when the number of inactive database connections detected is above a certain ratio compared to all database connections for the Autonomous Database instance. Subscribing to this event can help you keep track of unused connections. This event is generated once per day, when the following is true: • The number of inactive connections, where the elapsed time for the inactive connection is greater than 24 hours, is great than 10% of the total number of connections in any state. For this calculation, inactive connections are connections where the `status` is `"INACTIVE"`. Use the following query to report detailed information on sessions that have been inactive for more than 24 hours: `SELECT sid, serial#, last_call_et FROM v$session WHERE status = 'INACTIVE' AND last_call_et > 60 * 60 *24;`
`LongPendingTransaction`	Incident	This event is generated when a transaction is open for longer than 24 hours. Only one event is generated per transaction. The generated event includes the transaction id, address, and session address.
`MaintenanceBegin`	Maintenance	This event is triggered when the maintenance starts and provides the start timestamp for the maintenance (this event does not provide the scheduled start time). This event is also triggered when the maintenance starts for a local Autonomous Data Guard standby.
`MaintenanceEnd`	Maintenance	This event is triggered when the maintenance ends and provides the end timestamp for the maintenance (this event does not provide the scheduled end time). This event is also triggered when the maintenance ends for a local Autonomous Data Guard standby.
`NewMaintenanceSchedule`	Maintenance	This event is generated when the maintenance date is updated and the new date is shown on the Oracle Cloud Infrastructure Console. This event is also triggered when the maintenance date is updated and the new date is shown for a local Autonomous Data Guard standby. When the Java version will be updated, the event `description` field indicates this with the following: `This maintenance involves Java version update, please expect down time of Java service during this maintenance window.`

Event	Event Category	Description
`NetworkUsageInbound`	Security	This event is triggered when the average incoming network traffic to your Autonomous Database for TCP or HTTP database connections in the last 24 hours has exceeded 50% of the average incoming traffic observed a day before. When the trigger conditions for this event are met, the `NetworkUsageInbound` event is generated once per day.
`NetworkUsageOutbound`	Security	This event is triggered when the average outgoing network traffic from your Autonomous Database for TCP or HTTP database connections in the last 24 hours has exceeded 50% of the average outgoing traffic observed a day before. When the trigger conditions for this event are met, the `NetworkUsageOutbound` event is generated once per day.
`OperatorAccess`	Other	This event is triggered when operator access is detected for the database. You can query the access details from the `DBA_OPERATOR_ACCESS` view with the request ID provided in the event description. The `OperatorAccess` event is generated once every 24 hours.
`QueryPerformanceDegradationDetected`	Performance	This event is triggered when the average elapsed time of a query has exceeded ten times its average elapsed time over the past seven (7) days. The `QueryPerformanceDegradationDetected` event `description` field indicates the potential cause of a query performance degradation. For example, with a message such as: `Query performance slow down detected for SQL ID 9x25vyx9ujnn8. This could potentially be due to a recent compute scale down performed on this Autonomous Database. You might need to scale up your instance's compute allocation to address this performance degradation.` When the trigger conditions for this event are met, the `QueryPerformanceDegradationDetected` event is generated at most once per day.

Event	Event Category	Description
`ScheduledMaintenanceWarning`	Maintenance	This event is generated when the instance is 24 hours from a scheduled maintenance and again when the instance is 1 hour (60 minutes) from the scheduled maintenance. This event is also triggered when a local Autonomous Data Guard standby is 24 hours from a scheduled maintenance and again when the local Autonomous Data Guard standby is 1 hour (60 minutes) from the scheduled maintenance. When the Java version will be updated, the event `description` field indicates this with the following message: `This maintenance involves Java version update, please expect down time of Java service during this maintenance window.`
`SQLParseErrorWarning`	Incident	If a SQL parse error occurs several times in a certain time window, for example 200 times or more in an hour, this generates "`Too Many Parse Errors`" entries in the alert log. The `SQLParseErrorWarning` event is triggered when there is a new entry in the alert log, indicating that a SQL statement has too many parse errors. For example, when an invalid query runs 200 times in less than an hour, this triggers the `SQLParseErrorWarning` event. This event is generated at most once per day. This means there can be a delay of up to 24 hours before the event is generated.
`WorkloadCaptureBegin`	Incident	This event is triggered when a workload capture is initiated.
`WorkloadCaptureEnd`	Incident	This event is triggered when a workload capture completes successfully. This generates a pre-authenticated (PAR) URL to download the capture reports. This URL is contained in the `captureDownloadURL` field of the event and is valid for 7 days from the date of generation.
`WorkloadReplayBegin`	Incident	This event is triggered when a workload replay is initiated.
`WorkloadReplayEnd`	Incident	This event is triggered when a workload replay completes successfully. This generates a pre-authenticated (PAR) URL to download the replay reports. This URL is contained in the `replayDownloadURL` field of the event and is valid for 7 days from the date of generation.

Note:

When Autonomous Data Guard is enabled, any of these events that occur on the standby database do not trigger an Information event.

Use the event type **Autonomous Database - Information** to specify information events in Event rules.

See View Patch and Maintenance Window Information, Set the Patch Level for information on maintenance windows.

Autonomous Database Lifecycle Events

Provides a list of Autonomous Database lifecycle events.

Friendly Name	Event Type
Autonomous Database - Access Control Lists Update Begin	`com.oraclecloud.databaseservice.updateautonomousdatabaseacl.begin`
Autonomous Database - Access Control Lists Update End	`com.oraclecloud.databaseservice.updateautonomousdatabaseacl.end`
Autonomous Database - Auto Scaling Disabled	`com.oraclecloud.databaseservice.autonomousdatabaseautoscaledisabled`
Autonomous Database - Auto Scaling Enabled	`com.oraclecloud.databaseservice.autonomousdatabaseautoscaleenabled`
Autonomous Database - Automatic Backup Begin	`com.oraclecloud.databaseservice.automaticbackupautonomousdatabase.begin`
Autonomous Database - Automatic Backup End	`com.oraclecloud.databaseservice.automaticbackupautonomousdatabase.end`
Autonomous Database - Change Compartment Begin	`com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.begin`
Autonomous Database - Change Compartment End	`com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.end`
Autonomous Database - Change Database Name Begin	`com.oraclecloud.databaseservice.changeautonomousdatabasename.begin`
Autonomous Database - Change Database Name End	`com.oraclecloud.databaseservice.changeautonomousdatabasename.end`
Autonomous Database - Create Backup Begin	`com.oraclecloud.databaseservice.autonomous.database.backup.begin`
Autonomous Database - Create Backup End	`com.oraclecloud.databaseservice.autonomous.database.backup.end`
Autonomous Database - Create Begin	`com.oraclecloud.databaseservice.autonomous.database.instance.create.begin`
Autonomous Database - Create End	`com.oraclecloud.databaseservice.autonomous.database.instance.create.end`
Autonomous Database - Critical See Critical Events on Autonomous Database for more information.	`com.oraclecloud.databaseservice.autonomous.database.critical`
Autonomous Database - Deregister Autonomous Database with Data Safe Begin	`com.oraclecloud.databaseservice.deregisterautonomousdatabasedatasafe.begin`
Autonomous Database - Deregister Autonomous Database with Data Safe End	`com.oraclecloud.databaseservice.deregisterautonomousdatabasedatasafe.end`
Autonomous Database - Disable Data Guard Begin	`com.oraclecloud.databaseservice.disableautonomousdataguard.begin`
Autonomous Database - Disable Data Guard End	`com.oraclecloud.databaseservice.disableautonomousdataguard.end`

Friendly Name	Event Type
Autonomous Database - Disconnect Refreshable Clone from Source Database Begin	`com.oraclecloud.databaseservice.disconnectrefreshableautonomousdatabaseclonefromsource.begin`
Autonomous Database - Disconnect Refreshable Clone from Source Database End	`com.oraclecloud.databaseservice.disconnectrefreshableautonomousdatabaseclonefromsource.end`
Autonomous Database - Enable Data Guard Begin	`com.oraclecloud.databaseservice.enableautonomousdataguard.begin`
Autonomous Database - Enable Data Guard End	`com.oraclecloud.databaseservice.enableautonomousdataguard.end`
Autonomous Database - Free Database Automatic Stop Reminder This event is emitted 48 hours prior to database stop.	`com.oraclecloud.databaseservice.freeautonomousdatabasestopreminder`
Autonomous Database - Free Database Automatically Stopped	`com.oraclecloud.databaseservice.freeautonomousdatabasestopped`
Autonomous Database - Free Database Automatic Termination Reminder. This event is emitted 48 hours prior to database termination.	`com.oraclecloud.databaseservice.freeautonomousdatabaseterminationreminder`
Autonomous Database - Free Database Automatically Terminated	`com.oraclecloud.databaseservice.freeautonomousdatabaseterminated`
Autonomous Database - Generate Wallet	`com.oraclecloud.databaseservice.generateautonomousdatabasewallet`
Autonomous Database - Information See Information Events on Autonomous Database for more information.	`com.oraclecloud.databaseservice.autonomous.database.information`
Autonomous Database - Long term backup ended This event is triggered when a long term backup completes.	
Autonomous Database - Long term backup schedule disabled This event is triggered when a long term backup schedule is disabled.	
Autonomous Database - Long term backup schedule enabled / updated This event is triggered when a long term backup schedule is either enabled or updated.	
Autonomous Database - Long term backup started This event is triggered when a long term backup starts.	
Autonomous Database - Manual Failover Begin	`com.oraclecloud.databaseservice.failoverautonomousdatabase.begin`
Autonomous Database - Manual Failover End This event is emitted after failover completes successfully or unsuccessfully. Unsuccessful manual failovers may result in data loss. Check the Autonomous Database details page in the Oracle Cloud Infrastructure Console for additional information in the event of an unsuccessful manual failover.)	`com.oraclecloud.databaseservice.failoverautonomousdatabase.end`

Friendly Name	Event Type
Autonomous Database - Manual Refresh Begin The "Manual Refresh" events are used for Autonomous Database refreshable clones.	com.oraclecloud.databaseservice.manualrefresh.begin
Autonomous Database - Manual Refresh End	com.oraclecloud.databaseservice.manualrefresh.end
Autonomous Database - Deregister Autonomous Database with Data Safe Begin	com.oraclecloud.databaseservice.deregisterautonomousdatabasedatasafe.begin
Autonomous Database - Deregister Autonomous Database with Data Safe End	com.oraclecloud.databaseservice.deregisterautonomousdatabasedatasafe.end
Autonomous Database - Register Autonomous Database with Data Safe Begin	com.oraclecloud.databaseservice.registerautonomousdatabasedatasafe.begin
Autonomous Database - Register Autonomous Database with Data Safe End	com.oraclecloud.databaseservice.registerautonomousdatabasedatasafe.end
Autonomous Database - Restart Begin	com.oraclecloud.databaseservice.restartautonomousdatabase.begin
Autonomous Database - Restart End	com.oraclecloud.databaseservice.restartautonomousdatabase.end
Autonomous Database - Restore Begin	com.oraclecloud.databaseservice.autonomous.database.restore.begin
Autonomous Database - Restore End	com.oraclecloud.databaseservice.autonomous.database.restore.end
Autonomous Database - Rotate Encryption Key Begin	com.oraclecloud.databaseservice.rotateautonomousdatabaseencryptionkey.begin
Autonomous Database - Rotate Encryption Key End	com.oraclecloud.databaseservice.rotateautonomousdatabaseencryptionkey.end
Autonomous Database - Start Begin	com.oraclecloud.databaseservice.startautonomousdatabase.begin
Autonomous Database - Start End	com.oraclecloud.databaseservice.startautonomousdatabase.end
Autonomous Database - Stop Begin	com.oraclecloud.databaseservice.stopautonomousdatabase.begin
Autonomous Database - Stop End	com.oraclecloud.databaseservice.stopautonomousdatabase.end
Autonomous Database - Switchover Begin	com.oraclecloud.databaseservice.switchoverautonomousdatabase.begin
Autonomous Database - Switchover End This event is emitted after switchover completes successfully or unsuccessfully. Unsuccessful switchovers may result in data loss. Check the Autonomous Database details page in the Oracle Cloud Infrastructure Console for additional information in the event of an unsuccessful switchover.	com.oraclecloud.databaseservice.switchoverautonomousdatabase.end
Autonomous Database - Terminate Begin	com.oraclecloud.databaseservice.deleteautonomousdatabase.begin
Autonomous Database - Terminate End	com.oraclecloud.databaseservice.deleteautonomousdatabase.end
Autonomous Database - Update Begin	com.oraclecloud.databaseservice.updateautonomousdatabase.begin

Friendly Name	Event Type
Autonomous Database - Update End	`com.oraclecloud.databaseservice.updateautonomousdatabase.end`
Autonomous Database - Update Open Mode Begin	`com.oraclecloud.databaseservice.updateautonomousdatabaseopenmode.begin`
Autonomous Database - Update Open Mode End	`com.oraclecloud.databaseservice.updateautonomousdatabaseopenmode.end`
Autonomous Database - Upgrade Database Version Begin	`com.oraclecloud.databaseservice.upgradeautonomousdatabasedbversion.begin`
Autonomous Database - Upgrade Database Version End	`com.oraclecloud.databaseservice.upgradeautonomousdatabasedbversion.end`

Get Notified of Autonomous Database Events

Using Oracle Cloud Infrastructure Events you can subscribe to Autonomous Database events individually or in two categories, Critical and Information events.

> **Note:**
>
> When you subscribe to an event category, either Critical or Information, you are notified when any events in the category occur. For example, to get notified when the database goes down, subscribe to the Autonomous Database Critical event type.

If you want to subscribe to Critical or Information events:

- To subscribe to Critical events, create an event rule using the **Autonomous Database - Critical** event type.
- To subscribe to Information events, create an event rule using the **Autonomous Database - Information** event type.

If you want to subscribe to one or more individual Critical or Information events, create an event rule and add conditions. For example, to create an event rule that only applies for the `AdminPasswordWarning` Critical event, create a rule as follows:

1. On the Oracle Cloud Infrastructure Console click **Observability & Management**.
2. Under **Events Service**, click **Rules**.
3. To add a rule, click **Create Rule**.
4. On the Create Rule page, enter a Display Name and a Description.
5. Under Rule Conditions, enter a rule condition
   a. Enter the Condition: **Event Type**.
   b. Enter the Service Name: **Database**.
   c. Enter the Event Type, one of: **Autonomous Database - Critical** or **Autonomous Database - Information**.
6. Click **+ Another Condition**.
7. Under Condition, select **Attribute**.
   a. Under Attribute Name, select **eventName**.

b. Under Attribute Values, enter the event name. For example, enter `AdminPasswordWarning`.

   See Critical Events on Autonomous Database and Information Events on Autonomous Database for the list of event names.

For example with these entries the Rule Logic area shows:

```
MATCH event WHERE (
   eventType EQUALS ANY OF (
      com.oraclecloud.databaseservice.autonomous.database.critical
   )
   AND (
         eventName MATCHES ANY OF (
             AdminPasswordWarning
         )
   )
)
```

8. In the **Actions** area, select the actions you want.
9. Click **Create Rule**.

Critical events and Information events include an event category attribute (in the `eventCategory` field). Optionally you can subscribe to events by event type and include an event category to receive notifications about events in that category, or to perform other types of automation for events.

The event categories are:

- **Incident**: Database incident events
- **Maintenance**: Database maintenance events
- **Performance**: Database performance events
- **Security**: Database security events
- **Other**: Other events

For example, if you want to subscribe Critical events with the event category `Security`, create an event rule as shown, and in Step 7, select the `eventCategory` attribute and enter a value.

The result would look like this:

```
MATCH event WHERE (
   eventType EQUALS ANY OF (
      com.oraclecloud.databaseservice.autonomous.database.critical
   )
   AND (
     eventCategory MATCHES ANY OF (
       Security
     )
   )
)
```

See Getting Started with Events for information on using Oracle Cloud Infrastructure Events, creating event rules, and for information on configuring actions for notifications.

Manage Time Zone File Updates on Autonomous Database

Autonomous Database provides several options to automatically update time zone files on an Autonomous Database database instance.

- About Time Zone File Update Options
  For time zone support Oracle Database uses time zone files that store the list of all time zones. The time zone files for Autonomous Database are periodically updated to reflect the latest time zone specific changes.
- Use AUTO_DST_UPGRADE Time Zone File Option
- Use AUTO_DST_UPGRADE_EXCL_DATA Time Zone File Option

About Time Zone File Update Options

For time zone support Oracle Database uses time zone files that store the list of all time zones. The time zone files for Autonomous Database are periodically updated to reflect the latest time zone specific changes.

Autonomous Database provides the following options for updating time zone files:

- `AUTO_DST_UPGRADE`: Automatically upgrades the time zone files and automatically updates the data on your database to use the latest time zone data. This option requires that you restart or stop and then start your Autonomous Database instance.
- `AUTO_DST_UPGRADE_EXCL_DATA`: Automatically upgrades the time zone files and does not automatically update the data on your database to use the latest time zone data. The time zone files are upgraded to the latest version when you enable this option and versions are kept up to date with the latest version. This option does not require that you restart your Autonomous Database instance.

> **Note:**
>
> By default, both `AUTO_DST_UPGRADE` and `AUTO_DST_UPGRADE_EXCL_DATA` are disabled. You can enable one or the other of these options, but not both.

With every Daylight Saving Time (DST) version release, there are DST file changes introduced to make existing data comply with the latest DST rules. Applying a change to the database time zone files not only affects the way new data is handled, but potentially alters data stored in `TIMESTAMP WITH TIME ZONE` columns.

When a load or import operation results in the following time zone related error, this indicates that the version of your time zone files is out of date and you need to update to the latest version available for your database:

```
ORA-39405: Oracle Data Pump does not support importing from a source database
with TSTZ version y
into a target database with TSTZ version n.
```

You can enable the `AUTO_DST_UPGRADE` feature that automatically upgrades an instance to use the latest available version of the time zone files, and automatically updates the rows on your database to use the latest time zone data. The latest version of time zone files are applied and values in `TIMESTAMP WITH TIME ZONE` columns are updated at the next database restart.

However, depending on your database usage, the required database restart might restrict you from using AUTO_DST_UPGRADE to upgrade to the latest time zone files.

You can enable AUTO_DST_UPGRADE_EXCL_DATA to update your time zone files. This option allows you to immediately update your database if you encounter import/export errors due to a version mismatch of time zone files (where you receive the ORA-3940 error).

Enabling AUTO_DST_UPGRADE_EXCL_DATA on your database can be beneficial in the following cases:

- Data on the instance is in UTC and the database is not impacted by DST time zone file updates.
- The instance does not have any data in TIMESTAMP WITH TIME ZONE columns.
- Data in the instance uses dates that are not altered with new time zone or daylight saving time policies.

In this case, when your Autonomous Database instance does not contain rows that are adversely impacted by the new time zone rules and you encounter the ORA-3940 error, you can enable the AUTO_DST_UPGRADE_EXCL_DATA option to update to the latest version of the time zone files. The AUTO_DST_UPGRADE_EXCL_DATA option prioritizes the success of Oracle Data Pump jobs over the data consistency issues due to changing DST.

See Oracle Support Document 406410.1 to help you determine whether time zone changes will affect your database.

> **Note:**
>
> Oracle recommends enabling the AUTO_DST_UPGRADE option when these limiting cases do not apply to your database.

In summary, the choice of enabling automatic time zone upgrades with AUTO_DST_UPGRADE or AUTO_DST_UPGRADE_EXCL_DATA involves the following considerations:

- Possible Data Inconsistency: Oracle recommends that you maintain your database on the latest time zone file version by enabling AUTO_DST_UPGRADE. This option automatically updates the rows on your database to use the latest time zone data.

  The alternative option, AUTO_DST_UPGRADE_EXCL_DATA allows you to maintain your database using the latest time zone version without requiring a database restart; however, data that might be affected by the updated time zone files is not updated, which could lead to possible data inconsistency.
- Database Restart: Oracle recommends that you maintain your database on the latest time zone file version by enabling AUTO_DST_UPGRADE. This option requires a restart to upgrade to the latest time zone files version and during the restart updates the rows for existing data of TIMESTAMP WITH TIME ZONE data type to use the latest version. Enabling AUTO_DST_UPGRADE can affect database restart time. A restart can require extra time compared to a restart without this option enabled when there are new time zone files and there is data that needs to be updated when the database restarts.

  When you enable AUTO_DST_UPGRADE_EXCL_DATA, at the time you enable this option the database is upgraded to the latest version the time zone files and during each maintenance window, if newer time zone files are available, Autonomous Database updates database to use the latest version. Enabling AUTO_DST_UPGRADE_EXCL_DATA does not require that you restart your Autonomous Database instance to keep up to date with the latest version of the time zone files.

See Datetime Data Types and Time Zone Support for more information.

Use AUTO_DST_UPGRADE Time Zone File Option

Autonomous Database provides the `AUTO_DST_UPGRADE` option to automatically update time zone files on an Autonomous Database database instance.

The `AUTO_DST_UPGRADE` feature automatically upgrades the time zone files and automatically upgrades the rows on your database to use the latest time zone data.

> **Note:**
>
> By default, both `AUTO_DST_UPGRADE` and `AUTO_DST_UPGRADE_EXCL_DATA` are disabled. You can enable one or the other of the automatic time zone file update options, but not both.

When you enable `AUTO_DST_UPGRADE` your Autonomous Database instance automatically applies updates for time zone files, depending on the state of the instance:

- **Stopped**: At the next start operation the update is automatically applied.
- **Available**: After a restart, or a stop and then start, the update is automatically applied.

When a load or import operation results in the following time zone related error, this indicates that your time zone files are out of date and you need to update to the latest version available for your database:

```
ORA-39405: Oracle Data Pump does not support importing from a source database
with TSTZ version n+1
into a target database with TSTZ version n.
```

To enable automatic time zone file updates with `AUTO_DST_UPGRADE`:

1. Enable the `AUTO_DST_UPGRADE` feature.

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
        feature_name => 'AUTO_DST_UPGRADE');
END;
/
```

2. Query `dba_cloud_config` to verify that `AUTO_DST_UPGRADE` is enabled.

```
SELECT param_name, param_value FROM dba_cloud_config WHERE
       LOWER(param_name) = 'auto_dst_upgrade';

PARAM_NAME              PARAM_VALUE
----------------------- ----------------------------------------
auto_dst_upgrade        enable
```

3. Query `dba_cloud_config` to check the time zone version.

```
SELECT param_name, param_value FROM dba_cloud_config
    WHERE LOWER(param_name) = 'latest_timezone_version';
```

```
PARAM_NAME              PARAM_VALUE
----------------------- -----------
latest_timezone_version 38
```

You can query the `DB_NOTIFICATIONS` view to see if the time zone version is the latest version:

```
SELECT type, time, description, expected_start_date FROM db_notifications
   WHERE TYPE='TIMEZONE VERSION';
```

When `AUTO DST UPGRADE` is enabled, Autonomous Database upgrades to the latest version of the time zone files (when you next restart, or stop and then start the database). The columns in your database with the datatype `TIMESTAMP WITH TIME ZONE` are converted to the new time zone version during the restart.

To disable `AUTO_DST_UPGRADE`:

1. Disable the `AUTO_DST_UPGRADE` feature:

```
BEGIN
   DBMS_CLOUD_ADMIN.DISABLE_FEATURE(
        feature_name => 'AUTO_DST_UPGRADE');
END;
/
```

2. Query `dba_cloud_config` to verify that `AUTO_DST_UPGRADE` is disabled.

```
SELECT param_name, param_value FROM dba_cloud_config WHERE
       LOWER(param_name) = 'auto_dst_upgrade';

0 rows selected.
```

See ENABLE_FEATURE Procedure and DISABLE_FEATURE Procedure for more information.

See TIMESTAMP WITH TIME ZONE Data Type for more information.

Use AUTO_DST_UPGRADE_EXCL_DATA Time Zone File Option

Autonomous Database provides the `AUTO_DST_UPGRADE_EXCL_DATA` option to automatically update time zone files on an Autonomous Database database instance.

The `AUTO_DST_UPGRADE_EXCL_DATA` automatically upgrades the time zone files and does not automatically upgrade the rows on your database to use the latest time zone data. When this option is enabled the database upgrades to the latest version of the time zone files and subsequently upgrades the database to use new versions of the time zone files during the Autonomous Database maintenance window (whenever a new version is available). This option does not require that you restart your Autonomous Database instance.

> **Note:**
>
> By default, both `AUTO_DST_UPGRADE` and `AUTO_DST_UPGRADE_EXCL_DATA` are disabled. You can enable one or the other of the automatic time zone file update options, but not both.

When a load or import operation results in the following time zone related error, this indicates that your time zone files are out of date and you need to update to the latest version available for your database:

```
ORA-39405: Oracle Data Pump does not support importing from a source database
with TSTZ version n+1
into a target database with TSTZ version n.
```

To enable automatic time zone file updates with `AUTO_DST_UPGRADE_EXCL_DATA`:

1. Enable the `AUTO_DST_UPGRADE_EXCL_DATA` feature.

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
           feature_name => 'AUTO_DST_UPGRADE_EXCL_DATA');
   END;
   /
   ```

2. Query `dba_cloud_config` to verify that `AUTO_DST_UPGRADE_EXCL_DATA` is enabled.

   ```
   SELECT param_name, param_value FROM dba_cloud_config WHERE
          LOWER(param_name) = 'auto_dst_upgrade_excl_data';

   PARAM_NAME                     PARAM_VALUE
   ------------------------------ ----------------------------------------
   auto_dst_upgrade_excl_data     enabled
   ```

3. Query `dba_cloud_config` to check the time zone version.

   ```
   SELECT param_name, param_value FROM dba_cloud_config
       WHERE LOWER(param_name) = 'latest_timezone_version';

   PARAM_NAME              PARAM_VALUE
   ----------------------- -----------
   latest_timezone_version 38
   ```

   You can query the `DB_NOTIFICATIONS` view to see if the time zone version is the latest version:

   ```
   SELECT type, time, description, expected_start_date FROM db_notifications
      WHERE TYPE='TIMEZONE VERSION';
   ```

When `AUTO_DST_UPGRADE_EXCL_DATA` is enabled, Autonomous Database upgrades to the latest version of the time zone files and checks and updates to new time zone file versions during each scheduled maintenance window. With `AUTO_DST_UPGRADE_EXCL_DATA` enabled, the

columns in your database with the datatype `TIMESTAMP WITH TIME ZONE` are not converted to the new time zone version.

To disable `AUTO_DST_UPGRADE_EXCL_DATA`:

1. Disable the `AUTO_DST_UPGRADE_EXCL_DATA` feature:

```
BEGIN
   DBMS_CLOUD_ADMIN.DISABLE_FEATURE(
        feature_name => 'AUTO_DST_UPGRADE_EXCL_DATA');
END;
/
```

2. Query `dba_cloud_config` to verify that `AUTO_DST_UPGRADE_EXCL_DATA` is disabled.

```
SELECT param_name, param_value FROM dba_cloud_config WHERE
       LOWER(param_name) = 'auto_dst_upgrade_excl_data';

0 rows selected.
```

See ENABLE_FEATURE Procedure and DISABLE_FEATURE Procedure for more information.

See TIMESTAMP WITH TIME ZONE Data Type for more information.

Monitor Autonomous Database Availability

Shows you the steps to view availability information for an Autonomous Database instance.

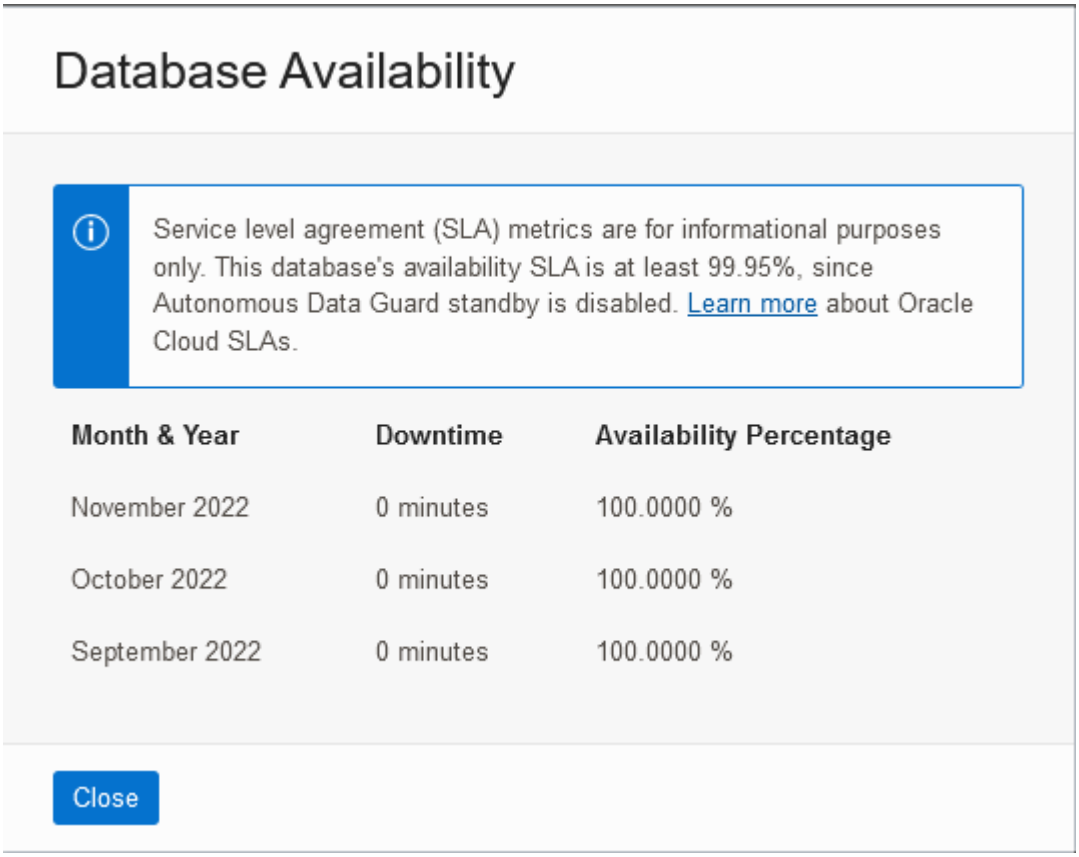
Database Availability is calculated based on the "Monthly Uptime Percentage" described in the Oracle PaaS and IaaS Public Cloud Services Pillar Document, document under **Delivery Policies** (see Autonomous Database Availability Service Level Agreement).

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To view Database Availability for an Autonomous Database instance:

1. On the **Details** page under General Information, click the Database Availability link in the **Lifecycle state** field.



2. Click **Close** to dismiss the page.

Note the following for the Autonomous Database instance availability:

- For databases with Cross-Region Autonomous Data Guard enabled, review both the primary database and the remote standby database availability.
- The Database Availability page shows information for the current month and for the previous two months.
- After you provision a new Autonomous Database instance, database availability information is only available for the current month.
- See View Metrics for an Autonomous Database Instance for more information on database availability. The Database Availability metric provides the Database Availability history for an Autonomous Database instance.
- Database availability information is not available prior to the introduction of this feature in April 2022.

See Monitor Regional Availability of Autonomous Databases for information on regional average availability metrics for Autonomous Database.

Monitor Regional Availability of Autonomous Databases

The regional availability is represented as a list of daily uptime percentages of Autonomous Databases across a set of services in each available region.

The regional availability data is updated daily on the following page:

Regional Average Availability Metrics for Oracle Autonomous Database

Notes for regional availability:

- The regional availability page shows information for the current month and for the previous two months.
- Regional availability information starts in June 2022 (availability data is not shown for dates prior to June 2022).

See View Metrics for an Autonomous Database Instance for more information regional availability.

See Monitor Autonomous Database Availability for information on Autonomous Database instance availability.

Manage Resource Availability with Compartment Quotas

Autonomous Database supports the compartment quotas feature of Oracle Cloud Infrastructure.

Compartment quotas give tenant and compartment administrators better control over how resources are consumed in Oracle Cloud Infrastructure, enabling administrators to easily allocate resources to compartments using the Console. Along with compartment budgets, compartment quotas create a powerful toolset to manage your spending in Oracle Cloud Infrastructure tenancies. You can start using compartment quotas from any compartment detail page in the Console.

Compartment quotas are similar to service limits. The biggest difference is that service limits are set by Oracle, and compartment quotas are set by administrators, using policies that allow them to allocate resources with a high level of flexibility.

Using compartment quotas, you can restrict, on a compartment by compartment basis, the availability of the following Autonomous Database resources in your tenancy:

- Number of Always Free Autonomous Databases. Tenancies can have a total of two Always Free Autonomous Databases, and these resources must be provisioned in the home region.
- Number of Autonomous Database for Developers databases.
- OCPUs available to Data Warehouse, Transaction Processing, JSON, or APEX databases.
- ECPUs available to Data Warehouse, Transaction Processing, JSON, or APEX databases.
- Total data storage available to Data Warehouse, Transaction Processing, JSON, or APEX databases.

> **Note:**
>
> Quotas are enforced only for provisioning databases and manually scaling their allocated ECPUs, OCPUs, or storage up or down.

You can manage the compartment quotas to limit the availability of a given resource in a given compartment using the `set`, `unset` and `zero` policy statements. These policy statements are written in a simple declarative language that is similar to the IAM policy language.

- **set:** Sets the maximum number of cloud resources that can be used for a compartment. For example, the following statement sets `atp-ecpu-count` quota to 10 ECPUs in the compartment `MyCompartment`:

```
set database quota atp-ecpu-count to 10 in compartment MyCompartment
```

- **unset:** Resets quotas back to the default service limits.
  For example, the following statement resets the quota for `atp-ecpu-count` in the entire tenancy:

  ```
  unset database quota atp-ecpu-count in tenancy
  ```

- **zero:** Removes access to a cloud resource for a compartment.
  For example, the following statement disallows use of ECPUs for APEX workload databases in the compartment `MyCompartment`:

  ```
  Zero apex-ecpu-count quotas in compartment MyCompartment
  ```

See Compartment Quotas for more information.

Compartment quotas are available on the OCI Console's Limits, Quotas and Usage page, which you can use to automatically generate quota statements. To access this page, on the **Governance & Administration** page, under **Tenancy Management** select **Limits, Quotas and Usage**. As a prerequisite, ensure you have the appropriate permissions to create quotas. See Policy Reference for the Quotas Service for more details.

Quotas for Oracle Autonomous Database

The following table lists the quotas for Oracle Autonomous Database

The family name associated with these quota names is: `database`

For example:

```
set database quota atp-ecpu-count to 10 in compartment MyCompartment
```

Name	Scope	Description
`adb-developer-count`	Regional	Number of Autonomous Database for Developers instances.
`adb-free-count`	Regional	Number of Always Free Autonomous Databases. Tenancies can have a total of two Always Free Autonomous Databases, and these resources must be provisioned in the home region. For each database, you can choose the workload type.
`adw-ecpu-count`	Regional	Number of Autonomous Databases for Analytics and Data Warehousing ECPUs for databases using Autonomous Database Serverless.
`adw-ocpu-count`	Regional	Number of Autonomous Databases for Analytics and Data Warehousing OCPUs for databases using Autonomous Database Serverless.
`adw-total-storage-tb`	Regional	Amount of storage (in TB) for Autonomous Database for Analytics and Data Warehousing databases using Autonomous Database Serverless.
`ajd-ecpu-count`	Regional	Number of JSON Database ECPUs with Autonomous Database Serverless.
`atp-ocpu-count`	Regional	Number of JSON Database OCPUs with Autonomous Database Serverless.
`ajd-total-storage-tb`	Regional	Total amount of storage (in TB) for JSON Database with Autonomous Database Serverless.

Name	Scope	Description
apex-ecpu-count	Regional	Number of APEX ECPUs with Autonomous Database Serverless.
apex-ocpu-count	Regional	Number of APEX OCPUs with Autonomous Database Serverless.
apex-total-storage-tb	Regional	Total amount of storage (in TB) for APEX with Autonomous Database Serverless.
atp-ecpu-count	Regional	Number of Autonomous Database for Autonomous Transaction Processing ECPUs for databases using Autonomous Database Serverless.
atp-ocpu-count	Regional	Number of Autonomous Database for Autonomous Transaction Processing OCPUs for databases using Autonomous Database Serverless.
atp-total-storage-tb	Regional	Amount of storage (in TB) for Autonomous Transaction Processing databases using Autonomous Database Serverless.
ex-cdb-count	Regional	External Container Database Count
ex-non-cdb-count	Regional	External Non Container Database Count
ex-pdb-count	Regional	External Pluggable Database Count

Managing and Viewing Maintenance Windows, Patching Options, Work Requests, and Customer Contacts

You can obtain information about system events, maintenance, and other important information for the operation of your Autonomous Database instance.

This includes the following:

- Oracle Cloud Infrastructure work requests allow you to monitor long-running operations such as cloning or backing up Autonomous Database.
- Oracle Cloud Infrastructure Console provides information on Autonomous Database maintenance windows and patching and provides a customer contacts area where you can view or manage the list of contacts to receive information on operational issues and service announcements.
- The DBA_OPERATOR_ACCESS view provides information on the top level SQL statements that Oracle Cloud Infrastructure cloud operations performs.

Topics

- About Work Requests
- View Patch and Maintenance Window Information, Set the Patch Level
  Autonomous Database uses predefined maintenance windows to automatically patch your database. You can view maintenance and patch information and see details for Autonomous Database maintenance history.
- View and Manage Customer Contacts for Operational Issues and Announcements
  You can view and manage the Autonomous Database customer contacts.

- View Oracle Cloud Infrastructure Operations Actions
  The `DBA_OPERATOR_ACCESS` view stores information on the actions that Oracle Cloud Infrastructure cloud operations performs on your Autonomous Database.

About Work Requests

You can view Oracle Cloud Infrastructure Work Requests on Autonomous Database.

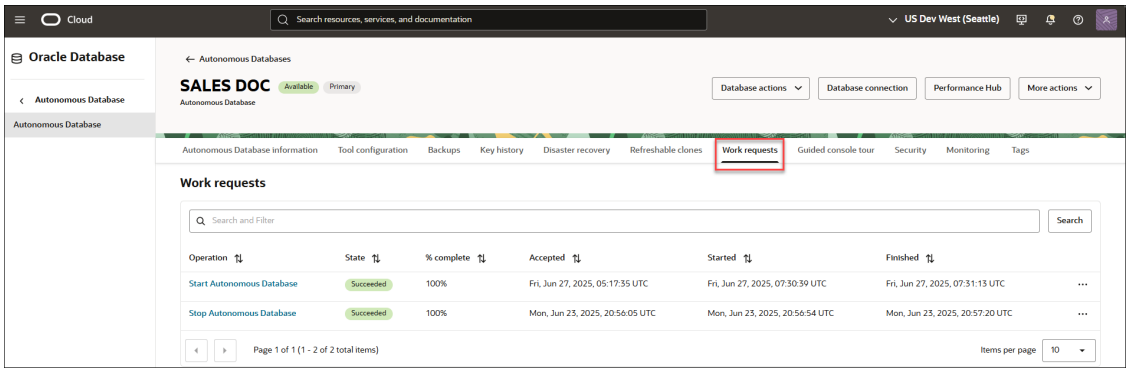
A work request is an activity log that enables you to track each step in an operation's progress. Each work request has an Oracle Cloud Identifier (OCID) that allows you to interact with it programmatically.

Autonomous Database work requests are created for many operations, including the following operations:

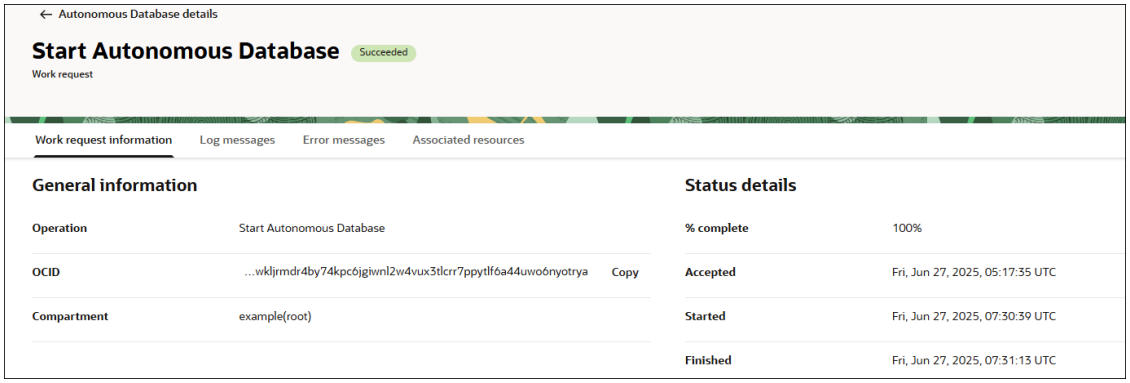
- Creating or terminating an Autonomous Database instance
- Starting or stopping an Autonomous Database instance
- Restoring an Autonomous Database instance
- Cloning an Autonomous Database instance
- Scaling database storage or CPU
- Updating the database license type
- Updating a database's network access control list (ACL)

To view work requests for an Autonomous Database instance:

On the Oracle Cloud Infrastructure Console, on the Autonomous Database details page, select the **Work requests** tab.



Click the work request link under the **Operation** column to see more details for a work request.



See Work Requests Integration for more information.

View Patch and Maintenance Window Information, Set the Patch Level

Autonomous Database uses predefined maintenance windows to automatically patch your database. You can view maintenance and patch information and see details for Autonomous Database maintenance history.

- About Scheduled Maintenance and Patching
  All Autonomous Database instances are automatically assigned to a maintenance window and different instances can have different maintenance windows.
- View Maintenance Event History
  You can view Autonomous Database maintenance event history for details about past maintenance events, such as the title, state, start time, and stop time.
- View Patch Details
  You can view Autonomous Database patch information, including a list of resolved issues and components.
- Set the Patch Level
  When you provision or clone an Autonomous Database instance you can select a patch level to apply to upcoming patches. You can also edit the patch level after an Autonomous Database instance is provisioned. There are two patch level options: **Regular** and **Early**.
- View Maintenance Status Notifications
  The `DB_NOTIFICATIONS` view stores information about maintenance status notifications for your Autonomous Database instance.
- Best Practices to Maintain Application Availability During Maintenance Windows
  Provides information on best practices to maintain application availability and to minimize application disruption during a scheduled maintenance window.

About Scheduled Maintenance and Patching

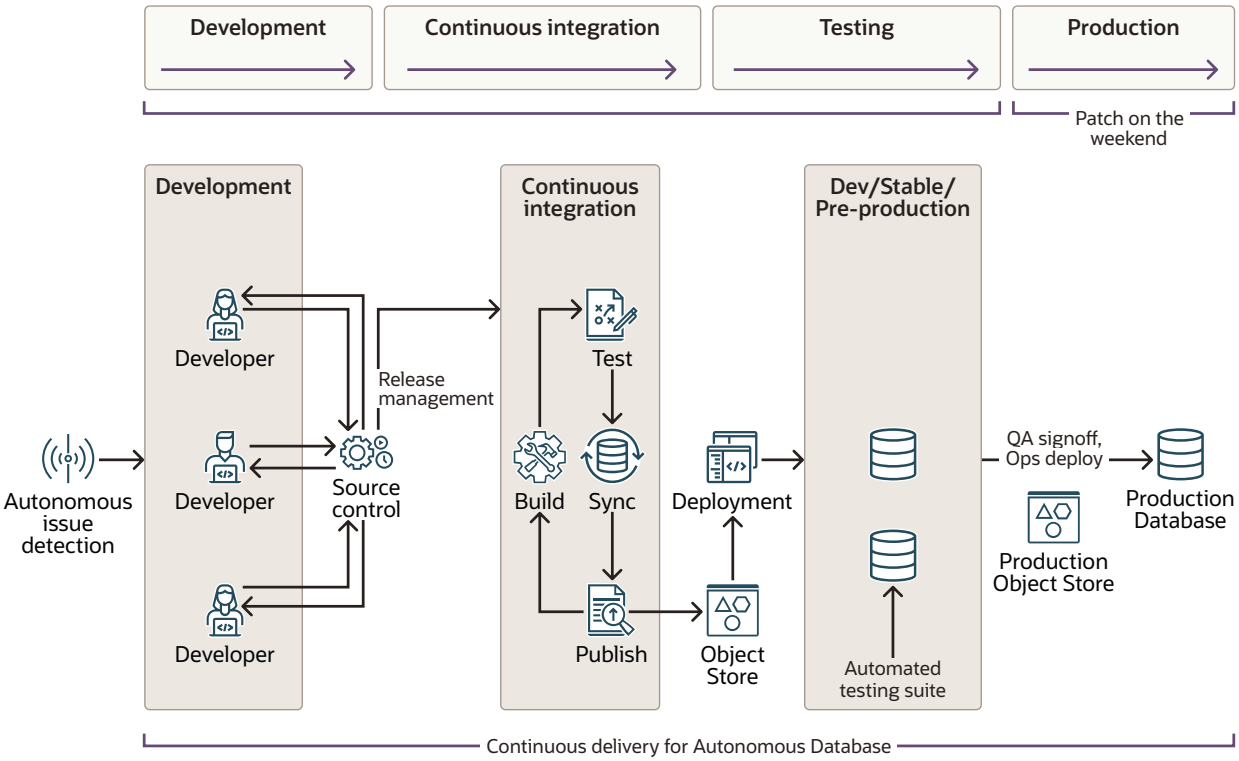
All Autonomous Database instances are automatically assigned to a maintenance window and different instances can have different maintenance windows.

Autonomous Database uses these maintenance windows to patch the entire stack used to run your database, including the database software, database dictionary, operating systems, Exadata storage, firmware, and more.

Patches include bug fixes, security fixes, and new features. Critical security fixes are always applied as soon as they are available. Patches are deployed uniformly across all databases, so you do not need to track one-off patches. After a fix for an issue is implemented, for example an issue seen in one database, the fix is deployed to all Autonomous Database instances.

All patches undergo a rigorous testing and validation process that is part of a continuous integration and development pipeline. Fixes are validated in multiple stages and environments before they are deployed to Early patch level and Always Free databases, followed by Regular patch level databases. This pipeline allows regressions to be caught and fixed before the patch is deployed to all databases. In the unlikely case that patching introduces a regression, Oracle has processes to mitigate the problem, including actions such as the following:

- Rolling back either a subset of the patch or the entire patch.
- Setting database parameters to disable the patch that introduced the regression.
- Applying an online patch to fix the problem without any downtime or connection disruption.



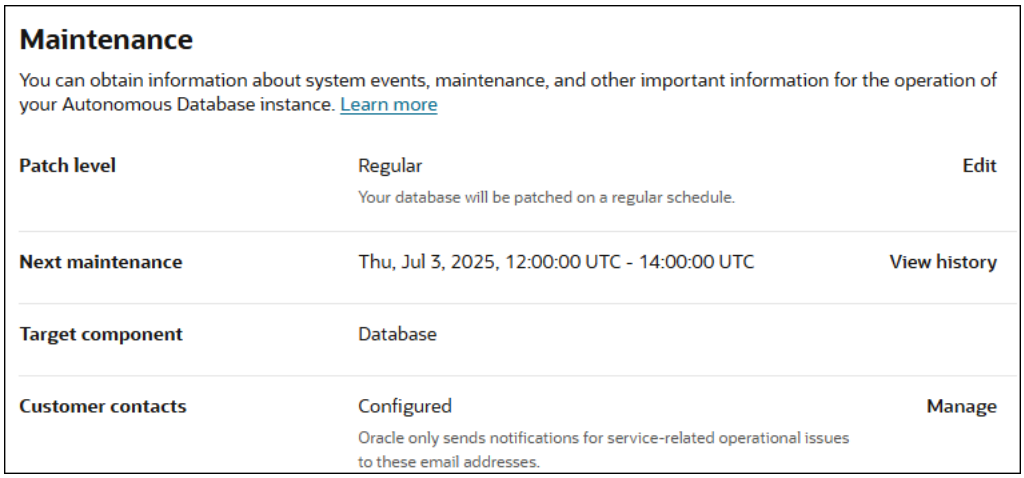
Automatic Regression Detection for Autonomous Database provides proactive handling of regressions and enables automated issue detection, diagnosis, and mitigation. This can reduce or eliminate the need for you to manually investigate issues and file service requests. Automatic Regression Detection monitors all databases, in both the Early and Regular patch levels, but it is especially useful when you test a workload on an **Early** patch level database. If Automatic Regression Detection finds an issue and identifies a regression, it automatically reports the issue with detailed information to diagnose it. This automated reporting, as part of the continuous delivery patching cycle, allows Oracle to mitigate or fix the issue before changes reach production databases (**Regular** patch level databases). Automatic Regression Detection may not be able to find every issue; in cases where you see issues yourself, you can file a service request.

Automatic Regression Detection includes the following:

- Automatic Regression Detection monitors the database and, in the event of an incident, files a bug for the incident with detailed diagnostic information extracted from the Automatic Workload Repository.

- The incident reporting system produces notifications to Oracle Cloud Infrastructure Operations and Development teams with Oracle Automatic Incident Monitoring.
- Issues are mitigated by analyzing the Automatic Regression Detection alerts.
- Learning and improvements are made to Automatic Regression Detection on an ongoing basis.

The Autonomous Database Details page shows the **Patch level** field and the **Next maintenance** field that includes the date and time for the upcoming maintenance window; the date is updated automatically when the next maintenance window is scheduled. The **View history** link provides details on past maintenance. The **Target component** field shows the component to be updated in the next maintenance window.



When Autonomous Data Guard is enabled the console also shows maintenance information for a local standby database.

The Maintenance area includes the following information:

Maintenance Field	Description
Patch level	Shows the patch level for the instance. There are two patch level options: **Regular** and **Early**. Click **Edit** to manage patch level settings. See Set the Patch Level for more information.
Next maintenance	Specifies the time period for the next scheduled maintenance window. Click **View history** to see details on past maintenance. See View Maintenance Event History for more information.
Target component	Lists the target components for the upcoming maintenance window. Possible values are: • Database: when the patch applies to the database home and executables. • Dictionary: when the patch applies to the data dictionary and to Oracle APEX. • Infrastructure: when the patch applies to the Exadata hardware or to the Grid Infrastructure.
Next maintenance (local peer)	Specifies the time period for the next scheduled maintenance window for a local Autonomous Data Guard standby. Click **View history** to see details on past maintenance.

Maintenance Field	Description
Target component (local peer)	Lists the target components for the upcoming maintenance window on the Autonomous Data Guard. Possible values are: • Database: when the patch applies to the database home and executables. • Dictionary: when the patch applies to the data dictionary and to Oracle APEX. • Infrastructure: when the patch applies to the Exadata hardware or to the Grid Infrastructure.
Customer contacts	When customer contacts are set, Oracle sends notifications to the specified email addresses for Autonomous Database service-related issues. See View and Manage Customer Contacts for Operational Issues and Announcements for more information.

Notes for scheduled maintenance and patching:

- The Autonomous Database operations team never accesses your data unless you explicitly grant permission through a Service Request for a specified duration.
- If your database is in the stopped state during the maintenance window, the database changes from the patch are applied when you start your database.
- Your database remains available during the maintenance window. New connections to the database will always succeed. Your existing database connections may get disconnected briefly, depending on the component being patched; however, you can immediately reconnect and continue using your database:
  - For Database patches, existing connections may get disconnected if they are running for longer than the drain time after patching starts.
  - For Infrastructure patches, existing connections may get disconnected if they are running for longer than the drain time after patching starts.
  - For Dictionary patches, existing connections may get disconnected if they are holding locks on the dictionary objects being patched. Otherwise, the existing connections will not be impacted. For example, if your application is running a procedure in the `DBMS_CLOUD` package during patching and the package needs to be patched, the session using that package may get disconnected.

    See SESSION_EXIT_ON_PACKAGE_STATE_ERROR for more information.
- You can use Oracle Cloud Infrastructure Events to be notified when maintenance begins and ends. See Information Events on Autonomous Database for more information.
- If you want to change the assigned maintenance window to a different 2-hour window on either Saturday or Sunday in the region's local time zone, file a Service Request at Oracle Cloud Support.

  If you want a specific time period for your maintenance window on either Saturday or Sunday in the region's local time zone, you can request the time period with the same Service Request. If you request a specific time period for your maintenance window, the change can only be made if the time period you request is available for your database.
- If your database's allocated storage is 384 TB, you can choose a custom 2-hour window by filing a Service Request at Oracle Cloud Support (that is you can file a Service Request to request a specific day and time period on either Saturday or Sunday in the region's local time zone for your maintenance window).

See Test Workloads Against an Upcoming Patch for information on capturing a workload from a production database and replaying the workload on a target early patch level refreshable clone.

See Zero-Regression Service Level Objective for details on the zero-regression SLO for Autonomous Database.

View Maintenance Event History

You can view Autonomous Database maintenance event history for details about past maintenance events, such as the title, state, start time, and stop time.

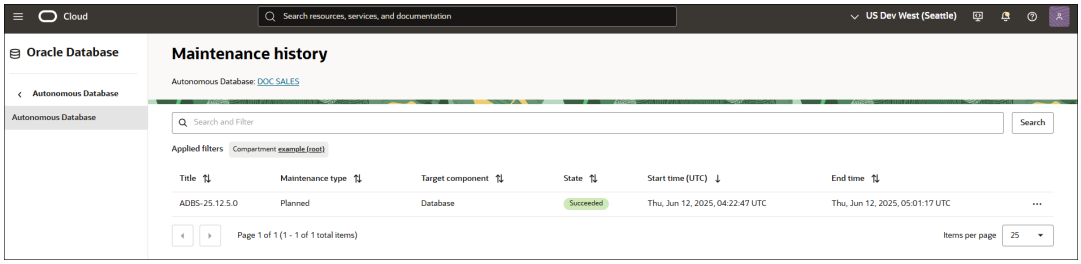
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To view maintenance history, do the following:

1. On the Autonomous Database Details page, under **Next Maintenance**, click **View history**.
2. The Oracle Cloud Infrastructure Console displays the Maintenance History page.
3. (Optional) Use the **Search and Filter** selector to filter events by state.

   For example, if you select **Succeeded**, the Maintenance History page shows only the maintenance events with the Succeeded state.



The Maintenance History page shows details for each maintenance event, including the following:

Field	Description
Title	The name of the maintenance event.
Maintenance type	Planned or Unplanned.
Target component	The type of the resource on which the maintenance event occurs: Database, Dictionary, or Infrastructure.
State	Succeeded, Failed, or In progress.
Start Time	Maintenance start time.
End Time	Maintenance end time.

> **Note:**
>
> Maintenance event history is available starting with maintenance events after February 2021.

View Patch Details

You can view Autonomous Database patch information, including a list of resolved issues and components.

The `DBA_CLOUD_PATCH_INFO` view provides patch information related to reported bugs (bugs reported by a customer). You can use this information to determine if a bug you reported is fixed and the patch version where the fix was applied to your Autonomous Database instance. If there were no customer bugs in a patch, `DBA_CLOUD_PATCH_INFO` does not include any rows for that patch.

To view patch information for a specific patch, do the following:

1. Select the Autonomous Database patch that you want to view. The Maintenance History page on the Oracle Cloud Infrastructure Console shows the list of patches under **Title**.
2. For the selected patch, query the `DBA_CLOUD_PATCH_INFO` view.

   For example, for patch `ADBS-21.7.1.1`, use the following query:

   ```
   SELECT * FROM DBA_CLOUD_PATCH_INFO WHERE PATCH_VERSION = 'ADBS-21.7.1.1';
   ```

3. For an issue of interest, query the view to obtain details for the issue:

   ```
   SELECT * FROM DBA_CLOUD_PATCH_INFO WHERE PATCH_VERSION = 'ADBS-21.7.1.1'
   and BUG_NUM = bug_number;
   ```

To view patch information for all available patches:

```
SELECT * FROM DBA_CLOUD_PATCH_INFO;
```

Notes for viewing patch information:

- The view `DBA_CLOUD_PATCH_INFO` is available to the ADMIN user.
- Patch information and details on resolved issues is available from `ADBS-21.7.1.1` onwards (starting in July 2021).
- The view `DBA_CLOUD_PATCH_INFO` has the following columns:

  ```
  BUG_NUM, BUG_TITLE, COMPONENT_NAME, PATCH_VERSION
  ```

See View Maintenance Status Notifications for details about the patches applied during maintenance.

Set the Patch Level

When you provision or clone an Autonomous Database instance you can select a patch level to apply to upcoming patches. You can also edit the patch level after an Autonomous Database instance is provisioned. There are two patch level options: **Regular** and **Early**.

When you select patch level **Early**, patches are applied for the Autonomous Database instance one week before the **Regular** scheduled patch. The **Next Maintenance** field in the Oracle Cloud Infrastructure Console reflects a maintenance window date and time based on the patch level.

The default patch level for provisioning an Autonomous Database instance is **Regular**. The default patch level for cloning is the patch level specified for the source database.

Provisioning or cloning an instance and setting the patch level to **Early** allows you to use and to test upcoming patches before they are applied to all systems. Oracle recommends you select the **Early** patch level for your development and test databases if you want to test the upcoming patches before the patches reach production. You can also test your workloads using Oracle Real Application Testing to capture a workload on a production system and replay it with **Early** patch level. See Test Workloads with Oracle Real Application Testing for more information.

> **Note:**
>
> Setting the patch level is only available on an Autonomous Database instance that uses the ECPU compute model.

To set the patch level while provisioning or cloning an instance, do the following:

- If provisioning a new instance, follow the provisioning instructions and select the patch level, either **Regular** or **Early**. See Provision an Autonomous Database Instance for more information.
- If cloning an instance, follow the cloning instructions and select a patch level, either **Regular** or **Early**. See Clone an Autonomous Database Instance for more information.

To change the patch level for an existing Autonomous Database, do the following:

1. On the **Autonomous Database Details** page, under **Maintenance**, in the Patch level field click **Edit**.

   > **Note:**
   >
   > The Edit button may be disabled under the following circumstances:
   >
   > - If early patch level is not available in your region for your database version.
   > - If your database has Autonomous Data Guard enabled.
   > - If your database is on early patch level and it is not feasible to move it to regular patch level. In this case, you should try again after the next maintenance window.

2. Select the patch level, **Regular** or **Early**, and click **Submit**.

The time it takes to change the patch level depends on the size of your database. You may see brief connection drops during this time.

Reporting Patch Issues to Oracle Support

When you report an issue for an **Early** patch level database, Oracle Support takes the necessary actions to prevent the problem from propagating to **Regular** patch level databases. A few examples of the possible actions are:

- The patch that caused the problem is removed before the regular patch level databases are patched.
- The patch that caused the problem is disabled using database parameters when it is being applied to the regular patch-level databases.
- Patching of regular patch level databases is paused until corrective action is taken.

If you have an issue to report, file a service request at Oracle Cloud Support or contact your support representative.

Oracle provides a service level objective of zero regressions in your production database. See Zero-Regression Service Level Objective for more information.

Notes for patching level:

- The option to set the patch level is not available in every region. In some regions all Autonomous Database instances are provisioned or cloned at the **Regular** patch level.
- Autonomous Data Guard is only available for instances with patch level **Regular**. When you configure an Autonomous Database instance with patch level **Early**, you cannot enable Autonomous Data Guard.
- Always Free Autonomous Database instances do not provide the **Early** patch level option.
- When the patch level of a source Autonomous Database instance is **Regular**, in regions that support the **Early** patch level you can set the patch level of a clone to **Early**.

View Maintenance Status Notifications

The `DB_NOTIFICATIONS` view stores information about maintenance status notifications for your Autonomous Database instance.

To show notification information:

1. Connect to your Autonomous Database instance.
2. Use the following query to view maintenance (patching) information.

```
SELECT * FROM DB_NOTIFICATIONS WHERE TYPE = 'MAINTENANCE';
```

The following provides details about the `DESCRIPTION` field values.

- **Maintenance run has ended**: Specifies maintenance has completed. The `MAINTENANCE_STATUS` shows the value `COMPLETED` with the start and end timestamps for the completed maintenance in `ACTUAL_START_DATE` and `ACTUAL_END_DATE`.
- **Maintenance run is scheduled for the instance**: Specifies a new maintenance has been scheduled. The `MAINTENANCE_STATUS` shows the value `SCHEDULED` with the expected start and end timestamps for the scheduled maintenance in `EXPECTED_START_DATE` and `EXPECTED_END_DATE`.

- **Maintenance run has begun**: Specifies the maintenance is in progress and provides the start timestamp for the active maintenance. The `MAINTENANCE_STATUS` shows the value `IN_PROGRESS` and `ACTUAL_START_DATE` stores the start timestamp.

The following table shows the `DB_NOTIFICATIONS` columns and datatypes.

Column	Datatype	Description
`TYPE`	`VARCHAR2(128)`	Specifies the type of the notification. Valid value is: `MAINTENANCE`.
`TIME`	`TIMESTAMP(6) WITH TIME ZONE`	Time when the notification entry was added.
`EXPECTED_START_DATE`	`TIMESTAMP(6) WITH TIME ZONE`	Scheduled maintenance start time.
`EXPECTED_END_DATE`	`TIMESTAMP(6) WITH TIME ZONE`	Scheduled maintenance end time.
`ACTUAL_START_DATE`	`TIMESTAMP(6) WITH TIME ZONE`	Actual maintenance start time.
`ACTUAL_END_DATE`	`TIMESTAMP(6) WITH TIME ZONE`	Actual maintenance end time.
`MAINTENANCE_PRODUCT`	`VARCHAR2(128)`	Product/component for which maintenance is scheduled/ongoing.
`MAINTENANCE_STATUS`	`VARCHAR2(128)`	Current status of the maintenance.
`DESCRIPTION`	`VARCHAR2(128)`	The notification message details.
`PATCH_ID`	`VARCHAR2(128)`	Patch version.

Best Practices to Maintain Application Availability During Maintenance Windows

Provides information on best practices to maintain application availability and to minimize application disruption during a scheduled maintenance window.

Autonomous Database patches are applied during a scheduled maintenance window as rolling patches. Using rolling patches, your Autonomous Database instance is made available on new cluster nodes before patching starts on the original nodes where it was running. After the database is available on new cluster nodes, all new connections are directed to the new nodes. This means the database remains online and available during maintenance and new database connection requests will succeed during the maintenance window.

Existing database connections on the original nodes are subject to draining for 5-minutes[2]. During the draining period the database waits for the client to release existing connections. After the draining period, if there are any database connections left on the original nodes, the remaining connections are disconnected and patching starts. The following best practices can help you to ensure that database connections are drained during the draining period and are reconnected to the new nodes, so that applications do not see disruptions during a maintenance window.

Use a Connection Pool and Return Connections to the Pool

Using a connection pool is recommended to hide scheduled maintenance from your application. Running an application during the maintenance window has no impact on an application when the application does the following:

- Uses a connection pool with the recommended settings.
- Checks out a connection from the connection pool.
- Uses the connection for less than the drain time (5 minutes).

[2] Note that this draining time may change in future releases.

- Returns the connection to the connection pool.

The best practice for an application working with a connection pool is to follow these steps. The application checks out a connection, uses the connection for database processing, and then releases the connection back to the connection pool immediately when the work is complete (this makes the connection available for use by other threads).

When the draining period starts the connection pool handles re-establishing the available connections in the connection pool so that new connections connect to the newly available nodes. When an application checks out a new connection it does not see any disruptions (new connections use the new nodes). However, if a connection is checked out before the start of the maintenance or during the drain time and it performs processing that continues for more than the drain time, the connection will be disconnected. In this case, to avoid disruptions you can stop such long-running operations before maintenance starts and restart them when maintenance ends. To know when to stop and when to restart long running operations you can subscribe to events, as explained in the following section, "Subscribe to Information Events".

The following table shows some of the common connection pool types and the recommended versions and settings.

Connection Pool	Version	Oracle JDBC Driver Version	Recommended Settings
Universal Connection Pool (UCP)	23ai	23ai	Use the default settings.
Universal Connection Pool (UCP)	19.12 or later	19.13 or later	`ValidateConnectionOnBorrow=true` Add `oracle.jdbc.defaultConnectionValidation=LOCAL` to your JDBC driver connection properties.

Weblogic	14.1.1 or later	19.13 or later	`test-connections-on reserve=true`
			`test-table-name=SQL ISVALID`
			`seconds-to-trust-an-idle-pool-connection=0`
			Apply the patch for the bug 35731335. See Patch 35731335 for more information.

Hikari	6.0.0 or later	19.21 or later	Set `com.zaxxer.hikari.aliveBypassWindowMs` to -1. Set `oracle.jdbc.defaultConnectionValidation` to `SOCKET` in your JDBC properties. Set `com.zaxxer.hikari.enableRequestBoundaries` to `true`.
Tomcat	9.0, 10.0, or 11.0	Any version	If you are using Tomcat with UCP, follow the UCP recommendations above. If you are using Tomcat with the JDBC Driver, call any Oracle JDBC draining API: `isValid()`, `isUsable()`, `pingDatabase()`, or `endRequest()`. Set `oracle.jdbc.defaultConnectionValidation` to `SOCKET` in your JDBC properties.

Use Connection Tests on the JDBC Driver if You Cannot Use a Connection Pool

If you cannot use a connection pool, the Oracle client drivers 19.13 (or later) can drain connections so your application does not see disruptions. To ensure connections are drained

properly you can call any Oracle JDBC draining API: `isValid()`, `isUsable()`, `pingDatabase()`, or `endRequest()`.

Subscribe to Information Events

If your application has long-running database operations that run for longer than the drain time (5 minutes), the pool or the JDBC driver cannot drain the connections, as they will not be released before the drain time ends. For such long running operations, to avoid disruptions you should not start the processes and jobs during or just before a maintenance window.

Autonomous Database publishes Information events to the OCI Events service to notify you about maintenance windows, including these Information events (with the event category Maintenance):

- When a new maintenance window is scheduled
- 24 hours before patching starts
- 60 minutes before patching starts
- When patching starts
- When patching ends

You can subscribe to Autonomous Database Information events, and optionally specify the event category maintenance, to receive notifications and to limit the notifications you receive to maintenance events. Then, based on the notification and rules you define, you can take actions to stop the long-running operations and to restart them after maintenance ends. Even though the announced maintenance windows are usually 2 hours long, actual patching happens in 5 to 10 minutes during that window. Using these events and your knowledge of the long running operations, you can determine when to stop long-running operations, and when to restart them.

See Use Autonomous Database Events for more information.

Handle PL/SQL Session State if Your Application is Using PL/SQL

The database parameter `SESSION_EXIT_ON_PACKAGE_STATE_ERROR` specifies the handling for a stateful PL/SQL package running in a session. When such a package undergoes modification, such as during planned maintenance for Oracle-supplied objects, the sessions that have an active instantiation of the package receive the following error when they attempt to run the package: `ORA-04068: existing state of packages has been discarded.`. However, the application code that receives the `ORA-4068` error may not be equipped to handle this error with its retry logic.

Setting `SESSION_EXIT_ON_PACKAGE_STATE_ERROR` to `TRUE` provides different handling for this case. When `SESSION_EXIT_ON_PACKAGE_STATE_ERROR` is `TRUE`, instead of just raising the `ORA-4068` error when the package state is discarded, the session immediately exits. This can be advantageous because many applications can handle session termination by automatically and transparently re-establishing the connection.

See SESSION_EXIT_ON_PACKAGE_STATE_ERROR for more information.

View and Manage Customer Contacts for Operational Issues and Announcements

You can view and manage the Autonomous Database customer contacts.

When customer contacts are set, Oracle sends notifications to the specified email addresses for Autonomous Database service-related issues. Contacts in the customer contacts list

receive unplanned maintenance notices and other notices, including but not limited to notices for database upgrades and upcoming wallet expiration. When customer contacts are not set the notifications go to the tenancy admin email address associated with the account. Oracle recommends that you set the customer contacts so that the appropriate people receive service-related notifications.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To view or manage customer contact email addresses:

1. On the Autonomous Database Details page, under **Maintenance**, in the **Customer Contacts** field, click the **Manage** link.

   This shows the Manage Customer Contacts page. On the Manage Customer Contacts page you can view the email contact list.
2. To add a contact, click **Add Customer Contact**.
3. Enter the contact email address.

   Oracle recommends adding an administrator group's email address over an individual's email address when possible, so as to not miss important notifications or announcements.
4. To add additional contacts, click **Add Customer Contact** again.

The lifecycle state changes to Updating while the customer contact list is updated.

To remove customer contacts:

1. On the Manage Customer Contacts page select the email addresses to remove.
2. To remove all email addresses, select the top column next to **Email**.
3. Click **Remove**.
4. On the Confirm remove contact page, click **Remove** to confirm.

The lifecycle state changes to Updating while the customer contact list is updated.

To edit customer contacts:

1. On the Manage Customer Contacts page select the email addresses to edit.
2. To edit all email addresses, select the top column next to **Email**.
3. Click **Edit**.
4. On the Edit Contacts page edit the contacts as needed and click **Save**.

The lifecycle state changes to Updating while the customer contact list is updated.

Notes for adding customer contacts for operational issues and announcements:

- Oracle recommends adding an administrator group's email address over an individual's email address when possible, so as to not miss important notifications or announcements.
- The "&" character is not allowed in the email address you provide for a customer contact. As an alternative, use an email address that does not contain this character.

- In addition to sending information for operational issues and announcements to customer contacts, you can subscribe to Oracle Cloud Infrastructure Events to be notified of Autonomous Database events such as when regular maintenance is scheduled or when regular maintenance starts and ends. Event notification requires a subscription for each email address, independent of the customer contacts list.

  See Use Autonomous Database Events for more information.

View Oracle Cloud Infrastructure Operations Actions

The `DBA_OPERATOR_ACCESS` view stores information on the actions that Oracle Cloud Infrastructure cloud operations performs on your Autonomous Database.

These steps use **Database Actions** to query the `DBA_OPERATOR_ACCESS` view. You can query this view from any SQL connection by connecting as a user with the proper privileges.

1. On the Autonomous Database Details page select **Database Actions** and from the quick actions list click **SQL**.
2. Within the SQL Worksheet, query the `DBA_OPERATOR_ACCESS` view.

   For example:

   ```
   SELECT * FROM DBA_OPERATOR_ACCESS;
   ```

Notes for the `DBA_OPERATOR_ACCESS` view:

- You can continuously move this audit data to the object store for purposes such as integration with Security Information and Event Management (SIEM) tools. See Create and Configure a Pipeline for Export with Timestamp Column for more information on using pipelines to continuously export query results to object store.
- The `DBA_OPERATOR_ACCESS` view provides information starting on October 4, 2022, the date this feature was introduced. The view does not provide information prior to October 4, 2022.
- The `DBA_OPERATOR_ACCESS` view may not show results if Oracle Cloud Infrastructure cloud operations hasn't performed any actions or run any statements in your Autonomous Database instance. In this case, when you query the view you will not see any rows returned.
- DBA_OPERATOR_ACCESS View
  The `DBA_OPERATOR_ACCESS` view describes top level statements executed in the Autonomous Database instance by Oracle Cloud Infrastructure operations.

DBA_OPERATOR_ACCESS View

The `DBA_OPERATOR_ACCESS` view describes top level statements executed in the Autonomous Database instance by Oracle Cloud Infrastructure operations.

Column	Datatype	Description
`SQL_TEXT`	`VARCHAR2(4000)`	SQL text of the statement executed by the operator.
`EVENT_TIMESTAMP`	`DATE`	Timestamp of the operator action in UTC (Coordinated Universal Time).

Column	Datatype	Description
REQUEST_ID	VARCHAR2(64)	Request number related to the reason behind the operator action. This could be a bug number, an SR number, or a change ticket request number that provides information on the reason for the action.
REASON	VARCHAR2(64)	Reason for the operator action. This provides context for the reason behind the action and may have a value such as: MITIGATION, DIAGNOSTIC COLLECTION, or CUSTOMER REQUEST.

Monitor and Manage Performance

Describes the Database Dashboard card in Database Actions where you can find information about the performance of an Autonomous Database instance.

- Monitor the Performance of Autonomous Database with Database Actions
  The **Database Dashboard** card in Database Actions provides the **Overview** and **Monitor** tabs where you can find information about the performance of an Autonomous Database instance.
- Monitor Autonomous Database with Performance Hub
  Use Performance Hub to monitor your database for a defined time period and download statistical reports. Performance Hub also lets you view real-time and historical performance data for an Autonomous Database instance.
- Manage Concurrency and Priorities on Autonomous Database
  Concurrency and prioritization of user requests in Autonomous Database is determined by the database service the user is connected with, and whether compute auto scaling is enabled.
- Manage CPU/IO Shares on Autonomous Database
  Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can modify these predefined CPU/IO shares if your workload requires different CPU/IO resource allocations.
- Manage Runaway SQL Statements on Autonomous Database
  Specifies how you configure Autonomous Database to terminate SQL statements automatically based on their query runtime or their IO usage.
- Use Fast Ingest on Autonomous Database
- Enable Database Management Service to Monitor and Manage Autonomous Database
  You can use the Diagnostics & Management features in the Database Management service for advanced monitoring and management of Autonomous Databases.
- Perform SQL Tracing on Autonomous Database
  Use SQL tracing to help you identify the source of an excessive database workload, such as a high load SQL statement in your application.
- Monitor Performance with Autonomous Database Metrics
  You can monitor the health, capacity, and performance of your databases with metrics, alarms, and notifications. You can use Oracle Cloud Infrastructure Console or Monitoring APIs to view metrics.
- Available Metrics: oci_autonomous_database
  This topic describes the metrics emitted by the Database service in the oci_autonomous_database namespace.

Monitor the Performance of Autonomous Database with Database Actions

The **Database Dashboard** card in Database Actions provides the **Overview** and **Monitor** tabs where you can find information about the performance of an Autonomous Database instance.

- Use Database Actions to Monitor Activity and Utilization
  Database Actions provides the **Database Dashboard** card, with **Overview** and **Monitor** tabs to provide real-time and historical information about the utilization of an Autonomous Database instance.
- Use Database Actions to Monitor Active Session History Analytics and SQL Statements
  In Database Actions the Performance Hub card provides information about Active Session History (ASH) analytics and current and past monitored SQL statements.

Use Database Actions to Monitor Activity and Utilization

Database Actions provides the **Database Dashboard** card, with **Overview** and **Monitor** tabs to provide real-time and historical information about the utilization of an Autonomous Database instance.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

To view the **Overview** tab that shows general information about utilization, do the following:

1. Access Database Actions as the ADMIN user.

   See Access Database Actions as ADMIN for more information.
2. On the Database Actions Launchpad, under **Monitoring**, click **Database Dashboard**.

> **Note:**
>
> You can bookmark the Launchpad URL and go to that URL directly without logging in to the Oracle Cloud Infrastructure Console. If you logout and use the bookmark, then you need to enter the `ADMIN` username and *password*, and click **Sign in**. See Set the ADMIN Password in Autonomous Database if you need to change the password for the `ADMIN` user.

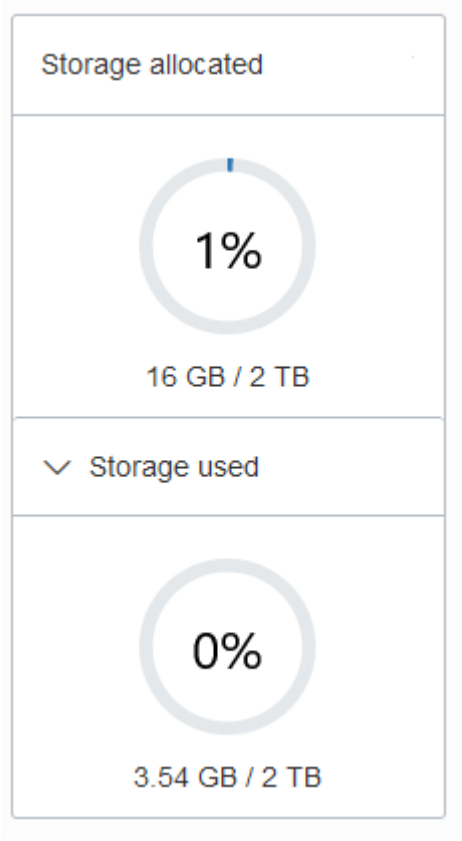
- Database Dashboard Overview
  The **Overview** tab shows real-time and historical information about the Autonomous Database utilization.
- Database Dashboard Activity
  The **Monitor** tab shows real-time and historical information about the Autonomous Database performance data, activity, and utilization.

Database Dashboard Overview

The **Overview** tab shows real-time and historical information about the Autonomous Database utilization.

The charts shown on this page include:

- **Storage:** This chart shows the provisioned, allocated, and used storage. The chart indicates what percentage of the space is currently in-use.



Provisioned storage is the amount of storage you select when you provision the instance or when you modify storage by scaling storage.

Storage allocated is the amount of storage physically allocated to all data tablespaces and temporary tablespaces and includes the free space in these tablespaces. This does not include storage for the sample schemas.

Storage used is the amount of storage actually used in all data and temporary tablespaces. This does not include storage for the sample schemas. The storage used is the storage in the Autonomous Database as follows:

- Storage used by all database objects. Note: the chart does not include storage for the sample schemas as they do not count against your storage.
- Storage for files users put in the file system.
- Storage used by temporary tablespaces.
- Used storage excludes the free space in the data and temporary tablespaces.

By default the chart does not show the used storage. Select **Storage used** to expand the chart to see used storage (the values are calculated when you open the chart).

For an Autonomous JSON Database the chart shows an additional field showing the percentage of storage used that is not storing JSON documents.

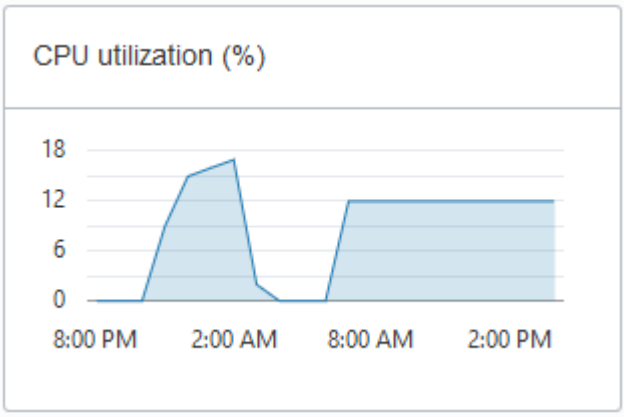
> **Note:**
>
> If you drop an object, the space continues to be consumed until you empty the recycle bin. See Purging Objects in the Recycle Bin for more information.

See Use Sample Data Sets in Autonomous Database for information on sample schemas SH and SSB.

- **CPU utilization (%) for ECPU Compute Model:** This chart shows the historical CPU utilization of the service:
  - Compute auto scaling disabled: this chart shows hourly data. A data point shows the average CPU utilization for that hour. For example, a data point at 10:00 shows the average CPU utilization for 9:00-10:00.

    The utilization percentage is reported with respect to the number of ECPUs the database is allowed to use. For example, if the database has four (4) ECPUs, the percentage in this graph is based on 4 ECPUs.

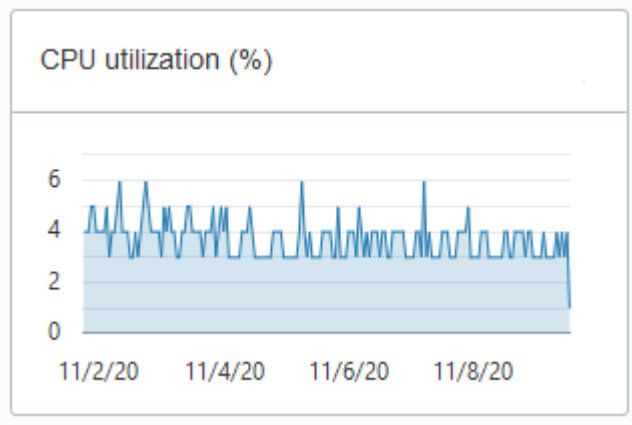
    
  - Compute auto scaling enabled: For databases with compute auto scaling enabled the utilization percentage is reported with respect to the maximum number of ECPUs the database is allowed to use, which is three times the number of ECPUs. For example, if the database has four (4) ECPUs with auto scaling enabled, the percentage in this graph is based on 12 ECPUs.

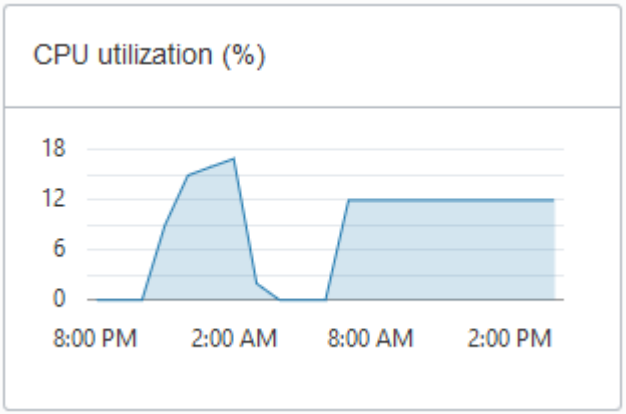
- **CPU utilization (%) for OCPU Compute Model:** This chart shows the historical CPU utilization of the service:

- Compute auto scaling disabled: this chart shows hourly data. A data point shows the average CPU utilization for that hour. For example, a data point at 10:00 shows the average CPU utilization for 9:00-10:00.

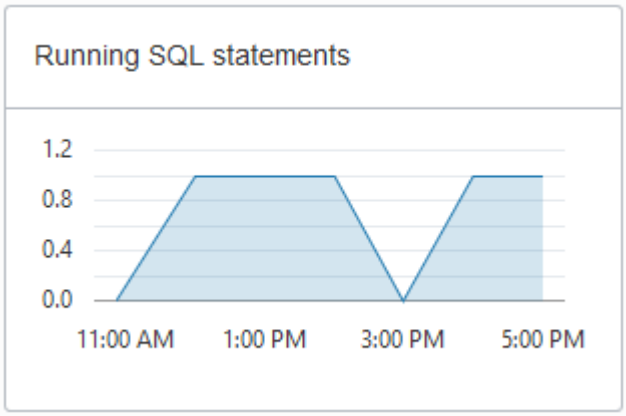
  The utilization percentage is reported with respect to the number of OCPUs the database is allowed to use. For example, if the database has four (4) OCPUs, the percentage in this graph is based on 4 OCPUs.



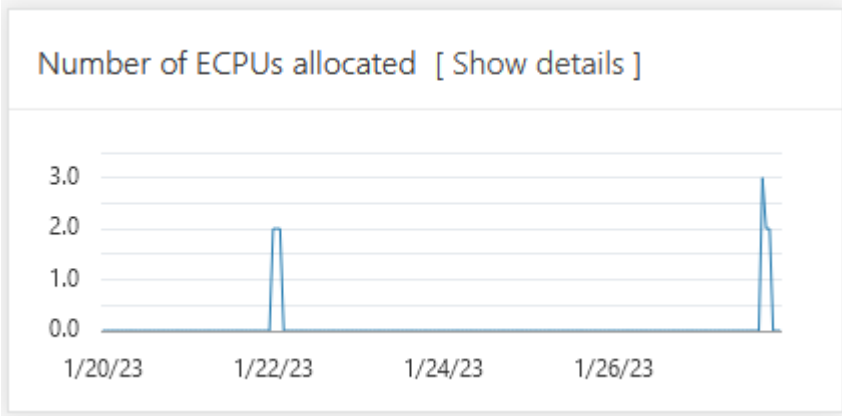
- Compute auto scaling enabled: For databases with compute auto scaling enabled the utilization percentage is reported with respect to the maximum number of OCPUs the database is allowed to use. For example, if the database has four (4) OCPUs with auto scaling enabled, the percentage in this graph is based on 12 OCPUs.



- **Running SQL statements**: This chart shows the average number of running SQL statements historically. This chart shows hourly data. A data point shows the running SQL statements for that hour. For example, a data point at 10:00 shows the average number of running SQL statements for 9:00-10:00.



- **Number of ECPUs allocated (only shown for ECPU Compute Model):**



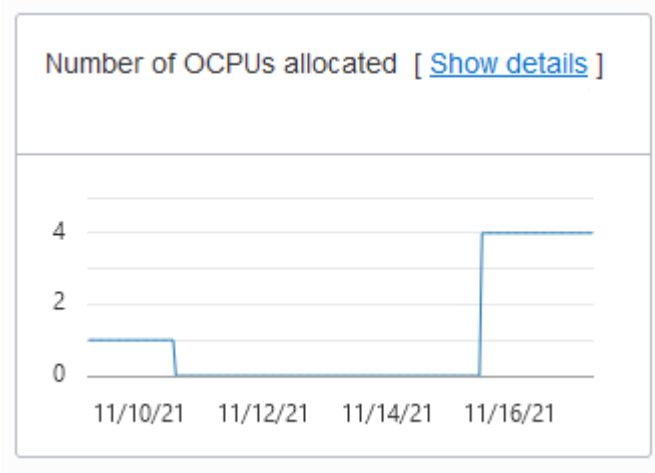
Notes for display results:

  - Compute auto scaling disabled: For databases with compute auto scaling disabled, for each hour the chart shows the number of ECPUs allocated to the database if the database is open for at least some part of the hour.
  - Compute auto scaling enabled: For databases with compute auto scaling enabled, for each hour the chart shows the average number of ECPUs used during that hour if that value is higher than the number of ECPUs provisioned. If the number of ECPUs used is not higher than the number of ECPUs provisioned, then the chart shows the number of ECPUs allocated for that hour.
  - Stopped Database: If the database was stopped for the full hour the chart shows 0 ECPUs allocated for that hour.

  Click **Show details** for more information, including the number of ECPUs allocated to the database and to external resources, and the total allocated ECPUs.

  The Show details view includes separate values for database ECPU usage and external resource ECPU usage. External resources include: Cloud SQL, Graph, OML4PY, and others. The Total ECPUs are the total number of ECPUs in use on the Autonomous Database. The external ECPUs value shows how external ECPUs contribute to the total ECPU usage.

- **Number of OCPUs allocated (only shown for OCPU Compute Model):**



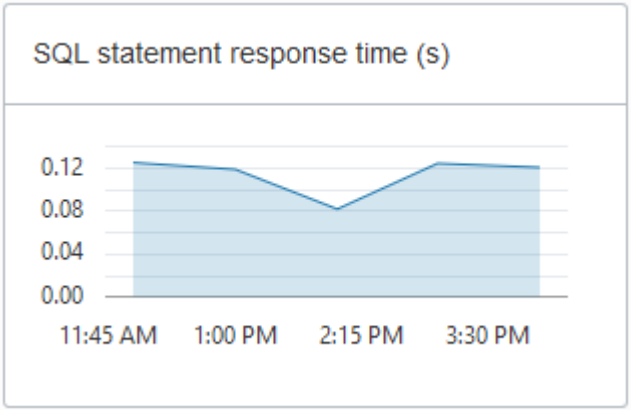
Notes for display results:

- Compute auto scaling disabled: For databases with compute auto scaling disabled, for each hour the chart shows the number of OCPUs allocated to the database if the database is open for at least some part of the hour.
- Compute auto scaling enabled: For databases with compute auto scaling enabled, for each hour the chart shows the average number of OCPUs used during that hour if that value is higher than the number of OCPUs provisioned. If the number of OCPUs used is not higher than the number of OCPUs provisioned, then the chart shows the number of OCPUs allocated for that hour.
- Stopped Database: If the database was stopped for the full hour the chart shows 0 OCPUs allocated for that hour.

Click **Show details** for more information, including the number of OCPUs allocated to the database and to external resources, and the total allocated OCPUs.

The Show details view includes separate values for database OCPU usage and external resource OCPU usage. External resources include: Cloud SQL, Graph, OML4PY, and others. The Total OCPUs are the total number of OCPUs in use on the Autonomous Database. The external OCPUs value shows how external OCPUs contribute to the total OCPU usage.

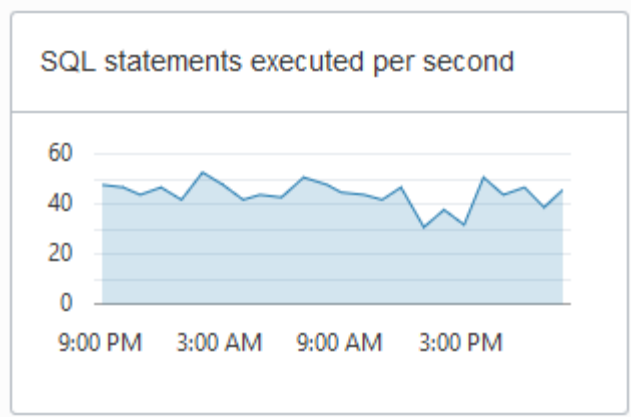
- **SQL statement response time (s)**: This chart shows the average response time, in seconds, of SQL statements historically. This chart shows hourly data. A data point shows the average SQL statement response time for that hour. For example, a data point at 10:00 shows the average SQL statement response time, in seconds, for the hour from 9:00-10:00.



- **SQL statements executed per second**

> **Note:**
>
> Database Dashboard does not show this chart when the Autonomous Database instance workload type is **Data Warehouse**.

.



The default retention period for performance data is thirty (30) days. The CPU utilization, running statements, and average SQL response time charts show data for the last eight (8) days by default.

You can change the retention period by modifying the Automatic Workload Repository retention setting with the PL/SQL procedure `DBMS_WORKLOAD_REPOSITORY.MODIFY_SNAPSHOT_SETTINGS()`. The maximum retention you can set is 30 days. See *Oracle Database PL/SQL Packages and Types Reference*.

If you need to store more performance data you can use the OCI Ops Insights AWR Hub. See Analyze Automatic Workload Repository (AWR) Performance Data for more information.

Database Dashboard Activity

The **Monitor** tab shows real-time and historical information about the Autonomous Database performance data, activity, and utilization.

> **Note:**
>
> The default view in the **Monitor** tab is real-time. This view shows performance data for the last hour.

The charts on this page are:

- **Database Activity**

  This chart shows the average number of sessions in the database using CPU or waiting on a wait event. See *Oracle Database Reference* for more information on wait events.

- **CPU Utilization** (with ECPU compute model)

This chart shows the CPU utilization of each consumer group. The utilization percentage is reported with respect to the number of ECPUs the database is allowed to use. For example, if the database has four (4) ECPUs, the percentage in this graph is based on 4 ECPUs.

For databases with compute auto scaling enabled the utilization percentage is reported with respect to the maximum number of ECPUs the database is allowed to use, which is three times the number of ECPUs. For example, if the database has four (4) ECPUs with auto scaling enabled, the percentage in this graph is based on 12 ECPUs.

See Manage Concurrency and Priorities on Autonomous Database for detailed information on consumer groups.

- **CPU Utilization** (with OCPU compute model)

  This chart shows the CPU utilization of each consumer group. The utilization percentage is reported with respect to the number of OCPUs the database is allowed to use. For example, if the database has four (4) OCPUs, the percentage in this graph is based on 4 OCPUs.

  For databases with compute auto scaling enabled the utilization percentage is reported with respect to the maximum number of OCPUs the database is allowed to use. For example, if the database has four (4) OCPUs with auto scaling enabled, the percentage in this graph is based on 12 OCPUs.

  See Manage Concurrency and Priorities on Autonomous Database for detailed information on consumer groups.

- **Running Statements**

  This chart shows the average number of running SQL statements in each consumer group.

  See Manage Concurrency and Priorities on Autonomous Database for detailed information on consumer groups.

- **Queued Statements**

  This chart shows the average number of queued SQL statements in each consumer group.

  See Manage Concurrency and Priorities on Autonomous Database for detailed information on consumer groups.

To see earlier data click **Time period**. The default retention period for performance data is thirty (30) days. By default in the Time Period view the charts show information for the last eight (8) days.

In the time period view you can use the calendar to look at a specific time period in the past 30 days. You can also use the time slider to change the period for which performance data is shown.

> **Note:**
>
> The retention time can be changed by changing the Automatic Workload Repository retention setting with the PL/SQL procedure `DBMS_WORKLOAD_REPOSITORY.MODIFY_SNAPSHOT_SETTINGS`. Be aware that increasing the retention time results in more storage usage for performance data. See *Oracle Database PL/SQL Packages and Types Reference*.

Use Database Actions to Monitor Active Session History Analytics and SQL Statements

In Database Actions the Performance Hub card provides information about Active Session History (ASH) analytics and current and past monitored SQL statements.

Perform the following prerequisite step as necessary:

- Access Database Actions as the ADMIN user. See Access Database Actions a ADMIN for more information.
- The Performance Hub Page

The Performance Hub Page

The Performance Hub page shows performance data for a time period you specify.
To navigate to the Performance Hub page, do either of the following:

- In the Launchpad page, select the **Monitoring** tab and click **Performance Hub**.
- Click **Selector** to display the navigation menu. Under Monitoring, select **Performance Hub**.

> **Note:**
>
> The Performance Hub page is available in the following user interface languages: French, Japanese, Korean, Traditional Chinese, and Simplified Chinese. If you change the language to German, Spanish, Italian, or Portuguese in Preferences, the Performance Hub page reverts to English.

The Performance Hub page consists of these parts:

- **Time Range Area**: Use the controls in time range area at the top of the page to specify the time period for which you want to view performance data.
- **ASH Analytics Tab**: Use this tab to explore ASH (Active Session History) information across a variety of different dimensions for the specified time period.
- **SQL Monitoring Tab**: Use this tab to view the top 100 SQL statement executions by different dimensions for the specified time period, and to view details of SQL statement executions you select.

See Performance Hub in the Database service documentation for more information.

Monitor Autonomous Database with Performance Hub

Use Performance Hub to monitor your database for a defined time period and download statistical reports. Performance Hub also lets you view real-time and historical performance data for an Autonomous Database instance.

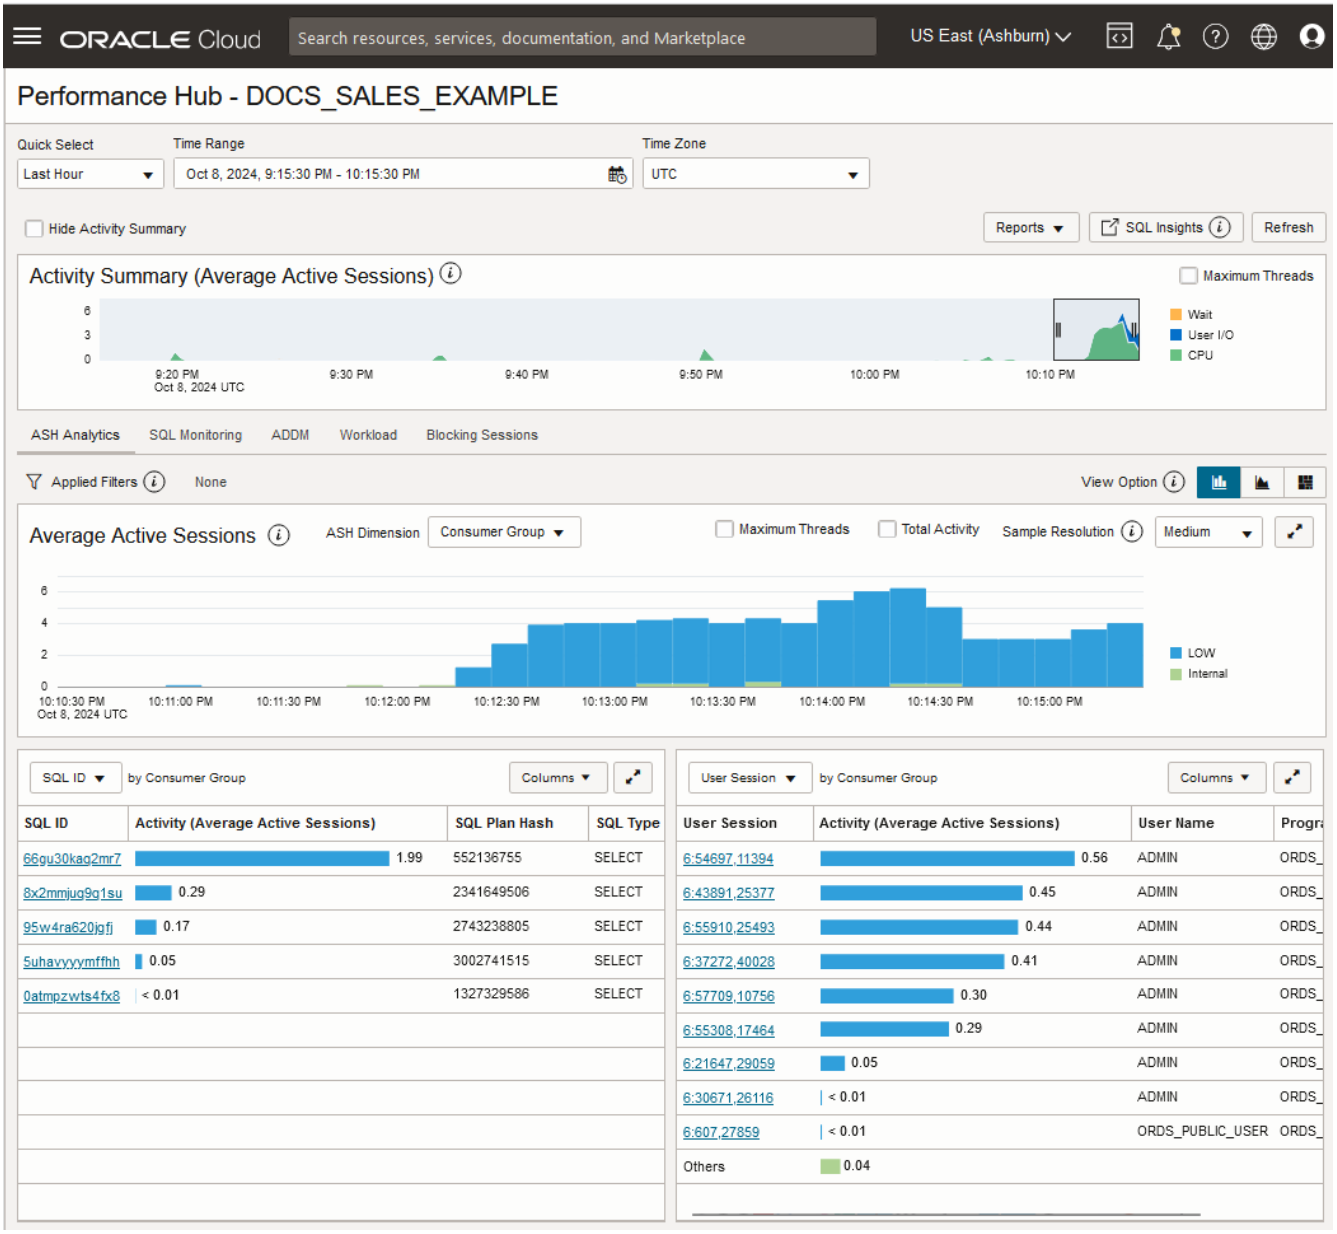
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.

- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database**, and then click Autonomous Database.

To view Performance Hub:

1. On the Autonomous Database page, select an Autonomous Database from the links under the **Display name** column.
2. From the Autonomous Database details page click **Performance Hub**.



See Using Performance Hub to Analyze Database Performance more information.

Component	Description
Top Area	The top of the Performance Hub page shows the following: • **Quick Select**: Use to quickly set the time range to one of Last Hour, Last 8 Hours, Last 24 Hours, or Last Week. • **Time Range**: Use to set the date and time range for Performance Hub to monitor. • **Time Zone**: Select an entry from this list to specify times based on Coordinated Universal Time (UTC), your local web browser time (Browser), or the database time zone setting (Database). • **Activity Summary (Average Active Sessions)**: shows active sessions during the selected time range. It displays the average number of active sessions broken down by CPU, User I/O, and Wait. It also shows the Max CPU usage. You can hide or show the activity summary by selecting **Hide Activity Summary**. • **Reports**: Allows you to generate and view different types of performance diagnostic reports, including: – **Automatic Workload Repository** (AWR): This report is available by default. The AWR report collects, processes, and maintains performance statistics for problem detection and self-tuning purposes. This data is both in memory and stored in the database. – **Active Session History** (ASH): This report requires that you enable Database Management. The ASH report contains data that helps you triage transient performance problems and perform scoped or targeted performance analysis by various dimensions such as time, session, module, action, or SQL identifier. See Enable Database Management Service to Monitor and Manage Autonomous Database for more information.
Active Session History (ASH) Analytics	**ASH Analytics** is displayed by default. This tab shows Active Session History (ASH) analytics charts to explore the Active Session History data. You can drill down into database performance across multiple dimensions such as Consumer Group, Wait Class, SQL ID, and User Name. Select an Average Active Sessions dimension and view the top activity for that dimension for the selected time period. For more information, see ASH Analytics.
SQL Monitoring	SQL statements are only monitored if they've been running for at least five seconds or if they're run in parallel. The table displays monitored SQL statement executions by dimensions including Last Active Time, CPU Time, and Database Time. The table displays currently running SQL statements and SQL statements that completed, failed, or were terminated. The columns in the table provide information for monitored SQL statements including Status, Duration, and SQL ID. For more information, see SQL Monitoring.
Automatic Database Diagnostic Monitor (ADDM)	**ADDM** tab provides access to analysis information gathered by the Automatic Database Diagnostic Monitor (ADDM) tool. ADDM analyzes AWR (Automatic Workload Repository) snapshots on a regular basis, locates root causes of any performance problems, provides recommendations for correcting the problems, and identifies non-problem areas of the system. AWR is a repository of historical performance data, therefore ADDM can analyze performance issues after the event, often saving time and resources in reproducing a problem. For more information, see Automatic Database Diagnostic Monitor (ADDM).

Component	Description
Workload	Use the **Workload** tab to visually monitor the database workload to identify spikes and bottlenecks. This tab shows four chart areas that show database workload in various ways: • **CPU Statistics**: Charts CPU usage. • **Wait Time Statistics**: Shows the wait time across the database's foreground sessions, divided by wait classes. • **Workload Profile**: Charts user (client) workload on the database. • **Sessions**: Shows the number of sessions, successful logons, and current logons. For more information, see Workload.
Blocking Sessions	**Blocking Sessions** hierarchically lists sessions that are waiting or are blocked by sessions that are waiting. You can set the minimum wait time required for sessions to be displayed in the list, and you can view a variety of information about a session to determine whether to let it continue or to end it. For more information, see Blocking Sessions.

See Using Performance Hub to Analyze Database Performance more information.

Manage Concurrency and Priorities on Autonomous Database

Concurrency and prioritization of user requests in Autonomous Database is determined by the database service the user is connected with, and whether compute auto scaling is enabled.

- Database Service Names for Autonomous Database
  Autonomous Database comes with predefined database services with different performance and concurrency characteristics. You must choose one of these services for each application or user that connects to the database.
- Idle Time Limits
  Autonomous Database has predefined idle time limits for sessions so that idle sessions do not hold system resources for a long time.
- Service Concurrency
  The consumer groups of the predefined service names provide different levels of performance and concurrency. The available service names are different depending on your workload: Data Warehouse, Transaction Processing, or JSON Database.
- Change MEDIUM Service Concurrency Limit (ECPU Compute Model)
  If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.
- Change MEDIUM Service Concurrency Limit (OCPU Compute Model)
  If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.
- Predefined Job Classes with Oracle Scheduler
  Autonomous Database includes predefined `job_class` values to use with Oracle Scheduler.

Database Service Names for Autonomous Database

Autonomous Database comes with predefined database services with different performance and concurrency characteristics. You must choose one of these services for each application or user that connects to the database.

The following table compares the database services. This table applies to databases with 2 OCPUs or more, or 4 ECPUs or more. You cannot use parallelism in databases that have fewer than 2 OCPUs or fewer than 4 ECPUs unless you use manual parallelism, as explained below.

Service Name	Degree of Parallelism Footnote 1	Resource Shares Footnote 2	Concurrent Statements Footnote 3	
			Without Compute Auto Scaling	**With Compute Auto Scaling**
`TPURGENT` Footnote 5	Set manually Footnote 4	12	Bounded by the sessions parameter. **OCPU model**: The sessions parameter is set to 300 times the number of base OCPUs. **ECPU model**: The sessions parameter is set to 75 times the number of base ECPUs.	Same values as without Auto Scaling
`TP` Footnote 5	No parallelism	8	Bounded by the sessions parameter. **OCPU model**: The sessions parameter is set to 300 times the number of base OCPUs. **ECPU model**: The sessions parameter is set to 75 times the number of base ECPUs.	Same values as without Auto Scaling
`HIGH`	Enabled **OCPU model**: The degree of parallelism will be equal to the number of base OCPUs **ECPU model**: The degree of parallelism will be half the number of base ECPUs rounded down to the nearest integer value.	4	3	9

Service Name	Degree of Parallelism Footnote 1	Resource Shares Footnote 2	Concurrent Statements Footnote 3	
			Without Compute Auto Scaling	**With Compute Auto Scaling**
MEDIUM	Enabled **OCPU model**: The degree of parallelism will be 2 with 2 OCPUs, 3 with 3 OCPUs, and 4 for more than 3 OCPUs. **ECPU model**: The degree of parallelism will be half the number of base ECPUs rounded down to the nearest integer value with 4 to 7 ECPUs. It will be 4 with 8 ECPUs or more.	2	**OCPU model**: 1.25 × number of base OCPUs **ECPU model**: 0.25125 × number of base ECPUs A decimal result is truncated.	**OCPU model**: 3.75 × number of base OCPUs **ECPU model:** 0.75375 × number of base ECPUs A decimal result is truncated.
LOW	No parallelism	1	Bounded by the sessions parameter. **OCPU model**: The sessions parameter is set to 300 times the number of base OCPUs. **ECPU model**: The sessions parameter is set to 75 times the number of base ECPUs.	Same values as without Auto Scaling.

Footnote 1

The HIGH and MEDIUM services have Parallel Query, DDL, and DML enabled by default.

If you are using Autonomous Database with Oracle Database 19c, parallel DML requires you to commit or rollback your transaction before you can access the same table again. If you try to access the same table without committing or rolling back the transaction, you will get the ORA-12839 error. This restriction has been lifted in Oracle Database 23ai, so you can access the same table again using the same session without a commit or rollback.

If needed, you can disable parallel DML in your session by running:

```
alter session disable parallel dml;
```

You can also create a logon trigger to run this statement for all your sessions. Note that the performance of your large DML statements may be impacted when you disable parallel DML.

Note that these degree of parallelism values may be doubled for simple queries like a query on a single table.

The parallelism hints in your SQL statements are ignored by default in Autonomous Database instances with the Data Warehouse workload type. The parallelism hints in your SQL statements are honored in Autonomous Database instances with Transaction Processing, JSON, or APEX workload types. If you want to control parallelism using hints in an Autonomous Database instance with the Data Warehouse workload, you can enable hints using the following command.

```
alter session set optimizer_ignore_parallel_hints=false;
```

See the following for more information:

- About Parallel DML Operations if you are using Autonomous Database with Oracle Database 23ai.
- Transaction Restrictions for Parallel DML if you are using Autonomous Database with Oracle Database 19c.

Footnote 2

The CPU shares assigned to each service determine how much CPU and IO the sessions using those services will get when CPU utilization in your database reaches 100%. In that case, each service will get CPU and IO resources proportional to its assigned CPU shares. You can modify these shares when needed to adjust them for your workload. The automated tasks that run on Autonomous Database, such as automatic optimizer statistics gathering, run with a resource share of 1. See Manage CPU/IO Shares on Autonomous Database for more information.

Footnote 3

Concurrency in this table means the number of active sessions running SQL statements concurrently. The number of sessions that do not use parallelism, for example sessions in the `LOW` service, is bounded by the `sessions` database parameter. This parameter determines the number of sessions you can have in the database independent of what service those sessions are using. After that limit is reached, new sessions will not be able to connect to the database. For example, if your database has the `sessions` parameter set to 300, you can have different numbers of sessions using `LOW` and `TP`, with the total being limited to 300.

The `HIGH` and `MEDIUM` services allow as many concurrent SQL statements to run as indicated in this table, assuming you are only using one of these services. You can still submit more SQL statements using those services, but subsequent statements will be queued after these numbers are reached. As the running statements finish, queued sessions will be picked from the queue. If you use parallelism in multiple services concurrently, or if you use parallelism hints to set the degree of parallelism for your SQL statements, the concurrency you get may be different than the documented numbers shown in this table.

To see the concurrency levels for your database, run the following command:

```
SELECT * FROM CS_RESOURCE_MANAGER.LIST_CURRENT_RULES();
```

You can also see the currency levels in the Set Resource Management Rules card in Database Actions. See Manage CPU/IO Shares on Autonomous Database for more information.

Footnote 4

Manual parallelism is the type of parallelism where you can control the parallelism for queries, DDL, and DML statements by setting parallelism degrees on your tables and indexes. See Manually Specifying the Degree of Parallelism for more information.

Footnote 5

The `TP` and `TPURGENT` services are not available for Data Warehouse workloads. If you have a workload that requires manual parallelism, which is only available with `TPURGENT`, file a Service Request at Oracle Cloud Support to request to enable the `TP` and `TPURGENT` services in your Autonomous Database instance.

Topics

- Where Do I Find Connection Descriptions for Database Services?
  The available database services are part of your database connect strings and you can view the services from the Oracle Cloud Infrastructure Console or view the database services names in the `tnsnames.ora` in the wallet file you can download.
- Which Database Service Should I Choose for My Connection, Application, or Tool?
  The service you choose for your connection, application, or tool depends on your workload characteristics.
- Database Service Names for Autonomous Data Warehouse
  Describes the available service names for connecting to Autonomous Database instance with a Data Warehouse workload type.
- Database Service Names for Autonomous Transaction Processing and Autonomous JSON Database
  Describes the available service names for connecting to Autonomous Database instance with a Transaction Processing, JSON, or APEX workload type.

Where Do I Find Connection Descriptions for Database Services?

The available database services are part of your database connect strings and you can view the services from the Oracle Cloud Infrastructure Console or view the database services names in the `tnsnames.ora` in the wallet file you can download.

See View TNS Names and Connection Strings for an Autonomous Database Instance for the steps to view the connection strings on the Oracle Cloud Infrastructure Console,

See Download Client Credentials (Wallets) for more information.

For example, for an Autonomous Database instance with the Transaction Processing workload type named sales, the TNS aliases will be `sales_tpurgent`, `sales_tp`, `sales_high`, `sales_medium`, and `sales_low`.

Which Database Service Should I Choose for My Connection, Application, or Tool?

The service you choose for your connection, application, or tool depends on your workload characteristics.

The following general guidelines can help you choose.a database service to use:

- `TP`, `TPURGENT`, or `LOW`: Use the `TP` or the `LOW` service for running OLTP applications or tools that are expected to run short-running queries and transactions. If you have different types of users who need to have different CPU and IO priorities, use `TP`, `TPURGENT`, and `LOW`, depending on their priorities, and adjust the CPU shares for these services based on your requirements.
- `MEDIUM`: Use the `MEDIUM` service for analytic workloads like long-running queries scanning large data sets, batch data load processes, adhoc operational queries, and so on. If the documented degree of parallelism and concurrency level for this service does not fit your

needs, you can set the concurrency level for it so that its degree of parallelism and concurrency is adjusted for your workload.

Use the `MEDIUM` service for running single-user benchmarks that measure the data scan, query and DML performance for analytic workloads and set its concurrency level to 1 to allow every SQL statement to use the maximum degree of parallelism possible.

See Change MEDIUM Service Concurrency Limit (ECPU Compute Model) for more information on changing the concurrency level.

- `HIGH`: Use the `HIGH` service for low-concurrency analytic workloads, such as a reporting database that is accessed by only a few users simultaneously.

If you need to switch to a different service in the same session to run SQL statements in that service, you can use the `CS_SESSION` package to do that. See CS_SESSION Package for more information.

Database Service Names for Autonomous Data Warehouse

Describes the available service names for connecting to Autonomous Database instance with a Data Warehouse workload type.

The service names for connections to an Autonomous Database instance with a Data Warehouse workload type are in the format:

- *databasename*_high
- *databasename*_medium
- *databasename*_low

These services map to the `LOW`, `MEDIUM`, and `HIGH` consumer groups.

For example, if you create an Autonomous Database with a Data Warehouse workload type and specify the database name as `DB2024`, your service names are:

- db2024_high
- db2024_medium
- db2024_low

If you connect using the `db2024_low` service, the connection uses the `LOW` consumer group.

The basic characteristics of these consumer groups are:

- HIGH: Highest resources, lowest concurrency. Queries run in parallel.
- MEDIUM: Less resources, higher concurrency. Queries run in parallel.

  Picking one of the predefined services provides concurrency values that work well for most applications. In cases where selecting one of the default services does not meet your application's performance needs, you can use the MEDIUM service and modify the concurrency limit. For example, when you run single-user benchmarks, you can set the concurrency limit of the MEDIUM service to 1 in order to obtain the highest degree of parallelism (DOP).

  Depending on your compute model, ECPU or OCPU, see the following for more information.

  – Change MEDIUM Service Concurrency Limit (ECPU Compute Model)
  – Change MEDIUM Service Concurrency Limit (OCPU Compute Model)
- LOW: Least resources, highest concurrency. Queries run serially.

> **Note:**
>
> After connecting to the database using one service, do not attempt to manually switch that connection to a different service by simply changing the consumer group of the connection. When you connect using a service, Autonomous Database performs more actions to configure the connection than just setting its consumer group. You can use the procedure `CS_SESSION.SWITCH_SERVICE` to switch to a different service.
> See SWITCH_SERVICE Procedure for more information.

Database Service Names for Autonomous Transaction Processing and Autonomous JSON Database

Describes the available service names for connecting to Autonomous Database instance with a Transaction Processing, JSON, or APEX workload type.

The available service names for connections to an Autonomous Database instance with one of: Transaction Processing, JSON, or APEX workload type are in the format:

- *databasename*_tpurgent
- *databasename*_tp
- *databasename*_high
- *databasename*_medium
- *databasename*_low

These services map to the `TPURGENT`, `TP`, `HIGH`, `MEDIUM` and `LOW` consumer groups.

For example, if you create an Autonomous Database with a Transaction Processing workload type and specify the database name as `DB2024`, your connection service names are:

- db2024_tpurgent
- db2024_tp
- db2024_high
- db2024_medium
- db2024_low

If you connect using the `db2024_tp` service, the connection uses the `TP` consumer group.

The basic characteristics of these consumer groups are:

- TPURGENT: The highest priority application connection service for time critical transaction processing operations. This connection service supports manual parallelism.
- TP: A typical application connection service for transaction processing operations. This connection service does not run with parallelism.
- HIGH: A high priority application connection service for reporting and batch operations. All operations run in parallel and are subject to queuing.
- MEDIUM: A typical application connection service for reporting and batch operations. All operations run in parallel and are subject to queuing.

  Picking one of the predefined services provides concurrency values that work well for most applications. In cases where selecting one of the default services does not meet your

application's performance needs, you can use the MEDIUM service and modify the concurrency limit. For example, when you run single-user benchmarks, you can set the concurrency limit of the MEDIUM service to 1 in order to obtain the highest degree of parallelism (DOP).

Depending on your compute model, ECPU or OCPU, see the following for more information.

- Change MEDIUM Service Concurrency Limit (ECPU Compute Model)
- Change MEDIUM Service Concurrency Limit (OCPU Compute Model)

- LOW: A lowest priority application connection service for reporting or batch processing operations. This connection service does not run with parallelism.

> **Note:**
>
> After connecting to the database using one service, do not attempt to manually switch that connection to a different service by simply changing the consumer group of the connection. When you connect using a service, Autonomous Database performs more actions to configure the connection than just setting its consumer group. You can use the procedure `CS_SESSION.SWITCH_SERVICE` to switch to a different service.
> See SWITCH_SERVICE Procedure for more information.

Idle Time Limits

Autonomous Database has predefined idle time limits for sessions so that idle sessions do not hold system resources for a long time.

A session may be terminated if it stays idle for more than five (5) minutes and the resources it consumes are needed by other users. This allows other active sessions to proceed without waiting for the idle session.

If you want sessions to be terminated after a certain amount of time, independent of the consumed resources needed by other users, then set the `MAX_IDLE_TIME` initialization parameter. The `MAX_IDLE_TIME` parameter specifies the maximum number of minutes that a session can be idle. After the specified amount of time, `MAX_IDLE_TIME` kills sessions.

> **Note:**
>
> Sessions that are idle for more than 24 hours are terminated whether they are holding resources or not.

See Initialization Parameters for more information.

Service Concurrency

The consumer groups of the predefined service names provide different levels of performance and concurrency. The available service names are different depending on your workload: Data Warehouse, Transaction Processing, or JSON Database.

Picking one of the predefined services provides concurrency values that work well for most applications. In cases where selecting one of the default services does not meet your

application's performance needs, you can use the MEDIUM service and modify the concurrency limit. For example, when you run single-user benchmarks, you can set the concurrency limit of the MEDIUM service to 1 in order to obtain the highest degree of parallelism (DOP).

In this topic, the "number of ECPUs" is the **ECPU count** shown in the Oracle Cloud Infrastructure Console. Likewise, if your database uses the OCPU compute model, the "number of OCPUs" is the **OCPU count**.

> **Note:**
>
> OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

- Service Concurrency Limits for Data Warehouse Workloads (ECPU Compute Model)
  The `tnsnames.ora` file provided with the credentials zip file contains three database service names identifiable as high, medium, and low for Autonomous Database with Data Warehouse workloads.
- Service Concurrency Limits for Transaction Processing Workloads (ECPU Compute Model)
  The `tnsnames.ora` file provided with the credentials zip file contains five database service names identifiable as tpurgent, tp, high, medium, and low for Autonomous Database with Transaction Processing or JSON workloads.
- Service Concurrency Limits for Data Warehouse Workloads (OCPU Compute Model)
  The `tnsnames.ora` file provided with the credentials zip file contains three database service names identifiable as high, medium and low for Autonomous Database with Data Warehouse workloads.
- Service Concurrency Limits for Transaction Processing and JSON Database Workloads (OCPU Compute Model)
  The `tnsnames.ora` file provided with the credentials zip file contains five database service names identifiable as tpurgent, tp, high, medium, and low for Autonomous Database with Transaction Processing or with JSON Database workloads.

Service Concurrency Limits for Data Warehouse Workloads (ECPU Compute Model)

The `tnsnames.ora` file provided with the credentials zip file contains three database service names identifiable as high, medium, and low for Autonomous Database with Data Warehouse workloads.

The following shows the details for the number of concurrent statements for each connection service for Data Warehouse workloads, with **Compute auto scaling** disabled, and with **Compute auto scaling** enabled.

> **Note:**
>
> The values in this table apply when the number of ECPUs is equal to or greater than 4.
> When the number of ECPUs is 2, all services use the concurrency limit 150. When the number of ECPUs is 3, all services use the concurrency limit 225 (this applies for **Compute auto scaling** enabled or disabled).

Database Service Name	Number of Concurrent Queries with Compute Auto Scaling Disabled	Number of Concurrent Queries with Compute Auto Scaling Enabled
`high`	3	9
`medium`	0.25125 × number of ECPUs A decimal result is truncated.	0.75375 × number of ECPUs A decimal result is truncated.
`low`	75 × number of ECPUs	75 × number of ECPUs

> **Note:**
>
> By default the HIGH consumer group can run at least 1 SQL statement when the MEDIUM consumer group is also running statements. If you change the concurrency for the MEDIUM service, this might not apply.

The following table shows sample concurrent connections values for a database with 32 ECPUs with **Compute auto scaling** disabled and with **Compute auto scaling** enabled.

Database Service Name	Number of Concurrent Queries with Compute Auto Scaling Disabled	Number of Concurrent Queries with Compute Auto Scaling Enabled
`high`	3	9
`medium`	8	24
`low`	Up to 2400	Up to 2400

See Database Service Names for Autonomous Database and Change MEDIUM Service Concurrency Limit (ECPU Compute Model) more information.

Service Concurrency Limits for Transaction Processing Workloads (ECPU Compute Model)

The `tnsnames.ora` file provided with the credentials zip file contains five database service names identifiable as tpurgent, tp, high, medium, and low for Autonomous Database with Transaction Processing or JSON workloads.

The following shows the details for the default number of concurrent statements for each connection service for Transaction Processing or JSON workloads.

> **Note:**
>
> The values in this table apply when the number of ECPUs is equal to or greater than 4.
> When the number of ECPUs is 2, all services use the concurrency limit 150. When the number of ECPUs is 3, all services use the concurrency limit 225 (this applies for **Compute auto scaling** enabled or disabled).

Database Service Name	Concurrent Statements with Compute Auto Scaling Disabled	Concurrent Statements with Compute Auto Scaling Enabled
`tpurgent`	75 × number of ECPUs	75 × number of ECPUs
`tp`	75 × number of ECPUs	75 × number of ECPUs
`high`	3	9
`medium`	0.25125 × number of ECPUs A decimal result is truncated.	0.75375 × number of ECPUs A decimal result is truncated.
`low`	75 × number of ECPUs	75 × number of ECPUs

See Database Service Names for Autonomous Database and Change MEDIUM Service Concurrency Limit (ECPU Compute Model) more information.

Service Concurrency Limits for Data Warehouse Workloads (OCPU Compute Model)

The `tnsnames.ora` file provided with the credentials zip file contains three database service names identifiable as high, medium and low for Autonomous Database with Data Warehouse workloads.

The following shows the details for the number of concurrent statements for each connection service for Data Warehouse workloads, with OCPU auto scaling disabled, and with OCPU auto scaling enabled.

> **Note:**
>
> The values in this table apply when the number of OCPUs is greater than 1. With 1 OCPU, the concurrency limit for each service is 300 and the DOP is 1.

OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

Database Service Name	Concurrent Statements with OCPU Auto Scaling Disabled	Concurrent Statements with OCPU Auto Scaling Enabled
`high`	3	9
`medium`	1.26 × number of OCPUs	3.78 × number of OCPUs
`low`	300 × number of OCPUs	300 × number of OCPUs

The following table shows sample concurrent connections values for a database with 16 OCPUs, showing the values with both OCPU auto scaling enabled and disabled.

Database Service Name	Number of Concurrent Queries with OCPU Auto Scaling Disabled	Number of Concurrent Queries with OCPU Auto Scaling Enabled
high	3	9
medium	20	60
low	Up to 4800	Up to 4800

See Database Service Names for Autonomous Database and Change MEDIUM Service Concurrency Limit (ECPU Compute Model) more information.

Service Concurrency Limits for Transaction Processing and JSON Database Workloads (OCPU Compute Model)

The tnsnames.ora file provided with the credentials zip file contains five database service names identifiable as tpurgent, tp, high, medium, and low for Autonomous Database with Transaction Processing or with JSON Database workloads.

The following shows the details for the default number of concurrent statements for each connection service for Transaction Processing or JSON Database workloads, with OCPU auto scaling disabled, and with OCPU auto scaling enabled.

> **Note:**
>
> The values in this table apply when the number of OCPUs is greater than 1. With 1 OCPU, the concurrency limit for each service is 300 and the DOP is 1.

OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

Database Service Name	Concurrent Statements with OCPU Auto Scaling Disabled	Concurrent Statements with OCPU Auto Scaling Enabled
tpurgent	300 × number of OCPUs	300 × number of OCPUs
tp	300 × number of OCPUs	300 × number of OCPUs
high	3	9
medium	1.26 × number of OCPUs	3.78 × number of OCPUs
low	300 × number of OCPUs	300 × number of OCPUs

See Database Service Names for Autonomous Database and Change MEDIUM Service Concurrency Limit (ECPU Compute Model) more information.

Change MEDIUM Service Concurrency Limit (ECPU Compute Model)

If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.

Picking one of the predefined services provides concurrency values that work well for most applications. In cases where selecting one of the default services does not meet your application's performance needs, you can use the MEDIUM service and modify the

concurrency limit. For example, when you run single-user benchmarks, you can set the concurrency limit of the MEDIUM service to 1 in order to obtain the highest degree of parallelism (DOP).

> **Note:**
>
> Changing the concurrency limit is only allowed for an instance that has four (4) or more ECPUs.

For example, with **Compute auto scaling** disabled, if your instance is configured with 400 ECPUs, by default Autonomous Database provides a concurrency limit of 100 for the MEDIUM service:

`0.25125 x number of ECPUs` sessions (up to 100 concurrent queries). A decimal result is truncated.

In this example the MEDIUM service supports an application with up to 100 concurrent queries with DOP of 4. If you only need 50 concurrent queries and you want a higher DOP you can decrease the concurrency limit and the database increases the DOP. To do this, set the MEDIUM service concurrency limit to 50. When you change the concurrency limit the database calculates and sets the DOP based on the concurrency limit you select and the number of ECPUs. For this example, with the concurrency limit set to 50, the new DOP is 12.

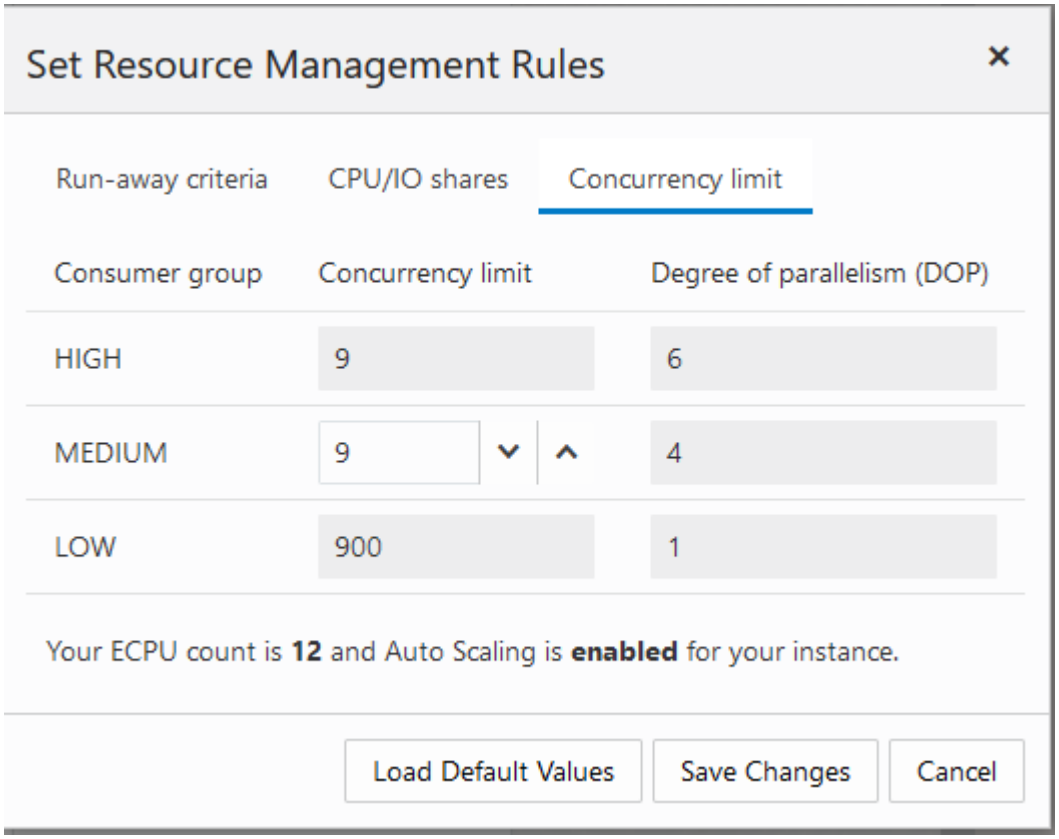
With **Compute auto scaling** enabled, the DOP is set to a value three times greater. In this example the DOP value would be 36.

You can change the concurrency limit for the MEDIUM service in Database Actions or using the PL/SQL package `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE`.

Follow these steps to change the MEDIUM service concurrency limit in Database Actions:

1. Access Database Actions as the ADMIN user.

   See Access Database Actions as ADMIN for more information.
2. On the Database Actions Launchpad, under **Administration**, click **Set Resource Management Rules**.
3. On the Set Resource Management Rules page, select the **Concurrency limit** tab.



4. For the MEDIUM service, change the value to the desired concurrency limit by entering a value or by clicking the Decrement or Increment icons.

   If the concurrency limit you specify is not valid, based on the number of ECPUs, you will receive a message such as the following, listing the valid range of values for your instance:

   ```
   Enter a number between 1 and 12.
   ```

5. Click **Save Changes**.
6. Click **OK**.

To reset the concurrency limit for the MEDIUM service to its default value, click **Load Default Values** and click **Save Changes**.

- Change MEDIUM Service Concurrency Limit with PL/SQL Procedure UPDATE_PLAN_DIRECTIVE (ECPU Compute Model)
  As an alternative to using the **Set Resource Management Rules** card in Database Actions, you can use PL/SQL to change the concurrency limit for the MEDIUM service.
- Change MEDIUM Service Concurrency Limit Notes (ECPU Compute Model)

Related Topics

- Change MEDIUM Service Concurrency Limit (OCPU Compute Model)
  If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.

Change MEDIUM Service Concurrency Limit with PL/SQL Procedure UPDATE_PLAN_DIRECTIVE (ECPU Compute Model)

As an alternative to using the **Set Resource Management Rules** card in Database Actions, you can use PL/SQL to change the concurrency limit for the MEDIUM service.

To change the MEDIUM service concurrency limit with `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE`:

1. Call the PL/SQL procedure `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE` to update the concurrency limit for the MEDIUM consumer group.

   For example, with 12 ECPUs, change the MEDIUM service's concurrency limit to 2, as follows:

   ```
   BEGIN
       CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'MEDIUM',
   concurrency_limit => 2);
   END;
   /
   ```

   If the `concurrency_limit` you specify is not valid, based on the number of ECPUs, the procedure shows an error message, listing the valid range of values for your instance. For example with 12 ECPUs:

   ```
   ORA-20000: Invalid or missing value. Concurrency limit must be between 1
   and 9 for the specified CPU count
   ```

   This error message example is from an instance with 12 ECPUs.

2. Use the PL/SQL function `CS_RESOURCE_MANAGER.LIST_CURRENT_RULES` to verify the updated MEDIUM service concurrency limit and degree of parallelism:

   ```
   SELECT * FROM CS_RESOURCE_MANAGER.LIST_CURRENT_RULES();
   ```

   This procedure returns the list of values for all consumer groups. After you modify the concurrency limit as specified in Step 1, check the MEDIUM service `CONCURRENCY_LIMIT` and `DEGREE_OF_PARALLELISM` values to verify your changes.

3. After you change the concurrency limit for the MEDIUM service, test your application by connecting with the MEDIUM service to verify that the customized concurrency limit meets your performance objectives.

When you want to go back to the default values, use the `CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES` PL/SQL procedure to revert to the default settings for the MEDIUM service.

For example:

```
BEGIN
    CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'MEDIUM',
concurrency_limit => TRUE);
END;
/
```

See CS_RESOURCE_MANAGER Package for more information.

Change MEDIUM Service Concurrency Limit Notes (ECPU Compute Model)

- Changing the concurrency limit is only allowed for the MEDIUM service.
- Changing the concurrency limit is only allowed when the number of ECPUs is greater than or equal to 4.
- Changing the concurrency limit also changes the degree of parallelism (in some cases the value does not change, depending on the magnitude of the difference between the old concurrency limit and the new value you set).
- The concurrency limit you set must be in the range:
  - With **Compute auto scaling** disabled: between 1 and `.75 x the number of ECPUs`
  - With **Compute auto scaling** enabled: between 1 and `2.25 x the number of ECPUs`
- The MEDIUM service sets the following concurrency limit and DOP values by default:

MEDIUM Database Service	Default Value with Compute Auto Scaling Disabled	Default Value with Compute Auto Scaling Enabled
Concurrency Limit	`0.25125 × number of ECPUs` when the number of ECPUs 8 A decimal result is truncated 2 when the number of ECPUs is in the range `4 ≤ ECPUs < 8`	`0.75375 × number of ECPUs` when the number of ECPUs 8 A decimal result is truncated 6 when the number of ECPUs is in the range: `4 ≤ ECPUs < 8`
DOP	4 when the number of ECPUs 8 or `TRUNC (ECPU/2)`, when the number of ECPUs < 8	4 when the number of ECPUs 8 or `TRUNC (ECPU/2)`, when the number of ECPUs < 8

- By changing the value of the concurrency limit, the DOP of the MEDIUM service can go as low as 2 and as high as `.75 * number of ECPUs` (if **Compute auto scaling** is disabled) or `2.25 x number of ECPUs` (if **Compute auto scaling** is enabled).

  See Use Auto Scaling for information on **Compute auto scaling**.
- At any time you can return to the default values for the MEDIUM service concurrency limit and DOP.

Change MEDIUM Service Concurrency Limit (OCPU Compute Model)

If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.

Picking one of the predefined services provides concurrency values that work well for most applications. In cases where selecting one of the default services does not meet your application's performance needs, you can use the MEDIUM service and modify the concurrency limit. For example, when you run single-user benchmarks, you can set the concurrency limit of the MEDIUM service to 1 in order to obtain the highest degree of parallelism (DOP).

> **Note:**
>
> Changing the concurrency limit is only allowed for an instance that has two (2) or more OCPUs.

For example, if your instance is configured with 100 OCPUs, by default Autonomous Database provides a concurrency limit of 126 for the MEDIUM service:

`1.26 x number of OCPUs` sessions (up to 126 concurrent queries)

In this example using the MEDIUM service supports an application with up to 126 concurrent queries with DOP of 4. If you only need 50 concurrent queries and you want a higher DOP you can decrease the concurrency limit and thus increase the DOP. To do this, set the MEDIUM service concurrency limit to 50. When you change the concurrency limit the system calculates and sets the DOP based on the concurrency limit you select and the number of OCPUs. For this example, with the concurrency limit set to 50, the new DOP is 12. When **OCPU auto scaling** is enabled, the DOP is set to a value three times greater. In this example the DOP value would be 36.

You can change the concurrency limit for the MEDIUM service in Database Actions or using the PL/SQL package `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE`.

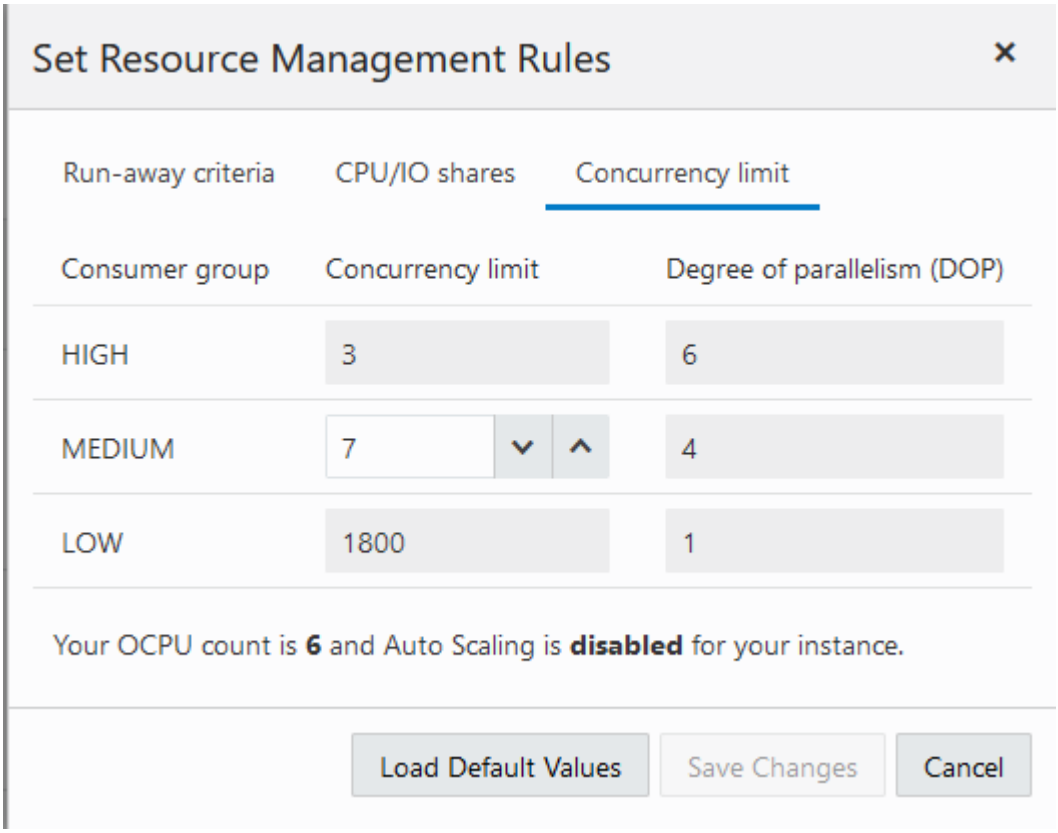
Follow these steps to change the MEDIUM service concurrency limit in Database Actions:

1. Access Database Actions as the ADMIN user.

   See Access Database Actions as ADMIN for more information.

2. On the Database Actions Launchpad, under **Administration**, click **Set Resource Management Rules**.

3. On the Set Resource Management Rules page, select the **Concurrency limit** tab.



4. For the MEDIUM service, change the value to the desired concurrency limit by entering a value or by clicking the Decrement or Increment icons.

   If the concurrency limit you specify is not valid, based on the number of OCPUs, you will receive a message such as the following, listing the valid range of values for your instance:

   ```
   Please enter a concurrency limit between 1 and 300
   ```

   This error message example is from an instance with 100 OCPUs (the 300 maximum value shown is 3 x number of OCPUs).

5. Click **Save Changes**.
6. Click **OK**.

To reset the concurrency limit for the MEDIUM service to its default value, click **Load Default Values** and click **Save Changes**.

- Change MEDIUM Service Concurrency Limit with PL/SQL Procedure UPDATE_PLAN_DIRECTIVE (OCPU Compute Model)
  As an alternative to using the **Set Resource Management Rules** card in Database Actions, you can use PL/SQL to change the concurrency limit for the MEDIUM service.
- Change MEDIUM Service Concurrency Limit Notes (OCPU Compute Model)

Related Topics

- Change MEDIUM Service Concurrency Limit (ECPU Compute Model)
  If your application requires customized concurrency, you can modify the concurrency limit for your Autonomous Database MEDIUM service.

Change MEDIUM Service Concurrency Limit with PL/SQL Procedure UPDATE_PLAN_DIRECTIVE (OCPU Compute Model)

As an alternative to using the **Set Resource Management Rules** card in Database Actions, you can use PL/SQL to change the concurrency limit for the MEDIUM service.

To change the MEDIUM service concurrency limit with `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE`:

1. Call the PL/SQL procedure `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE` to update the concurrency limit for the MEDIUM consumer group.

   For example, with 3 OCPUs, change the MEDIUM service's concurrency limit to 2, as follows:

   ```
   BEGIN
       CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'MEDIUM',
   concurrency_limit => 2);
   END;
   /
   ```

   If the `concurrency_limit` you specify is not valid, based on the number of OCPUs, you will receive a message such as the following, listing the valid range of values for your instance:

   ```
   ORA-20000: Invalid or missing value. Concurrency limit must be between 1
   and 9 for the specified OCPU count
   ```

   This error message example is from an instance with 3 OCPUs.

2. Use the PL/SQL function `CS_RESOURCE_MANAGER.LIST_CURRENT_RULES` to verify the updated MEDIUM service concurrency limit and degree of parallelism:

   ```
   SELECT * FROM CS_RESOURCE_MANAGER.LIST_CURRENT_RULES();

   CONSUMER_GROUP ELAPSED_TIME_LIMIT IO_MEGABYTES_LIMIT SHARES
   CONCURRENCY_LIMIT DEGREE_OF_PARALLELISM
   -------------- ----------------- ----------------- ------
   ---------------- --------------------
   HIGH
   4                3                    3
   MEDIUM
   2                2                    9
   LOW                                                    1
   900                    1
   ```

   This procedure returns the list of values for all consumer groups. After you modify the concurrency limit as specified in Step 1, check the MEDIUM service `CONCURRENCY_LIMIT` and `DEGREE_OF_PARALLELISM` values to verify your changes.

3. After you change the concurrency limit for the MEDIUM service, test your application by connecting with the MEDIUM service to verify that the customized concurrency limit meets your performance objectives.

When you want to go back to the default values, use the `CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES` PL/SQL procedure to revert to the default settings for the MEDIUM service.

For example:

```
BEGIN
    CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'MEDIUM',
concurrency_limit => TRUE);
END;
/
```

See CS_RESOURCE_MANAGER Package for more information.

Change MEDIUM Service Concurrency Limit Notes (OCPU Compute Model)

- Changing the concurrency limit is only allowed for the MEDIUM service.
- Changing the concurrency limit is only allowed when the number of OCPUs is greater than 1.
- Changing the concurrency limit also changes the degree of parallelism (in most cases, depending on the magnitude of the difference between the old concurrency limit and the new value you set).
- The concurrency limit you set must be in the range:
  - With **OCPU auto scaling** disabled: between: `1` and `3 x the number of OCPUs`
  - With **OCPU auto scaling** enabled: between `1` and `9 x the number of OCPUs`
- The MEDIUM service sets the following concurrency limit and DOP values by default:

MEDIUM Database Service	Default Value with OCPU Auto Scaling Disabled	Default Value with OCPU Auto Scaling Enabled
Concurrency Limit	1.26 × number of OCPUs when the number of OCPUs 4 5 when the number of OCPUs < 4	3.78 × number of OCPUs when the number of OCPUs 4 15 when the number of OCPUs < 4
DOP	4 when the number of OCPUs 4 or The number of OCPUs, when the number of OCPUs < 4	4 when the number of OCPUs 4 or The number of OCPUs, when the number of OCPUs < 4

- By changing the value of the concurrency limit, the DOP of the MEDIUM service can go as low as 2 and as high as: `2 x number of OCPUs` (if compute auto scaling is disabled) or `6 x number of OCPUs` (if compute auto scaling is enabled).

  See Use Auto Scaling for information on compute auto scaling.
- At any time you can return to the default values for the MEDIUM service concurrency limit and DOP.

Predefined Job Classes with Oracle Scheduler

Autonomous Database includes predefined `job_class` values to use with Oracle Scheduler.

The predefined `job_class` values, `TPURGENT`, `TP`, `HIGH`, `MEDIUM` and `LOW` map to the corresponding consumer groups. These job classes allow you to specify the consumer group a job runs in with `DBMS_SCHEDULER.CREATE_JOB`.

The `DBMS_SCHEDULER.CREATE_JOB` procedure supports `PLSQL_BLOCK` and `STORED_PROCEDURE` job types for the `job_type` parameter in Autonomous Database.

For example: use the following to create a single regular job to run in `HIGH` consumer group:

```
BEGIN
   DBMS_SCHEDULER.CREATE_JOB (
     job_name => 'update_sales',
     job_type => 'STORED_PROCEDURE',
     job_action => 'OPS.SALES_PKG.UPDATE_SALES_SUMMARY',
     start_date => '28-APR-19 07.00.00 PM Australia/Sydney',
     repeat_interval => 'FREQ=DAILY;INTERVAL=2',
     end_date => '20-NOV-19 07.00.00 PM Australia/Sydney',
     auto_drop => FALSE,
     job_class => 'HIGH',
     comments => 'My new job');
END;
/
```

Notes for Oracle Scheduler:

- To use `DBMS_SCHEDULER.CREATE_JOB` additional grants for specific roles or privileges might be required. The `ADMIN` user and users with `DWROLE` have the required `CREATE SESSION` and `CREATE JOB` privileges. If a user does not have `DWROLE` then grants are required for `CREATE SESSION` and `CREATE JOB` privileges.
- The `instance_id` job attribute is ignored for Oracle Scheduler jobs running on Autonomous Database.

See Scheduling Jobs with Oracle Scheduler for more information on Oracle Scheduler and `DBMS_SCHEDULER.CREATE_JOB`.

See SET_ATTRIBUTE Procedure for information on job attributes.

Manage CPU/IO Shares on Autonomous Database

Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can modify these predefined CPU/IO shares if your workload requires different CPU/IO resource allocations.

The CPU/IO shares assigned to the consumer groups determine the CPU/IO resources a consumer group can use with respect to the other consumer groups. The default CPU/IO shares depend on the Autonomous Database workload.

The CPU shares assigned to each service determine how much CPU and IO the sessions using those services will get when CPU utilization in your database reaches 100%. In that case, each service will get CPU and IO resources proportional to its assigned CPU shares. The Oracle internal processes that run as automated tasks on Autonomous Database, such as automatic optimizer statistics gathering, run with a resource share of 1.

Workload Type	Details
Data Warehouse	By default, the CPU/IO shares assigned to the consumer groups HIGH, MEDIUM, LOW are 4, 2, and 1, respectively. With the default settings the consumer group HIGH will be able to use 4 times more CPU/IO resources compared to LOW and 2 times more CPU/IO resources compared to MEDIUM, when needed. The consumer group MEDIUM will be able to use 2 times more CPU/IO resources compared to LOW, when needed.
Transaction Processing JSON Database	By default, the CPU/IO shares assigned to the consumer groups TPURGENT, TP, HIGH, MEDIUM, and LOW are 12, 8, 4, 2, and 1, respectively. With the default settings the consumer group TPURGENT will be able to use 12 times more CPU/IO resources compared to LOW, when needed. The consumer group TP will be able to use 4 times more CPU/IO resources compared to MEDIUM, when needed.

You can set CPU/IO shares in Database Actions or using the PL/SQL package `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE`.

To use Database Actions to change the CPU/IO share values for consumer groups:

1. Access Database Actions as the ADMIN user.

   See Access Database Actions as ADMIN for more information.
2. On the Database Actions Launchpad, under **Administration**, click **Set Resource Management Rules**.
3. Select the **CPU/IO shares** tab to set CPU/IO share values for consumer groups.
4. Set the desired CPU/IO share value for a consumer group by entering a value or by clicking the Decrement or Increment icons.
5. Click **Save Changes**.
6. Click **OK**.

To reset CPU/IO shares values to the defaults, click **Load Default Values** and click **Save Changes** to apply the populated values.

As an alternative to using Database Actions, you can use the PL/SQL procedure `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE` to change the CPU/IO share values for consumer groups.

For example, on an Autonomous Data Warehouse database, run the following script as the `ADMIN` user to set the CPU/IO shares to 8, 2, and 1 for consumer groups HIGH, MEDIUM, and LOW respectively. This allows the consumer group HIGH to use 4 times more CPU/IO resources compared to the consumer group MEDIUM and 8 times CPU/IO resources compared to the consumer group LOW:

```
BEGIN
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'HIGH', shares => 8);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'MEDIUM', shares => 2);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'LOW', shares => 1);
END;
/
```

For example, on an Autonomous JSON Database or on an Autonomous Transaction Processing database, run the following script as the ADMIN user to set CPU/IO shares to 12, 4, 2, 1, and 1 for the consumer groups TPURGENT, TP, HIGH, MEDIUM, and LOW respectively. This allows the consumer group TPURGENT to use 3 times more CPU/IO

resources compared to the consumer group TP and 12 times CPU/IO resources compared to the consumer group MEDIUM:

```
BEGIN
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'TPURGENT', shares => 12);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'TP', shares => 4);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'HIGH', shares => 2);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'MEDIUM', shares => 1);
   CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'LOW', shares => 1);
END;
/
```

When you want to go back to the default shares values you can use the PL/SQL procedure `CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES` to revert to the default settings.

For example, on an Autonomous Data Warehouse database, run the following script as the `ADMIN` user to set the CPU/IO shares to default values for the consumer groups HIGH, MEDIUM, and LOW:

```
BEGIN
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'HIGH', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'MEDIUM', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'LOW', shares => TRUE);
END;
/
```

For example, on an or on an Autonomous JSON Database or on an Autonomous Transaction Processing database, run the following script as the ADMIN user to set the default values for CPU/IO shares for the consumer groups TPURGENT, TP, HIGH, MEDIUM, and LOW:

```
BEGIN
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'TPURGENT', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'TP', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'HIGH', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'MEDIUM', shares => TRUE);
   CS_RESOURCE_MANAGER.REVERT_TO_DEFAULT_VALUES(consumer_group => 'LOW', shares => TRUE);
END;
/
```

See CS_RESOURCE_MANAGER Package for more information.

Manage Runaway SQL Statements on Autonomous Database

Specifies how you configure Autonomous Database to terminate SQL statements automatically based on their query runtime or their IO usage.

You can set runtime run-away rules for query run time and IO usage in Database Actions or using the PL/SQL package `CS_RESOURCE_MANAGER`.

Follow these steps to use Database Actions to set runtime usage rules:

1. Access Database Actions as the ADMIN user.

   See Access Database Actions as ADMIN for more information.

2. On the Database Actions Launchpad, under **Administration**, click **Set Resource Management Rules**.
3. Select the **Run-away criteria** tab to set usage rules for a consumer group.
4. Select the **Consumer group**.
5. Set runaway criteria values:
   - **Query run time (seconds)**
   - **Amount of IO (MB)**
6. Click **Save Changes**.
7. Click **OK**.

When a SQL statement in the specified consumer group runs more than the specified runtime limit or does more IO than the specified amount, then the SQL statement will be terminated.

Click **Load Default Values** to load the default values; then click **Save Changes** to apply the populated values.

You can also use the procedure `CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE` to set these rules. For example, to set a runtime limit of 120 seconds and an IO limit of 1000MB for the HIGH consumer group run the following command when connected to the database as the ADMIN user:

```
BEGIN
     CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'HIGH',
io_megabytes_limit => 1000, elapsed_time_limit => 120);
END;
/
```

To reset the values and lift the limits, you can set the values to null:

```
BEGIN
     CS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(consumer_group => 'HIGH',
io_megabytes_limit => null, elapsed_time_limit => null);
END;
/
```

See CS_RESOURCE_MANAGER Package for more information.

Use Fast Ingest on Autonomous Database

Fast ingest optimizes the processing of high-frequency, single-row data inserts into the database from applications, such as Internet of Things (IoT) applications, to improve data insert performance.

The intent of fast-ingest is to support applications that generate lots of informational data that has important value in the aggregate but that doesn't necessarily require full ACID guarantees. Many applications in the Internet of Things (IoT) have a rapid "fire and forget" type workload, such as sensor data, smart meter data or even traffic cameras. For these applications, data might be collected and written to the database in high volumes for later analysis.

Fast ingest is very different from normal Oracle Database transaction processing where data is logged and never lost once "written" to the database (that is, committed). In order to achieve the maximum ingest throughput, the normal Oracle transaction mechanisms are bypassed, and it is the responsibility of the application to check to see that all data was indeed written to

the database. Special APIs have been added that can be called to check if the data has been written to the database.

For information on fast ingest and the steps involved in using this feature, refer to Using Fast Ingest in *Database Performance Tuning Guide*.

In addition, the following are required to use Fast Ingest on Autonomous Database:

- **Enable the Optimizer to Use Hints**:
  To use fast ingest with Autonomous Database, you must enable the optimizer to use hints by setting the `optimizer_ignore_hints` parameter to `FALSE` at the session or system level, as appropriate.

  Depending on your Autonomous Database workload type, by default `optimizer_ignore_hints` may be set to `FALSE` at the system level. See Manage Optimizer Statistics on Autonomous Database for more information.
- **Create a Table for Fast Ingest**:
  Prerequisites for Fast Ingest Table contains the limitations for tables to be eligible for Fast Ingest (tables with the specified characteristics cannot use fast ingest).

Enable Database Management Service to Monitor and Manage Autonomous Database

You can use the Diagnostics & Management features in the Database Management service for advanced monitoring and management of Autonomous Databases.

> **Note:**
>
> Certain metrics and Performance Hub features are available free of cost for Autonomous Databases, however, you must create a private endpoint to enable communication and enable Database Management to use the advanced monitoring and management features, which are available at an additional cost.

Prerequisite Steps to Use Database Management Diagnostics & Management for Autonomous Databases:

Before you enable Database Management Diagnostics & Management for an Autonomous Database:

- Complete the general Oracle Cloud Infrastructure prerequisite tasks listed in Perform General Oracle Cloud Infrastructure Prerequisite Tasks.
- Obtain the permissions required to enable Diagnostics & Management for Autonomous Databases, as detailed in Permissions Required to Enable Diagnostics & Management for Autonomous Databases.
- Complete the Autonomous Database-specific prerequisite tasks listed in Autonomous Database-related Prerequisite Tasks.

Enable Database Management Diagnostics & Management for an Autonomous Database Instance:

To enable Database Management Diagnostics & Management for an Autonomous Database instance:

1. On the Autonomous Database details page, under Associated Services, in the **Database Management** field, click **Enable**.

2. On the **Enable Database Management** panel, enter the required information and click **Enable Database Management**. See Enable Diagnostics & Management for Autonomous Databases for more information.

After you enable Diagnostics & Management features in Database Management, you can use the full suite of available capabilities to monitor and manage a single Autonomous Database or a fleet of Autonomous Databases.

Here are some of the important performance monitoring and administration-related features:

- Database fleet overview to monitor multiple databases in one location
- Performance Hub for real-time monitoring of the database workload
- AWR Explorer to visualize AWR data over time
- SQL Monitoring to view top and current running SQL statements with detailed execution statistics
- SQL performance tuning to optimize database performance
- AWR and ADDM reports for in-depth performance analysis
- User administration to track configuration and details of database users
- Parameter configuration to update and monitor database configuration parameters
- Database jobs to streamline collections and run at scale utilizing Database Groups

See the following for more information on these features:

- Monitor the Health of Your Oracle Database Fleet
- Monitor and Manage a Specific Managed Database
- Diagnostics & Management Feature Support Matrix for Oracle Databases

Perform SQL Tracing on Autonomous Database

Use SQL tracing to help you identify the source of an excessive database workload, such as a high load SQL statement in your application.

- Configure SQL Tracing on Autonomous Database
  Shows the steps to configure SQL tracing on Autonomous Database.
- Enable SQL Tracing on Autonomous Database
  Shows the steps to enable SQL tracing for the database session.
- Disable SQL Tracing on Autonomous Database
  Shows the steps to disable SQL tracing on Autonomous Database.
- View Trace File Saved to Cloud Object Store on Autonomous Database
  Describes the output file naming for SQL trace files and shows the commands to use `TKPROF` to organize and view trace file data.
- View Trace Data in SESSION_CLOUD_TRACE View on Autonomous Database
  When you enable SQL Tracing, the same trace information that is saved to the trace file on Cloud Object Store is available in the `SESSION_CLOUD_TRACE` view in the session where the tracing was enabled.

Configure SQL Tracing on Autonomous Database

Shows the steps to configure SQL tracing on Autonomous Database.

> **Note:**
>
> If you enable SQL Tracing your application performance for the session may be degraded while the trace collection is enabled. This negative performance impact is expected due to the overhead of collecting and saving trace data.

To configure your database for SQL tracing, do the following:

1. Create a bucket to store trace files in your Cloud Object Storage.

   To save the SQL tracing files, the bucket can be in any Cloud Object Store that Autonomous Database supports.

   For example, to create a bucket in Oracle Cloud Infrastructure Object Storage, do the following

   a. Open the Oracle Cloud Infrastructure Console.

   b. Select **Storage** from the menu.

   c. Under Storage, select **Object Storage and Archive Storage**.

   d. Click **Create Bucket**.

   e. In the Create Bucket page, enter the **Bucket Name** and click **Create**.

   If you are using an Oracle Cloud Infrastructure Object Storage, note that SQL tracing files are only supported with buckets created in the standard storage tier, make sure you pick **Standard** as the storage tier when creating your bucket. See Overview of Object Storage for information on the Standard Object Storage Tier.

2. Create a credential for your Cloud Object Storage account using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
   );
   END;
   /
   ```

   For Oracle Cloud Infrastructure the `username` is your Oracle Cloud Infrastructure user name. The `password` is your Oracle Cloud Infrastructure auth token. See Working with Auth Tokens for more information.

   See CREATE_CREDENTIAL Procedure for details on the parameters and their values, depending on the Cloud Object Storage.

3. Set initialization parameters to specify the Cloud Object Storage URL for a bucket for SQL trace files and to specify the credentials to access the Cloud Object Storage.

a. Set database property `DEFAULT_LOGGING_BUCKET` to specify the logging bucket on Cloud Object Storage.

   For example, if you create the bucket with Oracle Cloud Infrastructure Object Storage:

   ```
   SET DEFINE OFF;
   ALTER DATABASE PROPERTY SET
      DEFAULT_LOGGING_BUCKET = 'https://objectstorage.us-
   ashburn-1.oraclecloud.com/n/namespace-string/b/bucket_name/o/';
   ```

   Where *namespace-string* is the Oracle Cloud Infrastructure Object Storage namespace and *bucket_name* is the name of the bucket you previously created. See Understanding Object Storage Namespaces for more information.

   See Regions and Availability Domains for a list of regions.

   The Cloud Object Store you use for SQL Tracing files can be any Cloud Object Store that Autonomous Database supports.

b. Set the database property `DEFAULT_CREDENTIAL` to the credential you created in Step 2.

   Including the schema name with the credential is required. In this example the schema is "`ADMIN`".

   For example:

   ```
   ALTER DATABASE PROPERTY SET DEFAULT_CREDENTIAL = 'ADMIN.DEF_CRED_NAME';
   ```

Enable SQL Tracing on Autonomous Database

Shows the steps to enable SQL tracing for the database session.

> **Note:**
>
> If you enable SQL tracing your application performance for the session may be degraded while the trace collection is enabled. This negative performance impact is expected due to the overhead of collecting and saving trace data.

Before you enable SQL tracing you must configure the database to save SQL Trace files. See Configure SQL Tracing on Autonomous Database for more information.

To enable SQL tracing, do the following:

1. (Optional) Set a client identifier for the application. This step is optional but is recommended. SQL tracing uses the client identifier as a component of the trace file name when the trace file is written to Cloud Object Store.

   For example:

   ```
   BEGIN
     DBMS_SESSION.SET_IDENTIFIER('sqlt_test');
   END;
   /
   ```

2. (Optional) Set a module name for the application. This step is optional but is recommended. SQL tracing uses the module name as a component of the trace file name when the trace file is written to Cloud Object Store.

   For example:

   ```
   BEGIN
     DBMS_APPLICATION_INFO.SET_MODULE('modname', null);
   END;
   /
   ```

3. Enable the SQL Trace facility.

   ```
   ALTER SESSION SET SQL_TRACE = TRUE;
   ```

4. Run your workload.

   This step involves running the entire application or specific parts of the application. While you run your workload in the database session, SQL tracing data is collected.

5. Disable SQL Tracing.

   When you disable SQL tracing the collected data for the session is written to a table in your session and to a trace file in the bucket you configure when you set up SQL tracing. See Disable SQL Tracing on Autonomous Database for details.

Disable SQL Tracing on Autonomous Database

Shows the steps to disable SQL tracing on Autonomous Database.

To disable SQL tracing, do the following:

1. Disable the SQL Trace facility.

   ```
   ALTER SESSION SET SQL_TRACE = FALSE;
   ```

2. (Optional) as needed for your environment, you may want to reset the database property `DEFAULT_LOGGING_BUCKET` to clear the value for the logging bucket on Cloud Object Storage.

   For example:

   ```
   ALTER DATABASE PROPERTY SET DEFAULT_LOGGING_BUCKET = '';
   ```

When you disable SQL tracing, the tracing data collected while the session runs with tracing enabled is copied to a table and sent to a trace file on Cloud Object Store. You have two options to view trace data:

- View and analyze SQL Trace data in the trace file saved to Cloud Object Store. See View Trace File Saved to Cloud Object Store on Autonomous Database for more information.
- View and analyze SQL Trace data saved to the view `SESSION_CLOUD_TRACE`. See View Trace Data in SESSION_CLOUD_TRACE View on Autonomous Database for more information.

View Trace File Saved to Cloud Object Store on Autonomous Database

Describes the output file naming for SQL trace files and shows the commands to use `TKPROF` to organize and view trace file data.

You use SQL trace file data to analyze application performance on Autonomous Database. When you disable SQL trace in your database session, data is written to the Cloud Object Store bucket configured with `DEFAULT_LOGGING_BUCKET`.

The SQL Trace facility writes the trace data collected in the session to Cloud Object Store in the following format:

default_logging_bucket`/sqltrace/`*`clientID`*`/`*`moduleName`*`/sqltrace_`*`numID1`*`_`*`numID2`*`.trc`

The components of the file name are:

- *default_logging_bucket*: is the value of the `DEFAULT_LOGGING_BUCKET` database property. See Configure SQL Tracing on Autonomous Database for more information.
- *`clientID`*: is the client identifier. See Enable SQL Tracing on Autonomous Database for more information.
- *`moduleName`*: is the module name. See Enable SQL Tracing on Autonomous Database for more information.
- *`numID1`*`_`*`numID2`*: are two identifiers that the SQL Trace facility provides. The *`numID1`* and *`numID2`* numeric values uniquely distinguish each trace file name from other sessions using tracing and creating trace files in the same bucket in the Cloud Object Storage.

  When the database service supports parallelism and a session runs a parallel query, the SQL Trace facility can produce multiple trace files with different *`numID1`* and *`numID2`* values.

> **Note:**
>
> When SQL tracing is enabled and disabled multiple times within the same session, each trace iteration generates a separate trace file in Cloud Object Store. To avoid overwriting previous traces that were generated in the session, subsequently generated files follow the same naming convention and add a numeric suffix to the trace file name. This numeric suffix starts with the number 1 and is incremented by 1 for each tracing iteration thereafter.

For example, the following is a sample generated trace file name when you set the client identifier to "`sql_test`" and the module name to "`modname`":

```
sqltrace/sqlt_test/modname/sqltrace_5415_56432.trc
```

You can run `TKPROF` to translate the trace file into a readable output file.

1. Copy the trace file from Object Store to your local system.
2. Navigate to the directory in which the trace file is saved.
3. Run the `TKPROF` utility from the operating system prompt using the following syntax:

```
tkprof filename1 filename2 [waits=yes|no] [sort=option] [print=n]
    [aggregate=yes|no] [insert=filename3] [sys=yes|no] [table=schema.table]
    [explain=user/password] [record=filename4] [width=n]
```

The input and output files are the only required arguments.

4. To view online Help, invoke `TKPROF` without arguments.

See "Tools for End-to-End Application Tracing" in Oracle Database SQL Tuning Guide for information about using the `TKPROF` utility.

View Trace Data in SESSION_CLOUD_TRACE View on Autonomous Database

When you enable SQL Tracing, the same trace information that is saved to the trace file on Cloud Object Store is available in the `SESSION_CLOUD_TRACE` view in the session where the tracing was enabled.

While you are still in the database session you can view SQL tracing data in the `SESSION_CLOUD_TRACE` view. The `SESSION_CLOUD_TRACE` view includes two columns: `ROW_NUMBER` and `TRACE`:

```
DESC SESSION_CLOUD_TRACE

Name       Null? Type
---------- ----- ------------------------------
ROW_NUMBER       NUMBER
TRACE            VARCHAR2(32767)
```

The `ROW_NUMBER` specifies the ordering for trace data found in the `TRACE` column. Each line of trace output written to a trace file becomes a row in the table and is available in the `TRACE` column.

After you disable SQL tracing for the session, you can run queries on the `SESSION_CLOUD_TRACE` view.

For example:

```
SELECT trace FROM SESSION_CLOUD_TRACE ORDER BY row_number;
```

The data in `SESSION_CLOUD_TRACE` persists for the duration of the session. After you log out or close the session, the data is no longer available.

If SQL Trace is enabled and disabled multiple times within the same session, `SESSION_CLOUD_TRACE` shows the trace data for all the iterations cumulatively. Thus, re-enabling tracing in a session after previously disabling tracing does not remove the trace data produced by the earlier iteration.

Monitor Performance with Autonomous Database Metrics

You can monitor the health, capacity, and performance of your databases with metrics, alarms, and notifications. You can use Oracle Cloud Infrastructure Console or Monitoring APIs to view metrics.

- View Metrics for an Autonomous Database Instance
  Shows the steps to view the Autonomous Database metrics.
- View Metrics for Autonomous Databases in a Compartment
  Shows the steps to view metrics for Autonomous Databases in a compartment.

- Autonomous Database Metrics and Dimensions
  You can limit the instances where you see metrics with dimensions. The available dimensions include: workload type, instance display name, region, and the instance OCID.
- Use Custom Metrics on Autonomous Database
  Describes how to create and publish custom metrics on Autonomous Database.

View Metrics for an Autonomous Database Instance

Shows the steps to view the Autonomous Database metrics.

To view metrics you must have the required access as specified in an Oracle Cloud Infrastructure policy (whether you're using the Console, the REST API, or another tool). See Getting Started with Policies for information on policies.

Perform the following steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To view metrics for an Autonomous Database instance:

1. On the Autonomous Database Details page, select the **Monitoring** tab.
2. There is a chart for each metric. In each chart you can select the **Interval** and **Statistic** or use the default values.

> **Note:**
>
> The following table shows the default metrics shown on the Oracle Cloud Infrastructure Console **Monitoring** tab.
> See Available Metrics: oci_autonomous_database for a list of all the database metrics and dimensions.

Metric Name	Description
CPU utilization	CPU utilization expressed as a percentage, aggregated across all consumer groups. The utilization percentage is reported with respect to the number of CPUs the database is allowed to use, which is the number of ECPUs. If your database uses OCPUs, the number of CPUs allowed is two times the number of OCPUs.
Storage utilization	The percentage of provisioned storage capacity currently in use. Represents the total allocated space for all tablespaces.
Sessions	The number of sessions in the database.
Execute count	The number of user and recursive calls that ran SQL statements during the selected interval.
Running statements	The number of running SQL statements, aggregated across all consumer groups, during the selected interval.

Metric Name	Description
Queued statements	The number of queued SQL statements, aggregated across all consumer groups, during the selected interval.
Database availability	The database is available for connections during the selected time interval (data for this metric lags by 5 minutes). Possible values for this metric: • 1 = Database is Available • 0 = Database is Unavailable You can set an alarm that is triggered if the database is not available (value 0). **Note:** Availability is calculated based on the "Monthly Uptime Percentage" described in the Oracle PaaS and IaaS Public Cloud Services Pillar Document document under **Delivery Policies** (see Autonomous Database Availability Service Level Agreement).
Failed connections	Shows the total number of failed connections to the database during the selected interval. A connection is counted as failed when a connection attempt reaches the database and logs any of the following errors: `ORA-12514`, `ORA-12519` or `ORA-12529`.

To create an alarm on a metric, in a metric chart or table, select ... and in the menu select **Create an alarm on this query**. See Managing Alarms for information on setting and using alarms.

For more information about metrics see Available Metrics: oci_autonomous_database.

You can also use the Monitoring API to view metrics. See Monitoring API for more information.

- View Logs and Audit Trails
  Shows the steps to view the Autonomous Database logs and audit trails.

View Logs and Audit Trails

Shows the steps to view the Autonomous Database logs and audit trails.

Note:

To view logs and audit trials you must have the required access as specified in an Oracle Cloud Infrastructure policy (whether you're using the Console, the REST API, or another tool). See Getting Started with Policies for information on policies.

To view audit trails and logs for an Autonomous Database instance:

1. On the Details page, select the **Monitoring** tab.

2. On the Monitoring tab, click the **view audit and logs** link.
   - In the Logging area, click **Logs** to view log information.
   - In the logging area, click **Audit** to view audit information.

See Audit Autonomous Database and Audit Logs for more information.

View Metrics for Autonomous Databases in a Compartment

Shows the steps to view metrics for Autonomous Databases in a compartment.

To view metrics you must have the required access as specified in an Oracle Cloud Infrastructure policy (whether you're using the Console, the REST API, or other tool). See Getting Started with Policies for information on policies.

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the left navigation list click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.

To use the metrics service to view Autonomous Database metrics:

1. On the Service Metrics page, under **Compartment** select your compartment.
2. On the Service Metrics page, under **Metric Namespace** select **oci_autonomous_database**.
3. If there are multiple Autonomous Databases in the compartment you can show metrics aggregated across the Autonomous Databases by selecting **Aggregate Metric Streams**.
4. If you want to limit the metrics you see, next to **Dimensions** click **Add** (click **Edit** if you have already added dimensions).
   a. In the **Dimension Name** field select a dimension.
   b. In the **Dimension Value** field select a value.
   c. Click **Done**.

   In the Edit dimensions dialog click **+Additional Dimension** to add an additional dimension. Click **x** to remove a dimension.

To create an alarm on a specific metric, click **Options** and select **Create an Alarm on this Query**. See Managing Alarms for information on setting and using alarms.

Autonomous Database Metrics and Dimensions

You can limit the instances where you see metrics with dimensions. The available dimensions include: workload type, instance display name, region, and the instance OCID.

Use dimensions by selecting values in the Oracle Cloud Infrastructure Console Service Metrics page or by setting dimension values with the API. See View Metrics for Autonomous Databases in a Compartment to view metrics and to select metric dimensions.

Use Custom Metrics on Autonomous Database

Describes how to create and publish custom metrics on Autonomous Database.

Autonomous Database provides many database related metrics that are available through the OCI Monitoring service. In addition, you can create custom metrics to collect, publish, and analyze your own metrics. A custom metric collects specified data from your Autonomous

Database instance and publishes the data to the OCI Monitoring service using a REST API provided by the OCI SDK.

Prerequisites

1. Obtain Oracle Cloud Infrastructure access through Oracle Cloud Free Tier or a paid Cloud Account.

   See Get an Oracle Cloud Account for more information.

2. Create an Autonomous Database instance or have access to an existing Autonomous Database instance.

   See Provision an Autonomous Database Instance for more information.

3. Obtain ADMIN credentials for your Autonomous Database instance.

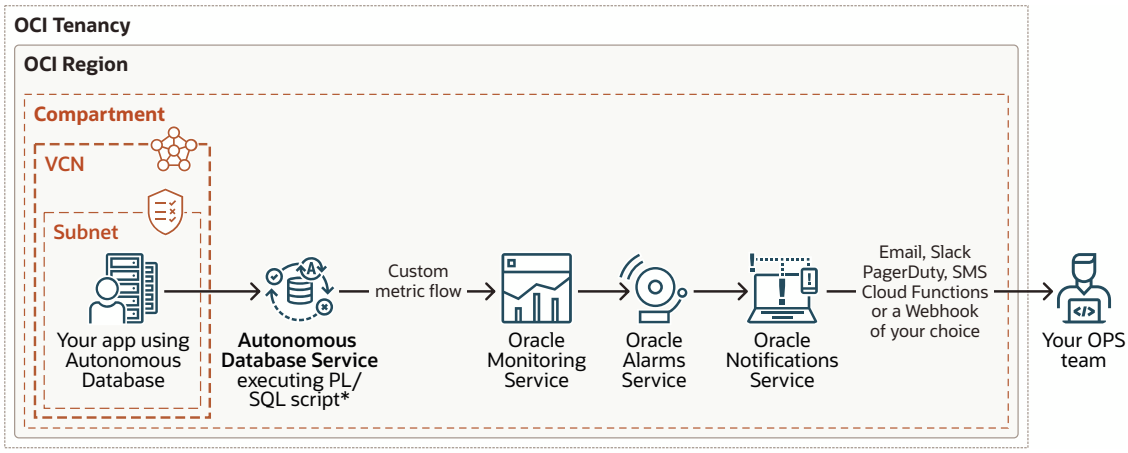
4. Use Database Actions or any of the Oracle Database clients, such as SQL Developer or SQL*Plus to connect to the database.

   See Connect to Autonomous Database for more information.

5. You need access to the OCI Monitoring service and OCI Identity and Access Management. See Publishing Custom Metrics Using the API for more information.

Overview of Custom Metrics with OCI Monitoring Service

The following figure shows the steps to create and publish custom metrics on Autonomous Database. This shows that you collect metric data with a script running on your Autonomous Database instance and you publish this data to the OCI Monitoring service, and how you can create alarms and notifications for metric values.



- Create and deploy a PL/SQL script on your Autonomous Database instance. This script runs periodically to compute, collect, and publish custom metrics to the OCI Monitoring service.
- The Autonomous Database instance can be on a public or on a private endpoint. The communication between the Autonomous Database instance and the OCI Monitoring service takes place on the Oracle Cloud network. This means, to publish metrics on the OCI Monitoring service you do not need to create a service gateway.

Create and Publish Custom Metrics

To create and publish custom metrics:

1. In OCI Identity and Access Management create a dynamic group for your Autonomous Database instance and create a policy to authorize the dynamic group to post metrics to the OCI Monitoring service.

   For example:

   a. In the Oracle Cloud Infrastructure console click **Identity & Security**.

   b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).

   c. Under **Identity domain**, click **Dynamic groups**.

   d. Click **Create dynamic group** and enter a **Name**, a **Description**, and a rule.

      For example, create a dynamic group named `adb_dg` for your Autonomous Database instance and create a rule:

      ```
      ALL {resource.type = 'autonomousdatabase', resource.compartment.id =
      'OCID_of_compartment'}
      ```

      Alternatively, you can select a single Autonomous Database instance instead of all the instances in the compartment:

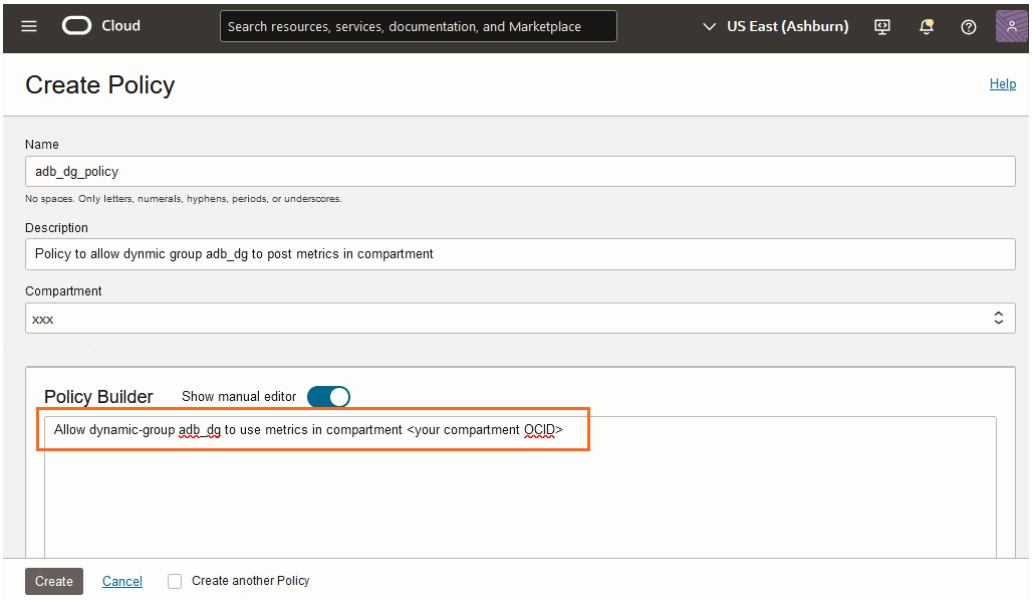
      ```
      ALL {resource.type = 'autonomousdatabase', resource.id =
      'OCID_of_autonomousdatabase_instance'}
      ```

   e. Click **Create**.

   f. Create an OCI Identity and Access Management (IAM) policy to authorize the dynamic group.

      For example, create a policy to authorize the dynamic group `adb_dg` to post metrics to the OCI Monitoring service with the policy `adb_dg_policy`:

      ```
      Allow dynamic-group adb_dg to use metrics in compartment
      OCID_of_compartment
      ```



After you define the policy, the dynamic group with the definition `adb_dg` is authorized to post metrics in the compartment.

At this point, the PL/SQL routine running on Autonomous Database can't post any metrics to the OCI Monitoring service because there are no Autonomous Database users authorized to publish metrics to the OCI Monitoring service. You provide this capability when you enable the resource principal in the following step (step 2c).

2. Create a new database user or schema with the requisite privileges in your Autonomous Database instance or update an existing database user or schema with the requisite privileges.

   For example:

   a. Create a database user or use an existing user to publish metrics. .

      For example, create a new user `ECOMMERCE_USER` on the Autonomous Database instance:

      ```
      CREATE USER ECOMMERCE_USER IDENTIFIED BY "password";
      ```

      Now you have the new user `ECOMMERCE_USER`. The following steps are the same with this user or with the user you specify. However if you create a user with a different name you need to replace `ECOMMERCE_USER` with the alternative user name.

   b. Grant requisite Oracle Database related privileges to the user.

      ```
      GRANT CREATE TABLE, ALTER ANY INDEX, CREATE PROCEDURE,
            CREATE JOB, SELECT ANY TABLE, EXECUTE ANY PROCEDURE, UPDATE ANY
      TABLE,
            CREATE SESSION, UNLIMITED TABLESPACE, CONNECT, RESOURCE
            TO ECOMMERCE_USER;
      GRANT  SELECT ON "SYS"."V_$PDBS" TO ECOMMERCE_USER;
      GRANT  EXECUTE ON "C##CLOUD$SERVICE"."DBMS_CLOUD" to ECOMMERCE_USER;
      GRANT  SELECT ON SYS.DBA_JOBS_RUNNING TO ECOMMERCE_USER;
      ```

c. Enable Oracle Database credentials for the Oracle Cloud Resource Principal and give access to the user.

   This step connects the dynamic group `adb_dg` you created in step 1 to the database user `ECOMMERCE_USER`, giving the user authorization to post metrics to the OCI Monitoring service.

   For example:

```
EXEC DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL(username =>
'ECOMMERCE_USER');
```

   See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   As an alternative to Resource Principal authentication, you can use OCI Native credentials for authentication. See CREATE_CREDENTIAL Procedure for more information.

d. (Optional) Verify the operations you completed in the previous step.

   For example:

```
SELECT OWNER, CREDENTIAL_NAME FROM DBA_CREDENTIALS WHERE
CREDENTIAL_NAME = 'OCI$RESOURCE_PRINCIPAL'  AND OWNER =  'ADMIN';
```

   To check if a user other than ADMIN has access to OCI Resource Principal, for example to check if the `ECOMMERCE_USER` has access to the database credential, use the `DBA_TAB_PRIVS` view:

```
SELECT * FROM DBA_TAB_PRIVS WHERE
DBA_TAB_PRIVS.GRANTEE='ECOMMERCE_USER';
```

3. Create a PL/SQL script that publishes metric data and schedule the script to run on your Autonomous Database instance.

   a. For example, create a PL/SQL script with a metric that counts of the rows of the Star Schema Benchmark sample data and publishes to the OCI Monitoring service.

```
CREATE OR REPLACE PROCEDURE publish_lineorder_metric (p_sql_statement
IN VARCHAR2)
IS
l_result NUMBER;
l_compartment_ocid VARCHAR2(255);
l_db_name VARCHAR2(255);
l_region VARCHAR2(255);
l_json_payload CLOB;
l_cloud_identity CLOB;
BEGIN

-- 1. Execute the SQL statement and get the result
EXECUTE IMMEDIATE p_sql_statement INTO l_result;

 -- 2. Get compartment OCID, DB name, and region from cloud identity
 SELECT cloud_identity INTO l_cloud_identity FROM v$pdbs;

 l_compartment_ocid := JSON_VALUE(l_cloud_identity,
```

```
'$.COMPARTMENT_OCID');
 l_db_name := JSON_VALUE(l_cloud_identity, '$.DATABASE_NAME');
 l_region := JSON_VALUE(l_cloud_identity, '$.REGION');

DBMS_OUTPUT.PUT_LINE(l_cloud_identity);

 -- 3. Construct the JSON payload for the metric

 l_json_payload :=
 '{' ||
 ' "metricData": [' ||
 ' {' ||
 ' "namespace": "custom_metrics",' ||
 ' "compartmentId": "' || l_compartment_ocid || '",' ||
 ' "name": "lineorder_metric",' ||
 ' "dimensions": {' ||
 ' "dbName": "' || l_db_name || '"' ||
 ' },' ||
 ' "datapoints": [' ||
 ' {' ||
 ' "timestamp": "' || TO_CHAR(SYSTIMESTAMP AT TIME ZONE 'UTC', 'YYYY-MM-
DD"T"HH24:MI:SS.FF3"Z"') || '",' ||
 ' "value": ' || l_result ||
 ' }' ||
 ' ]' ||
 ' }' ||
 ' ]' ||
 '}';

 -- 4. Publish the metric using DBMS_CLOUD.SEND_REQUEST

 DECLARE
 l_response DBMS_CLOUD_TYPES.resp;
 BEGIN
 l_response := DBMS_CLOUD.SEND_REQUEST(
 credential_name => 'OCI$RESOURCE_PRINCIPAL',
 uri => 'https://telemetry-ingestion.' || l_region || '.oraclecloud.com/
20180401/metrics',
 method => 'POST',
 body => UTL_RAW.CAST_TO_RAW(l_json_payload)
 );

 -- 5. Check response status

 IF DBMS_CLOUD.GET_RESPONSE_STATUS_CODE(l_response) = 200 THEN
 DBMS_OUTPUT.PUT_LINE('Metric published successfully!');
 ELSE
 DBMS_OUTPUT.PUT_LINE('Error publishing metric: ' ||
DBMS_CLOUD.GET_RESPONSE_STATUS_CODE(l_response));
 DBMS_OUTPUT.PUT_LINE(DBMS_CLOUD.GET_RESPONSE_TEXT(l_response));
 END IF;

 EXCEPTION
 WHEN OTHERS THEN
 DBMS_OUTPUT.PUT_LINE('Error during SEND_REQUEST: ' || SQLERRM);
 END;
```

```
EXCEPTION
 WHEN OTHERS THEN
 DBMS_OUTPUT.PUT_LINE('Error: ' || SQLERRM);
END;
/
```

See PostMetricData for more information.

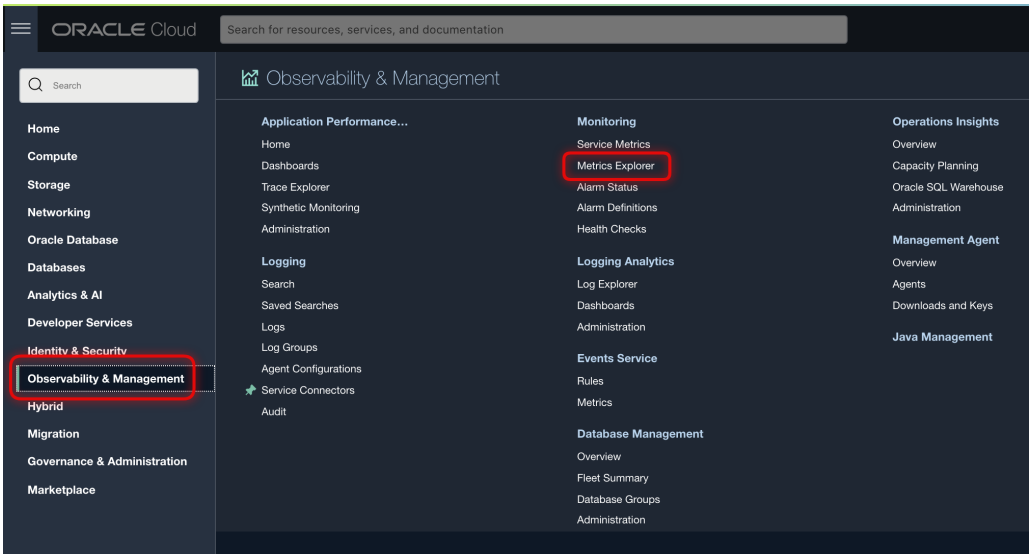
b. Schedule a job to call and publish the custom metric data point once per minute. In production the schedule would be configured to run according to your needs.

```
BEGIN
   DBMS_SCHEDULER.CREATE_JOB (
      job_name => 'publish_lineorder_count_job',
      job_type => 'STORED_PROCEDURE',
      job_action => 'ECOMMERCE_USER.publish_lineorder_metric',
      number_of_arguments => 1,
      start_date => SYSTIMESTAMP,
      repeat_interval => 'FREQ=MINUTELY;INTERVAL=1',
      enabled => FALSE,
      AUTO_DROP => FALSE,
      comments => 'Publishes the count of rows in SSB.LINEORDER every 1
minute'
);

  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE (
       job_name => 'publish_lineorder_count_job',
       argument_position => 1,
       argument_value => 'SELECT COUNT(*) FROM SSB.LINEORDER'
 );

   DBMS_SCHEDULER.ENABLE('ECOMMERCE_USER.PUBLISH_LINEORDER_COUNT_JOB');
END;
```

4. Explore the published custom metrics on the Metrics Explorer.
   a. From the Oracle Cloud Infrastructure Console navigation menu, click **Observability & Management**.
   b. Under **Observability & Management**, click **Metrics Explorer**.



c. In Metrics Explorer, select the namespace as `custom_metrics_from_adb`, `resourceGroup` as `ecommerece_adb`, and metric name as `lineorder_metric` (the name of the metric you created in the PL/SQL script).

   All the metadata and dimensions you set for custom metrics are available. You can construct Metrics Query Language (MQL) queries to analyze these metrics according to your needs and use case. You may also set up Oracle Cloud Alarms on the metric stream to alert your operational team. This automates the observability loop for the Autonomous Database metrics of your choice. Note that in the Metrics Explorer the metric screen by default shows graph view and you have the option to enable list view to highlight data points.

After you create custom metrics you can use the metrics just like any predefined metrics in OCI Monitoring service. This means you can analyze custom metrics with the Metrics Query Language (MQL) and set up alarms and notifications to notify you whenever an event of interest occurs.

See the following for more information:

- OCI Monitoring service
- PostMetricData API for publishing custom metrics
- dynamic groups and resource principles

Available Metrics: oci_autonomous_database

This topic describes the metrics emitted by the Database service in the `oci_autonomous_database` namespace.

To access a subset of the metrics from the Autonomous Database details page:

See View Metrics for an Autonomous Database Instance for details.

To access the complete metrics for the service:

See View Metrics for Autonomous Databases in a Compartment for details.

To access the metrics from the Metrics Explorer:

1. Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
2. From the Oracle Cloud Infrastructure left navigation menu click **Observability & Management**.
3. On the **Observability & Management** page, under **Monitoring**, select **Metrics Explorer**.
4. Use the **Metrics Explorer** to create a query and enter the **Metric namespace** value `oci_autonomous_database`.
5. Under Metric dimensions enter the **deploymentType** value **Shared**.
6. Enter a value in the **Metric name** field.

Database service metrics for Autonomous Databases include the following **dimensions**:

- **AUTONOMOUSDBTYPE**
  The type of Autonomous Database, Autonomous Data Warehouse (ADW) or Autonomous Transaction Processing (ATP).
- **deploymentType**
  The Exadata infrastructure type, shared or dedicated. When using the Console to view default metric charts for multiple Autonomous Databases, you must specify this dimension.

  This topic covers Oracle Autonomous Database Serverless metrics. See Monitor Databases with Autonomous Database Metrics for information on Oracle Autonomous Database on Dedicated Exadata Infrastructure metrics.
- **DISPLAYNAME**
  The friendly name of the Autonomous Database.
- **REGION**
  The **region** in which the Autonomous Database resides.
- **RESOURCEID**
  The **OCID** of the Autonomous Database.
- **RESOURCENAME**
  The name of the Autonomous Database.

The metrics listed in the following table are automatically available for any Autonomous Database that you create. You do not need to enable monitoring on the resource to get these metrics.

> **Note:**
>
> Valid alarm intervals are 5 minutes or greater due to the frequency at which these metrics are emitted. See To create an alarm for details on creating alarms.

In the following table, metrics that are marked with an asterisk (*) can be viewed only on the **Service Metrics** page of the Oracle Cloud Infrastructure console. All metrics can be filtered by the dimensions described in this topic.

Metric	Metric Display Name	Unit	Description	Collection Frequency
AverageActiveSessions	Average Active Sessions	integer	The average number of sessions that are actively executing or waiting for resources. Statistic: Mean Interval: 1 minute	1 minute
ConnectionLatency	Connection Latency	Milliseconds	The time taken to connect to an Oracle Autonomous Database Serverless instance in each region from a Compute service virtual machine in the same region. Statistic: Max Interval: 5 minutes	5 minutes
BlockingSessions	Blocking Sessions	count	The number of sessions that have been blocking other sessions for more than 60 seconds. Statistic: Max Interval: 1 minute	1 minute
ConnectionsDroppedByClient	Connections Dropped By Client	count	The number of connections dropped by the client. Statistic: Sum Interval: 1 minute	1 minute
ConnectionsDroppedByServer	Connections Dropped By Server	count	The number of connections dropped by the server. Statistic: Sum Interval: 1 minute	1 minute
CpuTime*	CPU Time	seconds per second	Average rate of accumulation of CPU time by foreground sessions in the database over the time interval. Statistic: Mean Interval: 1 minute	NA
CpuUtilization	CPU Utilization	percent	The CPU usage expressed as a percentage, aggregated across all consumer groups. The utilization percentage is reported with respect to the number of CPUs the database is allowed to use. Statistic: Mean Interval: 1 minute	NA
CurrentLogons*	Current Logons	count	The number of successful logons during the selected interval. Statistic: Count Interval: 1 minute	1 minute

Metric	Metric Display Name	Unit	Description	Collection Frequency
DatabaseAvailability	Database Availability	count	The database is available for connections during the selected time interval (data for this metric lags by 5 minutes). Possible values for this metric: • 1 = Database is Available • 0 = Database is Unavailable You can set an alarm that is triggered if the database is not available (value 0).	5 minutes

Note:

Availability is calculated based on the "Monthly Uptime Percentage" described in the Oracle PaaS and IaaS Public Cloud Services Pillar Document document under **Delivery Policies** (see Autonomous Database Availability Service Level Agreement).

Metric	Metric Display Name	Unit	Description	Collection Frequency
			Statistic: Mean Interval: 1 minute	
DBBlockChanges	DB Block Changes	count	The number of changes that were part of an update or delete operation that were made to all blocks in the SGA. Such changes generate redo log entries and become permanent changes to the database if the transaction is committed. This approximates total database work. This statistic indicates the rate at which buffers are being dirtied, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
DBTime*	DB Time	seconds per second	The amount of time database user sessions spend executing database code (CPU Time + WaitTime). DB Time is used to infer database call latency, because DB Time increases in direct proportion to both database call latency (response time) and call volume. It is calculated as the average rate of accumulation of database time by foreground sessions in the database over the time interval. Statistic: Mean Interval: 1 minute	NA
ExecuteCount	Execute Count	count	The number of user and recursive calls that executed SQL statements during the selected interval. Statistic: Sum Interval: 1 minute	NA
FailedConnections*	Failed Connections	count	The number of failed database connections. Statistic: Sum Interval: 1 minute	1 minute
FailedLogons	Failed Logons	count	The number of log ons that failed because of an invalid user name and/or password, during the selected interval. The counter is reset to 0 by a successful login. Statistic: Mean Interval: 1 minute	1 minute

Metric	Metric Display Name	Unit	Description	Collection Frequency
HardParseCount	Parse Count (Hard)	count	The number of parse calls (real parses) during the selected time interval. A hard parse is an expensive operation in terms of memory use, because it requires Oracle to allocate a workheap and other memory structures and then build a parse tree. Statistic: Sum Interval: 1 minute	1 minute
LogicalReads	Session Logical Reads	count	The sum of "db block gets" plus "consistent gets", during the selected time interval. This includes logical reads of database blocks from either the buffer cache or process private memory.	1 minute
ParseCount*	Parse Count (Total)	count	The number of hard and soft parses during the selected interval. Statistic: Sum Interval: 1 minute	1 minute
ParseFailureCount	Parse Count (Failures)	count	The number of parse failures during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
PeerLag	Peer Lag	Seconds	The total time in seconds by which the Disaster Recovery peer lags behind its Primary database. For a local Disaster Recovery peer, the metric is displayed under the Primary database. For a cross-region Disaster Recovery peer, this metric is displayed under the Disaster Recovery peer. Statistic: Max Interval: 1 minute	1 minute
PhysicalReads	Physical Reads	count	The number of data blocks read from disk, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
PhysicalReadTotalBytes	Physical Read Total Bytes	count	The size in bytes of disk reads by all database instance activity including application reads, backup and recovery, and other utilities, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute

Metric	Metric Display Name	Unit	Description	Collection Frequency
PhysicalWrites	Physical Writes	count	The number of data blocks written to disk, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
PhysicalWriteTotalBytes	Physical Write Total Bytes	count	The size in bytes of all disk writes for the database instance including application activity, backup and recovery, and other utilities, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
QueryLatency	Query Latency	Milliseconds	The time taken to display the results of a simple query on the user's screen. Statistic: Max Interval: 5 minutes	5 minutes
QueuedStatements	Queued Statements	count	The number of queued SQL statements, aggregated across all consumer groups, during the selected interval. Statistic: Sum Interval: 1 minute	NA
RedoGenerated	Redo Generated	count	Amount of redo generated in bytes, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
RunningStatements	Running Statements	count	The number of running SQL statements, aggregated across all consumer groups, during the selected interval. Statistic: Mean Interval: 1 minute	1 minute
Sessions	Sessions	count	The number of sessions in the database. Statistic: Sum Interval: 1 minute	1 minute
SessionUtilization	Session Utilization	Percent	The maximum session utilization expressed as a percentage, aggregated across all consumer groups. Statistic: Mean Interval: 1 minute	1 minute
SQLNetBytesFromClient	Bytes Received via SQL*Net from Client	count	The number of bytes received from the client over Oracle Net Services, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute

Metric	Metric Display Name	Unit	Description	Collection Frequency
SQLNetBytesFromDBLink	Bytes Received via SQL*Net from DBLink	count	The number of bytes received from a database link over Oracle Net Services, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
SQLNetBytesToClient	Bytes Sent via SQL*Net to Client	count	The number of bytes sent to the client from the foreground processes, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
SQLNetBytesToDBLink	Bytes Sent via SQL*Net to DBLink	count	The number of bytes sent over a database link, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
StorageAllocated*	Storage Space Allocated	GB	Amount of space allocated to the database for all tablespaces, during the interval. Statistic: Max Interval: 1 hour	1 hour
StorageMax	Maximum Storage Space	GB	Maximum amount of storage reserved for the database during the interval. Statistic: Max Interval: 1 hour	1 hour
StorageUsed*	Storage Space Used	GB	Maximum amount of space used during the interval. Statistic: Max Interval: 1 hour	1 hour
StorageUtilization	Storage Utilization	percent	The percentage of the reserved maximum storage currently allocated for all database tablespaces. Represents the total reserved space for all tablespaces. Statistic: Mean Interval: 1 hour	1 hour
TransactionCount*	Transaction Count	count	The combined number of user commits and user rollbacks during the selected interval. Statistic: Sum Interval: 1 minute	1 minute
UserCalls*	User Calls	count	The combined number of logons, parses, and execute calls during the selected interval. Statistic: Sum Interval: 1 minute	1 minute

Metric	Metric Display Name	Unit	Description	Collection Frequency
UserCommits	User Commits	count	The number of user commits during the selected time interval. When a user commits a transaction, the generated redo that reflects the changes made to database blocks must be written to disk. Commits often represent the closest thing to a user transaction rate. Statistic: Sum Interval: 1 minute	1 minute
UserRollbacks	User Rollbacks	count	Number of times users manually issue the ROLLBACK statement or an error occurs during a user's transactions, during the selected time interval. Statistic: Sum Interval: 1 minute	1 minute
WaitTime*	Wait Time	seconds per second	Average rate of accumulation of non-idle wait time by foreground sessions in the database over the time interval. Statistic: Mean Interval: 1 minute	1 minute

Use Sample Data Sets in Autonomous Database

For users who want to start using the service without creating their own tables, Autonomous Database provides the read-only Sales History and Star Schema Benchmark data sets.

These data sets are provided as Oracle Database schemas SH and SSB respectively. Any user can query these data sets without any manual configuration.

Notes for the Sample Data sets:

- Both the SH and SSB are provided as schema-only users, so you cannot unlock or drop those users or set a password.
- The storage size of the sample data sets is not counted towards or billed for in your database's storage.
- The sample data sets SH and SSB are not included in backups and do not impact the size or speed of either backup or restore operations.

Sales History (SH) Schema

The SH schema provides a small data set you can use to run the sample queries in the *Oracle Database Data Warehousing Guide*. Note that you need to prefix the table names with the schema name SH in your queries. For example, the following query shows you how the SQL function RANK() works:

```
SELECT channel_desc, TO_CHAR(SUM(amount_sold), '9,999,999,999') SALES$,
   RANK() OVER (ORDER BY SUM(amount_sold)) AS default_rank,
   RANK() OVER (ORDER BY SUM(amount_sold) DESC NULLS LAST) AS custom_rank
```

```
FROM sh.sales, sh.products, sh.customers, sh.times, sh.channels, sh.countries
WHERE sales.prod_id=products.prod_id AND sales.cust_id=customers.cust_id
  AND customers.country_id = countries.country_id AND
sales.time_id=times.time_id
  AND sales.channel_id=channels.channel_id
  AND times.calendar_month_desc IN ('2000-09', '2000-10')
  AND country_iso_code='US'
GROUP BY channel_desc;
```

For more information on the SH schema see *Sample Schemas* and *Schema Diagrams*.

Star Schema Benchmark (SSB) Schema

The SSB schema provides a well-known large sample data set. The SSB schema contains 1 TB of data (storage of the sample data sets does not count towards your database storage). You can use this schema to test the performance of your service. You can run the sample queries on this schema with different database services, HIGH, MEDIUM, LOW and with different number of ECPUs (OCPUs if your database uses OCPUs) to test the performance of Autonomous Database.

The SSB schema contains the tables: `lineorder`, `customer`, `supplier`, `part`, and `dwdate`. See Sample Star Schema Benchmark (SSB) Queries and Analytic Views for a list of sample queries you can use against the SSB schema. Note that you need to prefix the table names with the schema name `SSB` in your queries.

For more information on database services, see Database Service Names for Autonomous Database.

Use the Autonomous Database Free Container Image

Use the Autonomous Database Free Container Image to run Autonomous Database in a container in your own environment, without requiring access to the Oracle Cloud Infrastructure Console or to the internet.

- About the Free Container Image
  You can access the Autonomous Database Free Container Image from a repository and run it in your local environment.
- Container Registry Locations for Autonomous Database Free Container Image
  There are multiple locations where you can obtain Autonomous Database Free Container Image, including: Oracle Cloud Infrastructure Registry (Container Registry) and GitHub.
- Start Free Container Image
  After you download Autonomous Database Free Container Image, you can start the image in a container.
- Perform Database Operations using adb-cli
  The `adb-cli` command-line utility can be used to perform database operations after the container is up and running.
- Connect to an Free Container Image
  When the Free Container Image is running in a container, you can connect to an Autonomous Database instance.
- Migrate Data Between Autonomous Database Free Containers

About the Free Container Image

You can access the Autonomous Database Free Container Image from a repository and run it in your local environment.

Autonomous Database provides a fully managed Oracle Database that is available on Oracle Cloud Infrastructure. On Oracle Cloud Infrastructure, you perform lifecycle management operations and run Autonomous Database using the Oracle Cloud Infrastructure Console and you connect to your database through the public internet or through a private network that you set up (depending on your network configuration and security needs).

> **Note:**
>
> Autonomous Database supports both the Oracle Autonomous Database Free Container Image 19c and Oracle Autonomous Database Free Container Image 23ai versions.

The Autonomous Database Free Container Image provides an alternative to run Autonomous Database in a container in your own environment, without requiring access to Oracle Cloud Infrastructure Console or to the internet. When you run Autonomous Database in a container, the container provides a local, isolated environment with additional options for development, testing, and exploration of Oracle Autonomous Database features.

- Autonomous Database Free Container Image License
  Describes licensing for Autonomous Database Free Container Image.
- Autonomous Database Free Container Image Features
  The Autonomous Database Free Container Image provides many of the features available with Autonomous Database Serverless.
- Autonomous Database Free Container Image Recommendations and Restrictions
  Describes requirements and restrictions for Free Container Image.

Autonomous Database Free Container Image License

Describes licensing for Autonomous Database Free Container Image.

Autonomous Database Free Container Image is subject to licensing.

The container image you have selected and all of the software that it contains is licensed under Oracle Free Use Terms and Conditions that are provided in the container image. Your use of the container is subject to the terms of those licenses.

Autonomous Database Free Container Image Features

The Autonomous Database Free Container Image provides many of the features available with Autonomous Database Serverless.

- Each Free Container Image provides two Autonomous Database instances, one instance with Data Warehouse workload type and one instance with Transaction Processing workload type.
- The database will be started with either the Transaction Processing workload type or the Data Warehouse workload type based on the workload type you specify during startup.

- You can perform database operations using the `adb-cli` command-line utility.
- The Free Container Image resource allocation is 4 ECPUs and 20 GB of storage, and allows a maximum of 30 simultaneous database sessions.
- Each Free Container Image supports the Autonomous Database consumer groups:
  - Data Warehouse workload: You connect through HIGH, MEDIUM, or LOW services
  - Transaction Processing workload: You connect through HIGH, MEDIUM, LOW, TP, or TPURGENT services

  See About Autonomous Database Workload Types for more information.
- The Free Container Image provides support for the following built-in database tools:
  - Database Actions
  - Oracle REST Data Services (ORDS)
  - Oracle APEX
  - Oracle Database API for MongoDB

Autonomous Database Free Container Image Recommendations and Restrictions

Describes requirements and restrictions for Free Container Image.

Recommendations for Resource Allocation for the Free Container Image

The following is the recommended resource allocation for the Free Container Image:

- 4 CPUs
- 8 GB memory

Restrictions for Free Container Image

- There is no automatic patching or maintenance windows for the Free Container Image. The repository provides the latest version of the Free Container Image. Check the repository to find newer versions of Free Container Image.
- The following Autonomous Database built-in tools are not supported:
  - Graph
  - Oracle Machine Learning
  - Data Transforms
- When Autonomous Database runs in a container, the container provides a local Autonomous Database instance. The container image does not include the features that are only available through the Oracle Cloud Infrastructure Console or the APIs. Some features that are available in-database and also available through the Oracle Cloud Infrastructure Console can still be used through in-database commands, such as resetting the `ADMIN` password. The following lists some of the features that are not available:

Feature	Available or Not Available
Backup an Instance	Not available
Choose a Character Set	Not available
Clone an Instance	Not available
Create an Elastic Pool	Not available
Customer-managed keys	Not available

Feature	Available or Not Available
Database rename	Not available
Data Safe	Not available
Disable compute auto scaling	Not available
Disable Built-in Database Tools	Not available
Disable storage auto scaling	Not available
Disaster recovery options, including Autonomous Data Guard and Backup-Based Disaster Recovery.	Not available
Download wallet	Not available
Enable Built-in Database Tools	Not available
Enable compute auto scaling	Not available
Enable storage auto scaling	Not available
Join an Elastic Pool	Not available
Network ACLs	Not available
Oracle Cloud Infrastructure events	Not available
Performance hub	Not available
Private endpoints	Not available
Real Application Testing	Not available
Resource Principal based authentication	Not available
Restart Instance	Not available
Restore an Instance	Not available
Rotate wallet	Not available
Sample Schema	Not available
Scale down CPU and storage	Not available
Scale up CPU and storage	Not available
Selecting the Instance Patch Level	Not available
Start Instance	Not available
Stop Instance	Not available

> **Note:**
>
> When you run Free Container Image in a container, you can start an instance, stop an instance, or restart an instance by starting, stopping or restarting the container.

Container Registry Locations for Autonomous Database Free Container Image

There are multiple locations where you can obtain Autonomous Database Free Container Image, including: Oracle Cloud Infrastructure Registry (Container Registry) and GitHub.

You can obtain the Autonomous Database Free Container Image in multiple locations. The examples shown use `podman` commands (see Podman for more information).

1. Start a podman virtual machine.

For example:

```
podman machine init
podman machine set --cpus 4 --memory 8192
podman machine start
```

2. Obtain the Free Container Image.

   Oracle Cloud Infrastructure Registry:

   For example, use `podman` command to pull the latest Free Container Image image:

   ```
   podman pull container-registry.oracle.com/database/adb-free:latest-23ai
   ```

   > **Note:**
   >
   > Oracle Autonomous Database Serverless also supports 19c container images.
   >
   > - For 19c container image names, specify `latest` tag as your database version.
   > - In the above example, to pull the Autonomous Database Free Container Image 19c , use the following command in the image name tag:
   >
   >   ```
   >   podman pull container-registry.oracle.com/database/adb-free:latest
   >   ```
   >
   > Throughout the document, the image name tag refers to the `latest-23ai` version.

   For more details and additional information, search for "Oracle Autonomous Database Free" on Oracle Cloud Infrastructure Registry.

   GitHub Packages:

   For example, use `podman` command to pull the Free Container Image from: GitHub Packages:

   ```
   podman pull ghcr.io/oracle/adb-free:latest-23ai
   ```

3. Verify the image.

   For example:

   ```
   podman images container-registry.oracle.com/database/adb-free:latest-23ai
   ```

Start Free Container Image

After you download Autonomous Database Free Container Image, you can start the image in a container.

The database will be started with either the Transaction Processing workload type or the Data Warehouse workload type based on the workload type you specify.

- Start a container to run Free Container Image.

For example, with podman:

```
podman run -d \
-p 1521:1522 \
-p 1522:1522 \
-p 8443:8443 \
-p 27017:27017 \
-e WORKLOAD_TYPE='ATP' \
-e WALLET_PASSWORD=*** \
-e ADMIN_PASSWORD=*** \
--cap-add SYS_ADMIN \
--device /dev/fuse \
--name adb-free \
container-registry.oracle.com/database/adb-free:latest-23ai
```

Command notes:

- Autonomous Database Serverless also supports 19c container images.
  - For 19c container image names, specify `latest` tag as your database version.
  - In the above example, to start a container to run the Autonomous Database Free Container Image 19c, use the following command in the image name tag:

    `container-registry.oracle.com/database/adb-free:`**`latest`**
- Throughout the document, the image name tag refers to the `latest-23ai` version.
- The `WORKLOAD_TYPE` can be either `ATP` or `ADW`. The default value is `ATP`.
- By default, the database is named either `MYATP` or `MYADW`, depending on the passed `WORKLOAD_TYPE` value. Optionally, if you want a different database name than the default, you can set the `DATABASE_NAME` parameter. The database name can contain only alphanumeric characters.
- On container startup, the corresponding `MY<WORKLOAD_TYPE>.pdb` is downloaded and plugged in from a public Object Storage bucket.
- The wallet is generated using the provided `WALLET_PASSWORD`.
- It is necessary to change the `ADMIN_PASSWORD` upon initial login.
- Ensure you check the following requirements when you create or modify the `ADMIN_PASSWORD`:
  - The password must be between 12 and 30 characters long and must include at least one uppercase letter, one lowercase letter, and one numeric character.
  - The password cannot contain the username.
- Ensure you check the following requirements when you create or modify the `WALLET_PASSWORD`:
  - The password must be between 8 and 30 characters long and include alphabetic characters combined with numeric characters or special characters.
- For an OFS mount, the container starts with `SYS_ADMIN` capability. Also, virtual device `/dev/fuse` must be accessible.
- This `-p` options specify that the following ports are forwarded to the container process:

Port	Description
1521	TLS
1522	mTLS
8443	HTTPS port for ORDS / APEX and Database Actions
27017	Mongo API

If you are behind a corporate proxy, include `-e` options to specify environment variables for proxies. For example, with podman:

```
podman run -d \
-p 1521:1522 \
-p 1522:1522 \
-p 8443:8443 \
-p 27017:27017 \
-e WORKLOAD_TYPE='ATP' \
-e WALLET_PASSWORD=*** \
-e ADMIN_PASSWORD=*** \
-e http_proxy=http://example-corp-proxy.com:80/ \
-e https_proxy=http://example-corp-proxy.com:80/ \
-e no_proxy=localhost,127.0.0.1 \
-e HTTP_PROXY=http://example-corp-proxy.com:80/  \
-e HTTPS_PROXY=http://example-corp-proxy.com:80/  \
-e NO_PROXY=localhost,127.0.0.1 \
--cap-add SYS_ADMIN \
--device /dev/fuse \
--name adb-free \
container-registry.oracle.com/database/adb-free:latest-23ai
```

Perform Database Operations using `adb-cli`

The `adb-cli` command-line utility can be used to perform database operations after the container is up and running.

To use `adb-cli`, you can define the following alias for convenience:

```
alias adb-cli="podman exec <container_name> adb-cli"
```

Available Commands

You can view the list of available commands using the following command:

```
adb-cli --help
Usage: adb-cli [OPTIONS] COMMAND [ARGS]...
    ADB-S Command Line Interface (CLI) to perform container-runtime database
operations
Options:
    -v, --version Show the version and exit.
    --help Show this message and exit.
Commands:
    add-database
    change-password
```

Add Database

You can add a database using the following command:

```
adb-cli add-database --workload-type "ATP" --admin-password
"Welcome_MY_ATP_1234"
```

Change Password

You can change the admin password using the following command:

```
adb-cli change-password --database-name "MYATP"
    --old-password "Welcome_MY_ATP_1234" --new-password "Welcome_12345"
```

Connect to an Free Container Image

When the Free Container Image is running in a container, you can connect to an Autonomous Database instance.

To connect to an Autonomous Database instance running in a container, you can either setup the wallet and connect or use a TLS walletless connection.

- Connect to ORDS, APEX, or Database Actions from an Autonomous Database Container Image
  The container `hostname` is used to generate self-signed SSL certificates to serve HTTPS traffic on port 8443. Oracle APEX and Database Actions can be accessed using the container host (or simply `localhost`).
- Available TNS Aliases for Connecting to an Autonomous Database Container Image
  You can use any one of the following aliases to connect to an Autonomous Database Container Image.
- Connect to an Autonomous Database Container Image with a Wallet
  Describes the steps to connect to an Autonomous Database container image with a Wallet.
- Connect to an Autonomous Database Container Image without a Wallet (TLS)
  Describes the steps to connect to an Autonomous Database container image without a Wallet (TLS).

Connect to ORDS, APEX, or Database Actions from an Autonomous Database Container Image

The container `hostname` is used to generate self-signed SSL certificates to serve HTTPS traffic on port 8443. Oracle APEX and Database Actions can be accessed using the container host (or simply `localhost`).

Application	URL
Oracle APEX	https://localhost:8443/ords/apex
Database Actions	https://localhost:8443/ords/sql-developer

> **Note:**
>
> For additional databases plugged in using `adb-cli add-database` command, use the URL formats `https://localhost:8443/ords/{database_name}/apex` and `https://localhost:8443/ords/{database_name}/sql-developer` to access APEX and Database Actions respectively.

Available TNS Aliases for Connecting to an Autonomous Database Container Image

You can use any one of the following aliases to connect to an Autonomous Database Container Image.

Table 3-7 Available TNS Aliases

Protocol	Transaction Processing Workload	Data Warehouse Workload
mTLS	• myatp_medium • myatp_high • myatp_low • myatp_tp • myatp_tpurgent	• myadw_medium • myadw_high • myadw_low
TLS	• myatp_medium_tls • myatp_high_tls • myatp_low_tls • myatp_tp_tls • myatp_tpurgent_tls	• myadw_medium_tls • myadw_high_tls • myadw_low_tls

The TNS alias mappings for these connect strings are in `$TNS_ADMIN/tnsnames.ora`. See Manage Concurrency and Priorities on Autonomous Database for information on the service names in `tnsnames.ora`.

Connect to an Autonomous Database Container Image with a Wallet

Describes the steps to connect to an Autonomous Database container image with a Wallet.

Perform the following steps to setup a wallet and connect:

1. Copy the generated wallet to your host.

   When you start the container, Autonomous Database generates a wallet in `/u01/app/oracle/wallets/tls_wallet`.

   For example, copy the generated wallet to the local folder `/scratch/tls_wallet`:

   ```
   podman cp adb-free:/u01/app/oracle/wallets/tls_wallet /scratch/tls_wallet
   ```

   This copies the wallet to the folder: `/scratch/tls_wallet`.

2. Set the value of the `TNS_ADMIN` environment variable to the wallet directory.

   For example:

   ```
   export TNS_ADMIN=/scratch/tls_wallet
   ```

3. If you want to connect to a remote host where the Free Container Image is running, replace `localhost` in `$TNS_ADMIN/tnsnames.ora` with the remote host FQDN.

   For example:

   ```
   sed -i 's/localhost/example.com/g' $TNS_ADMIN/tnsnames.ora
   ```

4. Connect to the Autonomous Database instance.

   For example use `sqlplus` to connect to the **Transaction Processing** workload Autonomous Database instance:

   ```
   sqlplus admin/password@myatp_low_tls
   ```

   For example, use `sqlplus` to connect to the **Data Warehouse** workload Autonomous Database instance:

   ```
   sqlplus admin/password@myadw_low_tls
   ```

Connect to an Autonomous Database Container Image without a Wallet (TLS)

Describes the steps to connect to an Autonomous Database container image without a Wallet (TLS).

To connect without a wallet, you need to update your client's truststore with the self-signed certificate generated at container start.

Perform the following steps to setup a TLS connection and connect.

1. Copy `/u01/app/oracle/wallets/tls_wallet/adb_container.cert` from the container and update your system truststore.

   For example:

   ```
   podman cp adb-free:/u01/app/oracle/wallets/tls_wallet/adb_container.cert
   adb_container.cert
   sudo cp adb_container.cert /etc/pki/ca-trust/source/anchors
   sudo update-ca-trust
   ```

2. Connect to the Autonomous Database instance.

   For example, use `sqlplus` to connect to the Transaction Processing workload Autonomous Database instance:

   ```
   sqlplus admin/password@myatp_low
   ```

   For example, use `sqlplus` to connect to the Data Warehouse workload Autonomous Database instance:

   ```
   sqlplus admin/password@myadw_low
   ```

Migrate Data Between Autonomous Database Free Containers

When a new version of the Free Container Image is available, you can migrate data from a container to another container.

For example, use existing data that you created in a container by migrating that data to the latest version of Free Container Image when a new update is available.

1. Create a podman volume.

   For example:

   ```
   podman volume create adb_container_volume
   ```

2. Verify the volume mountpoint.

   The mountpoint is a podman managed directory location.

   ```
   podman inspect adb_container_volume

   [
        {
             "Name": "adb_container_volume",
             "Driver": "local",
             "Mountpoint": "/share/containers/storage/volumes/
   adb_container_volume/_data",
             "CreatedAt": "2023-09-11T21:23:34.305877073Z",
             "Labels": {},
             "Scope": "local",
             "Options": {},
             "MountCount": 0,
             "NeedsCopyUp": true,
             "NeedsChown": true
        }
   ]
   ```

3. Start the source container, mounting the volume to `/u01/data` in the container.

   For example:

   ```
   podman run -d \
   -p 1521:1522 \
   -p 1522:1522 \
   -p 8443:8443 \
   -p 27017:27017 \
   -e WORKLOAD_TYPE='ATP' \
   -e WALLET_PASSWORD=*** \
   -e ADMIN_PASSWORD=*** \
   --cap-add SYS_ADMIN \
   --device /dev/fuse \
   --name source_adb_container \
   --volume adb_container_volume:/u01/data \
   container-registry.oracle.com/database/adb-free:latest-23ai
   ```

> **Note:**
>
> Autonomous Database Serverless also supports 19c container images.
>
> - For 19c container image names, specify `latest` tag as your database version.
> - In the above example, to start the Autonomous Database Free Container Image 19c , use the following command in the image name tag:
>
>   `container-registry.oracle.com/database/adb-free:`**`latest`**
>
> Throughout the document, the image name tag refers to the `latest-23ai` version.

4. This example assumes you have previously created your data in schema, `app_user`.
5. Export the data from `app_user`'s schema to the container volume.
   a. Connect as `ADMIN` and create `ORA_EXP_DIR` directory pointing to `/u01/data`.

```
sqlplus admin/**************@myadw_high

SQL> exec DBMS_CLOUD_CONTAINER_ADMIN.create_export_directory('/u01/
data');

SQL> select directory_path from dba_directories where
directory_name='ORA_EXP_DIR';

DIRECTORY_PATH
--------------------------------------------------------------------------------
--------
/u01/data
```

   b. Run the export job in schema mode and for both `ADMIN` and `APP_USER` schemas.

```
SET scan off
SET serveroutput ON
SET escape off

DECLARE
    h1 NUMBER;
    s VARCHAR2(1000):=NULL;
    errorvarchar VARCHAR2(100):= 'ERROR';
    tryGetStatus NUMBER := 0;
    success_with_info EXCEPTION;
    PRAGMA EXCEPTION_INIT(success_with_info, -31627);
BEGIN
    h1 := dbms_datapump.OPEN(operation => 'EXPORT', job_mode =>
'SCHEMA', job_name => 'EXPORT_MY_ADW_4', version => 'COMPATIBLE');
    tryGetStatus := 1;
    dbms_datapump.add_file(handle => h1, filename =>
'EXPORT_MY_ADW.LOG', directory => 'ORA_EXP_DIR', filetype =>
DBMS_DATAPUMP.KU$_FILE_TYPE_LOG_FILE);
    dbms_datapump.metadata_filter(handle => h1, name => 'SCHEMA_EXPR',
```

```
VALUE => 'IN(''ADMIN'', ''APP_USER'')');
    dbms_datapump.add_file(handle => h1, filename => 'MY_ADW_%L.DMP',
directory => 'ORA_EXP_DIR', filesize => '500M',  filetype =>
DBMS_DATAPUMP.KU$_FILE_TYPE_DUMP_FILE);
    dbms_datapump.start_job(handle => h1, skip_current => 0, abort_step
=> 0);
    dbms_datapump.detach(handle => h1);
    errorvarchar := 'NO_ERROR';
EXCEPTION
    WHEN OTHERS THEN
    BEGIN
        IF ((errorvarchar = 'ERROR')AND(tryGetStatus=1)) THEN
            DBMS_DATAPUMP.DETACH(h1);
        END IF;
    EXCEPTION
    WHEN OTHERS THEN
        NULL;
    END;
    RAISE;
END;
/
```

6. Verify the export.

   List the files in the container `/u01/data`.

   ```
   podman exec -it source_adb_container bash
   cd /u01/data
   ```

   Verify the export log (`export log`), check for any errors and successful completion.

7. Stop and remove the source container.

   ```
   podman stop source_adb_container
   podman rm source_adb_container
   ```

   > **Note:**
   >
   > The `adb_container_volume` will live across container restarts and removals

8. Start a destination container mounting the same volume to `/u01/data` in the container.

   ```
   podman run -d \
   -p 1521:1522 \
   -p 1522:1522 \
   -p 8443:8443 \
   -p 27017:27017 \
   -e WORKLOAD_TYPE='ATP' \
   -e WALLET_PASSWORD=*** \
   -e ADMIN_PASSWORD=*** \
   --cap-add SYS_ADMIN \
   --device /dev/fuse \
   --name dest_adb_container \
   ```

```
--volume adb_container_volume:/u01/data \
container-registry.oracle.com/database/adb-free:latest-23ai
```

9. Import data in destination container.

   Connect as `ADMIN` and create `ORA_EXP_DIR` directory pointing to `/u01/data`.

```
SQL> exec DBMS_CLOUD_CONTAINER_ADMIN.create_export_directory('/u01/data');

PL/SQL procedure successfully completed.

SQL> select directory_path from dba_directories where
directory_name='ORA_EXP_DIR';

DIRECTORY_PATH
--------------------------------------------------------------------------------
-----
/u01/data
```

10. Run the import PL/SQL commands.

```
SET scan off
SET serveroutput ON
SET escape off

DECLARE
    h1 NUMBER;
    s VARCHAR2(1000):=NULL;
    errorvarchar VARCHAR2(100):= 'ERROR';
    tryGetStatus NUMBER := 0;
    success_with_info EXCEPTION;
    PRAGMA EXCEPTION_INIT(success_with_info, -31627);
BEGIN
    h1 := dbms_datapump.OPEN(operation => 'IMPORT', job_mode => 'SCHEMA',
job_name => 'IMPORT_MY_ADW_4', version => 'COMPATIBLE');
    tryGetStatus := 1;
    dbms_datapump.add_file(handle => h1, filename => 'IMPORT_MY_ADW.LOG',
directory => 'ORA_EXP_DIR', filetype =>
DBMS_DATAPUMP.KU$_FILE_TYPE_LOG_FILE);
    dbms_datapump.metadata_filter(handle => h1, name => 'SCHEMA_EXPR',
VALUE => 'IN(''ADMIN'', ''APP_USER'')');
    dbms_datapump.add_file(handle => h1, filename => 'MY_ADW_%L.DMP',
directory => 'ORA_EXP_DIR', filesize => '500M',  filetype =>
DBMS_DATAPUMP.KU$_FILE_TYPE_DUMP_FILE);
    dbms_datapump.start_job(handle => h1, skip_current => 0, abort_step =>
0);
    dbms_datapump.detach(handle => h1);
    errorvarchar := 'NO_ERROR';
EXCEPTION
    WHEN OTHERS THEN
    BEGIN
        IF ((errorvarchar = 'ERROR')AND(tryGetStatus=1)) THEN
            DBMS_DATAPUMP.DETACH(h1);
        END IF;
    EXCEPTION
    WHEN OTHERS THEN
```

```
            NULL;
        END;
        RAISE;
    END;
    /
```

11. Verify the import log.
12. Verify the import data.

Load and Analyze Your Data with Autonomous Database

Learn about Autonomous Database Serverless and learn how to create an Autonomous Database in just a few clicks. Then load data into your database, query it, and visualize it.

Load and analyze data in Autonomous Database Workshop

- Provision a new Autonomous Database instance.
- Run Queries on the sample data sets
- Upload files to the Oracle Cloud Infrastructure Object Storage, create sample tables, load data into them from files on the OCI Object Storage
- Query files on the Oracle Cloud Infrastructure Object Storage directly without loading them to your database
- Visualize your data using Oracle Analytics Desktop

Self-service Tools for Everyone Using Oracle Autonomous Database

Introduces the suite of data tools built into Oracle Autonomous Database.

Data Studio - Self-service tools for everyone using Oracle Autonomous Database

This is an overview Data Studio workshop to introduce you to different tools using a sample data analysis task. After this workshop you will have a working knowledge on how to use these tools.

The tools covered are:

- Catalog

- Data Load
- Data Transforms
- Data Analysis
- Data Insight

After completing this workshop, you can look at the individual in-depth workshops for each tool.

Manage and Monitor Autonomous Database

Connect using secure wallets and monitor your Autonomous Database instances.

Manage and Monitor Autonomous Database Workshop

- Get comfortable with Oracle's public cloud services
- Provision a new Autonomous Database instance Serverless
- Run sample queries against the sample data sets
- Load data from the object store
- Query external data from the object store
- Scale an Autonomous Database instance

Integrate, Analyze and Act on All Data using Autonomous Database

This workshop uses Oracle Cloud's modern data platform for analytics to enable MovieStream to better understand their customers, predict churn and provide targeted recommendations and promotions.

- MovieStream stores its data across Oracle Object Storage and Autonomous Database.
- Data is captured from various sources into a landing zone in object storage. This data is then processed, cleansed, transformed, and optimized, and stored in a gold zone on object storage.
- After the data is curated, it is loaded into an Autonomous Database where users can take advantage of a variety of Autonomous Database capabilities: advanced Oracle SQL to glean customer insights, Oracle Machine Learning to predict churn, and Oracle Spatial and Graph to provide targeted promotions.

Innovate with Autonomous Database's built-in Select AI, Graph, ML and Spatial analytics

Load the Autonomous Database with Data Studio

Data Studio is built into every Autonomous Database, and provides tools to load, transform and prepare data from a wide range of source systems.

This workshop provides practical examples of how to load data from several different systems, as well as how to link to, and feed data in from, data in cloud storage systems.

Load the Autonomous Database with Data Studio

QuickStart Java applications with Autonomous Database

Follow these easy steps to connect your Java applications to Autonomous Database using the Oracle JDBC driver and Universal Connection Pool.

QuickStart Java applications with Oracle Autonomous Database

5
Features

- Use Data Lake with Autonomous Database
  Learn the benefits of using Data Lake with Autonomous Database.
- Data Lake Accelerator
  Use Data Lake Accelerator with your Autonomous Database instance to accelerate the scanning and processing of external data stored in Object Stores.
- The Data Studio Overview Page
  The Data Studio comprises of the Data Load, the Data Analysis, the Data Insights, Catalog, Data Marketplace and the Data Share tool.
- High Availability
  You can configure and manage Autonomous Data Guard and maintain continuous availability using disaster recovery.
- Security
  Autonomous Database stores all data with inbuilt security. Only authenticated users and applications can access the data when they connect to the database.
- Performance Monitor and Management
  Oracle Autonomous Database Serverless includes several features that automatically monitor, analyze and optimize the performance of your Autonomous Database.
- Using Oracle Graph with Autonomous Database
  Oracle Graph with Autonomous Database enables you to create graphs from data in your Autonomous Database. With graphs you can analyze your data based on connections and relationships between data entities.
- Use Oracle Machine Learning with Autonomous Database
- Creating Analytic Views
  You can create Analytic Views and view information about them. You can also edit and perform other actions on them.
- Use Select AI for Natural Language Interaction with your Database
- JSON Document Stores
  Autonomous Database has full support for data represented as JSON documents. In Autonomous Databases, JSON documents can coexist with relational data.
- Cache Messages with Singleton Pipes and Using Pipes for Persistent Messaging
- Full-Text Search Queries
  The PL/SQL package `DBMS_CLOUD` enables you to build a text index on the object store files, which allows you to search the text and use wildcards with your search. You can use `JSON_TEXTCONTAINS` to do full-text JSON search on files stored in Object Storage.
- Use Oracle Workspace Manager on Autonomous Database
  Workspace Manager provides an infrastructure that enables applications to create workspaces and group different versions of table row values in different workspaces.
- Use and Manage Elastic Pools on Autonomous Database
  Use an elastic pool to consolidate your Autonomous Database instances, in terms of their allocation of compute resources, and to provide up to 87% cost savings.

- Migrate to Autonomous Database
  Database migration is the process of migrating your database from a source database to a target database.
- Use Database In-Memory with Autonomous Database
  The Database In-Memory feature available on Autonomous Database can significantly improve performance for real-time analytics and mixed workloads.

Use Data Lake with Autonomous Database

Learn the benefits of using Data Lake with Autonomous Database.

- About Data Lake with Autonomous Database
  Oracle Autonomous Database is a versatile solution for accommodating any type of data and workload.
- What is a Data Lake?
  Data lakes are centralized repositories designed to store vast amounts of raw data in their native format until the data is needed for analysis.
- Key Data Lake Features of Autonomous Database
  Oracle Autonomous Database is designed to seamlessly support data lake workloads, eliminating the need for management or installation. It delivers robust capabilities to handle various data formats across different cloud environments, ensuring flexible and comprehensive data analysis.

About Data Lake with Autonomous Database

Oracle Autonomous Database is a versatile solution for accommodating any type of data and workload.

Autonomous Database provides cost-efficient storage, with a cost per TB comparable to object stores, while supporting diverse data types like JSON, Graph, and Vector. With Autonomous Database, businesses can consolidate their data onto a single platform. They can leverage converged capabilities such as Oracle Machine Learning (OML), Graph, Spatial, Vector, and Blockchain to manage their data comprehensively.

For organizations that already have existing data lakes on other platforms, Oracle Autonomous Database integrates seamlessly, allowing businesses to benefit from Autonomous Database's advanced features without disrupting their current setups.

To learn more, try the LiveLabs Build a Data Lake with Autonomous Data Warehouse.

What is a Data Lake?

Data lakes are centralized repositories designed to store vast amounts of raw data in their native format until the data is needed for analysis.

They are highly flexible and scalable, making them a powerful complement to traditional data warehouses by enabling organizations to store and process various types of data, including structured, semi-structured, and unstructured.

Key attributes of a Data Lake:

- **Open File and Table Formats**

  Data lakes store data in open file formats, such as CSV, Parquet, and table formats like Iceberg. This ensures interoperability and flexibility in data processing by allowing multiple engines to write and read these datasets.

- **Support for Multiple Data Processing Engines**

  Data lakes are compatible with various data processing engines, such as Apache Spark, Presto, and Hive, enabling diverse analytical workloads.

- **Schema-on-Read**

  Data lakes often use a schema-on-read approach, meaning there is no need to define a schema upfront. This allows for rapid data ingestion, where data can be loaded without prior structuring, much like object stores that “capture data now, and ask questions later".

- **Support for Unstructured Data**

  Beyond structured data, data lakes can store unstructured data such as images (JPG), documents (PDF, Word), and other binary data, offering a comprehensive storage solution.

Key Data Lake Features of Autonomous Database

Oracle Autonomous Database is designed to seamlessly support data lake workloads, eliminating the need for management or installation. It delivers robust capabilities to handle various data formats across different cloud environments, ensuring flexible and comprehensive data analysis.

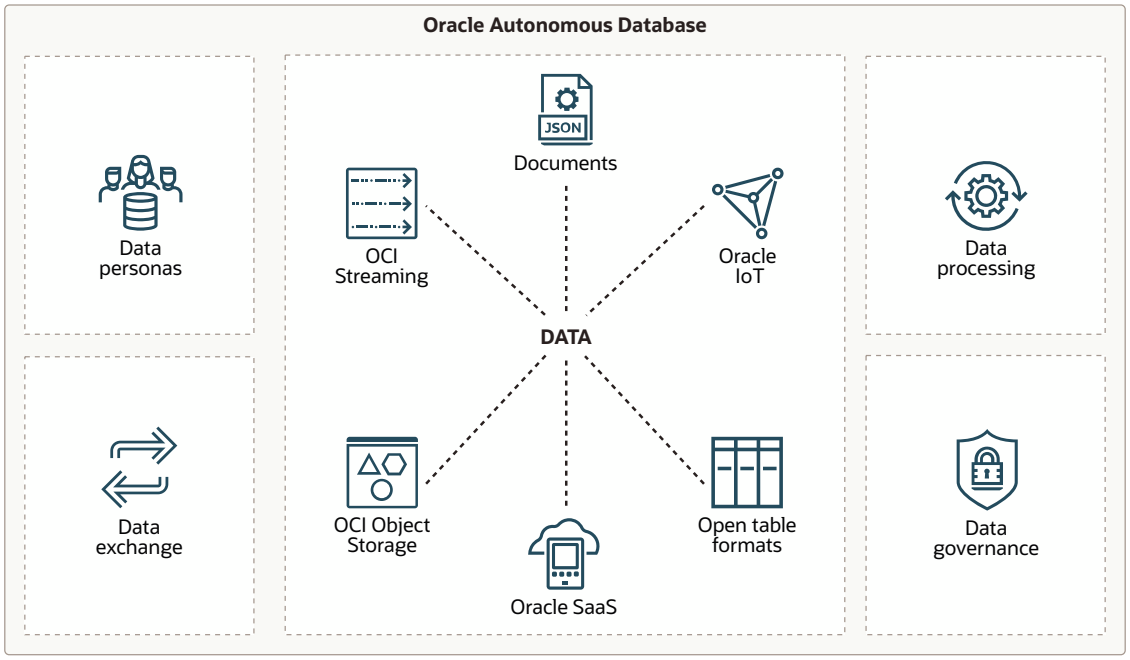
- Ready for Data Lake Workloads
  Oracle Autonomous Database is fully ready for data lake workloads out-of-the-box, requiring no additional components. This readiness extends to key data lake tasks such as data transformation, metadata management, and integration with popular data lake tools—all available from day one without extra setup.
- Multi-Cloud Support
  For organizations that already have existing data lakes on other platforms, Autonomous Database integrates seamlessly, allowing businesses to benefit from Autonomous Database advanced features without disrupting their current setups.
- End-To-End Data Format Support
  Oracle Autonomous Database is designed with the flexibility to handle a broad spectrum of data formats, making it a universal solution for diverse data sources and workloads.
- Enhanced Capabilities: Autonomous Database for Unstructured Data Management
  While Oracle Database is recognized for its powerful processing of structured and semi-structured data, Autonomous Database extends its capabilities to handle unstructured datasets as well.
- Flexible Metadata Management
  Oracle Autonomous Database provides users with various ways to define metadata for their datasets, making data management more adaptable and efficient.
- Federated Metadata Support
  Autonomous Database supports a federated metadata catalog, enabling users to unify metadata from different sources into a single view, providing a unified interface for metadata management.
- Collaboration
  After users finish their analysis, they often need to share their results with others. Oracle Autonomous Database makes sharing easy by offering several ways to collaborate, providing unique advantages over other databases, such as integrated security features, open protocols, and seamless cloud connectivity.
- Broad Compatibility with Oracle Database Tools
  The Autonomous Database environment is fully compatible with a wide array of Oracle database tools.

Ready for Data Lake Workloads

Oracle Autonomous Database is fully ready for data lake workloads out-of-the-box, requiring no additional components. This readiness extends to key data lake tasks such as data transformation, metadata management, and integration with popular data lake tools—all available from day one without extra setup.

This comprehensive readiness is what makes Autonomous Database stand out, offering an integrated, hassle-free experience that accelerates time-to-insight for data lake workloads. This means users can immediately start handling data lake tasks without any setup or configuration, making it a true plug-and-play solution for data lake environments. This built-in capability simplifies operations, reduces maintenance costs, and ensures higher reliability with fewer errors.

Autonomous Database provides a set of tools for all user types, from developers to business analysts, making the platform universal and accessible.



Developers can use tools such as the PL/SQL API for advanced operations, scripting, and automation, allowing seamless integration with existing tools and creating customized database solutions efficiently. See Autonomous Database Supplied Package Reference, for more information.

For business users, Data Studio can be used—a web-based interface for simplifying data interaction, exploration, and visualization. Data Studio enables non-technical users to derive insights, create reports, and collaborate effectively, reducing complexity and supporting informed decision-making. See The Data Studio Overview Page, for more information.

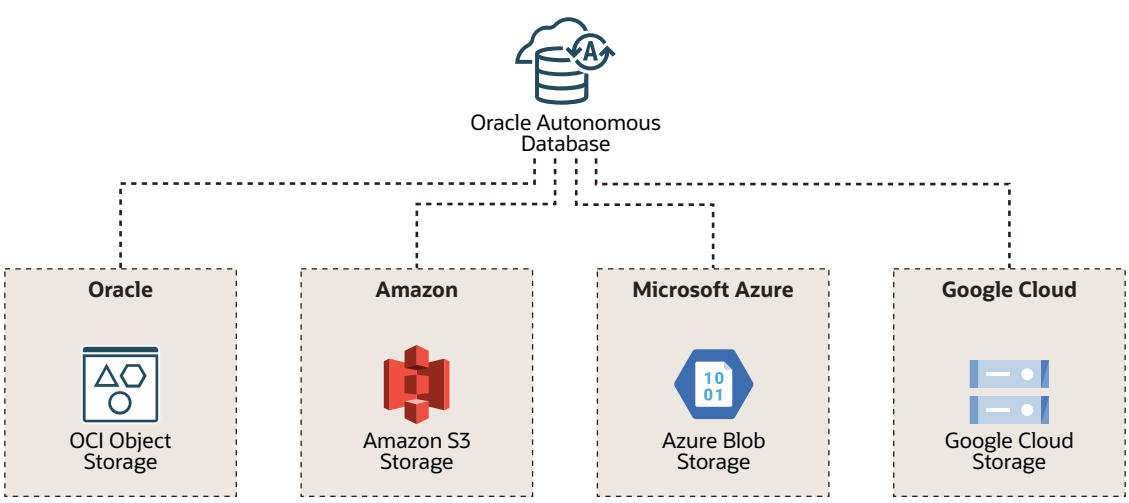
Multi-Cloud Support

For organizations that already have existing data lakes on other platforms, Autonomous Database integrates seamlessly, allowing businesses to benefit from Autonomous Database advanced features without disrupting their current setups.

Provide Autonomous Database access to your data lake by granting the necessary privileges and access for your data lake to be connected to Autonomous Database. Once you've provided the necessary credentials, Autonomous Database can seamlessly connect to data lakes across various cloud environments, including AWS, Azure, Google Cloud, and Oracle OCI object store.

This capability allows you to securely access and manage your data, leveraging the native security features of each cloud provider. With this multi-cloud support, you gain the flexibility to deploy and scale your data lake across different cloud platforms while maintaining a unified and secure environment.

Oracle Autonomous Database supports native security for other clouds, to learn more, see Use Amazon Resource Names (ARNs) to Access AWS Resources, Use Azure Service Principal to Access Azure Resources and Use Google Service Account to Access Google Cloud Platform Resources for your corresponding cloud platform.



End-To-End Data Format Support

Oracle Autonomous Database is designed with the flexibility to handle a broad spectrum of data formats, making it a universal solution for diverse data sources and workloads.

Whether your data resides in structured, semi-structured, or unstructured formats, Autonomous Database seamlessly supports them across various cloud environments. This allows businesses to ingest, store, and analyze data without worrying about format compatibility.

Autonomous Database provides native support for traditional formats like CSV and JSON, as well as advanced formats such as AVRO, Parquet, and ORC. See Query External Data with Autonomous Database, for more information. Autonomous Database supports the following file formats: CSV, JSON, XML, AVRO, ORC, Parquet, Delta Sharing, Iceberg, Word, PDF.

With the added support for the Iceberg Table format, Autonomous Database offers enhanced capabilities for large-scale data lake environments. Iceberg allows for optimized, high-performance querying, better version control, and easier data management, making it a good fit for large, evolving datasets. See Query Apache Iceberg Tables, for more information.

Enhanced Capabilities: Autonomous Database for Unstructured Data Management

While Oracle Database is recognized for its powerful processing of structured and semi-structured data, Autonomous Database extends its capabilities to handle unstructured datasets as well.

These capabilities include managing and analyzing a wide range of formats like JPG, PDF, Word documents, and more. With these advancements, Autonomous Database brings a comprehensive solution for businesses dealing with unstructured data sources.

- **AI-Driven Insights with Retrieval Augmented Generation (RAG)**: Autonomous Database integrates advanced AI models, enabling Vector Search for unstructured data. This allows for efficient retrieval of relevant information across massive datasets using AI, enhancing search accuracy and speed. See Select AI with Retrieval Augmented Generation (RAG), for more information.
- **Full-Text Indexing**: Autonomous Database supports the creation of full-text indexes on unstructured files, making it possible to perform advanced text searches on documents such as PDFs, Word files, and more. This capability greatly improves how unstructured content can be queried, indexed, and analyzed. See Use Full-Text Search on Files in Object Storage
- **Parse and Load Unstructured Data**: Autonomous Database enhanced parsing and data ingestion features allow users to load unstructured data seamlessly, automatically transforming it into a tabular format, ready to be load into database. See Perform Table Extraction from Image, for more information.
- **AI as a Source of Data (Prompt-to-Table)**: Leveraging AI, Autonomous Database enables prompt-to-table functionality, allowing users to generate data directly from AI models and load it into tables. This opens up possibilities for extracting valuable insights from AI-generated outputs and using them as a new source of structured data. See Loading Data from AI Source

These expanded capabilities position Autonomous Database as a powerful tool for handling the growing demands of unstructured data, while also tapping into AI-powered solutions, making it a versatile and future-proof platform for modern data challenges.

Flexible Metadata Management

Oracle Autonomous Database provides users with various ways to define metadata for their datasets, making data management more adaptable and efficient.

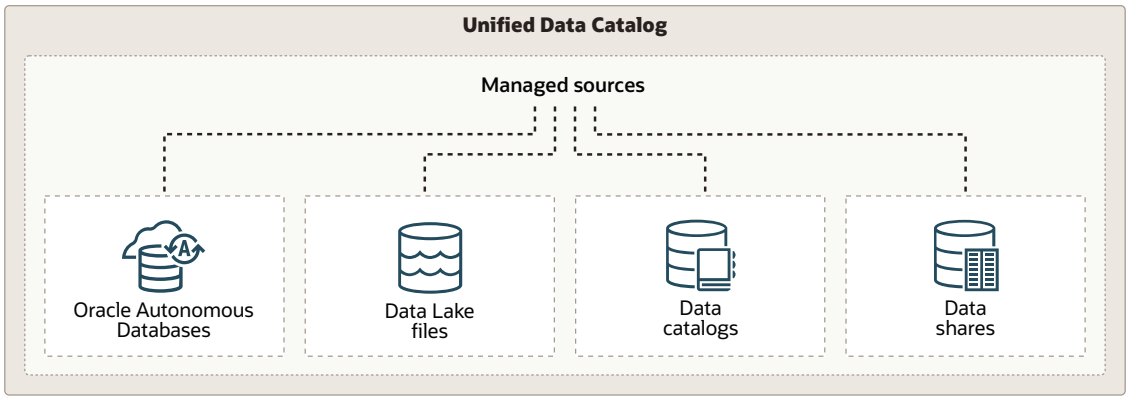
- **Catalog-Based Metadata Integration**
  Users can bring metadata from various catalogs into a centralized view, making it easier to control and maintain data consistency across the organization. Supported catalogs include:
  - **OCI Data Catalog**: A tool within Oracle Cloud Infrastructure (OCI) that helps users discover, organize, and manage data assets. It offers a clear view of all data assets, helping users maintain compliance, ensure data quality, and facilitate collaboration across teams. See Example: MovieStream Scenario , for more information.
  - **AWS Glue**: A managed ETL (extract, transform, load) service from Amazon Web Services that includes a data catalog for organizing and managing metadata. See Query External Data with AWS Glue Data Catalog, for more information.
- **Manual Metadata Definition**
  Users can also define metadata directly at the table level for datasets in object stores such as Oracle Cloud Infrastructure (OCI) Object Storage or Amazon S3. This allows for customized organization of data for individual files or groups of files, tailored to user

requirements. Autonomous Database can also automatically infer metadata, such as column names and data types, to save time and reduce errors. For example, when uploading a CSV file, the system can automatically detect headers as column names and assign appropriate data types like number or varchar2 based on the content. This helps users quickly prepare their data for analysis without manual intervention, reducing setup time and minimizing the chance of errors.

Federated Metadata Support

Autonomous Database supports a federated metadata catalog, enabling users to unify metadata from different sources into a single view, providing a unified interface for metadata management.

This approach simplifies metadata management across various environments by connecting data sources across multiple clouds and platforms. Whether using catalog-based metadata or defining it manually, all information is available in a unified catalog for easy browsing. For example, an organization can use this federated view to manage data assets from both AWS and Oracle Cloud, ensuring consistent governance and discoverability across platforms.



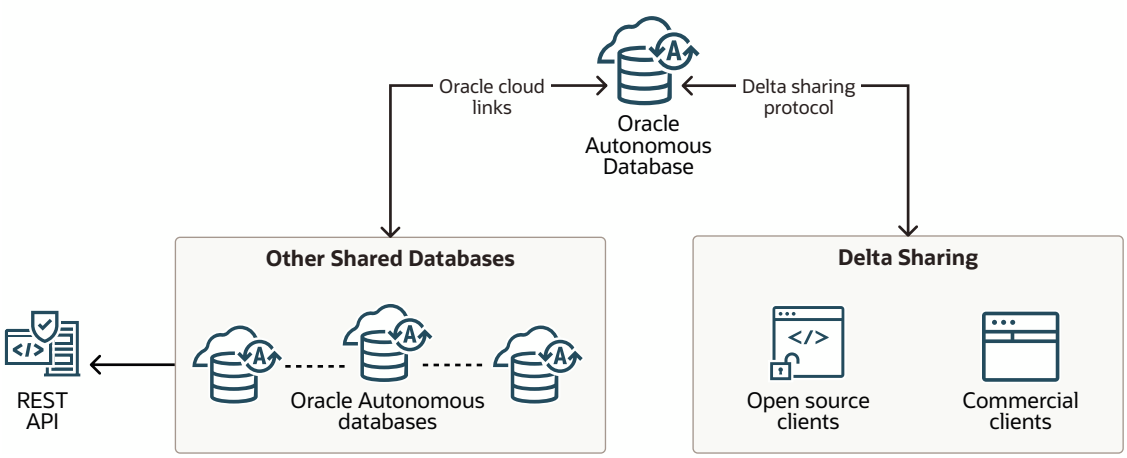
Collaboration

After users finish their analysis, they often need to share their results with others. Oracle Autonomous Database makes sharing easy by offering several ways to collaborate, providing unique advantages over other databases, such as integrated security features, open protocols, and seamless cloud connectivity.

These options are made to be flexible and secure, so they fit different collaboration needs:

- **Delta Sharing Protocol**: This lets you share data outside of Oracle using an open protocol called Delta Sharing. It supports secure data sharing with external partners, without needing complex integration, making it ideal for cross-cloud and cross-platform analytics. This way, data can be used smoothly in different analytics tools that are not part of Oracle. See Share Data Versions Using Object Storage, for more information.
- **Cloud Links**: You can share data between different Autonomous Database instances using secure cloud links. For example, Cloud Links are particularly effective for connecting different databases. This ensures consistent data availability and reduces latency for applications needing quick and reliable access to data across multiple databases, without the need to copy or duplicate. It keeps collaboration smooth for teams that are spread out and need to work together. See Share Live Data Using Direct Connection

- **Table Hyperlinks**: You can share data directly by creating special URLs that give access to the data without needing a separate login. Users can control the permissions and set expiration times for these URLs, ensuring secure and flexible sharing options. This feature is built specifically for REST clients. See Generate a Table Hyperlink for a Table or a View, for more information.



Broad Compatibility with Oracle Database Tools

The Autonomous Database environment is fully compatible with a wide array of Oracle database tools.

Any tool you already use to interact with Oracle databases—whether for data visualization, analytics, ETL, or administration—can also be leveraged seamlessly to analyze datasets within Autonomous Database . This compatibility ensures a frictionless experience, allowing users to integrate Autonomous Database into their existing workflows without needing to adopt new tools or processes, thereby maximizing efficiency and reducing the learning curve.

See The Data Studio Overview Page, for information on a few of the tools available to use with Oracle databases.

Data Lake Accelerator

Use Data Lake Accelerator with your Autonomous Database instance to accelerate the scanning and processing of external data stored in Object Stores.

> **Note:**
>
> Only Oracle Database 19c supports Data Lake Accelerator.

- About Data Lake Accelerator
  Data Lake Accelerator is an advanced software solution designed to enhance external data processing performance and scalability.

- Configure Data Lake Accelerator
  Configure Data Lake Accelerator for your Autonomous Database instance during provisioning, cloning or when you update your instance.

About Data Lake Accelerator

Data Lake Accelerator is an advanced software solution designed to enhance external data processing performance and scalability.

Deployed on an Oracle-managed VM cluster, it integrates seamlessly with your Autonomous Database to accelerate the scanning and processing of external data stored in Object Stores. By automatically allocating additional CPUs based on query demands, it ensures efficient resource utilization and significantly improves query response times, offering a scalable and cost-effective solution for handling large and complex data sets.

Configure Data Lake Accelerator

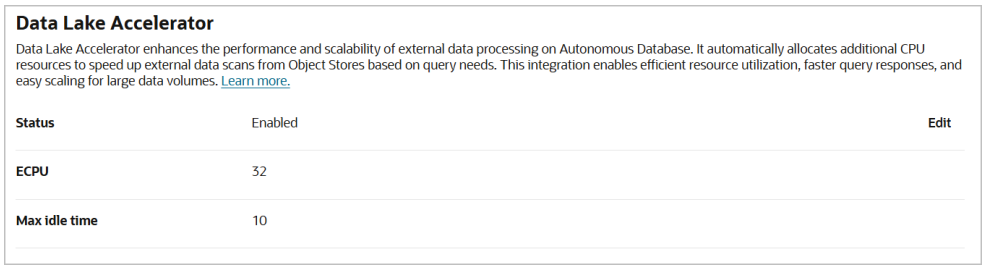
Configure Data Lake Accelerator for your Autonomous Database instance during provisioning, cloning or when you update your instance.

During provisioning or cloning, the Data Lake Accelerator options are included in the advanced section. See Provision an Autonomous Database Instance and Clone an Autonomous Database Instance for more information. When modifying Data Lake Accelerator options for existing instances, use the Tools tab on the instance Details page.

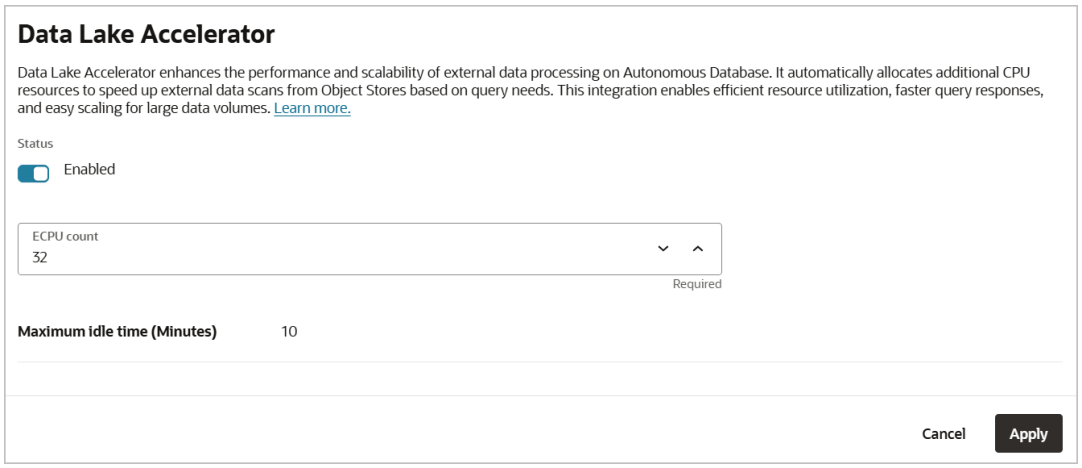
To select Data Lake Accelerator options for an Autonomous Database instance, do the following:

1. Navigate to the Data Lake Accelerator options.
   a. During the process of provisioning or cloning an Autonomous Database instance, do the following:
      - Open **Advanced options**.
      - Open **Tools**.
      - Scroll to **Data Lake Accelerator**.

   b. For an existing Autonomous Database instance, do the following:
      - On the **Details** page for your Autonomous Database instance, select **Tool configuration**.
      - Scroll to the **Data Lake Accelerator** options.



2. Click **Edit**.
   The Data Lake Accelerator edit page displays.



3. On the Data Lake Accelerator edit page, you can make these selections:
   - **Status**: Toggle **Status** to Disabled, to disable Data Lake Accelerator. Toggle **Status** to Enabled to enable.
   - **ECPU count**: Enter number of ECPUs, or use up and down arrows to change number of ECPUs. The default is 32 ECPUs. This is the number of ECPUs you are requesting to be allocated. You are billed for the number of ECPUs actually allocated. The range is 32 to 1024 in multiples of 32. In other words: 32, 64, 96, 128 … 1024.
   - **Maximum idle time (Minutes)**: The default is 10 minutes and can not be changed.
4. Click **Apply**.

The Data Studio Overview Page

The Data Studio comprises of the Data Load, the Data Analysis, the Data Insights, Catalog, Data Marketplace and the Data Share tool.

The Data Studio Tools enables you to load data from cloud and other diverse sources, analyzes it and gain insights from it. You can share the result of the analysis with other users. It is a one-stop application of your analytics tool from multiple data sources. This tool makes sure that there is seamless transition between different applications. The multiple ways of navigation do not impact the progress of your work. For instance, if you are working on data analysis and decide you need some additional data, you can navigate to the Data Load page, bring in the new contents, and return to your analysis in progress. Select **Data Studio** tab from the Launchpad.

Data Studio Overview page

Click the **Data Studio Overview** menu from the **Data Studio** to view the Data Studio Overview page consists of four sections:

1. A navigation pane which consists of the following tools in the menu: Data Load, Data Analysis, Data Insights, the Catalog and the Data Share tools.

2. A widget with slides which displays information on the tools and their purpose. For example, the Data Load tool loads data from files on your computer or from cloud storage. Click **<** or **>** button to navigate back and forth the slides.
3. The right pane toolbar displays the help links to the Data Studio tool documentation.
4. A Recent Objects section which displays recently updated or created objects. Each entry has a context menu available at the end of the row. Click on the entries to view the details of the selected object.

Load your data from diverse sources such as files, databases and cloud storage, which are all consolidated in a single location. Some of the cloud data warehouses the Data Studio tool supports are Oracle Cloud Infrastructure (OCI), Amazon S3, Microsoft Azure Blob Storage and Google Cloud Storage.

Once your data is available, analyze it, generate insights, and create reports.

On the right of the Data Studio Overview page, refer to the Getting Started panel to know more about this tool.

> **Note:**
>
> You will lose your data once you click the Database Actions in the header or click the selector icon.

Let us run analysis with data from different sources and generate insights from it.

Load Data

Select the **Data Load** menu from the navigation pane in the Data Studio Overview page to load data from files on your local device, from remote databases, or from cloud storage buckets. Clicking Data Load opens Data Load Dashboard page.

The Data Load menu has the following submenus:

- **Home**: This menu takes you to the home page of the Data Load tool in the Launchpad. You can perform any of the following activities from the submenus such as Load local file, Load cloud store, Load Database Tables, Link Cloud Store, Link Database Tables, Create Live feed and search for cloud location and then select the Home menu. This does not break the continuity of the action you perform. Refer to The Data Load Page for more details.
- **Load Data**:
  Click **Load Data** to view the following options to load data:

  - **Load Local File**: This option enables us to load data from files on your local device. Refer to the Loading Data From Local Files section for more details.

  - **Load Cloud Store**: This menu enables you to load data from a cloud store location to a table in your Autonomous Database. Refer to the Loading Data from Cloud Storage section for more details.
  - **Load Share**: This menu enables you to load data from Shares where you can select tables from a Share. See Loading Data from a Share.
  - **Load Database**: This menu enables you to load data from tables in another database into your Oracle Autonomous Database. Refer to the Loading Data from other Databases section for more details.
  - **Load AI Source**: This menu enables you to load data from an AI source. See Loading Data from AI.
  - **Load File System**: This menu enables you to load data from file system directories to your Autonomous Database.

- **Link Data**:
  Click **Link Data** to view the following options of linking data:

  - **Link Cloud Store**: This menu enables you to link to data in cloud storage buckets. Refer to the Linking to Objects in Cloud Storage section for more details.
  - **Link Share**: This menu enables you to link a share with your Autonomous Database. See Linking to Share.
  - **Linking Data Catalog** : This menu enables you to link Data Catalog to your Autonomous Database. See Linking Data Catalog.
  - **Link Database**: This menu enables you to link to data in tables in another database from your Oracle Autonomous Database. Refer to the Linking to Other Databases section for more details.
  - **Linking File System**: This menu enables you to link file system directories to your Autonomous Database. See Linking to File System.

- **Live Feed**: This menu enables us to create a live table feed on demand, on a schedule, or as the result of a notification. Refer to the Feeding Data section for more details.
- **Connections**: You can view all the existing connections from this option. This option enables you to edit or delete a cloud storage link and manage catalogs and shares. You can also create new cloud storage links. Refer to the Managing Connections chapter for more details.

After you load the data using the data load job, it becomes available in the Data Load page. You can later inspect, review and delete the table on clicking the **Actions** icon. You could also reload the cart from the Reload Cart button to reload cart using the current cart in case you want to make changes to the table. This data will be the source data of the Analytic View. Use breadcrumbs at the top of the page to navigate back to the home page.

Follow the steps described in The Data Load Page chapter in this book to load data from Oracle Cloud Infrastructure to your Autonomous Database.

Data Analysis

Analytic views provide metadata that highlight the parts of your data that are most important to your organization. By creating an AV, you can improve the value of automatic insights and the analysis of your data because the system has this metadata.

Select the **Data Analysis** menu from the navigation pane in the Data Studio Overview page to create Analytic Views and analyze the data from the Analytic View. The table you loaded using the Load Data feature will be used to create the Analytic View. You can select both hierarchies and measures from Analytic Views. Analytic Views utilize diagrams, symbols, and text, that represents how the data flows and the connection in between them. The Data Analysis tool helps you find the structural errors in the Analytic View you create. It spots anything from null values in a join column to duplicated fields. You can develop a visual representation of your analysis in the form of tables, Pivot tables and bar charts. You can also export the Analytic View to Tableau or Power BI for better visualization.

Create Analytic Views by referring to The Data Analysis Tool chapter in this book.

The **Related Insights** panel in the right works with the measures associated with the Analytic View to visualize data in the form of bar charts.

Table AI Assist

Select the **Table AI Assist** menu from the navigation pane in the Data Studio Overview page to effortlessly enhance your local data tables with the power of AI. You can use natural language prompts to augment and correct your information with this tool.

Refer to The Table AI Assist Tool chapter of this book for more information on the Table AI Assist page.

Automatic Insights

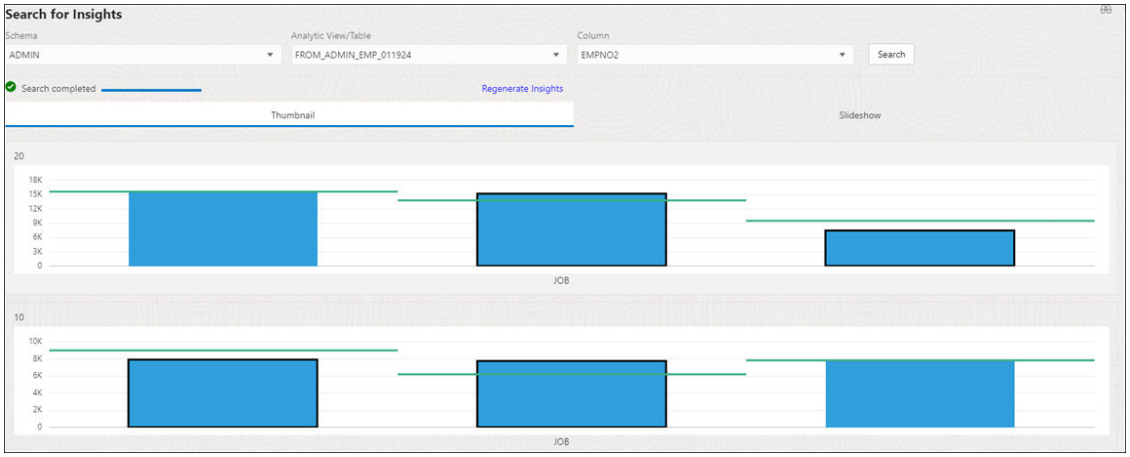
Select the **Automatic Insights menu** from the navigation pane in the Data Studio Overview page to generate insights automatically. The insights appear in the Data Insights dashboard as a series of bar charts.

By selecting the user, Analytic View, and the column name, you can view the data points of the actual values that deviate considerably from the forecast values. This type of predictive analytics will enable you to understand a pattern better and make better decisions. Then you can act on your data to optimize it or to improve its performance.

For example, consider that the fact table for the insights records values about different companies, and the measures of the fact table are Value (USD), Acquisition date and Acquisition year. Then you can generate insights for the Value measure. The dashboard will have a series of charts labeled Acquisition date and Acquisition year. Let’s say you want to view the value of your company **A**. Click the chart whose sale you want to display for a particular range of Acquisition year. Clicking a chart displays more details about it.

Generate automatic insights by referring to The Data Insights Page in this book.

Below is the chart that displays the values and insights.



According to the insights generated by the tool, you notice that your company is lagging from the expected value by a significant number. In order to lead you need to change a few factors that affect the sales of your organization.

The insights that Data Insights generates for the analytic view are more useful than those for a table because of the additional metadata that an analytic view provides.

Catalog

Select the **Catalog** menu from the navigation pane in the Data Studio Overview page to view information about the upstream dependencies of the entity, how the entity was created and how it is linked to other entities.

This page lists details about the database objects such as cloud storage links and tables you create from the Data Analysis tool and the Data load tool. It also displays lists of the database dictionary objects such as tables, columns, and Analytic Views.

Use the Catalog page to locate objects in the catalog and perform tasks specific to those objects.

Refer to The Catalog Tool chapter of this book for more information on the Catalog page.

Data Marketplace

Select the **Marketplace** menu from the navigation pane in the Data Studio Overview page to easily exchange metadata from data providers to data consumers, allowing easy data discovery and use.

Refer to The Data Marketplace Tool chapter of this book for more information on the Data Marketplace.

Data Share

Select the **Data Share** menu from the navigation pane in the Data Studio Overview page to provide data shares and consume data shares.

See The Data Share Tool

High Availability

You can configure and manage Autonomous Data Guard and maintain continuous availability using disaster recovery.

- Use Application Continuity on Autonomous Database
  Autonomous Database provides application continuity features for making connections to the database.
- Use Standby Databases with Autonomous Data Guard for Disaster Recovery
- Backup and Restore Autonomous Database Instances
  This section describes backup and recovery tasks on Autonomous Database.
- Use OraMTS Recovery Feature on Autonomous Database
  Use Oracle MTS (OraMTS) Recovery Service to resolve an in-doubt Microsoft Transaction Server transaction.
- Use Backup-Based Disaster Recovery
  Backup-Based Disaster Recovery provides a lower-cost disaster recovery option for Autonomous Database (the RTO is higher with this option, as compared to using Autonomous Data Guard).
- Track Table Changes with Flashback Time Travel
  Use Flashback Time Travel to view past states of database objects or to return database objects to a previous state without using point-in-time media recovery.
- Use OCI Full Stack Disaster Recovery with Autonomous Database
  You can enable the Oracle Cloud Infrastructure Full Stack Disaster Recovery on Autonomous Database.

Use Application Continuity on Autonomous Database

Autonomous Database provides application continuity features for making connections to the database.

- About Application Continuity on Autonomous Database
  Application Continuity masks outages from end users and applications by recovering the in-flight work for impacted database sessions following outages. Application Continuity performs this recovery beneath the application so that the outage appears to the application as a slightly delayed execution.
- Configure Application Continuity on Autonomous Database
  To configure Application Continuity you must enable application continuity for the database service your application uses and configure the failover type and the drain timeout. In addition, you must set several connection string parameters that enable high availability.
- Client Configuration for Continuous Availability on Autonomous Database
  You do not need to restart applications for planned maintenance activities when you enable Application Continuity and you follow the coding best practices.
- Notes for Application Continuity on Autonomous Database
  There are restrictions for Application Continuity on Autonomous Database, as follows:

About Application Continuity on Autonomous Database

Application Continuity masks outages from end users and applications by recovering the in-flight work for impacted database sessions following outages. Application Continuity performs this recovery beneath the application so that the outage appears to the application as a slightly delayed execution.

Your applications achieve *continuous availability* when planned maintenance, unplanned outages, and load rebalances of the database are hidden from the application. The combination of application coding best practices, application continuity configuration, and Autonomous Database ensures that your applications are continuously available.

The best approach for hiding planned maintenance activities from your applications is to transparently drain or failover applications. Oracle's connection pools and mid-tiers, including the WebLogic Server, Oracle Universal Connection Pool (UCP), OCI session pool and ODP.NET Unmanaged Provider are Fast Application Notification (FAN) aware and therefore are notified when maintenance is underway on Autonomous Database to allow graceful draining of work before maintenance. Application Continuity runs during planned maintenance to failover those sessions that do not drain in the predefined drain interval (5 minutes on Autonomous Database).

In order to hide unplanned outages resulting from a component or communication failure Oracle provides:

- **Notification.** FAN is the first step to hiding outages. FAN notifies clients and breaks them out of their current network wait when an outage occurs. This avoids stalling applications for long network waits. For Autonomous Database, FAN is handled at the driver and by the Autonomous Database cloud connection manger.

  FAN notification automatically triggers closing idle connections, opening new connections in the new service location, and allows a configurable time for active work to complete in the soon-to-be-shutdown service location. The major third-party JDBC mid-tiers, such as IBM WebSphere, allow for the same behavior when configured with UCP. For JDBC-based applications that cannot use UCP, Oracle provides solutions using Oracle Drivers and connection tests. On Autonomous Database FAN for planned maintenance is sent in-Band.

- **Recovery.** After the client is notified, failover handling with Transparent Application Continuity (TAC) or Application Continuity (AC) re-establishes a connection to the Autonomous Database and replays in-flight, uncommitted, work when possible. By replaying in-flight work, the application can usually continue executing without knowing that any failure happened.

You enable Application Continuity on Autonomous Database in one of two configurations, depending on the application:

- **Application Continuity (AC)**

  Application Continuity hides outages for thin Java-based applications, and Oracle Database Oracle Call Interface and ODP.NET based applications with support for open-source drivers, such as Node.js, and Python. Application Continuity rebuilds the session by recovering the session from a known point which includes session states and transactional states. Application Continuity rebuilds all in-flight work. The application continues as it was, seeing a slightly delayed execution time when a failover occurs.

- **Transparent Application Continuity (TAC)**

  Transparent Application Continuity (TAC) transparently tracks and records session and transactional state so the database session can be recovered following recoverable outages. This is done with no reliance on application knowledge or application code changes, allowing Transparent Application Continuity to be enabled for your applications. Application transparency and failover are achieved by consuming the state-tracking information that captures and categorizes the session state usage as the application issues user calls.

See Overview of Application Continuity for more information on Application Continuity.

> **Note:**
>
> By default Application Continuity is disabled on Autonomous Database.

Configure Application Continuity on Autonomous Database

To configure Application Continuity you must enable application continuity for the database service your application uses and configure the failover type and the drain timeout. In addition, you must set several connection string parameters that enable high availability.

- Configure Your Service to Enable Application Continuity
  Use `DBMS_APP_CONT_ADMIN` to enable Application Continuity or Transparent Application Continuity:
- Use Fast Application Notification (FAN)
  When connecting to Autonomous Database, the Oracle database auto-configures FAN. For application deployments with Autonomous Database, Fast Application Notification (FAN) events for unplanned outages are directed to the connection manager (CMAN) and no client application configuration steps required to use FAN.
- Configure Connection String for High Availability
  To maintain high availability, Oracle recommends that you set certain connection string parameters when you connect to Oracle Autonomous Database.
- Configure Driver Specific Client Options
  Depending on your client and your driver, you need to assure that the client is properly configured to use Application Continuity when you connect to Autonomous Database

Configure Your Service to Enable Application Continuity

Use `DBMS_APP_CONT_ADMIN` to enable Application Continuity or Transparent Application Continuity:

- **Application Continuity (AC)**: Set this failover option using the procedure `DBMS_APP_CONT_ADMIN.ENABLE_AC`. The `ENABLE_AC` procedure takes three parameters: `SERVICE NAME` is the service name to change, `FAILOVER_RESTORE`, set to `LEVEL1` to select Application Continuity(AC), and `REPLAY_INITIATION_TIMEOUT`, is the replay timeout that specifies how many seconds after a request is submitted to allow that request to replay.

  For example, as the ADMIN user, to enable Application Continuity for the `TPURGENT` service:

  ```
  execute DBMS_APP_CONT_ADMIN.ENABLE_AC(
          'databaseid_tpurgent.adb.oraclecloud.com', 'LEVEL1', 600);
  ```

- **Transparent Application Continuity (TAC)**: Set this failover option using the procedure `DBMS_APP_CONT_ADMIN.ENABLE_TAC`. The `ENABLE_TAC` procedure takes three parameters: `SERVICE NAME` is the service name to change, `FAILOVER_RESTORE`, set to `AUTO` to select Transparent Application Continuity (TAC), and `REPLAY_INITIATION_TIMEOUT` is the replay timeout that specifies how many seconds after a request is submitted to allow that request to replay.

  For example, as the ADMIN user, to enable Transparent Application Continuity for the `TP` service with the replay timeout set to 20 minutes:

  ```
  execute DBMS_APP_CONT_ADMIN.ENABLE_TAC(
          'databaseid_tp.adb.oraclecloud.com', 'AUTO', 1200);
  ```

- **Disabled**: Disable failover using the procedure `DBMS_APP_CONT_ADMIN.DISABLE_FAILOVER()`.

For example, as the ADMIN user, to disable failover for the `TP` service:

```
execute DBMS_APP_CONT_ADMIN.DISABLE_FAILOVER(
        'databaseid_tp.adb.oraclecloud.com');
```

Find the Service Name Parameter for Application Continuity

Depending on your workload type, use a command similar to the following to `SELECT` from `DBA_SERVICES` on your database and identify the service where you want to enable Application Continuity:

- **Data Warehouse**

```
SELECT name, failover_type FROM DBA_SERVICES;
NAME                                                  FAILOVER_TYPE
----------------------------------------------------- -------------
nvt21_adb1_low.adb.oraclecloud.com
nvt21_adb1_high.adb.oraclecloud.com
nvt21_adb1_medium.adb.oraclecloud.com
```

- **Transaction Processing** or **JSON Database**

```
SELECT name, failover_type FROM DBA_SERVICES;
NAME                                                  FAILOVER_TYPE
----------------------------------------------------- ----------------
nvt21_adb1_tp.adb.oraclecloud.com
nvt21_adb1_tpurgent.adb.oraclecloud.com
nvt21_adb1_low.adb.oraclecloud.com
nvt21_adb1_high.adb.oraclecloud.com
nvt21_adb1_medium.adb.oraclecloud.com
```

Notice the `FAILOVER_TYPE` for the `high` service has the no value and indicates that Application Continuity is disabled.

Verify Application Continuity is Enabled for a Service

Depending on your workload type, check the output of the query on `DBA_SERVICES` to verify that Application Continuity is enabled.

- **Data Warehouse**

```
SELECT name, failover_type FROM DBA_SERVICES;
NAME                                                  FAILOVER_TYPE
----------------------------------------------------- -------------
nvt21_adb1_low.adb.oraclecloud.com
nvt21_adb1_high.adb.oraclecloud.com                   AUTO
nvt21_adb1_medium.adb.oraclecloud.com
```

- **Transaction Processing** or **JSON Database**

```
SELECT name, failover_type FROM DBA_SERVICES;
NAME                                                  FAILOVER_TYPE
----------------------------------------------------- -------------
nvt21_adb1_tp.adb.oraclecloud.com
nvt21_adb1_tpurgent.adb.oraclecloud.com               TRANSACTION
nvt21_adb1_low.adb.oraclecloud.com
```

```
nvt21_adb1_high.adb.oraclecloud.com                    AUTO
nvt21_adb1_medium.adb.oraclecloud.com
```

The `FAILOVER_TYPE` value for the `high` service is now `AUTO`, indicating that Transparent Application Continuity (TAC) is enabled and the `FAILOVER_TYPE` value for the `tpurgent` service is now `TRANSACTION`, indicating that Application Continuity (AC) is enabled.

Use Fast Application Notification (FAN)

When connecting to Autonomous Database, the Oracle database auto-configures FAN. For application deployments with Autonomous Database, Fast Application Notification (FAN) events for unplanned outages are directed to the connection manager (CMAN) and no client application configuration steps required to use FAN.

FAN is automatically handled for you by the client driver and by the Autonomous Database Connection Manager (CMAN):

- For planned maintenance events, FAN is sent in-band, directly to the drivers. This requires that applications use Oracle Pools or TAC for request boundaries, or use connection tests.
- The Oracle Database and Oracle client drivers drain on connection tests and at request boundaries.

See Client Configuration for Continuous Availability on Autonomous Database for more information.

Configure Connection String for High Availability

To maintain high availability, Oracle recommends that you set certain connection string parameters when you connect to Oracle Autonomous Database.

Set the `CONNECT_TIMEOUT`, `RETRY_DELAY`, `RETRY_COUNT`, and `TRANSPORT_CONNECT_TIMEOUT` parameters in the connection string when you connect to Oracle Autonomous Database. The connect strings embedded in the Oracle-supplied `tnsnames.ora` file are preconfigured with appropriate values for most applications. In some cases, depending on your applications needs, you may need to change the preconfigured values for a connection string.

Use this TNS for all Oracle clients version 12.2 or higher:

```
alias =
(DESCRIPTION =
(CONNECT_TIMEOUT= 90)(RETRY_COUNT=50)
(RETRY_DELAY=3)(TRANSPORT_CONNECT_TIMEOUT=3)
(ADDRESS_LIST =
  (LOAD_BALANCE=on)
  (ADDRESS = (PROTOCOL = TCP)(HOST=scan-host)(PORT=1521)))
(CONNECT_DATA=(SERVICE_NAME = service-name)))
```

Use the following for JDBC connections using Oracle driver version 12.1 or earlier:

```
alias =
(DESCRIPTION =
(CONNECT_TIMEOUT= 15)(RETRY_COUNT=50)
(RETRY_DELAY=3)
(ADDRESS_LIST =
   (LOAD_BALANCE=on)
   (ADDRESS = (PROTOCOL = TCP)(HOST=scan-host)(PORT=1521)))
 (CONNECT_DATA=(SERVICE_NAME = service-name)))
```

Notes for connection strings:

- For JDBC and ODP clients, the pool connection wait time should be configured to be longer than the `CONNECT_TIMEOUT` in the connect string.
- Do not use Easy Connect Naming on the client because such connections do not have high-availability capabilities.

See Download Client Credentials (Wallets) for information on the `tnsnames.ora` file.

Configure Driver Specific Client Options

Depending on your client and your driver, you need to assure that the client is properly configured to use Application Continuity when you connect to Autonomous Database

- Configure JDBC Thin Driver
  Shows details to use Application Continuity with Autonomous Database with a client using the JDBC Thin Driver.
- Configure Oracle Call Interface (OCI) Driver
  Shows details to use Application Continuity with Autonomous Database with a client using the Oracle Call Interface (OCI) driver.
- Configure ODP.NET Unmanaged Provider Driver
  Shows details to use Application Continuity with Autonomous Database with a client using the ODP.NET Unmanaged Provider Driver.

Configure JDBC Thin Driver

Shows details to use Application Continuity with Autonomous Database with a client using the JDBC Thin Driver.

If your application uses the JDBC Thin Driver, follow these recommended practices:

1. Use JDBC Statement Cache for Coverage and Performance.

   For best coverage and performance, use the JDBC driver statement cache in place of an application server statement cache. This allows the driver to know that statements are closed and memory is to be freed at the end of requests.

   To use the JDBC statement cache, use connection property `oracle.jdbc.implicitStatementCacheSize (OracleConnection.CONNECTION_PROPERTY_IMPLICIT_STATEMENT_CACHE_SIZE)`. The statement cache is per connection. The value for the cache size matches your number of `open_cursors`. For example:

   `oracle.jdbc.implicitStatementCacheSize=`*`nnn`* where *`nnn`* is typically between 10 and 100 and is equal to the number of open cursors your application maintains.

2. Tune the Garbage Collector.

   For many applications the default Garbage Collector tuning is sufficient. For applications that return and keep large amounts of data you can use higher values, such as 2GB or larger. For example:

   ```
   java -Xms3072m -Xmx3072m
   ```

   It is recommended to set the memory allocation for the initial Java heap size (ms) and maximum heap size (mx) to the same value. This prevents using system resources on growing and shrinking the memory heap.

3. When using the Universal Connection Pool (UCP), disable Fast Connection Failover. For example:

```
PoolDataSource.setFastConnectionFailoverEnabled(false)
```

Configure Oracle Call Interface (OCI) Driver

Shows details to use Application Continuity with Autonomous Database with a client using the Oracle Call Interface (OCI) driver.

If the client application uses the Oracle Call Interface (OCI) Driver, follow this recommended practice:

- Replace `OCIStmtPrepare` with `OCIStmtPrepare2`. `OCIStmtPrepare()` has been deprecated since 12.2. All applications should use `OCIStmtPrepare2()`. Transparent Application Continuity (TAC) and Application Continuity (AC) allow `OCIStmtPrepare` but do not replay this statement.

Do not configure ONS servers in `oraaccess.xml`:

```
<ons>
   <servers>
   <!—Do not enter any values -->
   </servers>
</ons>
```

Also, for Autonomous Database Serverless, do not configure the <fan> section:

```
<fan>
<!-- only possible values are "trace" or "error" -->
    <subscription_failure_action>
   </subscription_failure_action>
</fan>
```

Configure ODP.NET Unmanaged Provider Driver

Shows details to use Application Continuity with Autonomous Database with a client using the ODP.NET Unmanaged Provider Driver.

The ODP.NET Unmanaged Provider driver automatically uses Application Continuity when Application Continuity is enabled on the database service that your application uses to connect to Autonomous Database.

When connecting an ODP.NET application to your Autonomous Database Serverless, do not configure ONS servers in `oraaccess.xml`:

```
<ons>
   <servers>
   <!—Do not enter any values -->
   </servers>
</ons>
```

Client Configuration for Continuous Availability on Autonomous Database

You do not need to restart applications for planned maintenance activities when you enable Application Continuity and you follow the coding best practices.

- Connect Using Database Services with Application Continuity Enabled
- Use Recommended Practices That Support Draining
  On Autonomous Database there is never a need to restart application servers when planned maintenance follows best practice.
- Steps for Using Application Continuity
  Perform these steps to use Application Continuity:
- Developer Best Practices for Continuous Availability
  Follow these best practices to code for continuous availability on Autonomous Database.

Connect Using Database Services with Application Continuity Enabled

Oracle database services provide transparency for the underlying Autonomous Database infrastructure.

The high availability and application continuity operations are predicated on the use of Autonomous Database connection services. To obtain application continuity, use a database service when you connect to your database.

The names of the predefined database services on Autonomous Database are different, depending on your workload, as described in Database Service Names for Autonomous Database.

Use Recommended Practices That Support Draining

On Autonomous Database there is never a need to restart application servers when planned maintenance follows best practice.

For planned maintenance, the recommended approach is to provide time for current work to complete before maintenance is started. On Autonomous Database this happens automatically and work is drained before starting maintenance activities when you follow these guidelines:

- FAN with Oracle Connection Pools or Oracle Drivers
- Connection tests

Use draining in combination with your chosen failover solution for those requests that do not complete within the allocated time for draining. Your failover solution will try to recover sessions that did not drain in the allocated time.

Return Connections to the Connection Pool

The application should return the connection to the connection pool on each request. It is best practice that an application checks-out a connection only for the time that it needs it. Holding a connection instead of returning it to the pool does not perform. An application should therefore check-out a connection and then check-in that connection immediately the work is complete. The connections are then available for later use by other threads, or your thread when needed again. Returning connections to a connection pool is a general recommendation regardless of whether you use FAN to drain, or connection tests to drain.

Use an Oracle Connection Pool

Using a FAN-aware, Oracle connection pool is the recommended solution for hiding planned maintenance. As the maintenance progresses and completes, sessions are moved and rebalanced. There is no impact to users when your application uses an Oracle Pool with FAN and returns connections to the pool between requests. Supported Oracle Pools include UCP, WebLogic GridLink, Tuxedo, OCI Session Pool, and ODP.NET Managed and Unmanaged providers. No application changes whatsoever are needed to use FAN other than making sure that your connections are returned to pool between requests.

Use UCP with a Third-Party Connection Pool

If you are using a third party, Java-based application server, the most effective method to achieve draining and failover is to replace the pooled data source with UCP. This approach is supported by many application servers including Oracle WebLogic Server, IBM WebSphere, IBM Liberty, Apache Tomcat, Red Hat WildFly (JBoss), Spring, and Hibernate, and others.

Use Connection Tests

If you cannot use an Oracle Pool with FAN, then the Autonomous Database or provided client drivers will drain the session. When services are relocated or stopped during maintenance, or there is a switchover to a standby site using Autonomous Data Guard, the Oracle Database and Oracle client drivers look for safe places to release connections according to the following rules:

- Standard connection tests for connection validity at borrow or return from a connection pool
- Custom SQL tests for connection validity
- Request boundaries are in effect and the current request has ended
- Use Connection Tests with Autonomous Database
  You can add, delete, enable or disable connection tests for Autonomous Database.
- Use Connection Tests with Thin Java Driver
- Use Connection Tests with OCI Driver

Use Connection Tests with Autonomous Database

You can add, delete, enable or disable connection tests for Autonomous Database.

Use the view `DBA_CONNECTION_TESTS` to show the available connection tests.

For example:

```
SQL> EXECUTE
   dbms_app_cont_admin.add_sql_connection_test('SELECT COUNT(1) FROM DUAL');
SQL> EXECUTE
   dbms_app_cont_admin.enable_connection_test(dbms_app_cont_admin.sql_test,
                                              'SELECT COUNT(1) FROM DUAL');
SQL> SELECT * FROM DBA_CONNECTION_TESTS;
```

Configure the same connection test that is enabled in your database at your connection pool or application server. Also configure flushing and destroying the pool on connection test failure to at least two times the maximum pool size or `MAXINT`.

Use Connection Tests with Thin Java Driver

If you would like to use connection tests that are local to the driver and cannot use UCP's full FAN support:

- Enable `validate-on-borrow=true`
- Set the Java system properties:
  - `-Doracle.jdbc.fanEnabled=true`
  - `-Doracle.jdbc.defaultConnectionValidation=SOCKET`

And then use one of the following tests:

- `java.sql.Connection.isValid(int timeout)`
- `oracle.jdbc.OracleConnection.pingDatabase()`
- `oracle.jdbc.OracleConnection.pingDatabase(int timeout)`
- A `HINT` at the start of your test SQL:
  - `/*+ CLIENT_CONNECTION_VALIDATION */`

Use Connection Tests with OCI Driver

If you would like to use the OCI driver directly, use `OCI_ATTR_SERVER_STATUS`. This is the only method that is a code change. In your code, check the server handle when borrowing and returning connections to see if the session is disconnected. During maintenance, the value of `OCI_ATTR_SERVER_STATUS` is set to `OCI_SERVER_NOT_CONNECTED`. When using OCI session pool, this connection check is done for you.

The following code sample shows how to use `OCI_ATTR_SERVER_STATUS`:

```
ub4 serverStatus = 0OCIAttrGet((dvoid *)srvhp,
          OCI_HTYPE_SERVER,
        (dvoid *)&serverStatus, (ub4 *)0, OCI_ATTR_SERVER_STATUS,
      errhp);if (serverStatus ==
        OCI_SERVER_NORMAL)printf("Connection is
        up.\n");else if (serverStatus ==
        OCI_SERVER_NOT_CONNECTED) printf("Connection is down.\n");
```

Steps for Using Application Continuity

Perform these steps to use Application Continuity:

- As a prerequisite, enable and configure Application Continuity or Transparent Application Continuity (TAC) for your database service on Autonomous Database. See Configure Application Continuity on Autonomous Database for more information.
- Oracle strongly recommends that you use the latest client drivers. Oracle Database 19c client drivers and later provide full support for Application Continuity (AC) and for Transparent Application Continuity (TAC). Use one of the following supported clients drivers:
  - Oracle JDBC Replay Driver 19c or later. This is a JDBC driver feature provided with Oracle Database 19c for Application Continuity

- Oracle Universal Connection Pool (UCP) 19c or later with Oracle JDBC Replay Driver 19c or later
- Oracle Weblogic Server 12c with Active GridLink, or third-party JDBC application servers using UCP with Oracle JDBC Replay Driver 19c or later
- Java connection pools or standalone Java applications using Oracle JDBC Replay Driver 19c or later
- Oracle Call Interface Session Pool 19c or later.SQL*Plus 19c (19.8) or later
- ODP.NET pooled, Unmanaged Driver 19c or later ("Pooling=true" default in 12.2 and later)
- Oracle Call Interface based applications using 19c OCI driver or later

Return Connections to the Connection Pool

The application should return the connection to the Oracle connection pool on each request. Best practice for application usage is to check-out (borrow) connections for only the time that they are needed, and then check-in to the pool when complete for the current actions. This is important for best application performance at runtime, for rebalancing work at runtime and during maintenance and failover events. This practice is also important for draining.

When using an Oracle connection pool, such as Universal Connection Pool (UCP) or OCI Session Pool, or ODP.Net Unmanaged Provider or when using WebLogic Active GridLink, following this practice embeds request boundaries that Application Continuity uses to identify safe places to resume and end capture. This is required for Application Continuity and is recommended for Transparent Application Continuity.

Transparent Application Continuity, in addition, will discover request boundaries if a pool is not in use or when replay is disabled. The conditions for discovering a boundary are:

- No open transaction
- Cursors are returned to the statement cache or cancelled
- No un-restorable session state exists (refer to Clean Session State between Requests in this paper)

Enable Mutables Used in the Application

Mutable functions are functions that can return a new value each time they are executed. Support for keeping the original results of mutable functions is provided for `SYSDATE`, `SYSTIMESTAMP`, `SYS_GUID`, and sequence.`NEXTVAL`. If the original values are not kept and different values are returned to the application at replay, replay is rejected.

If you need mutables for PL/SQL, issue `GRANT KEEP` as required.

For example:

```
SQL> GRANT KEEP DATE TIME to adb_user;
SQL> GRANT KEEP SYSGUID to adb_user;
SQL> GRANT KEEP SEQUENCE mySequence to adb_user on mysequence.myobject;
```

Side Effects

When a database request includes an external call such as sending MAIL or transferring a file then this is termed a side effect.

Side effects are external actions, they do not roll back. When replay occurs, there is a choice as to whether side effects should be replayed. Many applications choose to repeat side effects

such as journal entries and sending mail as duplicate executions cause no problem. For Application Continuity side effects are replayed unless the request or user call is explicitly disabled for replay. Conversely, as Transparent Application Continuity is on by default, TAC does not replay side effects. The capture is disabled, and re-enables at the next implicit boundary created by TAC.

Developer Best Practices for Continuous Availability

Follow these best practices to code for continuous availability on Autonomous Database.

Return Connections to the Connection Pool

The most important developer practice is to return connections to the connection pool at the end of each request. This is important for best application performance at runtime, for draining work and for rebalancing work at runtime and during maintenance, and for handing failover events. Some applications have a false idea that holding onto connections improves performance. Holding a connection neither performs nor scales.

Clean Session State between Requests

It is best practice to clean session state between database requests.

When an application returns a connection to the connection pool, cursors in FETCH status, and session state set on that session remain in place unless an action is taken to clear them. If your application is setting state, it is best practice to return your cursors to the statement cache and to clear application related session state to prevent leakage to later re-uses of that database session. Cleaning your session state ensures that TAC can discover boundaries.

To automatically clean your state between requests with Oracle Database 23ai, set the service attribute `RESET_STATE=LEVEL1`. Doing this will avoid state leakage and fetching from cursors by later usage of the connection pool.

If you are using Oracle Database 19c, use `DBMS_SESSION.RESET_PACKAGE` to clear PL/SQL global variables, use `TRUNCATE` to clear temporary tables, `SYS_CONTEXT.CLEAR_CONTEXT` to clear context and cancel your cursors by returning them to the statement cache.

If your application is stateless, such as REST, APEX, Microservice, and most web applications, it is best practice to use `RESET_STATE`.

Do not embed COMMIT in PL/SQL and Avoid Commit on Success and Autocommit

It is recommended practice to use a top-level commit, (`OCOMMIT` or `COMMIT()` or `OCITransCommit`). If your application is using `COMMIT` embedded in PL/SQL or `AUTOCOMMIT` or `COMMIT ON SUCCESS`, it may not be possible to recover following an outage or timeout. PL/SQL is not reentrant. Once a commit in PL/SQL has executed, that PL/SQL block cannot be resubmitted. Applications either need to unpick the commit which is not sound as that data may have been read, or for batch use a checkpoint and restart technique. When using `AUTOCOMMIT` or `COMMIT ON SUCCESS`, the output is lost.

If your application is using a top-level commit, then there is full support for Transparent Application Continuity (TAC), Application Continuity (AC), and TAF Select Plus. If your application is using `COMMIT` embedded in PLSQL or `AUTOCOMMIT` or `COMMIT ON SUCCESS`, it may not be possible to replay for cases where that the call including the `COMMIT` did not run to completion.

Use ORDER BY or GROUP BY in Queries

Application Continuity ensures that the application sees the same data at replay. If the same data cannot be restored, Application Continuity will not accept the replay. When a `SELECT` uses `ORDER BY` or `GROUP BY` order is preserved. In Autonomous Database the query optimizer most often uses the same access path, which can help in the same ordering of the results. Application Continuity also uses an `AS OF` clause to return the same query results where `AS OF` is allowed.

Considerations for SQL*Plus

SQL*Plus is often our go to tool for trying things out. SQL*Plus of course does not reflect our actual application that will be used in production, so it is always better to use the real application test suite to test your failover plan and to measure your protection. SQL*Plus is not a pooled application so does not have explicit request boundaries. Some applications do use SQL*Plus for example for reports. To use SQL*Plus with failover check the following:

1. FAN is always enabled for SQL*Plus. Use the recommended connect string that auto-configures ONS end points for you.
2. When using SQL*plus the key is to minimize round trips to the database: https://blogs.oracle.com/opal/sqlplus-12201-adds-new-performance-features
3. SQL*Plus is supported for TAC starting with Oracle Database 19c. For best results set a large arraysize. For example (set arraysize 1000). Avoid enabling serveroutput as this creates unrestorable session state.

Notes for Application Continuity on Autonomous Database

There are restrictions for Application Continuity on Autonomous Database, as follows:

- By default Application Continuity is disabled on Autonomous Database. See Configure Application Continuity on Autonomous Database for more information.
- For JDBC clients using Oracle Database JDBC driver and jars, draining for Java based applications on Autonomous Database requires that you use Oracle JDBC driver and Companion Jars 19.12.0.0 or newer, or apply a patch. See Patch Request 31112088 for more information.

Use Standby Databases with Autonomous Data Guard for Disaster Recovery

When you add an Autonomous Data Guard standby database, Autonomous Database provides data protection and disaster recovery for your database.

Autonomous Database Disaster Recovery Options

- **Autonomous Data Guard**: When you add an Autonomous Data Guard standby database, the system creates a standby database that continuously gets updated with the changes from the primary database. You can use Autonomous Data Guard with a standby in the current region, a local standby, or with a standby in a different region, a cross-region standby. You can also use Autonomous Data Guard with both a local standby and a cross-region standby.

  You can also create an Autonomous Data Guard standby in a different tenancy.

  Autonomous Data Guard is available for the following workload types:

  - Data Warehouse
  - Transaction Processing
- **Backup-Based Disaster Recovery**: uses backups to instantiate a peer database at the time of switchover or failover. This enables you to have a lower cost and higher Recovery Time Objective (RTO) disaster recovery option for your Autonomous Database, as compared with Autonomous Data Guard. For local Backup-Based Disaster Recovery, existing local backups are utilized. There are no additional costs for a local Backup-Based Disaster Recovery. Cross-Region Backup-Based Disaster Recovery incurs an additional cost. See Use Backup-Based Disaster Recovery for details on Backup-Based Disaster Recovery.

  Backup-Based Disaster Recovery is available for all workload types.

About Standby Databases

Provides information about enabling and using Autonomous Data Guard for disaster recovery on Autonomous Database.

When you use Autonomous Data Guard, the system creates a standby database that is continuously updated with the changes from the primary database. You can use Autonomous Data Guard with a standby in the current region, a local standby, or with one or more standby databases in different regions, cross-region standby databases, or you can add both a local standby and one or more a remote standby databases.

You can also create an Autonomous Data Guard standby, either local or remote in a different tenancy.

> **Note:**
>
> Autonomous Data Guard is available with the Data Warehouse and Transaction Processing workload types. Autonomous Data Guard is not available with the JSON and APEX workload types.

By selecting from the disaster recovery options that Autonomous Database provides, you can choose the features and options that meet your Recovery Time Objective (RTO) and Recovery Point Objective (RPO) requirements.

By default, each Autonomous Database instance provides a local Backup-Based Disaster Recovery peer database.

To add automatic failover and to lower your Recovery Time Objective (RTO), you can use a local Autonomous Data Guard standby database.

To use the most resilient disaster recovery option that Autonomous Database offers, you can add a local Autonomous Data Guard standby database and one or more cross-region Autonomous Data Guard standby databases.

In addition, other options using Backup-Based Disaster Recovery enable you to provide lower cost and higher Recovery Time Objective (RTO) disaster recovery options, as compared to Autonomous Data Guard. See Use Backup-Based Disaster Recovery for details on Backup-Based Disaster Recovery.

Topics

- Autonomous Data Guard with Local Standby
  When you use an Autonomous Data Guard standby database in the current region, Autonomous Database provisions a local standby database and monitors the primary database; if the primary database goes down, the standby instance automatically assumes the role of the primary instance.
- Autonomous Data Guard with Cross-Region Standby
  When you add a standby database in a different region, if the primary instance goes down, Autonomous Data Guard provides a standby database that is physically separated in a remote region. The standby database is available to assume the role of the unavailable primary instance.
- Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO)
- Autonomous Data Guard Operations
  Autonomous Data Guard provides a set of operations to manage a standby database, including: to enable, switchover, disconnect, or terminate a standby database.
- Autonomous Database Disaster Recovery Status
  Autonomous Database provides information about disaster recovery status on the Autonomous Database Details page.
- Autonomous Data Guard Events
  You can use Oracle Cloud Infrastructure events to respond when Autonomous Database changes its state due to an Autonomous Data Guard related event such as a failover or switchover operation.

Autonomous Data Guard with Local Standby

When you use an Autonomous Data Guard standby database in the current region, Autonomous Database provisions a local standby database and monitors the primary database; if the primary database goes down, the standby instance automatically assumes the role of the primary instance.

Local Autonomous Data Guard peer databases incur the additional cost of the base CPUs and the storage of the Primary database, including any auto-scaled storage usage, billed on the Primary database itself. Auto-scaled CPUs of the Primary database are not billed for additionally on the local Autonomous Data Guard peer database. See Oracle Autonomous Database Serverless Features Billing for more information.

Adding a local standby database provides an identical standby database that allows the following, depending on the state of the primary database:

- If your primary database goes down, Autonomous Data Guard converts the standby database to the primary database with minimal interruption. After failover completes, Autonomous Data Guard creates a new standby database for you.
- You can perform a switchover operation, where the primary database becomes the standby database, and the standby database becomes the primary database.

Autonomous Database does not provide access to a standby database in the current region. You perform all operations, such as scaling up the **ECPU count** (**OCPU count** if your database uses OCPUs) and enabling compute auto scaling on the primary database, and Autonomous Data Guard then performs the same actions on the local standby database. Likewise, you only perform actions such as stopping or restarting the database on the primary database.

A local standby database is created in the same region as the primary database (current region). For better resilience, the standby database is provisioned as follows:

- In regions with more than one availability domain, a local standby database is provisioned automatically in a different availability domain than the primary database.
- In regions with a single availability domain, a local standby database is provisioned automatically in a different fault domain than the primary database (that is, on a different physical machine).

See View Network Information on the OCI Console and Regions and Availability Domains for more information on availability domains.

All Autonomous Database features from the primary database are available when the local standby instance becomes the primary, after the system fails over or after you perform a switchover operation, including the following:

- **Database Options:** The **ECPU count** (**OCPU count** if your database uses OCPUs), Storage, Display Name, Database Name, Auto Scaling, Tags, and BYOL licensing options have the same values after a failover to the standby database or after you perform a switchover.
- **OML Notebooks:** Notebooks and users created in the primary database are available in the standby.
- **APEX Data and Metadata:** APEX information created in the primary database is copied to the standby.
- **ACLs:** The Access Control List (ACL) of the primary database is duplicated for the standby.
- **Private Endpoint:** The private endpoint from the primary database applies to the standby.

Oracle recommends that for a databases on a Private Endpoint, when you create the subnet you use the regional subnet option for optimum availability and latency. See Creating a Subnet for more information.

- **APIs or Scripts:** Any APIs or scripts you use to manage the Autonomous Database continue to work without any changes after a failover operation or after you perform a switchover.
- **Client Application Connections:** Client applications do not need to change their connection strings to connect to the database after a failover to the standby database or after you perform a switchover.
- **Wallet Based Connections:** You can continue using your existing wallets to connect to the database after a failover to the standby database or after you perform a switchover.

Autonomous Data Guard with Cross-Region Standby

When you add a standby database in a different region, if the primary instance goes down, Autonomous Data Guard provides a standby database that is physically separated in a remote region. The standby database is available to assume the role of the unavailable primary instance.

A cross-region standby database is a replica of the primary database and may be used for recovery in case of failure or when the primary is not available. Enabling Autonomous Data Guard with a cross-region standby provides a low RTO solution for disaster recovery in the event an entire region is not available or when the primary database is down for any reason.

Autonomous Data Guard cross-region standby databases incur the additional cost of the base CPUs and twice the storage of the Primary database, including any auto-scaled storage usage, billed on the remote peer database. Auto-scaled CPUs of the Primary are not billed for additionally on the remote peer database. The number of base CPUs is specified by the number of ECPUs (OCPUs if your database uses OCPUs) as shown in the **ECPU count** (**OCPU count**) field on the Oracle Cloud Infrastructure Console.

Autonomous Database allows you to create one or more remote disaster recovery peer databases, depending on your compute model:

- OCPU Compute Model: You can add one remote standby database in a paired region. Paired regions are remote regions where you can create a cross-region peer.
- ECPU Compute Model: You can add multiple remote disaster recovery peers, with up to one peer in each remote paired region. For example if your primary database is in the IAD region, you can add a standby database in PHX and a standby database in SJC, but you cannot add two remote disaster recovery peers in PHX.

Paired regions are remote regions where you can create a cross-region standby database. See Autonomous Database Cross-Region Paired Regions for more information on paired regions.

You perform almost all operations, such as scaling up the **ECPU count** (**OCPU count** if your database uses OCPUs) and enabling compute auto scaling on the primary database. Autonomous Data Guard then performs the same actions on the cross-region standby database.

After you add a remote standby database, Autonomous Database provides access to the remote standby database from the Oracle Cloud Infrastructure Console. Autonomous Database provides access to the remote standby database so that you can perform some operations independently on the remote standby, such as configuring networks and VCNs for private endpoints and adding tagging to define keys and values that are not replicated between the primary database and the remote standby.

> **Note:**
>
> Autonomous Data Guard does not perform automatic failover for a cross-region standby. If the primary database is unavailable and a local standby is unavailable, you can perform a manual failover to make a cross-region standby database assume the primary role.

You cannot connect to a cross-region standby while it operates as a standby database, and it is not available for read-only operations. You can connect to the database in the following cases:

- When the database assumes the primary role after a failover or switchover operation. See Perform a Switchover and Perform a Manual Failover for more information.
- After you convert a standby database to a snapshot standby database. See Convert Cross-Region Disaster Recovery Peer to a Snapshot Standby for more information.

The following areas have differences for failover or switchover from the primary database to a remote standby database, when compared to failover or switchover to a local standby:

- **Display Name**: The display name has a "*_region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

  If you created the cross-region peer before the introduction of support for multiple cross-region peers, the cross-region peer's display name has a "`_Remote`" extension.
- **OML Notebooks:** After a cross-region switchover or failover, OML notebooks from primary that was switched over or failed over are not present in the primary database (the current primary database after the role change). New OML notebooks can be created.
- **Private Endpoint**: You can independently configure and update private endpoints on a standby database before failover or before you perform a switchover. This allows you to have a private endpoint that is configured differently, after failover or after you perform a switchover. Autonomous Database does not keep the networking configuration synchronized from the primary to a remote standby.

  VCN Peering and domain forwarding are required for wallets to work across regions, with Autonomous Databases with a private endpoint with an Autonomous Data Guard standby, where the primary and the standby database are in different VCNs. See Remote VCN Peering using an RPC and DNS in Your Virtual Cloud Network for information on VCN peering and domain forwarding.
- **Network Access Control List**: By default a disaster recovery primary database and remote peer databases use the same network Access Control Lists (ACLs). Optionally, you can independently edit network ACLs on a remote peer database. This allows you to use different ACLs on a remote peer database.

  See Manage Remote Peer Network ACLs for more information.
- **Tags**: Tags are handled independently on a disaster recovery primary and on remote peer database. This means:
  - When you add, remove, or update a tag on a remote peer, the change applies only on the remote peer database.
  - When you add, update, or remove a tag on the primary, the tag is not added, updated, or removed on remote peer databases.
- **APIs or Scripts:** Any APIs or scripts you use to manage the Autonomous Database need to be updated to call the APIs on the primary database, the current primary database, after a failover or after you perform a switchover.

For mTLS connections, you must download a wallet from the primary database, the current primary database, after a failover or after you perform a switchover. See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.

- **Client Applications**: Client applications need to connect using the connection strings and wallet you download from the primary database, the current primary database, after a failover or after you perform a switchover. See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.
- **Wallet Based Connections:** You must download a wallet and connect using the connection strings from the primary database, the current primary database, to connect to the database after a failover or after you perform a switchover. See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.
- **Autonomous Database Tools**: The tools have different URLs in the primary database, the current primary database, after a failover or after you perform a switchover (the tools URLs do not change for a switchover or failover to a local standby):
  - Database Actions
  - Oracle APEX
  - Oracle REST Data Services (ORDS)
  - Graph Studio
  - Oracle Machine Learning Notebooks
  - Data Transforms
  - MongoDB API
- **Oracle Cloud Infrastructure Object Storage Usage**: After you failover or switchover from the primary database to a standby database, on the primary database (the current primary database) the credentials and the URLs that provide access to Object Storage continue to work as they did before the failover or the switchover, providing access to the following:
  - External tables
  - External partitioned tables
  - External hybrid partitioned tables

> **Note:**
>
> This applies when the Object Storage is available. For rare scenarios when the Object Storage is not available, Oracle recommends having Object Storage backups or replication to a different region. If the Object Storage is not available (that is the Object Storage resource you used with the Primary before a switchover or failover), you may update your user credentials and parameters that set URLs for Object Storage so that the parameters specify values to access an available region's Object Storage. See Using Replication for more information.

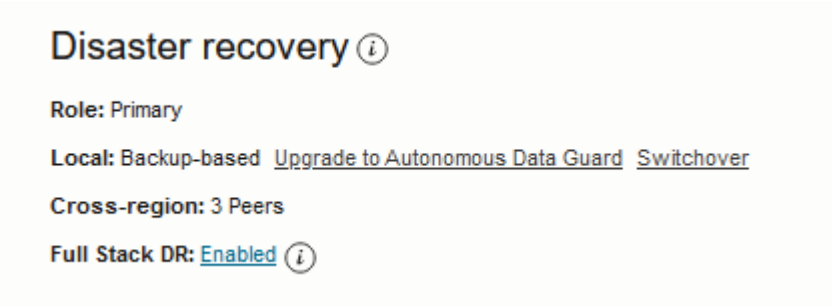
Cross Tenancy Autonomous Data Guard with Cross-Region Standby

You can enable cross tenancy Autonomous Data Guard with a cross-region standby. When you add a cross tenancy Autonomous Data Guard standby database in a different region, Autonomous Database provisions a cross-region standby database in the destination tenancy. With a cross tenancy Autonomous Data Guard standby, you can failover, switchover, or create a snapshot standby with a cross-region standby in a different tenancy. This feature allows you to use Autonomous Data Guard to migrate a database to a different tenancy.

See Use a Cross Tenancy Autonomous Data Guard Standby Database for more information.

OCI Full Stack Disaster Recovery with an Autonomous Data Guard Cross-Region Standby

When Full Stack Disaster Recovery is enabled, the Autonomous Database details page, under Disaster recovery, shows the **Full Stack DR** field as **Enabled**.



See Use OCI Full Stack Disaster Recovery with Autonomous Database for more information.

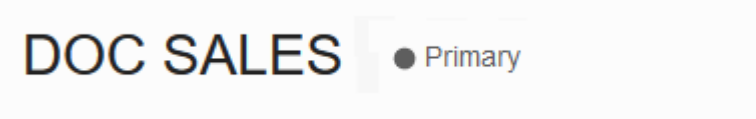
Topics

- Autonomous Data Guard Database Role
  After you add a cross-region standby database, each database has a designated role: primary, standby, or snapshot standby.
- Autonomous Data Guard Cross-Region Failover and Switchover
  You can have one local disaster recovery peer and optionally you can add one or more cross-region peers (multiple cross-region peers are allowed with the ECPU compute model). In both the local and cross-region cases, either peer can be a Backup-Based Disaster Recovery copy or an Autonomous Data Guard standby.
- Autonomous Data Guard Database Cross-Region Backup and Restore
  After you add an Autonomous Data Guard cross-region standby database, backup and restore from backup is handled as follows:
- Cross-Region Disaster Recovery Connection Strings and Wallets
  When you add an Autonomous Data Guard cross-region (remote) standby database, or when you use a cross-region Backup-Based Disaster Recovery peer, the wallet and connection string from the primary database contains only the hostname of the primary database.
- Autonomous Data Guard with Customer Managed Keys
  When you add an Autonomous Data Guard cross-region standby, there are special considerations when the primary database is using customer-managed keys, or if you want to switch to using customer-managed keys on the primary database.
- Replicating Backups to a Cross-Region Autonomous Data Guard Standby
  When you add a cross-region Autonomous Data Guard standby you can enable cross-region backup replication so that automatic backups from the primary are also available on a remote region.
- Autonomous Data Guard Cross-Region BYOL Licensing
  The **BYOL ECPU limit** you set on an Autonomous Data Guard Primary database does not apply to a cross-region or cross tenancy Autonomous Data Guard Standby database.

Autonomous Data Guard Database Role

After you add a cross-region standby database, each database has a designated role: primary, standby, or snapshot standby.

The role specifies the current state of a database, primary, standby, or snapshot standby, and this value changes after you perform a switchover or a failover or after you convert a standby database to a snapshot standby. You can view the Autonomous Database role in the icon that shows next to the display name on the Autonomous Database Information page. For example:



After you add a cross-region standby database, you can view the role in the **Disaster recovery** area on the details page. The role is one of:

- The **Role** shows **Primary** on the primary database.
- After a switchover or failover, on the same database the **Role** shows **Standby**.
- After you convert a cross-region peer to a snapshot standby, the **Role** shows as **Snapshot Standby**.

To view details for a peer, on the Autonomous Database details page, select the **Disaster recovery** tab. The list shows the peer database information and the **Peer role** column shows the peer role:

- **Standby** (local): the **Peer role** column shows **Standby** and the database has the same display name in the **Peer Autonomous Database** column. The **Region** column shows the name of the current region.
- **Standby** (cross-region) the **Peer role** column shows **Standby** for a remote standby database and the database has the same name with an "*_region*" extension in the **Peer Autonomous Database** column. You can click the link to access the remote database. The **Region** column shows the name of the remote region.

  If you created the cross-region peer before the introduction of support for multiple cross-region peers, the cross-region peer's display name has a "`_Remote`" extension.
- **Snapshot standby**: the **Peer role** column shows **Snapshot standby**. The **Region** column shows the name of the remote region.

Autonomous Data Guard Cross-Region Failover and Switchover

You can have one local disaster recovery peer and optionally you can add one or more cross-region peers (multiple cross-region peers are allowed with the ECPU compute model). In both the local and cross-region cases, either peer can be a Backup-Based Disaster Recovery copy or an Autonomous Data Guard standby.

With both a current region and one or more cross-region Autonomous Data Guard peer databases, depending on the state of the primary database, you have the following options:

- If your primary database goes down and the local standby database is available, Autonomous Data Guard automatically performs failover to convert the local standby

database to the primary database, with minimal interruption. After failover completes, Autonomous Data Guard creates a new local standby database for you. If automatic failover is not possible, you have the option to perform a manual failover.

Autonomous Data Guard continues to use the same cross-region peer databases.

- If your primary database goes down and the local standby database is not available, you can perform a manual failover to a cross-region peer database and the cross-region peer database you failover to becomes the primary database.

  In this case, after the failover completes, Autonomous Data Guard does not create a new local standby database (by default you have a backup copy peer).

- You can perform a switchover operation, where the primary database becomes the local standby database, and the local standby database becomes the primary database.

  Autonomous Data Guard continues to use the same cross-region peer databases.

- You can perform a switchover operation, where a cross-region peer database becomes the primary database (and the database that was the primary is recreated as a new standby database so that it becomes a peer database).

  A switchover changes the roles of the primary and a peer database. If you perform a switchover two times between the same two remote regions, the primary database returns to again be the primary database.

Autonomous Data Guard Database Cross-Region Backup and Restore

After you add an Autonomous Data Guard cross-region standby database, backup and restore from backup is handled as follows:

- If the primary database is restored from a backup, a new remote standby is created from the restored primary database.
- Automatic Backups are only taken on the primary database (the database showing **Role**: **Primary**). For example, after a switchover or failover, the database with the **Primary** role starts to perform automatic backups. A database with the **Standby** role no longer takes backups. If you switchover again, the database that becomes the **Primary** role database starts taking backups again.
- You cannot restore or clone from a backup when a peer database is in the **Standby** role. Backups are only taken on the database in the **Primary** role, and the restore operation is not available from the Oracle Cloud Infrastructure Console on a **Standby** database.

Cross-Region Disaster Recovery Connection Strings and Wallets

When you add an Autonomous Data Guard cross-region (remote) standby database, or when you use a cross-region Backup-Based Disaster Recovery peer, the wallet and connection string from the primary database contains only the hostname of the primary database.

In addition, the wallet and connection string from a remote peer database contains only the hostname of the remote database. This applies for both instance and regional wallets.

Oracle recommends that you configure your applications running on the Primary Role database to use the wallet or connection string downloaded from the Primary database. For applications that run on a remote database, use the wallet or connection string downloaded from the remote database (where the remote database is the current primary database after a failover or after you perform a switchover). You can obtain these connection strings or the wallet by clicking **Database connection** on the Oracle Cloud Infrastructure Console.

For example, if your cross-region Autonomous Data Guard is setup with the primary in Ashburn (IAD) and a cross-region standby in Phoenix (PHX), Oracle recommends that your

mid-tier applications running in IAD use the connection string or wallet from the primary database in IAD, and your corresponding applications that run in PHX after a failover or after you perform a switchover, use the connection string or wallet from the standby database in PHX. During regional failover or switchover, Oracle recommends failing over both your database and your mid-tier applications to the new Primary role database for optimum performance and to minimize any cross-regional latency.

See Download Client Credentials (Wallets) for more information.

If required by your application, you may manually construct connection strings containing both primary and remote database hostnames, to support connecting to either instance that is available and open for connections automatically, the primary or the remote database.

For details on the steps to manually create these connection strings see:

- Configure your mid-tier applications for cross-region disaster recovery
- Autonomous Data Guard Notes

Autonomous Data Guard with Customer Managed Keys

When you add an Autonomous Data Guard cross-region standby, there are special considerations when the primary database is using customer-managed keys, or if you want to switch to using customer-managed keys on the primary database.

> **Note:**
>
> Autonomous Database supports multiple customer-managed keys providers. Only Oracle Cloud Infrastructure Vault is supported for use with Autonomous Data Guard. Other vaults are not supported for customer-managed keys.

In order for a remote standby to be able to use the same master encryption key as the primary database, the master encryption key must be replicated to the remote region. Customer-Managed Encryption Keys are only supported with a single cross-region Autonomous Data Guard standby. Multiple cross-region standbys are not supported because Oracle Cloud Infrastructure Vault only supports replication to one remote region.

Consider the following cases:

- Adding an Autonomous Data Guard remote standby is allowed if the Autonomous Database is using customer-managed keys. When the database is using a customer-managed key and you add an Autonomous Data Guard cross-region standby, the **Region** list in the **Add peer database** dialog only shows the regions that contain the replicated vault and keys. If you don't see a remote region listed, you need to replicate your vault and keys to the region where you want your standby database (this must be a paired region).
- Switching to customer-managed keys is allowed on the primary when you have an Autonomous Data Guard cross-region standby. In the case when the database is using Oracle-managed keys and you switch to customer-managed keys on the primary, you only see the keys that are replicated in both the primary and the standby regions. The Manage Encryption Key **Vault** and **Master encryption key** lists only show vaults and keys that are replicated across both the primary and the standby regions. If you don't see a key listed, replicate your vault and keys to a paired region.

See the following for more information:

- Manage Master Encryption Keys in OCI Vault
- Replicating Vaults and Keys

- Overview of Vault
- Autonomous Database Cross-Region Paired Regions

Replicating Backups to a Cross-Region Autonomous Data Guard Standby

When you add a cross-region Autonomous Data Guard standby you can enable cross-region backup replication so that automatic backups from the primary are also available on a remote region.

By default the backups taken on the primary are not replicated to a cross-region standby database. When you enable cross-region backup replication, up to 7 days of automatic backups for the primary are replicated to a cross-region standby database. When this feature is enabled, automatic backups are available in the remote region as follows:

- After a switchover or failover you can restore or clone to any timestamp in the past seven (7) days, or to any timestamp in the specified retention period when the retention period is set to less than seven days.
- All backups for the primary that are replicated to the remote region are deleted on the remote region peer after seven days, or after the retention period number of days when the retention period is set to less than seven days.
- You cannot modify the backup retention period for replicated backups, except if you modify the backup retention period on the primary to specify a value less than seven days. In this case, the retention period for replicated backups on the remote region matches the automatic backup retention period set on the primary.

Cross-region backup replication incurs an additional cost. See Oracle Autonomous Database Serverless Features Billing for more information.

See Add a Cross-Region Standby Database and Enable or Disable Backup Replication for an Existing Cross-Region Standby for more information.

Note the following for cross-region automatic backup replication:

- After a switchover or a failover, while the cross-region database is in the primary role, backups are taken on the current primary and are replicated to the current (remote) standby.
- In a remote region you can create a clone from a replicated backup while the database is in the **Standby** role.

Autonomous Data Guard Cross-Region BYOL Licensing

The **BYOL ECPU limit** you set on an Autonomous Data Guard Primary database does not apply to a cross-region or cross tenancy Autonomous Data Guard Standby database.

On a cross-region or cross-tenancy Standby you can independently set the **BYOL ECPU limit**, as required. Setting a value for **BYOL License limit** limits how many ECPUs will be covered by BYOL licenses.

For example, consider an 8 ECPU Autonomous Data Guard Primary database using BYOL licensing. When you add a cross-region or cross tenancy Standby, the Standby takes its licensing from the Primary (using BYOL licensing).

In this example, if you set the **BYOL License limit** to 4 (ECPUs) on the Primary, then 4 of the 8 ECPUs use BYOL licensing. However, the **BYOL License limit** you set on the Primary does not apply on a cross-region or cross tenancy Standby. The Standby uses Bring your own license (BYOL) licensing (without a **BYOL License limit**). If you separately set a **BYOL License limit** on the Standby, for example if you set the **BYOL License limit** value to 2

(ECPUs), 2 ECPUs on the Standby are billed using BYOL licensing and 6 ECPUs. Similarly, the **BYOL ECPU limit** you set on the Standby does not affect the Primary's **BYOL ECPU limit**.

See Choose Bring Your Own License Option While Provisioning or Cloning and Choose Bring Your Own License on Autonomous Database (ECPU Compute Model) for more information.

Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO)

Autonomous Data Guard monitors the primary database and if the instance goes down, the local standby instance assumes the role of the primary instance, according to the Recovery Time Objective (RTO) and Recovery Point Objective (RPO).

If a local Autonomous Data Guard standby instance is not available and you have enabled cross-region disaster recovery, you can manually fail over to the cross-region standby.

If you do not add a cross-region Autonomous Data Guard standby, you have the option to add a cross-region Backup-Based Disaster Recovery peer. See Backup-Based Disaster Recovery Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for details on the RTO and RPO with Backup-Based Disaster Recovery.

The RTO is the maximum amount of time required to restore database connectivity to a standby database after a manual or automatic failover is initiated. The RPO is the maximum duration of potential data loss on the primary database.

Local Autonomous Data Guard Standby

When you add a local standby database Autonomous Data Guard provides these options for failover or switchover:

- **Automatic Failover or Switchover**:

  When you enable Autonomous Data Guard you can select a data loss limit. The default data loss limit for automatic failover is 0 (valid values are 0 to 3600 seconds). For example, a data loss limit of 0 means that Autonomous Data Guard only performs automatic failover when there is no data loss. This means if Autonomous Data Guard can verify that there is no data loss, it automatically fails over in case of a problem. When there is a problem and Autonomous Data Guard determines that the possible data loss is greater than the data loss limit, automatic failover does not happen and you have the option to perform a manual failover.

- **Manual Failover**: the RTO is two (2) minutes and the RPO 10 seconds

Cross-Region Autonomous Data Guard Standby

When you add a cross-region standby database, the RTO and RPO numbers for failover to the Autonomous Data Guard cross-region standby are as follows:

- **Switchover**: the RTO is less than ten (10) minutes and RPO is zero (0).
- **Automatic Failover**: Not available
- **Manual Failover**: the RTO is less than ten (10) minutes and RPO is up to one (1) minute.

See the following for more information:

- Automatic Failover with a Standby Database for details on automatic failover.
- Perform a Switchover
- Perform a Manual Failover
- Service Level Objectives (SLOs)

Autonomous Data Guard Operations

Autonomous Data Guard provides a set of operations to manage a standby database, including: to enable, switchover, disconnect, or terminate a standby database.

Operation	Description
Convert to Snapshot Standby	Converting a disaster recovery peer to a snapshot standby opens the database in read-write mode and the cross-region disaster recovery peer temporarily stops refreshing data from the source database. See Convert Cross-Region Peer to Snapshot Standby for more information.
Disable Autonomous Data Guard	If you have a local standby database or a cross-region standby database, you can change the disaster recovery type to Backup-Based Disaster Recovery for the local standby or you can terminate a cross-region standby. In either case, disabling Autonomous Data Guard terminates the standby database. See Update Standby to Use a Backup Copy Peer or Disable a Cross-Region Standby Database for details.
Disconnect Standby	When you disconnect a cross-region standby, the standby is disassociated from the Primary database. This converts the database from a peer database to a standalone database. Following the disconnect operation you are not allowed to reconnect to the Primary. See Disconnect a Peer Database and Disconnect a Snapshot Standby for more information.
Enable Autonomous Data Guard	If you are using Backup-Based Disaster Recovery, you can update your disaster recovery type to local (current region) Autonomous Data Guard, or you can add an Autonomous Data Guard cross-region standby. See Enable Autonomous Data Guard and Add a Cross-Region Standby Database for details.
Failover - Automatic	After you add a local Autonomous Data Guard standby database, the system monitors the primary instance and automatically fails over to a local standby database in certain scenarios. See Automatic Failover with a Standby Database for more information.
Failover - Manual	If the primary database is not available you can perform a manual failover to change roles to make a standby database the primary database: • If a local standby is available, you can manually failover to the local standby (you do not have the option to failover to a remote standby if a local standby is available). • If a local standby is not available, you have the option to manually failover to a remote standby. See Perform a Manual Failover for details.
Switchover	When Autonomous Data Guard is enabled, switchover changes the roles of the primary and the standby, the standby database becomes the primary, and the primary database becomes the standby. If you have both a local standby database (current region), and a cross-region standby database (remote), you can choose to switchover to either the local standby or the remote standby. See Perform a Switchover for details.
Terminate	If you want to terminate the primary instance, select **More actions** and **Terminate**. Terminating the primary instance also terminates a local standby database. If you have both a local standby database (current region), and a cross-region standby database, you must terminate the cross-region standby database before you terminate the primary database. See Terminate a Cross-Region Standby Database for details.

Autonomous Database Disaster Recovery Status

Autonomous Database provides information about disaster recovery status on the Autonomous Database Details page.

In the **Disaster recovery** area:

The **Role** field shows the role of the current database, as follows:

- When you have either a local backup copy peer or a local Autonomous Data Guard standby, the Oracle Cloud Infrastructure Console shows the **Role** field value **Primary**. Autonomous Database does not provide access to a local standby database (or to a local backup copy peer).
- When using either a cross-region backup copy peer or a cross-region Autonomous Data Guard standby, the Oracle Cloud Infrastructure Console shows the **Role** field value **Primary** if you are viewing the primary database and shows **Standby** if you are viewing the details for a standby database.
- **Switchover**: Provides a link so that you can perform a switchover operation.
- **Failover**: When the primary database is not available and you have a local standby and automatic failover was not successful, the failover link allows you initiate a manual failover.

  When the primary database is not available and you have a cross-region standby and failover to a local standby is not possible, the failover link allows you initiate a manual failover to the remote standby database.

To view the peer Autonomous Database information, on the Autonomous Database details page select the **Disaster recovery** tab. This shows the peer Autonomous Database information. The **State** column shows the state of a standby database, as follows:

- **Provisioning**
  - This state shows when you enable Autonomous Data Guard and indicates that a standby database is provisioning (until the standby database state changes to **Standby**).
  - This state shows after a failover to a local standby when a local standby database is being recreated.
  - This state shows if a restore from backup operation is performed on the primary database, the local standby is recreated and the **State** column shows Provisioning.
- **Standby**: Indicates that a standby is available and ready for either a switchover or a failover operation.

> **Note:**
>
> When a standby database is stopped, the standby state shows **Standby**. A standby database never shows the **Stopped** state.

- **Role Change in Progress**: Indicates a failover or switchover operation started.

Autonomous Data Guard Events

You can use Oracle Cloud Infrastructure events to respond when Autonomous Database changes its state due to an Autonomous Data Guard related event such as a failover or switchover operation.

Autonomous Database events include the following:

- Begin automatic failover
- End automatic failover
- Begin disable Autonomous Data Guard
- Begin enable Autonomous Data Guard
- Begin failover
- Begin switchover
- End disable Autonomous Data Guard
- End enable Autonomous Data Guard
- End failover with failover result of success or failure.
- End switchover with switchover result of success or failure.

Based on events you can perform actions or send notifications. See Events and Notifications for a Standby Database for more information on using events and producing notifications.

Enable Autonomous Data Guard

To enable Autonomous Data Guard you update the disaster recovery type to use a standby database.

By default and at no additional cost, Autonomous Database provides a local backup copy peer for each Autonomous Database instance. You enable Autonomous Data Guard by changing the disaster recovery type to use a standby database. Autonomous Data Guard provides a lower Recovery Time Objective (RTO), compared to using a backup copy peer, and provides for automatic failover to a local standby when the primary database is not available.

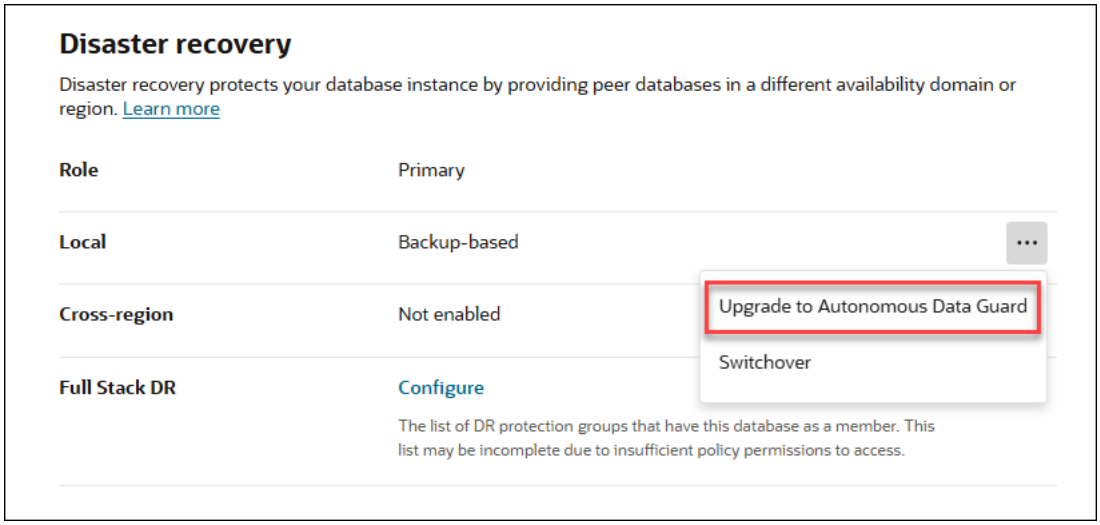
> **Note:**
>
> When you change your disaster recovery type to use a local standby database, you also have the option to add a second cross-region disaster recovery option, either a cross-region Autonomous Data Guard standby database or a cross-region backup copy peer.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

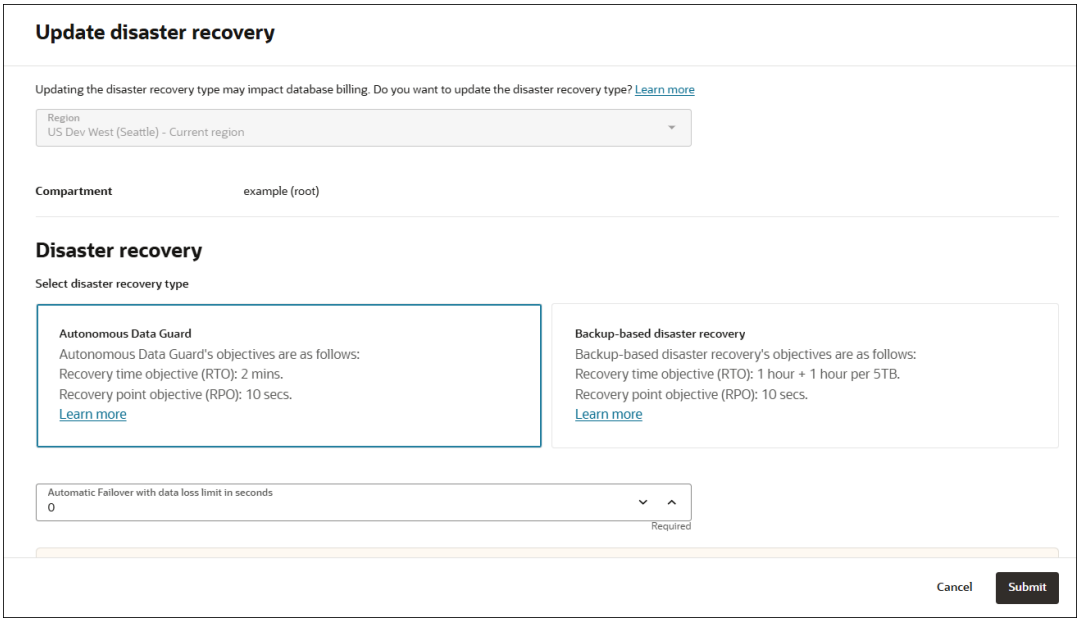
To change your disaster recovery type to add a local Autonomous Data Guard standby database:

1. On the **Autonomous Database information** tab, in the **Disaster recovery** area, click ··· at the end of the **Local** field and select **Upgrade to Autonomous Data Guard**.



This shows the Update disaster recovery page.

2. Select Autonomous Data Guard.



3. In the **Automatic Failover with data loss limit in seconds** field, accept the default data loss limit of 0, or enter a custom value for the automatic failover data loss limit.

   See Automatic Failover with a Standby Database for more information.

4. Click **Submit**.

   The Autonomous Database Lifecycle state changes to **Updating**.

   The **State** column shows Provisioning while Autonomous Database provisions the standby database.

   After some time the **Lifecycle state** shows **Available** and the standby database provisioning continues.

   When provisioning completes the **DR type** column shows Autonomous Data Guard.

> **Note:**
>
> While you add a new standby database, the primary database is available for read/write operations. There is no downtime on the primary database.

Notes for changing the disaster recovery type to a local Autonomous Data Guard standby database:

- Autonomous Database generates an Enable Autonomous Data Guard work request. To view the request, on the details page, select the **Work requests** tab.

  You may need to wait for the work request to complete to 100% before you see Autonomous Data Guard in the **DR type** column on the **Disaster recovery** tab. The provisioning process takes several minutes.
- While you add a local standby database, when the **Lifecycle state** field shows **Updating**, the following actions are disabled for the primary database:
  - Move Resource. See Move an Autonomous Database to a Different Compartment for information on moving an instance.
  - Stop. See Stop Autonomous Database for information on stopping an instance.
  - Restart. See Restart Autonomous Database for information on restarting an instance.
  - Restore. See Restore and Recover your Autonomous Database for information on restoring.

Update Standby to Use a Backup Copy Peer

Describes the steps to change the disaster recovery type from Autonomous Data Guard standby database to Backup-Based Disaster Recovery.

These steps terminate the standby database. By default Autonomous Database provides a Backup-Based Disaster Recovery peer and these steps change the disaster recovery type from Autonomous Data Guard to backup copy.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To change the disaster recovery type:

1. On the Autonomous Database Details page, select the **Disaster recovery** tab.
2. In the row showing the disaster recovery details, at the end of the row click ⋯ and select **Update disaster recovery**.

   This shows the Update disaster recovery pane.
3. Select **Backup-based disaster recovery**.
4. Click **Submit**.

   While the standby database is terminating, the **Lifecycle state** changes to **Updating**.

   Autonomous Database generates the Disable Autonomous Data Guard work request.

To view the request, on the Autonomous Database details page select the **Work requests** tab.

Autonomous Data Guard Switchover and Failover Operations

Describes switchover and failover operations with an Autonomous Data Guard standby database.

- Perform a Switchover
  When you perform a switchover, the primary database becomes the standby database and the standby database becomes the primary database, with no data loss.
- Automatic Failover with a Standby Database
- Perform a Manual Failover

Perform a Switchover

When you perform a switchover, the primary database becomes the standby database and the standby database becomes the primary database, with no data loss.

A switchover is typically done to test failover to the standby database for audit or certification reasons, or to test your application's failover procedures when you have added an Autonomous Data Guard standby database.

For switchover to a standby database, the Oracle Cloud Infrastructure Console on the primary database shows a **Switchover** link under **Disaster recovery** area when both the primary database and a standby database are available. You can perform a switchover when the primary database **Lifecycle state** shows **Available** or **Stopped**, and a standby database is available (the **State** field shows **Standby**).

To see either local or cross-region standby database state, on the Autonomous Database details page select the **Disaster recovery** tab and for a standby database listed in the **Peer Autonomous Database** column, check that the **State** shows **Standby**.

Using the Autonomous Database API, you can initiate the switchover operation at any time. See Use the API for more information.

> **Note:**
>
> When Full Stack Disaster Recovery is enabled, the Autonomous Database details page, under Disaster recovery, shows the **Full Stack DR** field as **Enabled**. See Use Full Stack Disaster Recovery to Perform Switchover or Failover Operations for details on performing a switchover or a failover when Full Stack Disaster Recovery is enabled.

- Perform a Switchover to a Local Standby
- Perform a Switchover to a Cross-Region Standby
- Notes for Performing a Switchover

Perform a Switchover to a Local Standby

When you perform a switchover, the primary database becomes the standby database and the standby database becomes the primary database, with no data loss.

To perform switchover to a local standby, you access the primary database from the Oracle Cloud Infrastructure Console.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To perform a switchover to a local standby:

1. On the Autonomous Database Details page, in the **Disaster recovery** area, in the **Local** field click and in the menu select **Switchover**.

   As an alternative, to initiate a switchover you can select **More actions** and in the menu select **Switchover**.
2. In the **Confirm switchover to peer** dialog, enter the peer database name to confirm that you want to perform the switchover.
3. In the **Confirm switchover to peer** dialog, click **Switchover**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

   The database **Lifecycle state** changes to **Updating**. To see the state of the peer database, select the **Disaster recovery** tab. The **State** column shows **Role change in progress**.

After the switchover completes, Autonomous Database reports the time of the last switchover in the **Role** field on the Autonomous Database Details page under **Disaster recovery**.

See Notes for Performing a Switchover for more information.

Perform a Switchover to a Cross-Region Standby

When you perform a switchover, the primary database becomes the standby database and the standby database becomes the primary database, with no data loss.

> **Note:**
>
> For a cross-region switchover you must initiate the switchover from the Standby database.

You have several options to access the Standby database:

- Select the remote region in Oracle Cloud Infrastructure Console and then access the Standby database.
- From the Oracle Cloud Infrastructure Console access the primary, and from the primary database's Autonomous Database Details page select the **Disaster recovery** tab. From this page click the link for a standby database in the **Peer Autonomous Database** column.

> **Note:**
>
> When Full Stack Disaster Recovery is enabled, the Autonomous Database details page, under Disaster recovery, shows the **Full Stack DR** field as **Enabled**. See Use Full Stack Disaster Recovery to Perform Switchover or Failover Operations for details on performing a switchover or a failover when Full Stack Disaster Recovery is enabled.

To perform a switchover to a cross-region standby:

1. On the cross-region standby database, on the Autonomous Database Details page, in the **Disaster recovery** area, in the **Role** field click ⋯ and in the menu select **Switchover**.

   As an alternative, to initiate a switchover you can select **More actions** and **Switchover**.
2. In the **Confirm switchover to peer** dialog, enter the peer database name to confirm that you want to perform the switchover.
3. In the **Confirm switchover to peer** dialog, click **Switchover**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

   The database **Lifecycle state** changes to **Updating**. To see the state of the peer database, select the **Disaster recovery** tab. The **State** column shows **Role change in progress**.

When the switchover completes, Autonomous Data Guard does the following:

- The display name shows the standby indicator.
- The **Disaster recovery** resource information is updated to reflect the switchover. Select the **Disaster recovery** tab to see the updated information.
- After the switchover completes, Autonomous Database reports the time of the last switchover in the **Role** field on the Autonomous Database Details page under **Disaster recovery**.

See Notes for Performing a Switchover for more information.

Notes for Performing a Switchover

Notes for performing a switchover on Autonomous Database.

- For a cross-region switchover, you must initiate the switchover from the Standby database.
- During the switchover most of the actions on the Oracle Cloud Infrastructure Console are not available and the Autonomous Database Information page shows the **Lifecycle state** with the value **Updating**.
- The switchover operation keeps the original state of the primary database. If the primary database is stopped when you perform a switchover, the primary database is stopped after the switchover.
- Autonomous Database generates the Switchover Autonomous Database work request. To view the request, on the Autonomous Database details page select the **Work requests** tab.
- After a switchover or failover to the standby, the standby becomes the primary:

  - The Oracle Cloud Infrastructure Metrics display information about the primary database.
  - The graphs on the **Database Dashboard** card in Database Actions display information about the primary database.
  - The graphs and metrics do not contain information about the database that was the primary database, before the switchover or failover operation.
- You cannot cancel a cross-region switchover operation after the switchover begins and the **State** shows **Role change in progress**. Your options are:
  - Try or retry a switchover or a failover until the operation succeeds.
  - File a service request at Oracle Cloud Support or contact your support representative.

Automatic Failover with a Standby Database

After you add a local Autonomous Data Guard standby database, the system monitors the primary instance and automatically fails over to a local standby database in certain scenarios.

If automatic failover is not possible, you have the option to perform a manual failover. Automatic failover does not apply to a cross-region standby.

Autonomous Database automatically fails over to a local standby database as follows:

- When the primary database becomes unavailable and users are not able to connect, Autonomous Data Guard automatically fails over to a local Autonomous Data Guard standby database if a local standby database is available, based on the Recovery Time Objective (RTO) and when Autonomous Data Guard determines that the automatic failover data loss limit will not be exceeded.
- Autonomous Data Guard performs automatic failover to a local standby database when a local standby database is available and the system can guarantee either the default zero data loss or up to the data loss limit you specified a data loss limit when you enabled Autonomous Data Guard. You can specify an automatic failover data loss limit between 0 and 3600 seconds. If this target cannot be met then automatic failover does not occur and you have the option to perform a manual failover.

  See Enable Autonomous Data Guard for information on setting the automatic failover data loss limit.
- After automatic failover to a local standby database completes, Autonomous Database creates a new local standby database for you.

  Autonomous Data Guard for a particular standby, either local or remote, is not enabled while the system is provisioning the new standby database. After Autonomous Data Guard completes the provisioning step for the standby database and it becomes available, you then have a new standby database with Autonomous Data Guard enabled on it.
- After the failover completes, Autonomous Database reports the time of the last failover in the **Role** field on the Autonomous Database Details page under **Disaster recovery**.
- After an automatic Autonomous Data Guard failover, if there was a regional failure, when the region comes back online the standby database is automatically reconnected or if required reprovisioned.

If the primary database has failed or is unreachable and the conditions for Autonomous Data Guard automatic failover have not been met, then Oracle Cloud Infrastructure console shows a banner indicating that automatic failover did not succeed, provides a reason, such as possible data loss above the default 0 RPO or above the limit you set for the automatic failover data loss limit, and provides a link for you to initiate manual failover. See Perform Manual Failover to a Local Standby Database for more information.

> **Note:**
>
> Autonomous Data Guard automatic failover is disabled when the **Lifecycle state** is either: **Restore in Progress** or **Upgrading**.

See Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.

Perform a Manual Failover

When Autonomous Data Guard cannot automatically fail over to a local standby database, if a local standby database is available you can perform a manual failover to make the local standby database the primary database.

If a cross-region standby is available, you can perform a switchover to make the cross-region standby database the primary database. If the switchover fails, you can initiate a manual failover to the cross-region standby. It is possible for data loss to occur with a manual failover.

When you initiate a manual failover Autonomous Data Guard fails over to the standby database based on the Recovery Time Objective (RTO) and Recovery Point Objective (RPO) targets. See Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.

- Perform Manual Failover to a Local Standby Database
- Perform Manual Failover to a Cross-Region Standby Database
  If a cross-region peer is available you can perform a switchover to make a cross-region peer the primary database. If the switchover fails, you can initiate a manual failover to the cross-region peer.
- Notes for Manual Failover with a Standby Database

Perform Manual Failover to a Local Standby Database

When Autonomous Data Guard cannot automatically fail over to a local standby database, if a local standby database is available you can perform a manual failover to make the local standby database the primary database.

When you add a local Autonomous Data Guard standby and automatic failover is not successful, Oracle Cloud Infrastructure console shows a banner with information about why the automatic failover was not successful. The Oracle Cloud Infrastructure console also shows a **failover** link in the **Role** field that you can click to initiate a manual failover to the local standby. The failover link only shows when the primary database is unavailable and a standby database is available. That is, the **Lifecycle state** field shows **Unavailable** and the local standby database is available.

Using the API, you can initiate manual failover at any time. See Use the API for information on using the API.

To see the standby database status, on the details page, select the **Disaster recovery** tab and for the standby database listed in the **Peer Autonomous Database** column, check that the **State** field shows **Available** or **Stopped**.

Perform the following prerequisite steps as necessary:

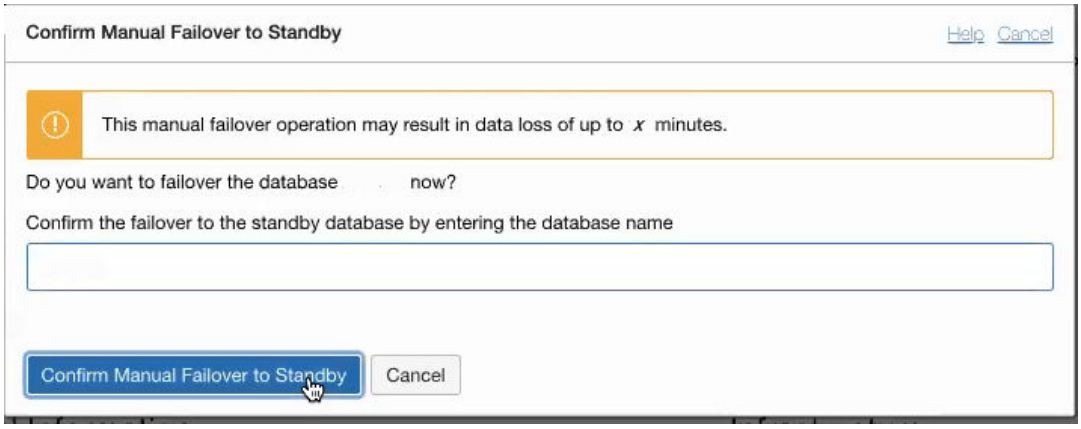
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.

- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To initiate a manual failover when the primary database is unavailable and the local standby is available:

1. On the Autonomous Database details page, under **Disaster recovery**, in the **Local** field, click **Failover**.

   This shows the **Confirm failover to peer** dialog, along with information on possible data loss that may result if you perform the manual failover to standby.



2. In the **Confirm failover to peer** dialog, enter the Autonomous Database name to confirm that you want to failover.
3. In the **Confirm failover to peer** dialog, click **Failover**.

After the failover completes, Autonomous Database reports the time of the last switchover in the **Role** field on the Autonomous Database Details page under **Disaster recovery**.

See Notes for Manual Failover with a Standby Database for information on steps that Autonomous Data Guard takes after failover completes.

Perform Manual Failover to a Cross-Region Standby Database

If a cross-region peer is available you can perform a switchover to make a cross-region peer the primary database. If the switchover fails, you can initiate a manual failover to the cross-region peer.

It is possible for data loss to occur with a manual failover. When you initiate a manual failover, Autonomous Database fails over to the peer database based on the Recovery Time Objective (RTO) and Recovery Point Objective (RPO) targets. See Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.

With both a local Autonomous Data Guard standby and one or more cross-region Autonomous Data Guard standby databases, when automatic failover is not successful and the local standby database is available, Oracle recommends that you attempt a manual failover to the local standby first (not to a remote standby).

If a local standby is unavailable or a manual failover to the local standby fails, you can perform a manual switchover to a cross-region standby. If the switchover to the cross-region standby fails, on the standby database the Oracle Cloud Infrastructure Console shows a **Failover** link in the **Role** field that you can click to initiate a manual failover to the standby database.

Using the API, you can initiate manual failover at any time. See Use the API for information on using the API.

> **Note:**
>
> When Full Stack Disaster Recovery is enabled, the Autonomous Database details page, under Disaster recovery, shows the **Full Stack DR** field as **Enabled**. See Use Full Stack Disaster Recovery to Perform Switchover or Failover Operations for details on performing a switchover or a failover when Full Stack Disaster Recovery is enabled.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To initiate a manual failover to a cross-region standby:

1. On the standby database, perform a switchover. See Perform a Switchover to a Cross-Region Standby for details.
2. If the switchover attempt in Step 1 fails, on the standby database the **Role** field shows a **Failover** link. On the standby database, click the **Failover** link.

   This shows the **Confirm failover to standby** dialog, along with information on possible data loss that may result if you perform the manual failover to the standby database.
3. In the **Confirm failover to standby** dialog, enter the Autonomous Database name to confirm that you want to failover.
4. In the **Confirm failover to standby** dialog, click **Failover**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

After the failover completes, Autonomous Database reports the time of the last switchover in the **Role** field on the Autonomous Database Details page under **Disaster recovery**.

See Notes for Manual Failover with a Standby Database for information on steps that Autonomous Data Guard takes after failover completes.

Notes for Manual Failover with a Standby Database

When the failover completes, Autonomous Data Guard performs post failover steps.

- For a failover to the local standby, Autonomous Data Guard creates a new local Standby database after the failover. Autonomous Data Guard is not enabled when the system is provisioning the new Standby database and the **Role** field shows **Provisioning**. After Autonomous Data Guard completes the provisioning step, then you have a new local Standby database and Autonomous Data Guard is enabled.
- For a failover to a cross-region standby, if there was a local standby before the failover, Autonomous Data Guard makes the local standby available again for a switchover or failover on the current Primary.

- After a manual failover operation completes, you can see any data loss associated with the manual failover in the message on the Oracle Cloud Infrastructure console banner. The manual failover data loss is specified in minutes.

  This information also shows when you hover over the in the **Role** field.
- After a manual Autonomous Data Guard failover, if there was a regional failure, when the region comes back online the standby database is automatically reconnected or if required reprovisioned.

Autonomous Data Guard Cross-Region and Cross Tenancy Operations

Describes cross-region and cross tenancy operations with Autonomous Data Guard.

- Add a Cross-Region Standby Database
  You can enable Autonomous Data Guard with a cross-region standby when Autonomous Database is available (Lifecycle state shows Available).
- Enable or Disable Backup Replication for an Existing Cross-Region Standby
- Convert Cross-Region Peer to Snapshot Standby
- Disconnect a Peer Database
  Shows you the steps to disconnect a peer database from the Primary database.
- Disable a Cross-Region Standby Database
  Disabling a cross-region Autonomous Data Guard standby database terminates the standby database. If you later add a cross-region Autonomous Data Guard standby, the system creates a new cross-region standby database.
- Use a Cross Tenancy Autonomous Data Guard Standby Database
  You can add a cross tenancy Autonomous Data Guard standby database. This creates an Autonomous Data Guard standby that resides in a different tenancy. The cross tenancy standby can be in the same region (local) or in a different region (cross-region).
- Manage Remote Peer Network ACLs
  You can independently modify network ACLs on a remote disaster recovery peer database.

Add a Cross-Region Standby Database

You can enable Autonomous Data Guard with a cross-region standby when Autonomous Database is available (Lifecycle state shows Available).

To add a standby database you must have adequate available resources. Adding an Autonomous Data Guard standby database will only be successful if adding the standby database does not cause you to exceed your Tenancy or compartment limits for CPU and Storage.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To add a cross-region Autonomous Data Guard standby:

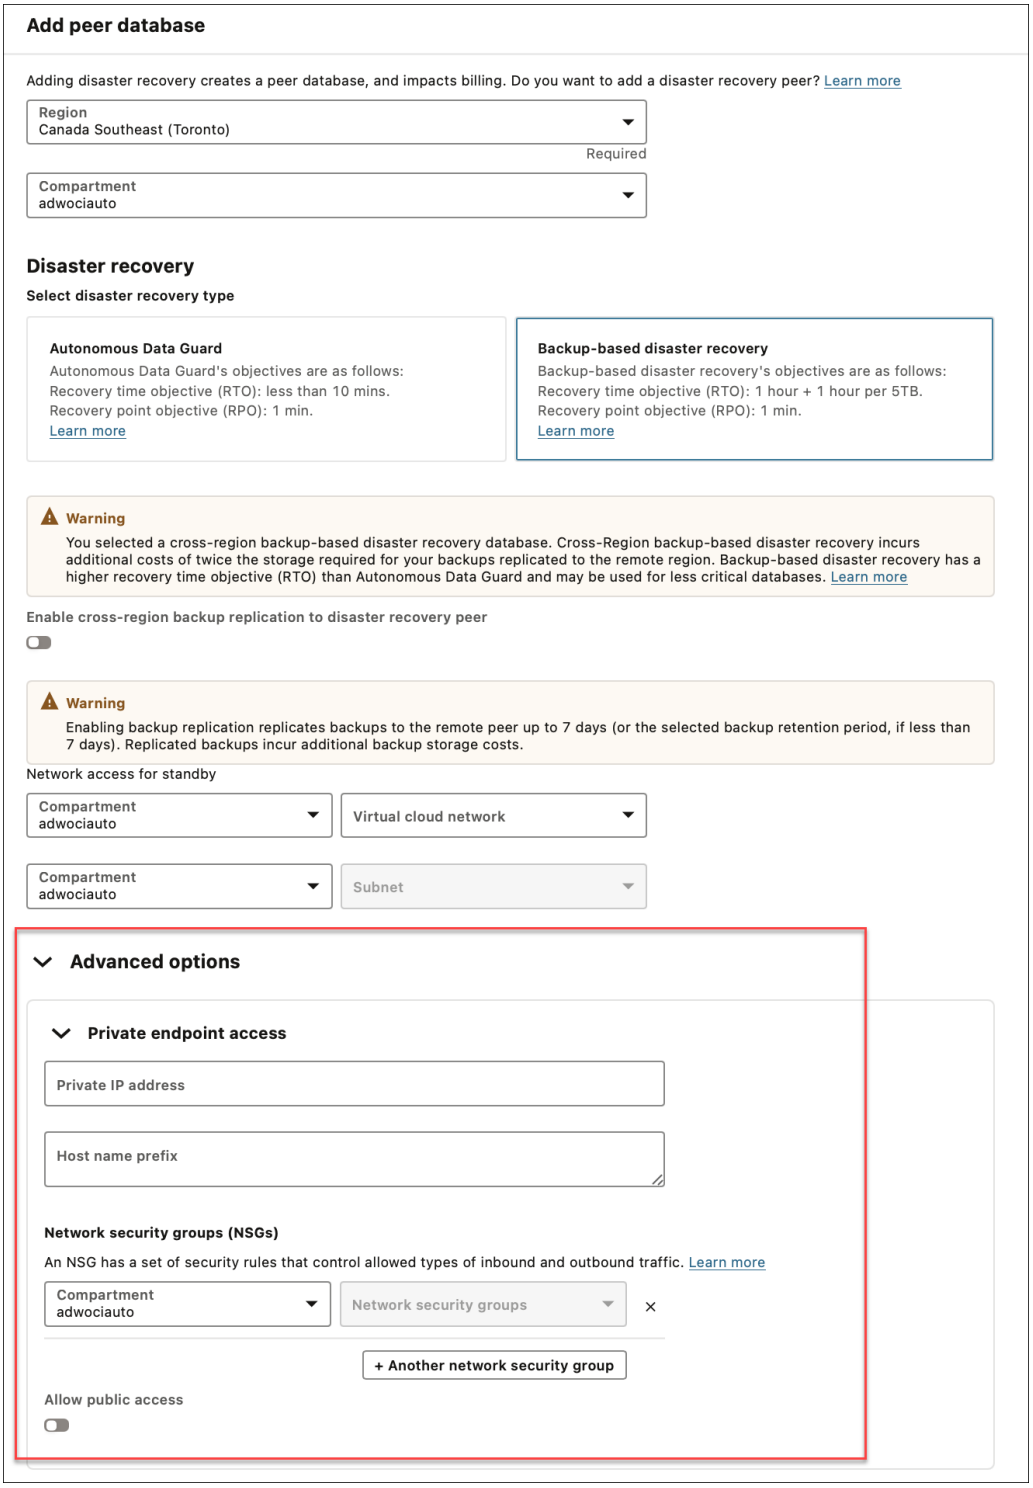
1. On the **Autonomous Database** details page, select the **Disaster recovery** tab.

2. On the **Disaster recovery** tab, click **Add peer database**.
3. In the **Region** list, select a region.

   The region list shows the available remote regions where you can create a cross-region standby. When you add a standby database, the list of available regions only shows a remote region if your tenancy is subscribed to the remote region (you must be subscribed to the paired remote region). See Autonomous Database Cross-Region Paired Regions for more information.
4. When you select a region, Autonomous Database shows the **Compartment** list. From this list select a compartment for the cross-region standby.
5. Select the disaster recovery type. In addition, when the source database is configured with a private endpoint, enter the private endpoint information for the peer.
   a. Select the disaster recovery type: **Autonomous Data Guard**.

   b. If you want to enable cross-region backup replication, switch the **Enable cross-region backup replication to disaster recovery peer** toggle on.

      See Replicating Backups to a Cross-Region Autonomous Data Guard Standby for more information.
   c. When the source database is configured with a private endpoint, in the **Network access for standby** area enter the **Virtual cloud network** and the **Subnet**.



In these Network access for standby fields you specify the private endpoint's VCN and Subnet on the remote region where the standby is created.

> **Note:**
>
> If you change your network access on the source database to enable a private endpoint after the standby is created, you must manually access the standby to enable a private endpoint on the peer.

6. Click **Add**.

   The Autonomous Database lifecycle state badge shows **Updating**. On the **Disaster recovery** tab the **State** column for the peer shows **Provisioning**.

   After some time the lifecycle state badge shows **Available** and the standby database provisioning continues.

> **Note:**
>
> While you add a standby database, the primary database is available for read/write operations. There is no downtime on the primary database.

When provisioning completes, on the Oracle Cloud Infrastructure Console, on the **Autonomous Database** details page, the **Disaster recovery** area the shows the following:

- **Role** shows **Primary**
- The **Local** field shows either **Backup-based** or **Autonomous Data Guard**.

  The local field also has an ⋮ menu. If the local standby is **Backup-based**, the actions menu shows the options **Upgrade to Autonomous Data Guard** and **Switchover**.
- The **Cross-region** field shows:
  - **Autonomous Data Guard** when you have single cross-region standby database.
  - *x* peers: When you have multiple cross-region disaster recovery peers, where *x* is the number of cross-region peers.

When you add a cross-region standby, the standby database created in the remote region has the same display name as the primary database with an "_*region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

On the **Disaster recovery** tab the **Peer Autonomous Database** column shows the standby database name and a provides a link. Click the link to go to the Oracle Cloud Infrastructure Console for the remote standby database.

Notes for adding a cross-region standby database:

- Autonomous Database generates the Enable cross-region disaster recovery work request. To view the request, on the Autonomous Database details page select the **Work requests** tab.
- After you add a cross-region (remote) standby database, the wallet and connection string from the primary database will contain only the hostname of the primary database, and the wallet and connection string from the remote database will contain only the hostname of the remote database. This applies for both instance and regional wallets.

  See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.
- If you switch on the **Enable cross-region backup replication to disaster recovery peer** toggle, replicating the backups to the remote region can take between several minutes and

several hours, depending on the size of the backups. After backups are replicated, on the peer's Autonomous Database details page, the **Backups** tab shows the list of replicated backups.

- While you add a standby database and the lifecycle state badge shows **Updating**. The following actions are disabled for the primary database while it is updating:
  - Move Resource. See Move an Autonomous Database to a Different Compartment for information on moving an instance.
  - Stop. See Stop Autonomous Database for information on stopping an instance.
  - Restart. See Restart Autonomous Database for information on restarting an instance.
  - Restore. See Restore and Recover your Autonomous Database for information on restoring.
  - Add cross-region disaster recovery peer. You need to wait until the update completes on the primary database before you can add an additional cross-region peer.
- See Cross-Region Autonomous Data Guard Notes and Notes for Customer-Managed Keys in OCI Vault with Autonomous Data Guard for information on using customer-managed keys and for additional notes for using Autonomous Data Guard with a cross-region standby.

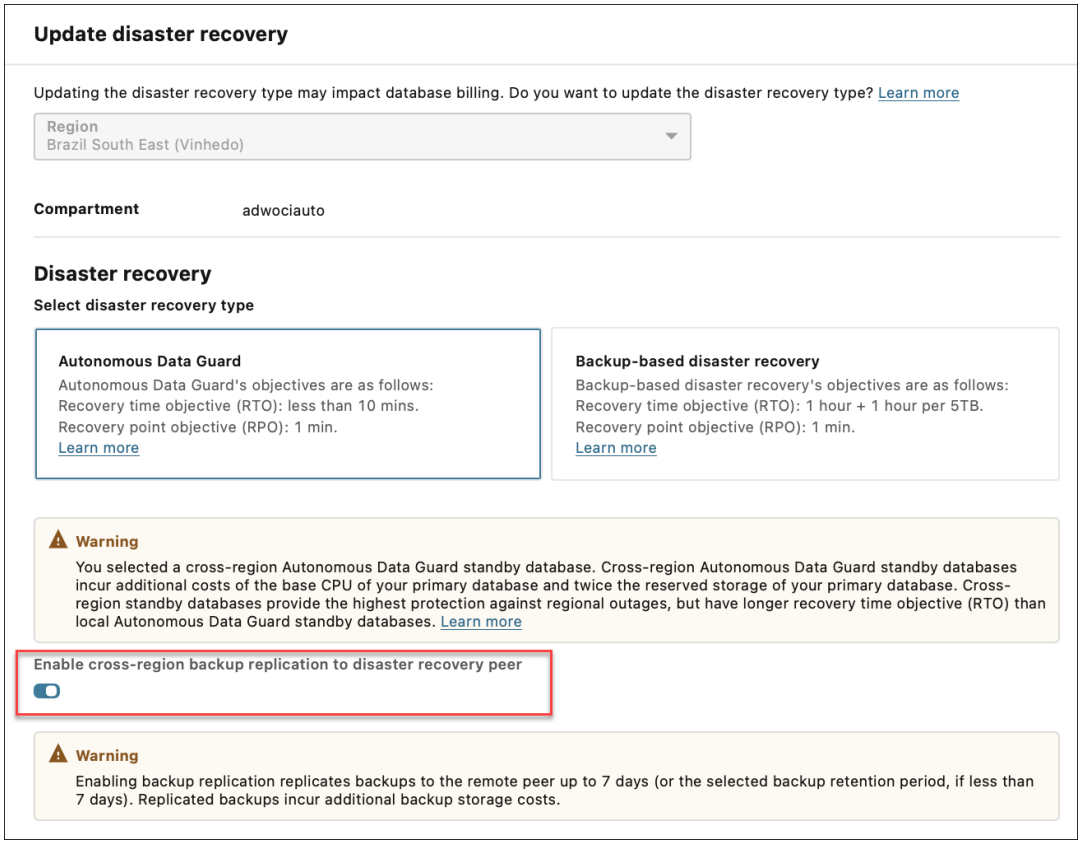
Enable or Disable Backup Replication for an Existing Cross-Region Standby

You can enable or disable backup replication on a Autonomous Data Guard cross-region standby.

To enable or disable backup replication for an existing cross-region Autonomous Data Guard standby:

1. On the **Autonomous Database** detail page select the **Disaster recovery** tab.
2. In a row that lists a cross-region standby, click ⋯ and in the menu select **Update disaster recovery**.

   This shows the Update disaster recovery page.



3. Switch on or off the toggle to enable backup replication.
   a. If cross-region backup replication is disabled, switch **Enable cross-region backup replication to disaster recovery peer** on to enable the option.
   b. If cross-region backup replication is enabled, switch **Enable cross-region backup replication to disaster recovery peer** off disable the option.
4. Click **Submit**.

   The Autonomous Database lifecycle state banner changes to **Updating**.

If you switch on the **Enable cross-region backup replication to disaster recovery peer** toggle, replicating the backups to the remote region can take between several minutes and several hours, depending on the size of the backups. After backups are replicated, on the peer's Autonomous Database details page, the **Backups** tab shows the list of replicated backups.

Convert Cross-Region Peer to Snapshot Standby

You can convert a cross-region peer database to a snapshot standby. This converts the peer to a read-write database for up to two days (48 hours).

Snapshot standby CPU usage is billed based on the base CPU count and any additional CPU usage if compute auto scaling is enabled. The number of base CPUs is specified by the number of ECPUs (OCPUs if your database uses OCPUs) as shown in the **ECPU count** or **OCPU count** field on the Oracle Cloud Infrastructure Console.

Snapshot standby storage usage is billed based on the storage of the snapshot standby plus 1 x the storage of the source primary database.

You can create a snapshot standby for a cross-region peer. You cannot create a snapshot standby for a local disaster recovery peer.

- About Disaster Recovery Snapshot Standby Databases
  Converting a disaster recovery peer to a snapshot standby opens the database in read-write mode and the cross-region disaster recovery peer temporarily stops refreshing data from the source database.
- Convert Cross-Region Disaster Recovery Peer to a Snapshot Standby
  You can convert a cross-region disaster recovery peer to a snapshot standby.
- Convert Snapshot Standby Back to a Cross-Region Disaster Recovery Peer
  You can manually convert a snapshot standby back to a disaster recovery peer for the primary (source database). After the converting back, the snapshot standby returns to its role as a disaster recovery standby.
- Disconnect a Snapshot Standby
  You can disconnect a snapshot standby from the primary database.

About Disaster Recovery Snapshot Standby Databases

Converting a disaster recovery peer to a snapshot standby opens the database in read-write mode and the cross-region disaster recovery peer temporarily stops refreshing data from the source database.

While operating as a snapshot standby, updates from the source database are still sent to the snapshot standby, and you are protected if the source database region were to encounter a failure, however the updates are not applied to the snapshot standby until the database is converted back to a disaster recovery peer.

See Oracle Autonomous Database Serverless Features Billing for information on Snapshot standby billing.

- Snapshot Standby Features and Restrictions
  Provides information on snapshot standby features and restrictions.
- Snapshot Standby Operations
  After you create a snapshot standby you can perform almost all database operations on the snapshot standby. There are some operations that are not allowed on a snapshot standby.
- Snapshot Standby Reconnect Time
  A banner on the Oracle Cloud Infrastructure Console indicates the date and time when the snapshot standby automatically reconnects to the source database. At the time indicated on the banner, Autonomous Database converts a snapshot standby back to the **Standby** role.

Snapshot Standby Features and Restrictions

Provides information on snapshot standby features and restrictions.

While the database is in the **Snapshot standby** role, note the following:

- By converting a cross-region disaster recovery peer to a snapshot standby, you can use the snapshot standby for testing and querying data in the database. This allows you to test with no downtime on the primary (source) database, compared to testing by using switchover to the remote peer.
- You can use a snapshot standby to completely test your disaster recovery environment, including making any changes required to verify your standby environment, such as the mid-tier configuration. Using a snapshot standby you can make configuration changes or perform DML operations on the database as needed for complete testing and verification of the standby environment.

While the database is in the **Snapshot standby** role, note the following restrictions:

- The restore operation is not allowed on a snapshot standby database.
- No new backups are taken or displayed from the time a disaster recovery peer is converted to a snapshot standby. Existing backups that were available before the conversion to a snapshot standby are available. You can only use the backups that are available on a snapshot standby for a clone from backup operation.
- Cloning from a snapshot standby is only allowed to create a clone the same region as the snapshot standby. You cannot clone a snapshot standby across regions.

Notes for reconnecting a snapshot standby to the primary (source database):

- Reconnect to the primary, source database, when you are done with the tasks that require the snapshot standby to be open for read-write operations. If you do not manually reconnect within two days (48 hours), the snapshot standby automatically reconnects to the primary.
- Oracle recommends you convert a snapshot standby back to a disaster recovery peer as soon as you are done with the operations that require the standby to be open for read-write operations. When you convert back to a to a disaster recovery peer, the accumulated changes from the source database are applied on the peer. If you keep the disaster recovery peer open as a snapshot standby for a longer period, assuming there are ongoing changes on the primary during this time, it takes longer to convert back to a disaster recovery peer.

When the snapshot standby reconnects to the primary database, Autonomous Database performs the following actions:

- The disaster recovery type you were using, and any associated billing returns to the type it was before you performed the convert disaster recovery peer to snapshot standby. That, the disaster recovery peer returns to the same type of disaster recovery peer, either Backup-Based Disaster Recovery (**Backup copy**) or **Autonomous Data Guard**, as shown in the DR Type column in the **Disaster Recovery** area.
- Any changes on the snapshot standby from the time it was converted to a snapshot standby, until the time it reconnects to the source are discarded. This means all changes, including metadata, that is inserted, updated, or deleted while the database operates as a snapshot standby are lost (discarded) when the snapshot standby reconnects to its source database.
- All changes that occurred on the primary are replicated to the remote region while the database operates as a snapshot standby, but the changes are not applied to the snapshot standby. The changes that occur on the primary during this period are applied to the snapshot standby when it is converted back to a disaster recovery peer.
- On the Oracle Cloud Infrastructure Console, the role updates from **Role: Snapshot standby** to **Role: Standby** or **Role: Backup copy**, depending on the disaster recovery type.

Snapshot Standby Operations

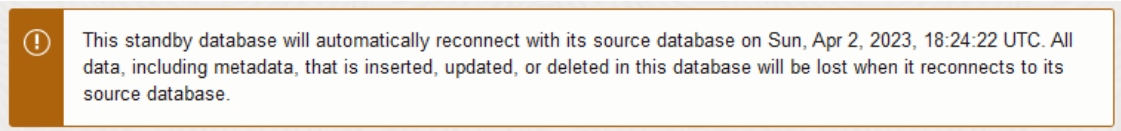
After you create a snapshot standby you can perform almost all database operations on the snapshot standby. There are some operations that are not allowed on a snapshot standby.

Operation	Description
Convert to Snapshot Standby	You can convert a cross-region peer to a snapshot standby. See Convert Cross-Region Disaster Recovery Peer to a Snapshot Standby for the steps to convert a peer database to snapshot standby.

Operation	Description
Start or Restart	When a snapshot standby is stopped, as indicated by the Lifecycle state **Stopped**, you can start the database. When a snapshot standby is available, as indicated by the Lifecycle state **Available**, you can restart the database or stop the database.
Convert Snapshot Standby Back to Disaster Recovery Peer	When a snapshot standby is in the **Snapshot standby** role, the database operates as a read-write database. A snapshot standby has a two day (48 hour) limit up to which it can stay in the **Snapshot standby** role. If you do not manually convert the snapshot standby back within two days, the snapshot standby automatically converts back to a disaster recovery peer. See Convert Snapshot Standby Back to a Cross-Region Disaster Recovery Peer for more information.
Stop	When a snapshot standby is stopped, database operations are not available and charging for CPU usage on the snapshot standby stops.
Disconnect Peer	When you disconnect a snapshot standby, the snapshot standby is disassociated from the primary database. This converts the database from a snapshot database to a standalone database. Following the disconnect operation you are not allowed to reconnect to the Primary. See Disconnect a Snapshot Standby for more information.
Terminate	You are not allowed to terminate a snapshot standby. You can reconnect the snapshot standby to the primary. See Convert Snapshot Standby Back to a Cross-Region Disaster Recovery Peer for more information.
Create Clone	Cloning from a snapshot standby is only allowed to create a clone the same region as the snapshot standby. You cannot clone a snapshot standby across regions.
Create Refreshable Clone	You are not allowed to create a refreshable clone on a snapshot standby.
Disaster Recovery Peer	You are not allowed to add an Autonomous Data Guard standby database or a Backup-Based Disaster Recovery peer to a snapshot standby.

Snapshot Standby Reconnect Time

A banner on the Oracle Cloud Infrastructure Console indicates the date and time when the snapshot standby automatically reconnects to the source database. At the time indicated on the banner, Autonomous Database converts a snapshot standby back to the **Standby** role.



Note:

When a snapshot standby is not reconnected within 48 hours, the snapshot standby automatically reconnects to the source database.

Convert Cross-Region Disaster Recovery Peer to a Snapshot Standby

You can convert a cross-region disaster recovery peer to a snapshot standby.

> **Note:**
>
> All data, including metadata, that is inserted, updated, or deleted in the database during the disconnect period will be lost when a snapshot standby reconnects to its source database. All changes that occur on the primary during the disconnect period are applied to the standby when it reconnects to the source database.

Perform the following prerequisite steps as necessary:

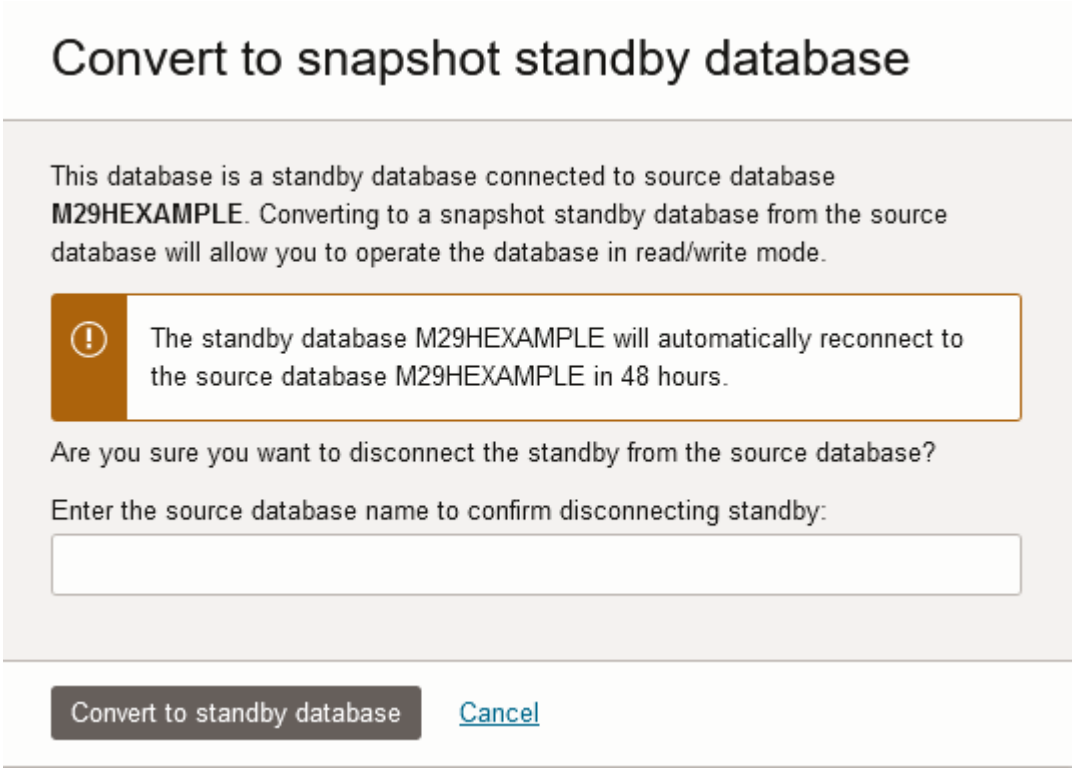
- Open the Oracle Cloud Infrastructure Console by clicking the next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To convert a cross-region disaster recovery peer to a snapshot standby:

1. On the Primary Region Autonomous Database instance, on the Autonomous Database Details page select the **Disaster recovery** tab.
2. Access the remote region peer.

   On the Primary Region Autonomous Database instance the **Disaster recovery** list shows the **Peer Autonomous Database** column.

   Under the **Peer Autonomous Database** column, click the link to access the cross-region peer.
3. On the cross-region peer, from the **More actions** drop-down list, select **Convert to snapshot standby database**.



4. On the **Convert to snapshot standby database** page, enter the source database name to confirm the disconnect.
5. Click **Convert to snapshot standby database**.

   The Autonomous Database Lifecycle state changes to **Updating**.

> **Note:**
>
> While you convert to a snapshot standby, the primary database is available for read/write operations. There is no downtime on the primary database.

When the operation completes, note the following:

- On the snapshot standby, there is a banner that indicates the date and time when the standby database will automatically reconnect with its source database
- On the snapshot standby, on the Autonomous Database details page, under **Disaster recovery**, the **Role** shows **Snapshot standby**.
- On the snapshot standby's source database, on the Autonomous Database details page, when you select the **Disaster recovery** tab, the **Peer role** shows **Snapshot standby**.
- On the snapshot standby, you can scale CPU or storage, independent of the source database.
- When you scale CPU or storage on the primary, the changes to the primary do not affect the snapshot standby until it is converted back to a disaster recovery peer.
- Cloning is only allowed from a snapshot standby when the clone is in the same region. Cloning across regions is not allowed from a snapshot standby.

- The clone from backup operation is allowed on a snapshot standby. However, a snapshot standby does not backup any of the temporarily updated data in the read-write snapshot standby. When you clone from a backup on a snapshot standby, the operation creates a clone using a Primary side backup which is replicated to the snapshot standby. See Clone an Autonomous Database Instance for more information.
- The restore operation is not allowed on a snapshot standby.

Convert Snapshot Standby Back to a Cross-Region Disaster Recovery Peer

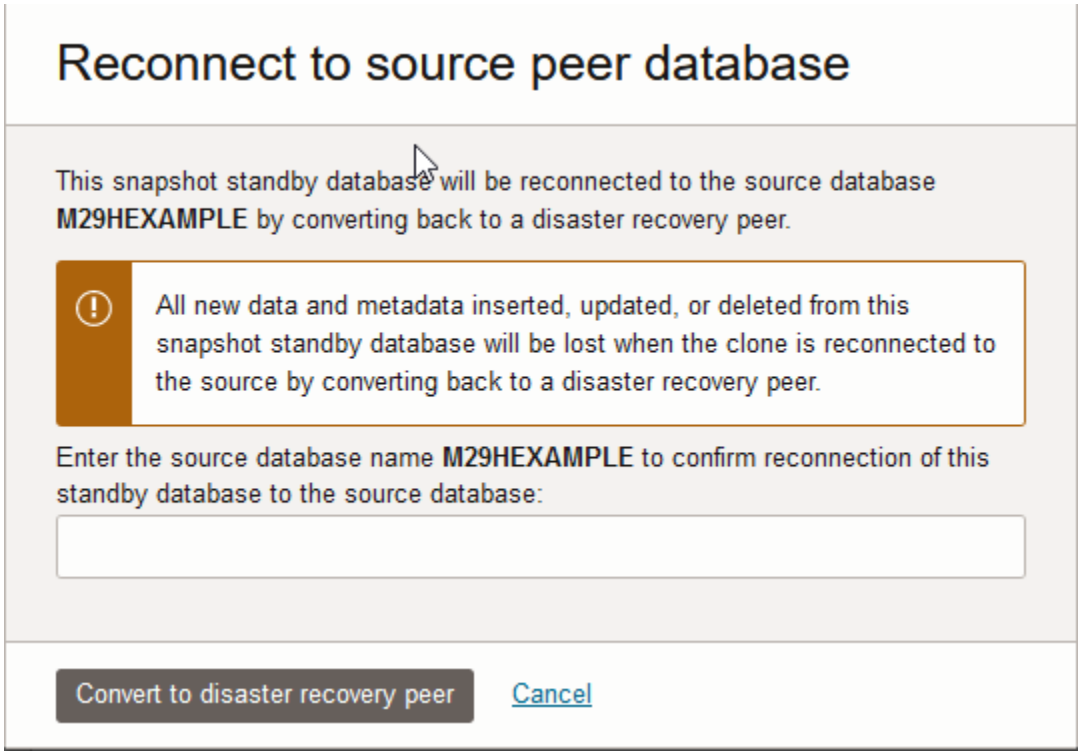
You can manually convert a snapshot standby back to a disaster recovery peer for the primary (source database). After the converting back, the snapshot standby returns to its role as a disaster recovery standby.

> **Note:**
>
> All data, including metadata, that is inserted, updated, or deleted in the snapshot standby database during the disconnect period will be lost when the snapshot standby reconnects to its source database.
> All changes on the primary that were sent to the snapshot standby but not applied during the disconnect period will be applied to the standby when it reconnects to the source database.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

1. On the snapshot standby, from the **More actions** drop-down list, select **Reconnect to source peer database**.



2. On the **Reconnect to source peer database** page, enter the source database name to confirm the reconnect.
3. Click **Convert to disaster recovery peer**.

   The Autonomous Database Lifecycle state changes to **Updating**.

> **Note:**
>
> While you reconnect the standby to the source database, the primary (source) database is available for read/write operations. There is no downtime on the primary database.

When the snapshot standby reconnects to the primary database, Autonomous Database does the following:

- The disaster recovery type you were using, and any associated billing returns to the type it was before you performed the convert disaster recovery peer to snapshot standby. That, the disaster recovery peer returns to the same type of disaster recovery peer, either Backup-Based Disaster Recovery (**Backup copy**) or **Autonomous Data Guard**, as shown in the DR Type column in the **Disaster Recovery** area.
- Any changes on the snapshot standby from the time it was converted to a snapshot standby, until the time it reconnects to the source are discarded. This means all changes, including metadata, that is inserted, updated, or deleted while the database operates as a snapshot standby are lost (discarded) when the snapshot standby reconnects to its source database.
- All changes that occurred on the primary are replicated to the remote region while the database operates as a snapshot standby, but the changes are not applied to the snapshot standby. The changes that occur on the primary during this period are applied to the snapshot standby when it is converted back to a disaster recovery peer.

- On the Oracle Cloud Infrastructure Console, the role updates from **Role: Snapshot standby** to **Role: Standby** or **Role: Backup copy**, depending on the disaster recovery type.

Disconnect a Snapshot Standby

You can disconnect a snapshot standby from the primary database.

When you disconnect a snapshot standby, the snapshot standby is disassociated from the primary database. This converts the database from a snapshot database to a standalone database. Following the disconnect operation you are not allowed to reconnect to the Primary.

The steps to disconnect a snapshot standby are the same as those to disconnect a standby database. See Disconnect a Peer Database for more information.

Notes for disconnecting a snapshot standby.

- There is no reconnect operation. After you disconnect a snapshot standby you are not allowed to reconnect to the Primary.
- The disconnect operation for a snapshot standby can only be performed on an Autonomous Database instance that uses the ECPU compute model.
- The disconnected database keeps any user inserted or updated data that was applied while the database was open in read/write mode as a Snapshot Standby.

  The disconnect operation does not apply any recent logs that were sent from the Primary.
- After the disconnect operation, the standalone database is no longer associated with the database that was the Primary database. To use the database as a standalone database, you must know the name of the database that was disconnected from the Primary database.
- After the disconnect operation the database starts taking new backups as a standalone database. Any backups that were associated with the standby database or with the primary database are not available on the standalone database.

Disconnect a Peer Database

Shows you the steps to disconnect a peer database from the Primary database.

When you disconnect a cross-region peer, the database is permanently disassociated from the Primary database. This converts the database from a peer database to a standalone database. After you disconnect a peer database you are not allowed to reconnect to the Primary.

Perform the following prerequisite steps as necessary:

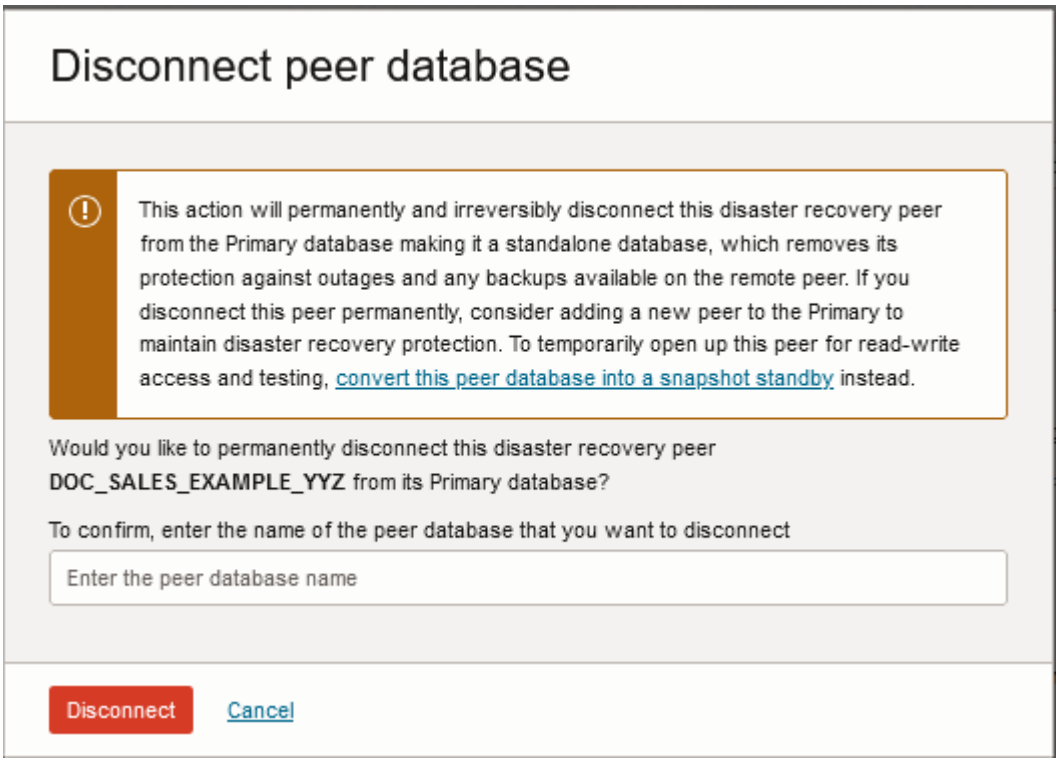
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

You can perform this operation from the Primary database or from a cross-region peer.

To perform the disconnect operation on a cross-region standby (or on a cross-region backup copy):

1. On the cross-region peer, on the Autonomous Database details page, under **Disaster recovery** in the **Role** field click **Disconnect peer**.

This shows the disconnect peer dialog:



2. On the **Disconnect peer database** dialog, enter the peer database name to confirm the disconnect.
3. Click **Disconnect**.

   The Autonomous Database Lifecycle state changes to **Updating**.

To perform the disconnect operation on the Primary:

1. On the Primary database, on the Autonomous Database Details page, in the **Resources** area click **Disaster recovery**.
2. At the end of the row for the peer you want to disconnect, click ... and select **Disconnect peer**.
3. On the **Disconnect peer database** dialog, enter the peer database name to confirm the disconnect.
4. Click **Disconnect**.
   The Autonomous Database Lifecycle state changes to **Updating**.

Notes for disconnecting a cross-region peer.

- The disconnect operation for a cross-region peer can only be performed on an Autonomous Database instance that uses the ECPU compute model.
- After the disconnect operation, the standalone database is no longer associated with the database that was the Primary database. To use the database as a standalone database, you must know the name of the database that was disconnected from the Primary database.
- There is no reconnect operation. After you disconnect a peer database you are not allowed to reconnect to the Primary.

- After the disconnect operation, the standalone database starts taking new backups as a standalone database.
- For a cross tenancy Autonomous Data Guard standby database, you can perform the disconnect operation on a local, same region, standby database, a cross-region standby database, or a snapshot standby database.

Disable a Cross-Region Standby Database

Disabling a cross-region Autonomous Data Guard standby database terminates the standby database. If you later add a cross-region Autonomous Data Guard standby, the system creates a new cross-region standby database.

You have two options to disable a cross-region Autonomous Data Guard standby:

You can update the cross-region disaster recovery type to use Backup-Based Disaster Recovery. This terminates the cross-region Autonomous Data Guard standby database and adds a cross-region backup copy peer.

You can terminate the cross-region Standby database.

- Update Cross-Region Standby to Use Backup-Based Disaster Recovery
  You can update the disaster recovery type from cross-region Autonomous Data Guard standby database to cross-region Backup-Based Disaster Recovery. This terminates the cross-region Autonomous Data Guard standby database.
- Terminate a Cross-Region Standby Database
  Describes the steps to terminate a cross-region standby database.
- Verify Cross-Region Autonomous Data Guard is Disabled
  Describes the steps to verify that an Autonomous Data Guard cross-region standby is disabled.

Update Cross-Region Standby to Use Backup-Based Disaster Recovery

You can update the disaster recovery type from cross-region Autonomous Data Guard standby database to cross-region Backup-Based Disaster Recovery. This terminates the cross-region Autonomous Data Guard standby database.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To change your disaster recovery type to use a cross-region backup-copy peer:

1. On the Primary Role Autonomous Database, on the Autonomous Database Details page select the **Disaster recovery** tab.
2. Access the remote standby.

   On the primary Autonomous Database instance the **Disaster recovery** area shows the remote standby list. A remote standby has the same display name as the primary database, with a "*_region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

If you created the cross-region standby before the introduction of support for multiple cross-region peers, the remote standby has the same display name as the primary database, with an "_Remote" extension.

Under **Peer Autonomous Database**, click the link to access a cross-region standby.

3. On the remote standby database, click **Update disaster recovery** under **Disaster recovery** on the Oracle Cloud Infrastructure Console.
4. On the Update disaster recovery type page, select **Backup-based disaster recovery**.
5. Click **Submit**.

   The Autonomous Database Lifecycle state changes to **Updating**.

> **Note:**
>
> While you update the disaster recovery type, the primary database is available for read/write operations. There is no downtime on the primary database.

Autonomous Database generates a Change Disaster Recovery Configuration work request. To view the request, on the Autonomous Database details page select the **Work requests** tab.

Terminate a Cross-Region Standby Database

Describes the steps to terminate a cross-region standby database.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

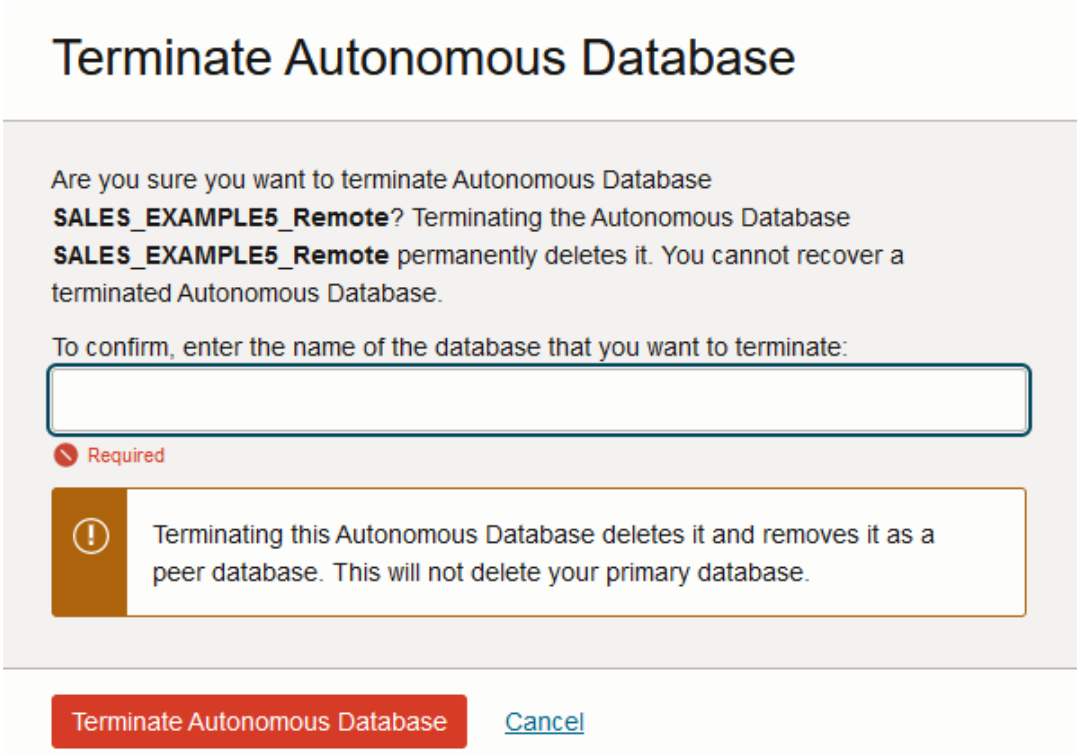
To terminate a cross-region standby database:

1. On the primary database, on the Autonomous Database Details page, select the **Disaster recovery** tab.
2. Access the remote standby.

   The **Disaster recovery** tab shows the **Peer Autonomous Database**. The remote standby database has the same display name as the primary database, with an "*_region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

   If you created the cross-region peer before the introduction of support for multiple cross-region peers, the remote standby database has the same display name as the primary database, with an "_Remote" extension.

   Under **Peer Autonomous Database**, click the link to access the cross-region peer.
3. On the console for the remote standby database, from the **More actions** drop-down list, select **Terminate**.



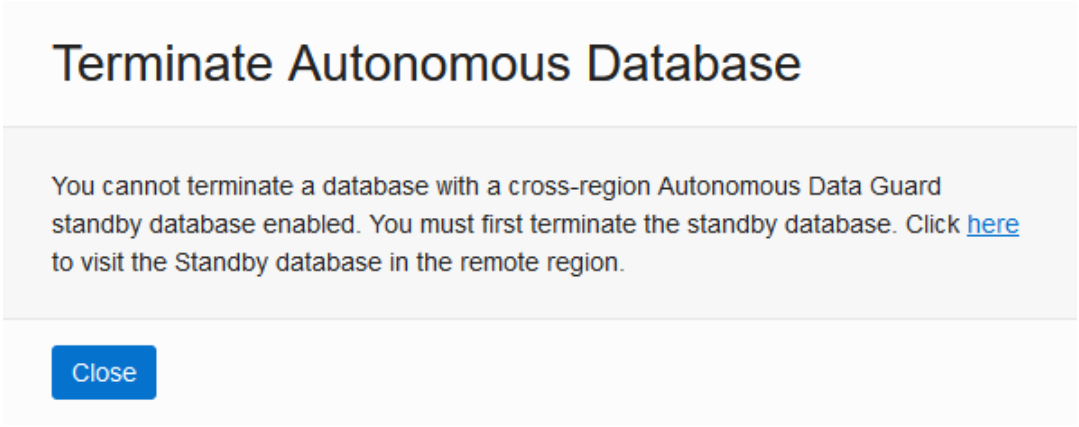
4. On the **Terminate Autonomous Database** page enter the database name to confirm that you want to terminate the cross-region standby database.
5. Click **Terminate Autonomous Database**.

   While the standby database is terminating, the **Lifecycle state** changes to **Terminating**.

> **Note:**
>
> If there is a local Autonomous Data Guard standby database, terminating the cross-region standby does not change the local disaster recovery option.

Note the following when your disaster recovery option includes a cross-region disaster recovery peer:

- A cross-region disaster recovery peer cannot be terminated from the primary database.
- You must terminate all cross-region disaster recovery peers before you terminate the primary database. If you attempt to terminate the primary when there is a cross-region disaster recovery peer, the system shows the following message:



In this case, first terminate the cross-region (remote) peers and then you can terminate the Primary role database.

After the cross-region disaster recovery peers are terminated, then terminate the Primary database. See Terminate an Autonomous Database Instance for more information.

Verify Cross-Region Autonomous Data Guard is Disabled

Describes the steps to verify that an Autonomous Data Guard cross-region standby is disabled.

To verify that a cross-region Autonomous Data Guard standby database is disabled:

1. On the primary database, on the Autonomous Database Details page select the **Disaster recovery** tab.
2. Verify that either the disaster recovery type is changed to backup copy or the cross-region Autonomous Data Guard standby is terminated.

- If you updated the disaster recovery type to use cross-region backup based disaster recovery, verify that the remote peer autonomous database **DR Type** shows **backup copy**.
- If you manually terminated standby database, verify that the cross-region standby count is 0 (that is there is no remote peer).

Use a Cross Tenancy Autonomous Data Guard Standby Database

You can add a cross tenancy Autonomous Data Guard standby database. This creates an Autonomous Data Guard standby that resides in a different tenancy. The cross tenancy standby can be in the same region (local) or in a different region (cross-region).

- About Cross Tenancy Autonomous Data Guard
  When you add a cross tenancy Autonomous Data Guard standby, Autonomous Database provisions a standby database in a remote tenancy.
- Prerequisites to Create a Cross Tenancy Autonomous Data Guard Standby
  Describes prerequisites for creating a cross tenancy Autonomous Data Guard standby.
- Add a Cross Tenancy Autonomous Data Guard Standby
  Shows the steps to create a cross tenancy Autonomous Data Guard standby. This covers creating a cross tenancy standby when the source database and the standby database are in the same region (local) and when the source database and the standby database are in different regions (cross-region).

- Switchover, Failover, or Create a Snapshot Standby with a Cross Tenancy Autonomous Data Guard Standby
  Describes the procedure to switchover, failover, or create a snapshot standby with a cross tenancy standby.
- Terminate a Cross Tenancy Autonomous Data Guard Standby
  Shows the steps to terminate a cross tenancy standby.

About Cross Tenancy Autonomous Data Guard

When you add a cross tenancy Autonomous Data Guard standby, Autonomous Database provisions a standby database in a remote tenancy.

With a cross tenancy Autonomous Data Guard standby you can failover or switchover to a standby database in a different tenancy (or create a snapshot standby in a different tenancy). This feature also allows you to easily use an Autonomous Data Guard standby to migrate a database to a different tenancy.

Note the following for adding a cross tenancy Autonomous Data Guard standby:

- You can only create a cross tenancy Autonomous Data Guard standby using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.
- Some of the features available when you enable an Autonomous Data Guard standby in the same tenancy, such as the automatic failover options, are not available with a cross tenancy Autonomous Data Guard standby.

  There are no automatic failover options for a cross tenancy Autonomous Data Guard standby and you can only use manual failover to failover to a cross tenancy standby.
- You can enable a cross tenancy Autonomous Database standby with either the ECPU or OCPU compute model. The standby database uses the same compute model as the primary database.
- A cross tenancy Autonomous Data Guard standby can be in the same region (local) or in a different region (cross-region).
- Only a single cross tenancy Autonomous Data Guard standby can be enabled, either local or cross-region. You cannot enable both a cross tenancy local and a cross tenancy cross-region Autonomous Data Guard standby.
  - In addition to a single cross tenancy Autonomous Data Guard standby, you can have one local or cross-region disaster recovery peer (either Autonomous Data Guard or Backup-Based Disaster Recovery).
- Customer-Managed Encryption Keys are not supported with a Cross Tenancy Autonomous Data Guard standby.

Prerequisites to Create a Cross Tenancy Autonomous Data Guard Standby

Describes prerequisites for creating a cross tenancy Autonomous Data Guard standby.

You must define OCI Identity and Access Management policies to authorize creating an Autonomous Data Guard standby in a different tenancy.

The OCI Identity and Access Management groups and policies you add support the following:

- A member of a group in the source tenancy allows a group in the destination tenancy to access (read) the source Autonomous Database instance on the source tenancy.

  You do not need to allow other actions on the source Autonomous Database instance (for example, start, stop terminate, or any write operations).

- A member of a group in the destination tenancy is allowed to read Autonomous Databases in the source tenancy.

  On the destination tenancy you also add a policy that allows a group to manage the Autonomous Databases in a compartment in the remote (destination) tenancy. For example, this policy allows the group to create the standby database.

1. Create a group on the remote tenancy that contains the user that will be allowed to add the Autonomous Data Guard standby.
   a. On the remote tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.
   b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).
   c. Under **Identity domain**, click **Groups**.
   d. To add a group, click **Create group**.
   e. On the Create group page, enter a Name and a Description.

      For example, enter the Name: **CrossTenancyStandbyGroup**.
   f. On the Create group page, click **Create**.
   g. Click **Create** to save the group.
   h. On the **Group** page, click **Assign user to groups** and select the users you want to add to the group.
   i. Click **Add**.
   j. On the **Group** page, from the **Group information** tab copy the OCID for use in Step 2.
2. On the source tenancy, define OCI Identity and Access Management policies for the source Autonomous Database instance.
   a. On the source tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.
   b. Under **Identity**, click **Policies**.
   c. To write a policy, click **Create Policy**.
   d. On the Create Policy page enter a Name and a Description.
   e. On the Create Policy page, select **Show manual editor**.
   f. In the policy builder, add policies so that the group in the destination tenancy is allowed to create a standby using an Autonomous Database instance on the source tenancy as the source.

      For example, define the following generic policies:

      ```
      define tenancy RemoteTenancy as ocid1.tenancy.oc1..unique_id
      define group GroupThatExistsInRemoteTenancy as
      ocid1.group.region1..unique_id
      admit group GroupThatExistsInRemoteTenancy of tenancy RemoteTenancy to
      read autonomous-databases
        in compartment id ocid1.compartment.region..unique_id
      ```

      This policy specifies the following:

      - Line 1: the OCID is the OCID of the remote tenancy. This is the tenancy where you are going to create the standby.

- Line 2: the OCID is the OCID of the group to which the user who will create the standby belongs. This is the OCID for the group you created in Step 1.
- Line 3: The OCID is the OCID of the compartment where the source database resides.

Policies on Primary (Source) Tenancy To Add a Cross Tenancy Standby

```
define tenancy RemoteTenancy as ocid1.tenancy.oc1..aaa_example_rcyx2a
define group CrossTenancyStandbyGroup as
ocid1.group.oc1..aaa_example_6vctn6xsaq
admit group CrossTenancyStandbyGroup of tenancy RemoteTenancy to read
autonomous-databases
   in compartment id ocid1.compartment.oc1..aaaaaaaabexample6q
```

This policy specifies the `CrossTenancyStandbyGroup` group of the `RemoteTenancy` can read from Autonomous Databases in the specified compartment (on the source tenancy). To create a cross tenancy standby, the policy only needs to allow read on the source Autonomous Database instance.

g. Click **Create** to save the policy.

3. Define policies for the remote tenancy.

a. On the destination tenancy, in the Oracle Cloud Infrastructure Console click **Identity & Security**.

b. Under **Identity**, click **Policies**.

c. To write a policy, click **Create Policy**.

d. On the Create Policy page enter a Name and a Description.

e. On the Create Policy page, select **Show manual editor**.

f. In the policy builder, add policies so that a group is endorsed to manage Autonomous Databases on the source tenancy.

For example:

```
Define tenancy PrimaryTenancy as ocid1.tenancy.oc1..aaaaaaaabexampleyx2a
Endorse group CrossTenancyStandbyGroup to read autonomous-databases in
tenancy PrimaryTenancy
Allow group CrossTenancyStandbyGroup to manage autonomous-databases in
tenancy
```

This policy specifies the following:

- Line 1: The OCID is the primary tenancy OCID. This is the tenancy where the primary Autonomous Database instance resides.
- Line 2: Specifies that the CrossTenancyStandbyGroup group is endorsed in their own tenancy to read the source Autonomous Database in the primary tenancy.
- Line 3: Specifies that the CrossTenancyStandbyGroup group is allowed to create/manage an Autonomous Database in the specified Tenancy (the tenancy where the Standby is going to be created).

> **Note:**
>
> If these polices are revoked, creating a cross tenancy Autonomous Data Guard Standby is no longer allowed.

See Getting Started with Policies for more information.

Add a Cross Tenancy Autonomous Data Guard Standby

Shows the steps to create a cross tenancy Autonomous Data Guard standby. This covers creating a cross tenancy standby when the source database and the standby database are in the same region (local) and when the source database and the standby database are in different regions (cross-region).

You can only create a cross tenancy Autonomous Data Guard standby using the CLI or the Autonomous Database REST APIs. This option is not available using the Oracle Cloud Infrastructure Console.

First, perform the prerequisite steps to define the OCI Identity and Access Management policies to authorize cross tenancy Autonomous Data Guard.

See Prerequisites to Create a Cross Tenancy Autonomous Data Guard Standby for details.

To create a local (same region) cross tenancy Autonomous Data Guard standby:

The API call to create the standby is sent to the different tenancy in the local region.

1. Copy the OCID of the Primary database (on the primary's Tenancy).
2. Access the tenancy where you want to create the standby, the remote tenancy, and use the CLI or the REST API to create the standby database.

   For example, with the CLI:

   ```
   oci db autonomous-database create-cross-tenancy-disaster-recovery-details
   --compartment-id ocid1.tenancy.oc1..fcue4_example --source-id
   ocid1.autonomousdatabase.oc1.ap-mumbai-1.anrgexamples3q  --disaster-
   recovery-type ADG
   ```

   See update for more information.

   See UpdateAutonomousDatabase for more information.

To create a remote (cross-region) cross tenancy Autonomous Data Guard standby:

The API call to create the standby runs in the different tenancy in the source region.

1. Copy the OCID of the Primary database (on the primary's Tenancy).
2. Access the tenancy where you want to create the standby, the remote tenancy in the remote region, and use the CLI or the REST API to create the standby database.

   For example, with the CLI:

   ```
   oci db autonomous-database create-adb-cross-region-data-guard-details
    --compartment-id ocid1.tenancy.oc1..fcue4_example --source-id
   ocid1.autonomousdatabase.oc1.ap-mumbai-1.anrg6example2vws3q --disaster-
   recovery-type ADG
   ```

See update for more information.

See UpdateAutonomousDatabase for more information.

Notes for adding a cross tenancy standby database:

- Autonomous Database generates the Enable cross-region disaster recovery work request. To view the request, on the Autonomous Database details page, select the **Work requests** tab.
- After you add a cross tenancy standby database either local or cross-region, the wallet and connection string from the primary database will contain only the hostname of the primary database, and the wallet and connection string from the remote tenancy database will contain only the hostname of the remote tenancy database. This applies for both instance and regional wallets.

  See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.
- While you add a standby database and the **Lifecycle state** shows **Updating**, the following actions are disabled for the primary database:
  - Move Resource. See Move an Autonomous Database to a Different Compartment for information on moving an instance.
  - Stop. See Stop Autonomous Database for information on stopping an instance.
  - Restart. See Restart Autonomous Database for information on restarting an instance.
  - Restore. See Restore and Recover your Autonomous Database for information on restoring.
- See Cross-Region Autonomous Data Guard Notes and Notes for Customer-Managed Keys in OCI Vault with Autonomous Data Guard for information on using customer-managed keys and for additional notes for using Autonomous Data Guard with the standby in a different tenancy.

Switchover, Failover, or Create a Snapshot Standby with a Cross Tenancy Autonomous Data Guard Standby

Describes the procedure to switchover, failover, or create a snapshot standby with a cross tenancy standby.

- Switchover: The steps to perform a switchover to a cross tenancy standby are the same whether the standby is local (same region) or in a different region (cross-region). You follow the same steps as for a switchover to a same tenancy cross-region standby. See Perform a Switchover to a Cross-Region Standby for more information.
- Failover: The steps to perform a failover to a cross tenancy standby are the same whether the standby is local (same region) or in a different region (cross-region). You follow the same steps as for a manual failover to a same tenancy cross-region standby. See Perform Manual Failover to a Cross-Region Standby Database for more information.
- Create a Snapshot Standby: The steps to create a snapshot standby with a cross tenancy standby are the same whether the cross tenancy standby is local (same region) or in a different region (cross-region). You follow the same steps as with a same tenancy cross-region standby. See Convert Cross-Region Disaster Recovery Peer to a Snapshot Standby for more information.

Terminate a Cross Tenancy Autonomous Data Guard Standby

Shows the steps to terminate a cross tenancy standby.

The steps to terminate either a same region or a cross-region cross tenancy standby are the same as those to terminate a cross-region same-tenancy standby. See Terminate a Cross-Region Standby Database for more information.

Manage Remote Peer Network ACLs

You can independently modify network ACLs on a remote disaster recovery peer database.

By default the disaster recovery primary and remote peer databases use the same network Access Control Lists (ACLs). Optionally, you can configure ACLs independently on remote peer databases. This provides an option to use different ACLs on remote peer databases.

If you modify the ACLs on a remote peer, Autonomous Database no longer keeps the ACL configuration synchronized between the primary and the remote peer. After you modify the ACLs on a remote peer, Autonomous Database manages the ACLs on the remote peer independently.

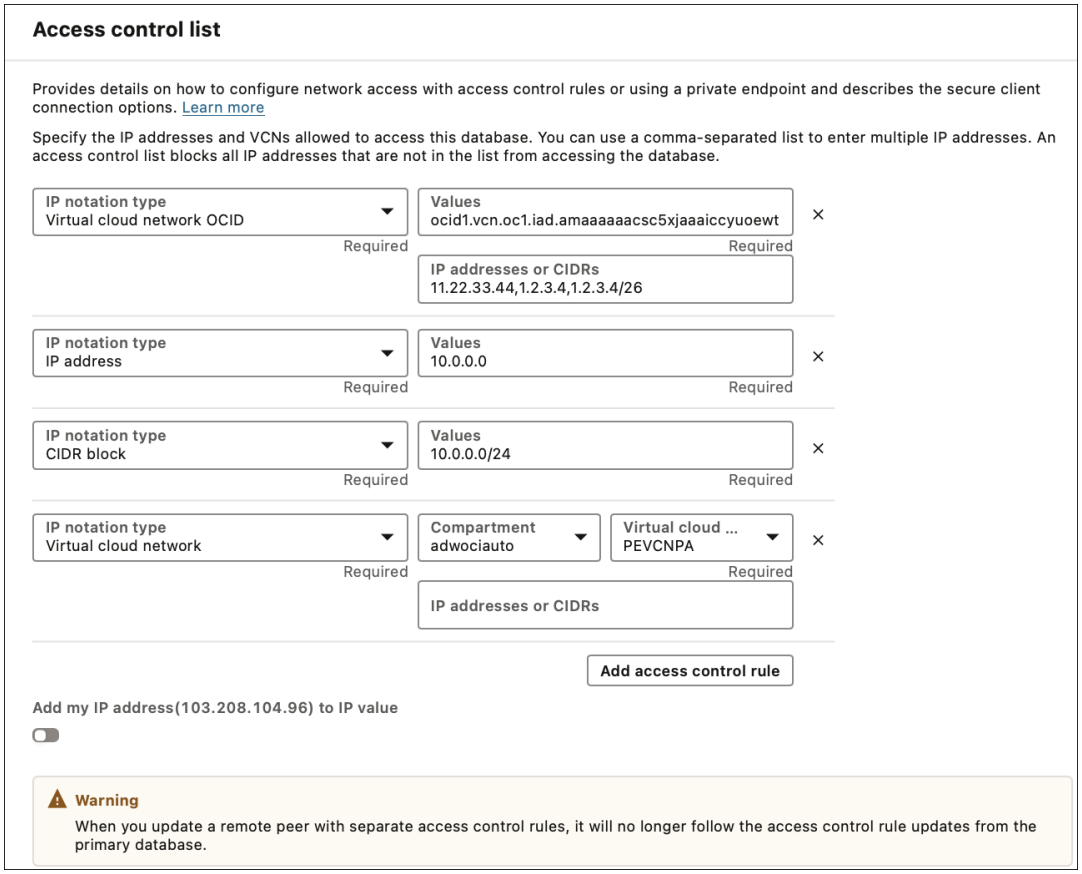
To use different network ACLs on a remote Autonomous Database peer:

1. On the primary database, on the Autonomous Database Details page, select the **Disaster recovery** tab.
2. Access the remote peer.

   The **Disaster recovery** information area shows the **Peer Autonomous Database**. The remote peer database by default has the same display name as the primary database, with an "_*region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

   Under **Peer Autonomous Database**, click the link to access a cross-region peer.
3. On the remote peer database, edit the access control list.

   Before you change ACL values the dialog shows a message indicating that ACLs on the peer database are syncing from the Primary database. For example:



See Configure Access Control Lists for an Existing Autonomous Database Instance for more information.

4. Add, remove, or modify one or more ACLs.
5. Click **Save**.

After you modify ACLs, the ACLs on the primary and on the remote peer are managed separately.

If you want to restart the synchronization of ACLs between the primary and the remote peer, you have two options:

- Terminate the peer Autonomous Database and create a new cross-region disaster recovery peer database.

  See Disable a Cross-Region Standby Database for details on terminating a remote standby database.

  See Disable a Cross-Region (Remote) Peer for details on terminating a remote peer.
- Contact Oracle Cloud Support and file a service request or contact your support representative.

Events and Notifications for a Standby Database

You can use Oracle Cloud Infrastructure Events to be notified of and to specify rules to automatically respond to Autonomous Data Guard operations.

> **Note:**
>
> When Autonomous Data Guard is enabled with a remote standby, events are only sent to the instance with the **Primary** role.

Event Description	Type
Automatic Failover Begin	`com.oraclecloud.databaseservice.automaticfailover.begin`
Automatic Failover End	`com.oraclecloud.databaseservice.automaticfailover.end`
Disable Data Guard Begin	`com.oraclecloud.databaseservice.disableautonomousdataguard.begin`
Disable Data Guard End	`com.oraclecloud.databaseservice.disableautonomousdataguard.end`
Enable Data Guard Begin	`com.oraclecloud.databaseservice.enableautonomousdataguard.begin`
Enable Data Guard End	`com.oraclecloud.databaseservice.enableautonomousdataguard.end`
Manual Failover Begin	`com.oraclecloud.databaseservice.failoverautonomousdatabase.begin`
Manual Failover End	`com.oraclecloud.databaseservice.failoverautonomousdatabase.end`
Switchover Begin	`com.oraclecloud.databaseservice.switchoverautonomousdatabase.begin`
Switchover End	`com.oraclecloud.databaseservice.switchoverautonomousdatabase.end`

See the following Oracle Cloud Infrastructure topics for information on events and notifications:

- Overview of Events
- Autonomous Database Event Types
- Notifications Overview

Autonomous Database Cross-Region Paired Regions

Autonomous Database provides paired regions for creating cross-region databases, including cross-region clones and cross-region disaster recovery peers.
The **Region** list shows paired regions when you add a remote disaster recovery peer or when you create a clone in a different region. The **Region** list only shows paired regions. That is, if your tenancy is not subscribed to a region that is paired to the source region, the region is not displayed. To subscribe to a region, see Managing Regions.

If you do not see a region that you are subscribed to in the **Region** list, open a support ticket to request that the region be added as a paired region for your source region. See Get Help, Search Forums, and Contact Support for more information.

Use the API

Provides links for details on using API operations to manage Autonomous Data Guard.

For information about using the API and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Autonomous Data Guard:

- To enable or disable Autonomous Data Guard, use UpdateAutonomousDatabase.
- To initiate a manual failover operation, use FailOverAutonomousDatabase.
- To initiate a switchover operation, use SwitchOverAutonomousDatabase.

Use these Terraform APIs to manage Autonomous Database resources:

For information about Terraform, see Terraform Provider and for information about Terraform APIs, see Data Source: oci_database_autonomous_database.

Autonomous Data Guard Notes

Provides notes for using Autonomous Database with an Autonomous Data Guard standby database.

- You cannot connect to a Standby database until it is made the Primary by a failover or a switchover. Thus, a Standby database cannot be opened for read-only access and cannot be used to offload queries from a Primary database.
- Autonomous Data Guard is available with the Data Warehouse and Transaction Processing workload types. Autonomous Data Guard is not available with the JSON and APEX workload types.
- Autonomous Data Guard is not available with Always Free Autonomous Databases.
- Autonomous Database does not provide access to a local Standby database:
  - You perform all operations, such as scaling up the **ECPU count** (**OCPU count** if your database uses OCPUs) enabling compute auto scaling on the Primary database and Autonomous Database performs the same actions on the local Standby database. Likewise, you only perform actions such as stopping or restarting the database on the Primary database.
  - A local Standby database is not available for use as a read-only database.

- The Number of ECPUs (OCPUs if your database uses OCPUs) allocated graph and the CPU utilization graph on the **Database Dashboard** card in Database Actions displays the ECPUs (OCPUs if your database uses OCPUs) allocated and the CPUs utilization for the Primary database. These graphs do not include information about a local Standby database or about a remote Standby database.

  The CPU Utilization metrics on the Oracle Cloud Infrastructure Console metrics page display the CPU utilization for the Primary database. Other metrics on this page also apply to the Primary database. These metrics do not include information about the local Standby database or remote Standby database.
- After a switchover or failover to a peer database, the peer database becomes the Primary and the graphs on the **Database Dashboard** in Database Actions and the Oracle Cloud Infrastructure Console metrics page display information about the Primary database. The graphs and metric do not contain information about the database that was the Primary before the switchover or failover operation.
- Automatic Failover to a local Standby is disabled during a Restore in Progress operation.
- Automatic Failover to a local Standby disabled when Upgrading a Database.
- When the **Lifecycle state** field for the Primary database shows **Stopped**, standby databases are also stopped. You may still perform a switchover when the Primary database is **Stopped**.
- Cross-Region Autonomous Data Guard Notes

Cross-Region Autonomous Data Guard Notes

The following are restrictions and limitations when you enable Autonomous Data Guard with a cross-region (remote) standby database:

- To disable Autonomous Data Guard with a cross-region standby database, you terminate the remote Standby database. See Terminate a Cross-Region Standby Database for more information.
- When a private endpoint is enabled or disabled on the Primary database, any previously configured Access Control List (ACL) on the Standby is enabled and the values are cleared. You must reset and verify the ACL on the Standby database after you disable a private endpoint on the Primary.
- You perform most operations, such as scaling up the **ECPU count** (**OCPU count** if your database uses OCPUs) and enabling compute auto scaling on the Primary database and Autonomous Database performs the same actions on the remote Standby database. Likewise, you only perform actions such as stopping or restarting the database on the Primary database.
- You can perform certain operations, such as configuring private endpoints on a remote Standby database.
- You can modify network configuration for ACLs on a remote Standby database. See Manage Remote Peer Network ACLs for more information.
- A remote Standby database is not available for use as a read-only database.
- Oracle Data Safe can be enabled on a database that has a cross-region Standby database enabled, but it only monitors the database within its region, and cannot monitor the standby in the event of a switchover or a failover.
- When you allow TLS authentication for the Primary database, Autonomous Data Guard enables TLS authentication in the cross- region Standby. Thus, when Autonomous Data Guard is enabled with a remote Standby, you can only allow TLS connections on the

Primary if both the Primary and the remote Standby are configured to support TLS connections. That is, the Primary and the remote Standby must either be configured with ACLs or with a private endpoint. See Network Configuration Prerequisites to Allow TLS Authentication for more information.

- See for the following information on using customer-managed keys with Autonomous Data Guard
  - Autonomous Data Guard with Customer Managed Keys
  - Notes for Customer-Managed Keys in OCI Vault with Autonomous Data Guard
- The **BYOL ECPU limit** you set on an Autonomous Data Guard Primary database does not apply to a cross-region or cross-tenancy Autonomous Data Guard Standby database. On a cross-region or cross-tenancy Standby you can independently set the **BYOL ECPU limit**, as required. Setting a value for **BYOL License limit** limits how many ECPUs will be covered by BYOL licenses.

  See Autonomous Data Guard Cross-Region BYOL Licensing for more information.
- When you enable Autonomous Data Guard with a cross-region standby database, the wallets for the primary and the standby specify different database hostnames and use different connection strings. Oracle recommends that applications use the connection string or wallet downloaded from the same region as the primary database.

  If you need to use a single connection string or wallet containing both the primary and the standby database hostnames, you may construct this manually.

  To manually construct a wallet that contains both the primary and the remote database connections strings:

  1. From the primary database's Oracle Cloud Infrastructure Console, click **Database connection** to download the primary's `wallet.zip`.
  2. From the remote standby database's Oracle Cloud Infrastructure Console, click **Database connection** to download the standby's `wallet.zip`.
  3. Unzip both wallet files and open the two `tnsnames.ora` files.
  4. Copy the remote database's connect descriptor into the primary database's connection string in the primary's `tnsnames.ora` file using your preferred retry delays.
  5. Zip the updated primary database wallet folder.

  With this updated `tnsnames.ora`, your primary database connection strings in the updated `wallet.zip` will contain both the primary and the standby hostnames, to support failover. An application using the updated wallet attempts to connect and retries connecting to the first listed database hostname, and if that connection fails due to the database being Unavailable, the application then automatically attempts to connect to the second database hostname.

  For example, if your Autonomous Data Guard is setup with the primary in Ashburn (IAD) and a cross-region standby in Phoenix (PHX), Oracle recommends that your mid-tier applications running in IAD use the connection string or wallet from that of the primary database in IAD, and your corresponding applications running in PHX use the connection string or wallet from that of the standby database in PHX. For a regional failover or switchover, Oracle recommends failing over both your database and your application or mid-tier, for optimum performance and to minimize any cross-regional latency.

  For example:

```
a6gxf2example9ep_high = (description_list=
     (failover=on) (load_balance=off)
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
```

```
(port=1522)(host=adb.us-ashburn-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_high.adb.oracl
ecloud.com))(security=(ssl_server_dn_match=yes)))
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
(port=1522)(host=adb.us-phoenix-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_high.adb.oracl
ecloud.com))(security=(ssl_server_dn_match=yes))))

a6gxf2example9ep_low =
     (description_list= (failover=on) (load_balance=off)
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
(port=1522)(host=adb.us-ashburn-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_low.adb.oracle
cloud.com))(security=(ssl_server_dn_match=yes)))
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
(port=1522)(host=adb.us-phoenix-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_low.adb.oracle
cloud.com))(security=(ssl_server_dn_match=yes))))

a6gxf2example9ep_medium =
     (description_list= (failover=on) (load_balance=off)
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
(port=1522)(host=adb.us-ashburn-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_medium.adb.ora
clecloud.com))(security=(ssl_server_dn_match=yes)))
     (description= (retry_count=15)(retry_delay=3)(address=(protocol=tcps)
(port=1522)(host=adb.us-phoenix-1.oraclecloud.com))
(connect_data=(service_name=mqssyowmexample_a6gxf2example9ep_medium.adb.ora
clecloud.com))(security=(ssl_server_dn_match=yes))))
```

Backup and Restore Autonomous Database Instances

This section describes backup and recovery tasks on Autonomous Database.

- About Backup and Recovery on Autonomous Database
- Edit Automatic Backup Retention Period on Autonomous Database
  You can change the backup retention period for automatic backups on Autonomous Database with a retention period between 1 day and up to 60 days.
- Create Long-Term Backups on Autonomous Database
- View Backup Information and Backups on Autonomous Database
  You can view backup information and view the available backups on Autonomous Database.
- Restore and Recover your Autonomous Database
  From the Oracle Cloud Infrastructure Console you can restore the database using the **Restore** operation, where you initiate recovery for your database.
- Backup and Restore Notes
  Provides notes for automatic backups, long-term backups, and restoring your database.

About Backup and Recovery on Autonomous Database

Describes Autonomous Database backup options.

All backups taken and managed by Oracle in Autonomous Database are immutable. Immutable backups cannot be deleted or modified.

Backups are designed to be highly durable, as follows:

- In regions with multiple availability domains, backups are automatically replicated across availability domains.
- In regions with a single availability domain, backups are automatically replicated across fault domains.

Automatic Backups

Autonomous Database performs periodic backups including full, cumulative, and incremental backups, to ensure data reliability and recoverability. Each database instance is continuously backed up to achieve the Recovery Point Objective (RPO) of less than 10 seconds. See Recovery Time Objective and Recovery Point Objective for more information.

The choices for automatic backups are different depending on your compute model:

- **OCPU compute model**
  Autonomous Database automatically backs up your database for you. The retention period for backups is 60 days. You can restore and recover your database to any point-in-time in this retention period.
- **ECPU compute model**
  By default Autonomous Database automatically backs up your database for you and the retention period for backups is 60 days. Optionally, you can choose the backup retention period in days, from 1 to 60. You can restore and recover your database to any point-in-time in the specified retention period.

Billing for automatic backups depends on the compute model that you select when you provision or clone an Autonomous Database instance:

- **OCPU compute model**: the storage for automatic backups is included in the cost of database storage.
- **ECPU compute model**: the storage for backups is billed separately and in addition to database storage.

See How Is Autonomous Database Billed? for more information.

Immutable Backup Retention Option

To protect your data, you can enable the **Immutable backup retention** option to lock the automatic backup retention period. If locked, Autonomous Database does not allow changes to the retention period for automatic backups. This prevents any unauthorized removal of older backups by modification of the backup retention period.

> **Note:**
>
> After setting **Immutable backup retention**, you cannot disable this option or change the retention period. To disable **Immutable backup retention** or to change the backup retention period, file a Service Request at Oracle Cloud Support.

If you enable cross-region disaster recovery or backup replication and you set the **Immutable backup retention** option, the current primary's backup retention period remains locked before or after a switchover or failover.

- While provisioning or cloning an Autonomous Database Instance, you can select the immutable backup retention option.

  See Provision an Autonomous Database Instance and Clone an Autonomous Database Instance for more information.

- For an existing instance, you can update the settings of automatic backup retention and set the immutable backup retention option.

  See Edit Automatic Backup Retention Period on Autonomous Database for more information.

The immutable backup retention option is applicable for automatic backups only and does not affect long-term backups.

Long-Term Backups

Using the long-term backup feature you can create a long-term backup as a one-time backup or as scheduled long-term backup. You select the retention period for long-term backups in the range of a minimum of 3 months up to a maximum of 10 years.

See About Long-Term Backups on Autonomous Database for more information.

Recovery

You can initiate recovery for your Autonomous Database using the Oracle Cloud Infrastructure Console. Autonomous Database automatically restores and recovers your database to the point-in-time you specify or using the backup you select from a list of backups.

See Restore and Recover your Autonomous Database for more information.

Clone from a Backup

You can use either an automatic backup or a long-term backup to create a clone of your database.

See Clone an Autonomous Database from a Backup for more information.

Listing Backups

The list of backups available for recovery is shown on the Autonomous Database details page on the **Backups** tab. Click the **Backups** tab to show the list of backups.

The Oracle Cloud Infrastructure Console Autonomous Database details page, in the Backup area shows the **Total backup storage** field. This fields shows the total storage being billed, including for automatic backups and if there are long-term backups, this also includes the long term backup storage.

See View Backup Information and Backups on Autonomous Database for more information.

- About Long-Term Backups on Autonomous Database
  Using the long-term backup feature you can create a long-term backup as a one-time backup or as scheduled long-term backup. You select the retention period for long-term backups in the range of a minimum of 3 months up to a maximum of 10 years.

About Long-Term Backups on Autonomous Database

Using the long-term backup feature you can create a long-term backup as a one-time backup or as scheduled long-term backup. You select the retention period for long-term backups in the range of a minimum of 3 months up to a maximum of 10 years.

Autonomous Database takes scheduled long-term backups automatically according to the schedule you create: one-time, weekly, monthly, or yearly.

You can create a new database by cloning from a long-term backup. You cannot use a long-term backup to recover or restore the same database where the long-term backup was created.

Long-term backup billing:

- **ECPU compute model:** Long-term backup storage is billed in addition to your database storage. The total of your automatic backups and long-term backups will be billed additionally as backup storage.

  See ECPU Compute Model Billing Information for more information about how backup storage is billed.
- **OCPU compute model**: Using the OCPU compute model, long-term backups are billed in addition to your database storage and long term backup storage is billed at the same rate as database storage. Long-term backup storage is billed based on the storage usage, rounded to the nearest Terabyte. If your long-term backup storage usage is 0.5 TB, you are billed for 1 TB (at the same rate as database storage).

  For example, if you provision your Autonomous Database with 3 TB of storage and you create several long-term backups amounting to 1.2 TB, you are billed for a total of 5 TB of storage, as follows:

  – 3 TB (the provisioned storage)

  plus

  – 2 TB (1.2TB of long-term backups rounded up)

  See OCPU Compute Model Billing Information for more information about how backup storage is billed.

Each long term backup is a standalone backup that allows you to create a point-in-time clone, based on the long-term backup timestamp.

See Create Long-Term Backups on Autonomous Database for more information.

Edit Automatic Backup Retention Period on Autonomous Database

You can change the backup retention period for automatic backups on Autonomous Database with a retention period between 1 day and up to 60 days.

Editing the backup retention period is only available for instances using the ECPU compute model. See Compute Models in Autonomous Database for more information.

> **Note:**
>
> The storage for backups incurs additional costs. See ECPU Compute Model Billing Information for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

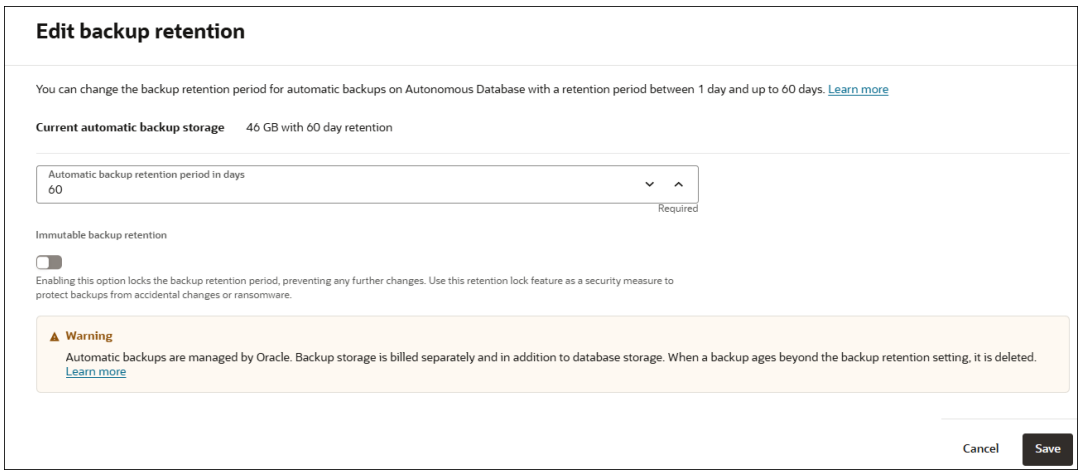
To change the automatic backup retention period:

1. On the Autonomous Database Details page, under **Backup**, in the **Automatic backup retention period** field, click **Edit**.

   This displays the Edit backup retention panel.

2. To edit the automatic backup retention period, enter the automatic backup retention period (in days).

   Enter a value in the text field or use the arrows to increase or decrease the backup retention period.



3. Select **Immutable backup retention** to lock the backup retention period.

   After setting the immutable backup retention option, you cannot disable this option or change the retention period. To disable immutable backup retention or to change the backup retention period, file a Service Request at Oracle Cloud Support.

   See About Backup and Recovery on Autonomous Database for more information.

4. Click **Save**.

Notes for specifying the automatic backup retention period:

- The backup retention period specifies how many days automatic backups are retained and the period for which you are billed for the automatic backups that are retained. If you change the backup retention period to a shorter period and automatic backups exist that

are older, you are no longer billed for the automatic backups with timestamps beyond the specified retention period (and Autonomous Database may delete the older automatic backups).

If you change the backup retention period to a longer period, for example if you change from 7 to 60 days, Autonomous Database starts retaining automatic backups up to 60 days, and billing for the retained backups. If older automatic backups already exist and were not deleted when you changed to a shorter backup retention period, the backups that have not been deleted show up and you are again billed for the automatic backups.

- The backup retention period for a remote peer database follows that of the source Primary database. Automatic backups are only taken on a peer database when it becomes the Primary database after a switchover or after a failover.

  See Use Standby Databases with Autonomous Data Guard for Disaster Recovery and Use Backup-Based Disaster Recovery for more information.

Create Long-Term Backups on Autonomous Database

You can create long-term backups on Autonomous Database with a retention period between three (3) months and up to ten (10) years.

When you create a long-term backup you select to create a one-time backup or set a schedule to automatically create backups that are taken weekly, monthly, or annually (yearly).

You can use a long-term backup to clone a new database. You may clone a new database from any timestamp between a long-term backup timestamp and up to 24 hours post (after) its timestamp. See Clone an Autonomous Database from a Backup for more information.

> **Note:**
>
> Long-term backups incur additional costs. See About Long-Term Backups on Autonomous Database for more information.

The Autonomous Database instance must have at least one automatic backup before you can create a long term backup. After you provision or clone an Autonomous Database instance, you may need to wait up to 4 hours before an automatic backup is available. See View Backup Information and Backups on Autonomous Database to find out if a backup exists.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To create a long-term backup:

1. On the Autonomous Database Details page, click the **Backups** tab.
2. On the **Backups** tab, click **Create long-term backup**.
3. Set the long-term backup retention period.

In the **Years**, **Months**, and **Days** fields, accept the default value, enter a value, or increment the values to increase or decrease the retention period for each of these choices.

4. If you want to begin the backup immediately, do not select **Schedule long-term backup** and skip to the next step.

   If you want to create a backup schedule, select **Schedule long-term backup**.

   a. Enter a **Backup date and time**.

   b. Select a repeat interval from the **Repeat** list.

      When you select **One-time (does not repeat)**, this schedules a single long-term backup to be created on the specified date and time.

      Selecting either **Weekly** specifies that Autonomous Database repeatedly creates long-term backups at the specified time at a weekly, every 7 days, interval. That is, backups are created and repeat at the same time weekly. For example, if the Backup date and Time is Jan 24, 2023 00:09:28 UTC and this is a Tuesday, and **Weekly** is selected, the long-term backup will happen every Tuesday.

      Selecting **Monthly** specifies that Autonomous Database repeatedly creates long-term backups at the specified time each month. When you select **Monthly**, the backup will occur every month at the date you select. If you select a day of the month >= 29, Autonomous Database takes the backup on the last the last day of the month instead (to account for months with fewer days and leap years).

      Selecting **Yearly** specifies that Autonomous Database repeatedly creates long-term backups at the specified time each year. When you select **Yearly**, the backup will occur every year at the date you select. If you select a day of the month >= 29, Autonomous Database takes the backup on the last the last day of the month instead (to account for months with fewer days and leap years).

5. Click **Create**.

   If you did not select **Schedule long-term backup**, Autonomous Database begins creating a long-term backup immediately.

- Edit Long-Term Backup Schedule
  You can edit the long-term backup schedule for an Autonomous Database instance.

- Delete Long-Term Backup Schedule
  You can delete the long-term backup schedule for an Autonomous Database instance.
- Delete a Long-Term Backup
  You can delete a long-term backup.

Edit Long-Term Backup Schedule

You can edit the long-term backup schedule for an Autonomous Database instance.

1. On the Autonomous Database Details page, in the **Long-term backup schedule** field under Backup, click **Edit**.

   This shows the Configure long-term backup schedule dialog.
2. Make changes to the long-term backup schedule.
3. Click **Save**.

Delete Long-Term Backup Schedule

You can delete the long-term backup schedule for an Autonomous Database instance.

1. On the Autonomous Database Details page, in the **Long-term backup schedule** field under Backup, click **Delete Schedule**.
2. In the Delete Schedule confirmation dialog, click **Delete**.

Delete a Long-Term Backup

You can delete a long-term backup.

To delete a long-term backup:

1. On the Autonomous Databases page select your Autonomous Database from the links under the **Display Name** column.
2. On the Autonomous Database Details page, select the **Backups** tab.
3. In the list of backups select the long-term backup you want to delete and click ⋯ at the end of a row.
4. In the list, select **Delete**.

View Backup Information and Backups on Autonomous Database

You can view backup information and view the available backups on Autonomous Database.

The Oracle Cloud Infrastructure Console shows information about backups. To view general backup information, view the Backup area on the Autonomous Database details page. Depending on your compute model, the Backup area includes the following information:

- **Automatic backup retention period**:
- **Total backup storage**: Shows the total storage being billed, including for automatic backups and if there are long-term backups, this also includes the long term backup storage.
- **Last automatic backup**: Shows the timestamp of the last automatic backup.
- **Next long-term backup**: When you configure scheduled long-term backups, this shows the timestamp for the next long-term backup.

- **Long-term backup schedule**: Shows the long-term backup schedule, with links to edit or delete a long-term backup schedule.

To list completed backups:

1. On the Autonomous Databases page select your Autonomous Database from the links under the **Display Name** column.
2. On the Autonomous Database Details page, select the **Backups** tab.

This shows the list of backups for the Autonomous Database instance.

If you click ... at the end of a row for a backup in the Backups list, this shows the actions you can perform.

- **Actions for Automatic Backups**:
  - Restore: See Restore and Recover your Autonomous Database for more information.
  - Create clone: See Clone an Autonomous Database from a Backup for more information.
- **Actions for long-term backups**:
  - Create clone: Clone an Autonomous Database from a Backup for more information.
  - Edit retention period: This allows you to change the retention period for a long-term backup.
  - Delete: This allows you to remove a long-term backup.

Restore and Recover your Autonomous Database

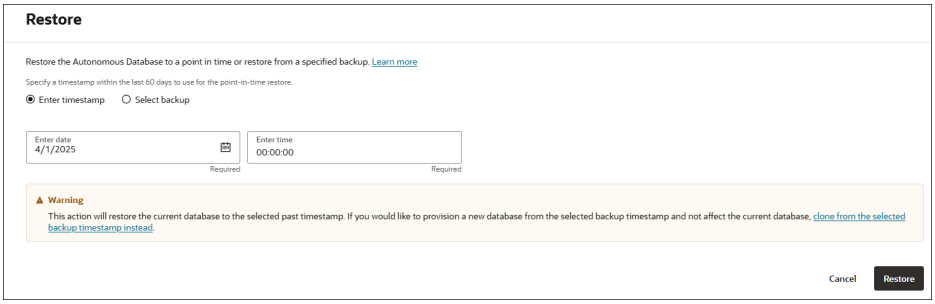
From the Oracle Cloud Infrastructure Console you can restore the database using the **Restore** operation, where you initiate recovery for your database.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To restore and recover your database, do the following:

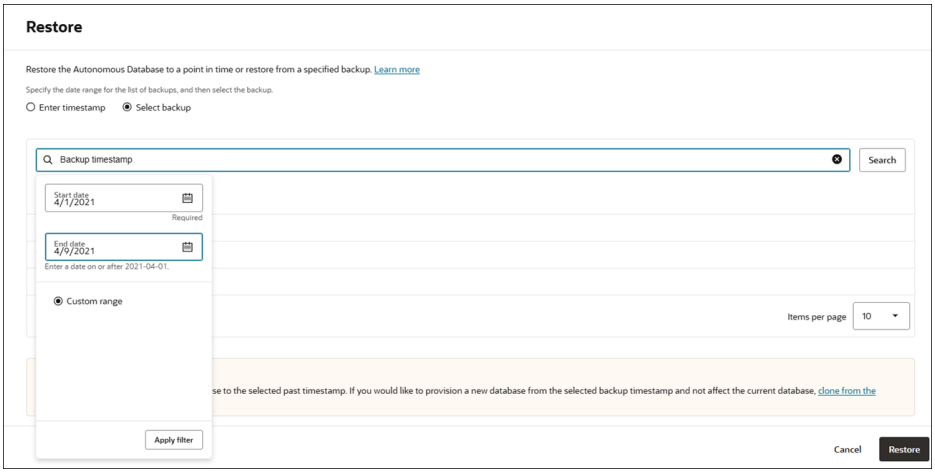
1. On the Autonomous Database Details page, from the **More actions** drop-down list, select **Restore** to display the **Restore** prompt.
2. In the Restore prompt, select **Enter Timestamp** or **Select Backup** to restore to a point in time or to restore from a specified backup.
   - **Enter Timestamp**: Enter a timestamp to restore to in the **Enter Timestamp** calendar field.



Click the Calendar icon to show the date and timestamp calendar selector. If automatic backups are enabled on your instance, you can select a timestamp to restore and recover your database to any point-in-time in the retention period.

Manually edit the values in the **Enter Timestamp** field if you prefer to use a more granular timestamp.

- **Select Backup**: Select a backup from the list of backups. Limit the number of backups you see by specifying a period using the **From** and **To** calendar fields.



3. Click **Restore**.

> **Note:**
>
> Restoring Autonomous Database puts the database in the unavailable state during the restore operation. You cannot connect to a database in that state. The only lifecycle management operation supported in unavailable state is **Terminate**.

When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

The details page shows Lifecycle state: **Restore In Progress**

4. When the restore operation finishes your Autonomous Database instance opens and the Lifecycle state shows **Available**.

At this point you can connect to your Autonomous Database instance and check your data to validate that the restore point you specified was correct. After checking your data if you find

that the restore date you specified was not the one you needed, you can initiate another restore operation to another point in time.

Notes:

- The restore operation also restores the `DATA_PUMP_DIR` directory and user defined directories to the timestamp you specified for the restore; files that were created after that timestamp would be lost.
- When you restore, the Oracle Machine Learning workspaces, projects, and notebooks are not restored.
- For external tables, partitioned external tables, and the external partitions of hybrid partitioned tables a backup does not include the external files that reside on your Object Store. Thus, for operations where you use a backup to restore your database, such as **Restore** or **Clone from a backup** it is your responsibility to backup, and restore if necessary, the external files associated with external tables, external partitioned tables, or the external files for a hybrid partitioned table.

  See Clone an Autonomous Database from a Backup for information on using **Clone from a backup**.

Backup and Restore Notes

Provides notes for automatic backups, long-term backups, and restoring your database.

- **Files on Object Store**: For external tables, partitioned external tables, and the external partitions of hybrid partitioned tables, backups do not include the external files that reside on Object Store. Thus, for operations where you use a backup to restore your database, such as **Restore** or **Clone from a backup**, it is your responsibility to backup and restore if necessary, the external files associated with external tables, external partitioned tables, or the external files for a hybrid partitioned table.

  See Restore and Recover your Autonomous Database for information on **Restore**.

  See Clone an Autonomous Database from a Backup for information on **Clone from a backup**.
- **Stopped Database**: Automatic backups occur when a database is stopped. If you stop your database, you do not miss a regularly scheduled automatic backup.
- **Manual Backups**: The Oracle Cloud Infrastructure Console does not provide the option to create a manual backup. Oracle recommends that you do not create or use manual backups. If required, manual backups are available using the API. See CreateAutonomousDatabaseBackup for more information.
- **Sample Data Sets SH and SSB**: The sample data sets are not included in backups and do not impact the size or speed of either backup or restore operations.

Long-Term Backup Notes

- Long-term backups are retained and managed by Oracle for the specified retention period you select when you create or schedule long-term backups.
- Each long-term backup creates a full backup and the backup can only be used from the Autonomous Database instance to clone a new database.

- After the long-term retention period is over a backup will be deleted and is no longer retained.
- The encryption key option that is selected when a long-term backup is created applies when you create a clone from the long-term backup. If a customer-managed master encryption key is in use at the time a long-term backup is created, then the same customer-managed master encryption key must be available to access a database that you clone from the long-term backup.

  See Manage Encryption Keys on Autonomous Database for more information.
- While backing up a database, the database is fully functional. However, during a long-term backup certain lifecycle management operations, such as stopping the database may affect the backup. See Long-Term Backup with Concurrent Operations for more information.
- Cloning from a long-term backup creates a new database with the most current available database version, which is possibly not the original database version in use at the time when the long-term backup was created. A database cloned from a long-term backup uses latest available database version.

  For example, if a long-term backup is taken on a database with version 19c, and then 4 years later the long-term backup is used to clone a new database, the new database may only offer the latest database version (for example Oracle Database 23ai, if version 19c is not available).
- Long-term backups are only accessible while a database exists. If you terminate an Autonomous Database instance, you no longer have access to long-term backups. If you want to retain long-term backups and minimize costs:

  1. Drop all tables and scale down the database to the minimum storage.
  2. Stop the database.

  This preserves the long-term backups that were created for the Autonomous Database instance.

Use OraMTS Recovery Feature on Autonomous Database

Use Oracle MTS (OraMTS) Recovery Service to resolve an in-doubt Microsoft Transaction Server transaction.

- About OraMTS Recovery Service
  The Oracle MTS (OraMTS) Recovery Service resolves an in-doubt Microsoft Transaction Server transaction.
- Prerequisites to Enable OraMTS Recovery Service on Autonomous Database
  Lists the prerequisites to enable OraMTS Recovery Service for an Autonomous Database.
- Enable OraMTS Recovery Service on an Autonomous Database
  Describes steps to enable OraMTS Recovery Service on an Autonomous Database.
- Disable OraMTS Recovery Service on an Autonomous Database
  Describes steps to disable OraMTS Recovery Service for an Autonomous Database.

About OraMTS Recovery Service

The Oracle MTS (OraMTS) Recovery Service resolves an in-doubt Microsoft Transaction Server transaction.

An Microsoft Transaction Server (MTS) is a COM-based transaction processing system that runs on an internet or network server.

An Oracle MTS Recovery Service is automatically installed with Oracle Services For Microsoft Transaction Server. The Oracle MTS (OraMTS) Recovery Service resolves in-doubt transactions on the computer that started the failed transaction. A scheduled recovery job for each MTS-enabled database lets the OraMTS Recovery Service resolve in-doubt transactions.

To use MTS with an Oracle database, distributed transaction capabilities are necessary.

When any of these components fails, Oracle transactions connected to Microsoft Transaction Server become in-doubt transactions:

- Microsoft Transaction Server application
- Network
- Microsoft Distributed Transaction Coordinator (MS DTC)

See Using Microsoft Transaction Server with Oracle Database for more information.

The Oracle MTS (OraMTS) Recovery Service resolves an in-doubt Microsoft Transaction Server transaction in this order:

1. The DBMS recovery job detects an in-doubt MTS-related transaction.
2. The DBMS recovery job extracts the recovery service's endpoint address from the `XID` of the in-doubt transaction and requests the recovery service for the outcome of the MTS/MS DTC transaction.
3. The recovery service requests its MS DTC for transaction outcome.
4. The recovery service reports transaction outcome to the DBMS job process.
5. The DBMS recovery job commits or terminates the in-doubt transaction based on the outcome reported by MS DTC.

> **Note:**
>
> Each computer can only have one instance of Oracle MTS (OraMTS) Recovery Service installed.

Prerequisites to Enable OraMTS Recovery Service on Autonomous Database

Lists the prerequisites to enable OraMTS Recovery Service for an Autonomous Database.

To enable Oracle MTS Recovery Service on an Autonomous Database:

- You must configure your database on a private endpoint.
- For your OraMTS Recovery Service, you must deploy the VM in the same private network as the database.
- You must configure an OCI Private Load Balancer (LBaaS) and the Load Balancer (LBaaS) must be able to access the VM on port 2030. See Load Balancer Management for more information.
- Your database must be able to communicate with the Load Balancer (LBaaS) on port 443. To enable this you need an egress rule for port 443 in VCN's security list or in the network security group.
- Your Load Balancer (LBaaS) must also be able to receive the communication from the database. To enable this you need an ingress rule for your Load Balancer (LBaaS) for port 443.

- Reserve a domain name with a domain provider.
- Generate an SSL certificate for the domain.
- You must configure a secure HTTPS endpoint using OCI Load Balancer to ensure that the communication between the Autonomous Database and the MTS server uses HTTPS protocol with SSL encryption. See Configure Network Access with Private Endpoints and Submit an HTTP Request to a Private Host for more information.

Enable OraMTS Recovery Service on an Autonomous Database

Describes steps to enable OraMTS Recovery Service on an Autonomous Database.

To enable OraMTS Recovery Service on your Autonomous Database, you must be logged in as the `ADMIN` user or have the `EXECUTE` object privilege on `DBMS_CLOUD_ADMIN`.

Run `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` to enable OraMTS Recovery Service on your Autonomous Database.

Example to Enable and Verify the OraMTS Recovery Service:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
        feature_name => 'ORAMTS',
        params       => JSON_OBJECT('location_uri' VALUE 'https://
mymtsserver.mycorp.com')
   );
END;
/

SELECT property_value FROM database_properties WHERE property_name =
'ORAMTS_SERVER';
```

The first example enables the OraMTS Recovery Service on your Autonomous Database.

The `feature_name` parameter specifies the name of the feature to enable. The `ORAMTS` value indicates that you are enabling the OraMTS recovery service feature for your database.

The `location_uri` parameter specifies the HTTPS URL for the OraMTS server in a customer network.

The second example is a SQL statement that you can run to verify that the OraMTS Recovery Service is enabled for your Autonomous Database.

See ENABLE_FEATURE Procedure for more information.

Disable OraMTS Recovery Service on an Autonomous Database

Describes steps to disable OraMTS Recovery Service for an Autonomous Database.

To disable OraMTS Recovery Service on your Autonomous Database, you must be logged in as the `ADMIN` user or have the `EXECUTE` object privilege on `DBMS_CLOUD_ADMIN`.

Run `DBMS_CLOUD_ADMIN.DISABLE_FEATURE` to disable OraMTS Recovery Service on your Autonomous Database.

Example to disable the OraMTS Recovery Service:

```
BEGIN
DBMS_CLOUD_ADMIN.DISABLE_FEATURE(
    feature_name => 'ORAMTS');
END;
/
```

This disables the OraMTS Recovery feature on your Autonomous Database.

The `feature_name` parameter specifies the name of the feature to disable. The `ORAMTS` value indicates that you are disabling the OraMTS recovery service feature for your database.

See DISABLE_FEATURE Procedure for more information.

Use Backup-Based Disaster Recovery

Backup-Based Disaster Recovery provides a lower-cost disaster recovery option for Autonomous Database (the RTO is higher with this option, as compared to using Autonomous Data Guard).

Autonomous Database Disaster Recovery Options

- **Backup-Based Disaster Recovery**: uses backups to instantiate a peer database at the time of switchover or failover. This enables you to have a lower cost and higher Recovery Time Objective (RTO) disaster recovery option for your Autonomous Database, as compared with Autonomous Data Guard. For local Backup-Based Disaster Recovery, existing local backups are utilized. There are no additional costs for a local Backup-Based Disaster Recovery. Cross-Region Backup-Based Disaster Recovery incurs an additional cost.

  Backup-Based Disaster Recovery is available for all workload types.
- **Autonomous Data Guard**: When you add an Autonomous Data Guard standby database, the system creates a standby database that continuously gets updated with the changes from the primary database. You can use Autonomous Data Guard with a standby in the current region, a local standby, or with a standby in a different region, a cross-region standby. You can also use Autonomous Data Guard with both a local standby and a cross-region standby.

  You can also create an Autonomous Data Guard standby in a different tenancy.

  Autonomous Data Guard is available for the following workload types:

  – Data Warehouse

  – Transaction Processing

  See Use Standby Databases with Autonomous Data Guard for Disaster Recovery for details on Autonomous Data Guard.

Topics

- About Backup-Based Disaster Recovery
  Backup-Based Disaster Recovery uses backups to instantiate a peer database at the time of switchover or failover. This enables you to have a lower cost and higher Recovery Time Objective (RTO) disaster recovery option for your Autonomous Database, as compared with Autonomous Data Guard.

- View Backup-Based Disaster Recovery Peer
  Backup-Based Disaster Recovery with a local peer is enabled by default for a newly created Autonomous Database instance, and for existing databases. A local Backup-Based Disaster Recovery peer does not incur any additional cost.
- Update Disaster Recovery Type
  Describes the steps to change to an alternative Disaster Recovery option.
- Backup-Based Disaster Recovery Switchover and Failover Operations
  Describes switchover and failover operations with an Backup-Based Disaster Recovery peer database.
- Backup-Based Disaster Recovery Cross-Region Operations
  Describes cross-region operations with Backup-Based Disaster Recovery.
- Backup-Based Disaster Recovery Events
  You can use Oracle Cloud Infrastructure events to respond when Autonomous Database changes its state due to a Backup-Based Disaster Recovery related event.
- Use the API
  Provides links for details on using API operations to manage Backup-Based Disaster Recovery.

About Backup-Based Disaster Recovery

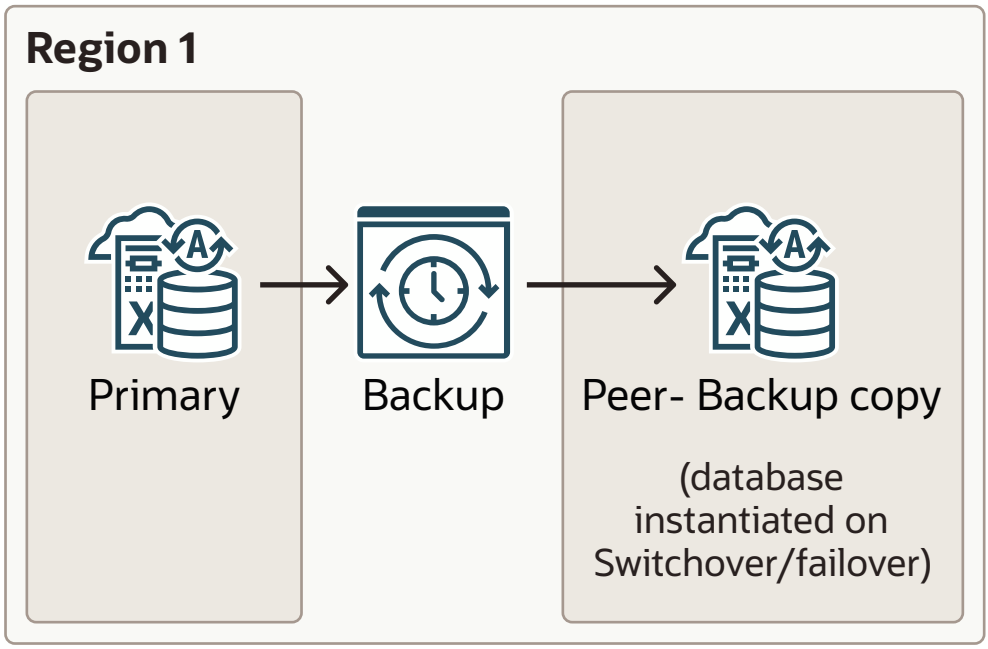
Backup-Based Disaster Recovery uses backups to instantiate a peer database at the time of switchover or failover. This enables you to have a lower cost and higher Recovery Time Objective (RTO) disaster recovery option for your Autonomous Database, as compared with Autonomous Data Guard.

You can use Backup-Based Disaster Recovery with a peer in the current region, a local peer, or with one or more disaster recovery peers in different regions, or you can add both a local disaster recovery peer and one or more a remote disaster recovery peers. You can also create a Backup-Based Disaster Recovery peer, either local or remote in a different tenancy.

> **Note:**
>
> Backup-Based Disaster Recovery (backup copy) is available in all Autonomous Database workload types. Backup-Based Disaster Recovery is not available with Always Free Autonomous Database.

Backup-Based Disaster Recovery with Local Peer

For local Backup-Based Disaster Recovery, existing local backups are utilized. There are no additional costs for local Backup-Based Disaster Recovery.



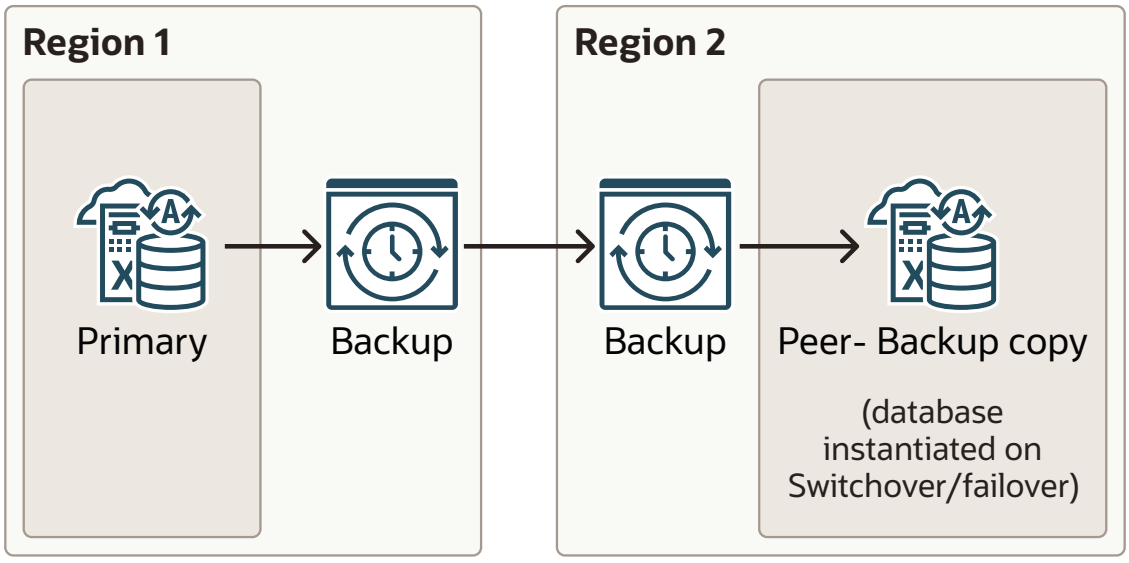
For better resilience for Backup-Based Disaster Recovery, a peer is instantiated as follows:

- In regions with more than one availability domain, a local peer is instantiated in a different availability domain than the primary database.
- In regions with a single availability domain, a local peer is instantiated in a different fault domain than the primary database (that is, on a different physical machine).

All Autonomous Database features from the primary database are available when a peer is instantiated and becomes the primary, after the system fails over or after you perform a switchover operation. See Autonomous Data Guard with Local Standby for more information.

Backup-Based Disaster Recovery with Cross-Region Peer

For backup-based disaster recovery with a cross-region peer, backups are copied to the remote region. Cross-region Backup-Based Disaster Recovery incurs additional costs.



Autonomous Database allows you to create one or more remote disaster recovery peer databases, depending on your compute model:

- OCPU Compute Model: You can add one remote disaster recovery peer in a paired region. Paired regions are remote regions where you can create a cross-region peer.
- ECPU Compute Model: You can add multiple remote disaster recovery peers, with up to one peer in each remote paired region. For example if your primary database is in the IAD region, you can add a remote peer in PHX and in SJC, but you cannot add two remote peers in PHX.

Paired regions are remote regions where you can create a cross-region disaster recovery peer. See Autonomous Database Cross-Region Paired Regions for more information on paired regions.

Topics

- Backup-Based Disaster Recovery Recovery Time Objective (RTO) and Recovery Point Objective (RPO)
  When you perform a failover using with Backup-Based Disaster Recovery enabled, the peer instance assumes the role of the primary instance, according to the Recovery Time Objective (RTO) and Recovery Point Objective (RPO).
- Replicating Backups to a Cross-Region Backup Based Disaster Recovery Peer
  When you add a cross-region Backup-Based Disaster Recovery peer you can enable cross-region backup replication for automatic backups.

Backup-Based Disaster Recovery Recovery Time Objective (RTO) and Recovery Point Objective (RPO)

When you perform a failover using with Backup-Based Disaster Recovery enabled, the peer instance assumes the role of the primary instance, according to the Recovery Time Objective (RTO) and Recovery Point Objective (RPO).

The RTO is the maximum amount of time required to restore database connectivity to a backup copy database after a failover is initiated. The RPO is the maximum duration of potential data loss, in minutes, on the primary database.

Backup-Based Disaster Recovery RTO and RPO numbers are:

Backup-Based Disaster Recovery Configuration	RTO	RPO
Local backup copy	one (1) hour + 1 hour per 5 TB	10 seconds
Cross-region (remote) backup copy	one (1) hour + 1 hour per 5 TB	1 min

Replicating Backups to a Cross-Region Backup Based Disaster Recovery Peer

When you add a cross-region Backup-Based Disaster Recovery peer you can enable cross-region backup replication for automatic backups.

By default, automatic backups are created and maintained at the current Primary database and are not replicated to a cross-region peer. Optionally, you can enable replication of the automatic backups to a cross-region peer.

When you enable cross-region backup replication, up to 7 days of automatic backups for the primary are replicated to a cross-region peer. When this feature is enabled automatic backups are available in the remote region as follows:

- After a switchover or failover you can restore or clone to any timestamp in the past seven (7) days, or to any timestamp in the specified retention period when the retention period is set to less than seven days.
- All backups for the primary that are replicated to the remote region are deleted on the remote region peer after seven days, or after the retention period number of days when the retention period is set to less than seven days.
- You cannot modify the backup retention period for replicated backups, except if you modify the backup retention period on the primary to specify a value less than seven days. In this case, the retention period for replicated backups on the remote region matches the automatic backup retention period set on the primary.

The cross-region backup replication incurs an additional cost. See Oracle Autonomous Database Serverless Features Billing for more information.

See the following for more information:

- Add a Cross-Region Disaster Recovery Peer
- Enable or Disable Backup Replication for an Existing Cross-Region Peer

Note the following for cross-region backup replication:

- After a switchover or a failover, while the cross-region database is in the primary role, backups are taken on the current primary and are replicated to the current (remote) peer.
- When using Backup-Based Disaster Recovery with a cross-region peer, this feature is supported for all workload types.

View Backup-Based Disaster Recovery Peer

Backup-Based Disaster Recovery with a local peer is enabled by default for a newly created Autonomous Database instance, and for existing databases. A local Backup-Based Disaster Recovery peer does not incur any additional cost.

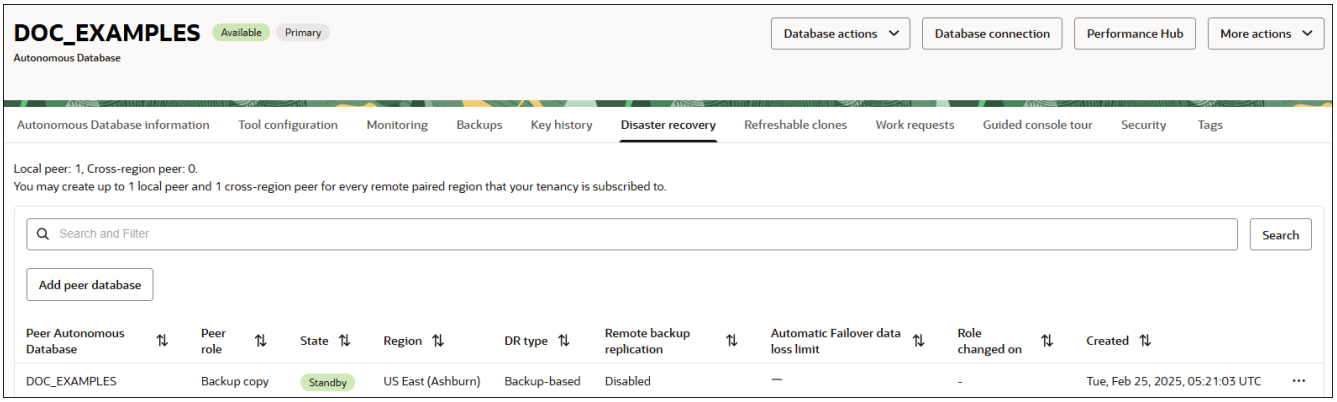
Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To view the disaster recovery information for your Autonomous Database, do the following:

On the Autonomous Database Details page, click **Disaster recovery**. The **DR type** field indicates the type of disaster recovery, either Backup-Based Disaster Recovery (Backup copy) or Autonomous Data Guard.

For example:



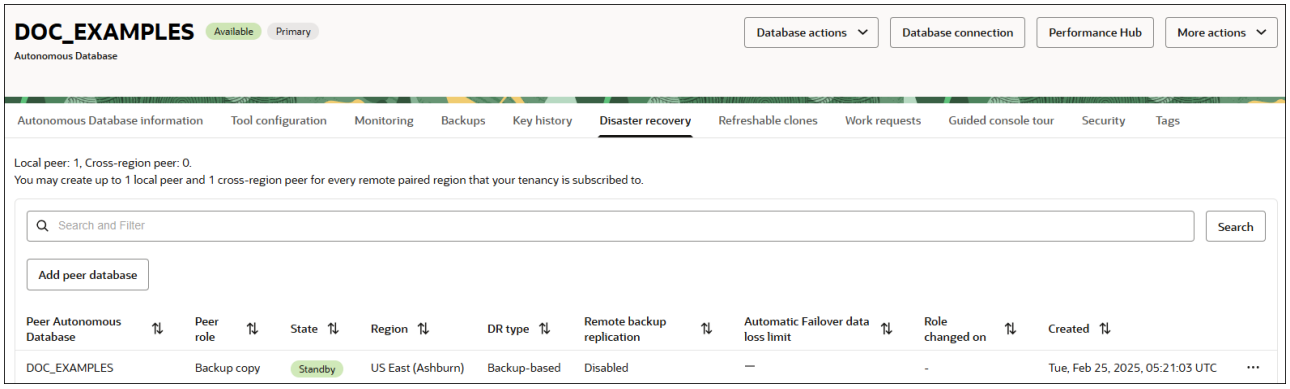
Update Disaster Recovery Type

Describes the steps to change to an alternative Disaster Recovery option.

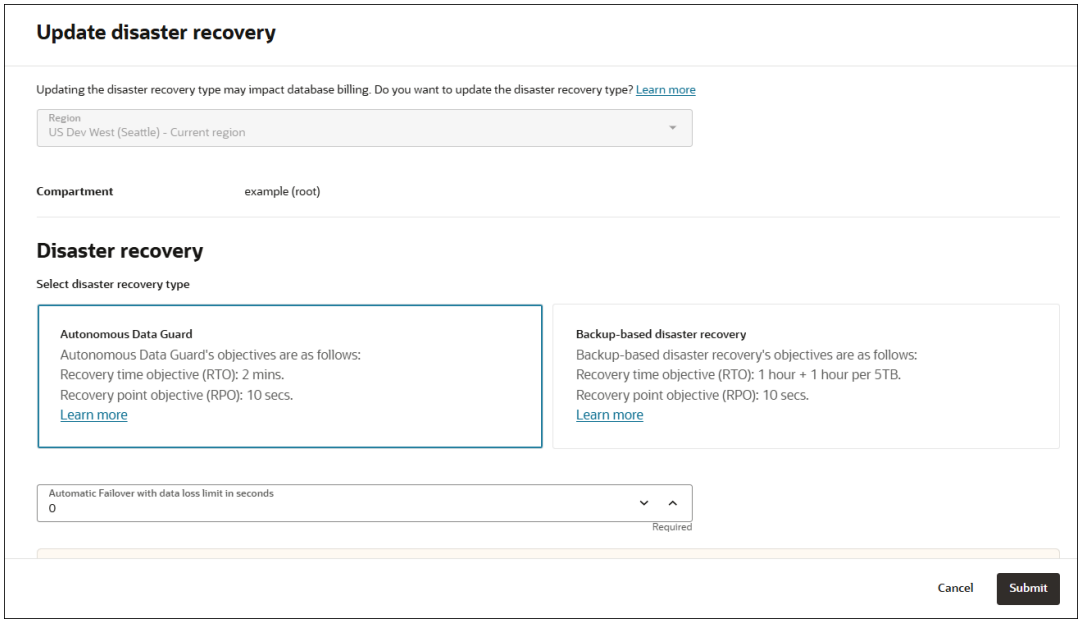
Backup-Based Disaster Recovery is enabled by default for an Autonomous Database with one local peer. Disaster Recovery cannot be disabled for an Autonomous Database instance. However, you can choose to update your Disaster recovery type to Autonomous Data Guard. See Use Standby Databases with Autonomous Data Guard for Disaster Recovery for more information about Autonomous Data Guard.

To update the Disaster recovery type:

1. On the Primary Autonomous Database Details page, click **Disaster recovery**.



2. In the row showing the database's disaster recovery details, click ⋯ at the end of the row and select **Update disaster recovery**.
3. On the Update disaster recovery page, choose **Autonomous Data Guard**.



4. Click **Submit**. This starts provisioning an Autonomous Data Guard standby database.
5. The disaster recovery type is changed to, Autonomous Data Guard, as shown in the **DR type** column.

Backup-Based Disaster Recovery Switchover and Failover Operations

Describes switchover and failover operations with an Backup-Based Disaster Recovery peer database.

- About Switchover to a Backup Copy Peer
  When you perform a switchover, the primary database becomes the backup copy and the backup copy becomes the primary database, with no data loss.
- Perform a Switchover to a Local Backup Copy Peer
  When you perform a switchover the primary database becomes the peer, and the peer becomes the primary database, with no data loss.
- Perform a Switchover to a Cross-Region Backup Copy Peer
- Perform a Failover
- Notes for Performing a Switchover to a Backup Copy Peer
  Provides notes for Backup-Based Disaster Recovery switchover:

About Switchover to a Backup Copy Peer

When you perform a switchover, the primary database becomes the backup copy and the backup copy becomes the primary database, with no data loss.

A switchover is typically done to test failover to the backup copy for audit or certification reasons, or to test your application's failover procedures when you have added a backup copy peer.

For switchover to a backup copy peer, the **Autonomous Database Details** page, shows the **Switchover** link under **Disaster recovery** and the Oracle Cloud Infrastructure Console on the primary database also shows a **Switchover** link in the **Role** field when both the primary database and a backup copy peer are available. You can perform a switchover when the

primary database **Lifecycle state** shows **Available** or **Stopped** and a backup copy is available (the **State** field shows **Standby**).

To see the peer state, on the Autonomous Database details page, select the **Disaster recovery** tab and for the peer listed in the **Peer Autonomous Database** column, check that the **State** shows **Standby**.

Using the Autonomous Database API, you can initiate the switchover operation at any time. See Use the API for more information.

Perform a Switchover to a Local Backup Copy Peer

When you perform a switchover the primary database becomes the peer, and the peer becomes the primary database, with no data loss.

A switchover is typically done to test failover to the peer for audit or certification reasons or to test your application's failover procedures with Backup-Based Disaster Recovery.

For a switchover to a backup copy, the **Autonomous Database Details** page, the Oracle Cloud Infrastructure Console on the database with the **Primary** role shows a **Switchover** link in the **Role** field when both the primary database and a peer are available. You can perform a switchover when the primary database **Lifecycle state** shows **Available** or **Stopped** and a peer is available (the **State** field shows **Standby**).

To see the peer status, select the **Disaster recovery** tab and for the peer listed in the **Peer Autonomous Database** column, check that the **State** field shows **Standby**.

Using the Autonomous Database API, you can initiate the switchover operation at any time. See Use the API for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To perform a switchover, do the following:

1. On the Autonomous Database Details page, under **Disaster recovery**, in the **Role** field, click **Switchover**.

   As an alternative, to initiate a switchover you can select **More actions** and **Switchover** or select the **Disaster recovery** tab anc click **Switchover**.
2. In the **Confirm switchover to peer** dialog, in the **Select peer** list, choose the peer to switchover.
3. Enter the database name to confirm that you want to switch over.
4. Click **Confirm switchover to peer**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

   The database lifecycle state badge shows **Updating**. To see the state of the peer select the **Disaster recovery** tab. On the **Disaster recovery** tab the **State** column shows **Role Change in Progress**.

When the switchover completes, Backup-Based Disaster Recovery does the following:

- The Backup-Based Disaster Recovery resource information is updated to reflect the switchover. On the Autonomous Database details page select the **Disaster recovery** tab to see the updated information.
- Autonomous Database reports the time in the **Role Changed On** the field.

Perform a Switchover to a Cross-Region Backup Copy Peer

When you perform a switchover, the primary database becomes the peer database and the peer database becomes the primary database, with no data loss.

> **Note:**
>
> For a cross-region switchover you must initiate the switchover from the cross-region peer.

You have several options to access the cross-region peer:

- Select the remote region in Oracle Cloud Infrastructure Console and then access the peer directly.
- Access the primary, and from the primary database you can access the peer from the Autonomous Database Details page by selecting the **Disaster recovery** tab and clicking the link for the backup copy peer in the **Peer Autonomous Database** column.

To perform a switchover:

1. On the cross-region peer, on the Autonomous Database Details page, under **Disaster recovery**, in the **Role** field, click **Switchover**.

   As an alternative, in the row showing the database's disaster recovery details, click ... at the end of the row and select **Switchover**.
2. In the **Confirm switchover to peer** dialog, enter the peer database name to confirm that you want to switch over.
3. In the **Confirm switchover to peer** dialog, click **Confirm switchover to peer**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

   The database **Lifecycle state** changes to **Role change in progress**. To see the state of the peer database, select the **Disaster recovery** tab. The state **State** shows **Updating**.

When the switchover completes, Autonomous Database does the following:

- The display name shows the Primary indicator.
- The **Disaster recovery** resource information is updated to reflect the switchover. Select the **Disaster recovery** tab to see the updated information.
- Autonomous Database reports the time of the last switchover when you hover over the in the **Role** field.

See Notes for Performing a Switchover for more information.

Perform a Failover

When the primary database goes down, with Backup-Based Disaster Recovery you can perform a manual failover to make the local peer the primary database.

Backup-Based Disaster Recovery does not provide an automatic failover option. If you want to provide automatic failover, where the system monitors the primary instance and automatically fails over to a local standby database in certain scenarios, you need to change the disaster recovery type for the local instance to use Autonomous Data Guard.

With both a local Backup-Based Disaster Recovery peer and a cross-region Backup-Based Disaster Recovery peer, Oracle recommends that you attempt a manual failover to the local peer first (not to the cross-region peer).

Depending on how you enable Backup-Based Disaster Recovery, there are different steps to perform a manual failover to a peer:

- **When you configure Backup-Based Disaster Recovery with only a local peer**:

  When you have a local peer and the switchover is not successful, the Oracle Cloud Infrastructure console shows a banner with information about why the switchover was not successful and the Oracle Cloud Infrastructure console shows a **failover** link in the **Role** field that you can click to initiate a failover to the local peer. The failover link only shows when the Primary database is unavailable and a peer is available. That is, the Primary database **Lifecycle state** field shows **Unavailable** and the local peer is available. Using the API, you can initiate manual failover at any time. See Use the API for information on using the API.

  To see the peer status, on the details page select the **Disaster recovery** and for the peer listed in the Peer Autonomous Database column check that the **State** field shows **Available** or **Stopped**.

- **When you use Backup-Based Disaster Recovery with both a local peer and a cross-region (remote) peer:**

  With Backup-Based Disaster Recovery enabled with both a local peer and a cross-region peer, and the local peer is available, Oracle recommends that you attempt a manual failover to the local peer first (not to the cross-region peer).

  If a local peer is unavailable or a manual failover to the local peer fails, you can perform a manual switchover to the cross-region peer. If the switchover to the cross-region peer fails, on the peer the Oracle Cloud Infrastructure console shows a **failover** link in the **Role** field that you can click to initiate a manual failover to the peer.

When you initiate a manual failover it is failed over to the peer based on the Recovery Time Objective (RTO) and Recovery Point Objective (RPO) targets. See Backup-Based Disaster Recovery Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To initiate a manual failover to a cross-region backup copy, do the following:

1. On the peer, perform a switchover. See Perform a Switchover to a Local Backup Copy Peer for details.
2. If the switchover attempt in Step 1 fails, on the peer the **Role** field shows a **Failover** link. On the peer, click the **Failover** link.

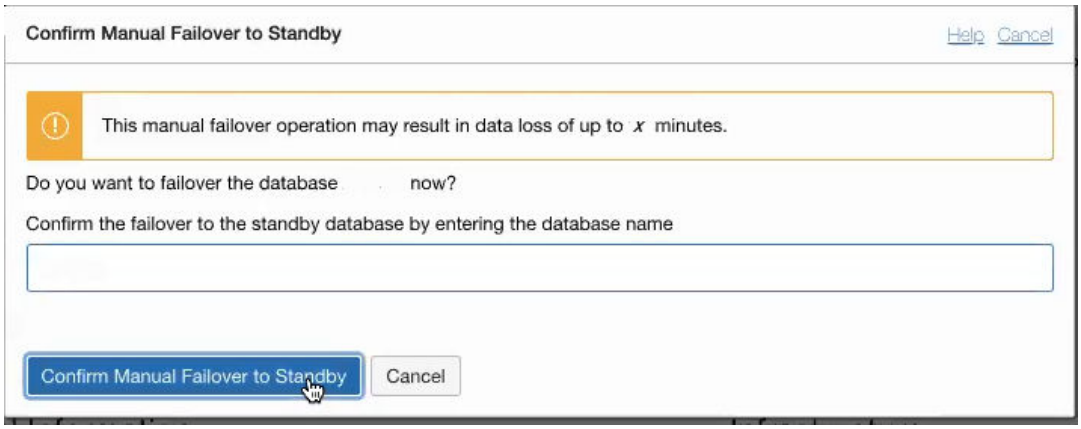
   This shows the **Confirm manual failover to peer** dialog, along with information on possible data loss that may result if you perform the manual failover to the peer.
3. In the **Confirm manual failover to peer** dialog, enter the Autonomous Database name to confirm that you want to failover.
4. In the **Confirm manual failover to peer** dialog, click **Confirm manual failover to peer**.

   When concurrent operations such as scaling are active, the confirmation also confirms either pausing or canceling the concurrent operation. See Concurrent Operations on Autonomous Database for more information.

To initiate a manual failover when the Primary database is unavailable and the local Peer is available, do the following:

1. On the **Details** page, under **Disaster recovery**, in the **Role** field, click **Failover**.

   This shows the **Confirm manual failover to peer** dialog, along with information on possible data loss that may result if you perform the manual failover to peer.



2. In the **Confirm manual failover to peer** dialog, enter the Autonomous Database name to confirm that you want to failover.
3. In the **Confirm manual failover to peer** dialog, click **Confirm manual failover to peer**.

When the failover completes, Backup-Based Disaster Recovery does the following:

- After a manual failover operation completes you can see any data loss associated with the manual failover in the message on the Oracle Cloud Infrastructure console banner and if you hover over the ⓘ in the **Role** field. The manual failover data loss is specified in minutes.
- After a manual failover with Backup-Based Disaster Recovery, if there was a regional failure, when the region comes back online the peer is automatically reconnected or if required reprovisioned.
- After you perform a manual failover to the cross-region peer, the cross-region peer becomes the primary database. In this case, if a local Autonomous Data Guard standby was enabled, a local Standby will be created and attached. If a local Autonomous Data Guard was not enabled before the failover in the primary database, as is the default, you have a local backup copy.

Notes for Performing a Switchover to a Backup Copy Peer

Provides notes for Backup-Based Disaster Recovery switchover:

- For a cross-region switchover, you must initiate the switchover from the cross-region peer.
- During the switchover, most of the actions on the Oracle Cloud Infrastructure Console are not available and the Autonomous Database Information page shows the **Lifecycle state** with the value **Updating**.
- The switchover operation keeps the original state of the Primary database. If the Primary database is stopped when you perform a switchover, the Primary database is stopped after the switchover.
- Autonomous Database generates the Switchover Autonomous Database work request. To view the request, on the Autonomous Database details page select the **Work requests** tab.
- After a switchover or failover to the peer, the peer becomes the Primary and the graphs on the **Database Dashboard** card in Database Actions and the Oracle Cloud Infrastructure Metrics display information about the Primary database. The graphs and metrics do not contain information about the database that was the Primary before the switchover or failover operation.
- You cannot cancel a cross-region switchover operation after the switchover begins and the **State** shows **Role change in progress**. Your options to cancel the switchover are:
  - Try or retry a switchover or a failover until the operation succeeds.
  - File a service request at Oracle Cloud Support or contact your support representative.

Backup-Based Disaster Recovery Cross-Region Operations

Describes cross-region operations with Backup-Based Disaster Recovery.

- Add a Cross-Region Disaster Recovery Peer
  In addition to a local Backup-Based Disaster Recovery peer, you can add one or more remote region (cross-region) Backup-Based Disaster Recovery peers.
- Enable or Disable Backup Replication for an Existing Cross-Region Peer
- Convert Cross-Region Backup-Based Disaster Recovery Peer to Snapshot Standby
  A cross-region Backup-Based Disaster Recovery peer can be converted to a snapshot standby. This converts the peer to a read-write database for up to two days (48 hours).
- Disconnect a Cross-Region Backup-Based Disaster Recovery Peer
  Shows you the steps to disconnect a cross-region Backup-Based Disaster Recovery peer from the Primary database.
- Disable a Cross-Region (Remote) Peer
  Describes the steps to terminate a cross-region (remote) peer.
- Update Remote Peer Network ACLs for a Backup-Based Disaster Recovery Peer
- Notes for Cross-Region Backup-Based Disaster Recovery Peer Operations
  Lists notes and restrictions for adding and managing a cross-region Backup-Based Disaster Recovery peer.

Add a Cross-Region Disaster Recovery Peer

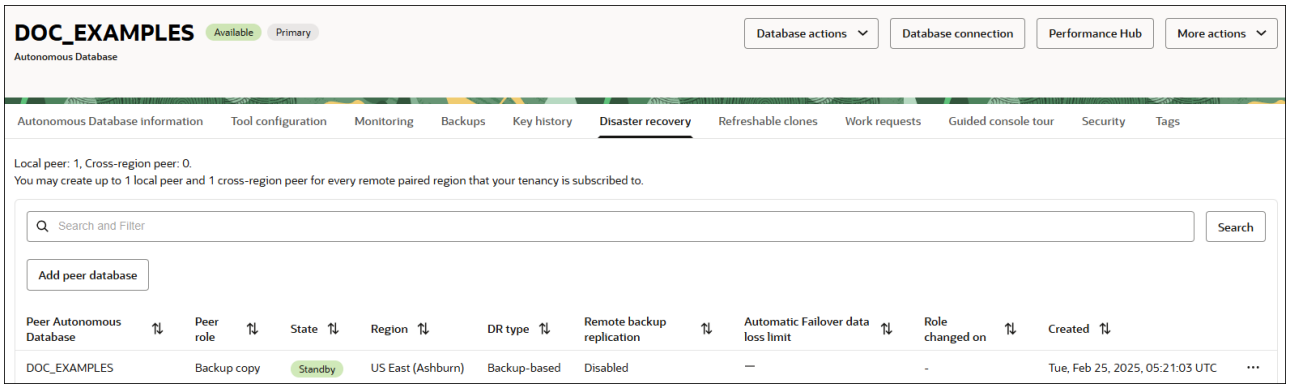
In addition to a local Backup-Based Disaster Recovery peer, you can add one or more remote region (cross-region) Backup-Based Disaster Recovery peers.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

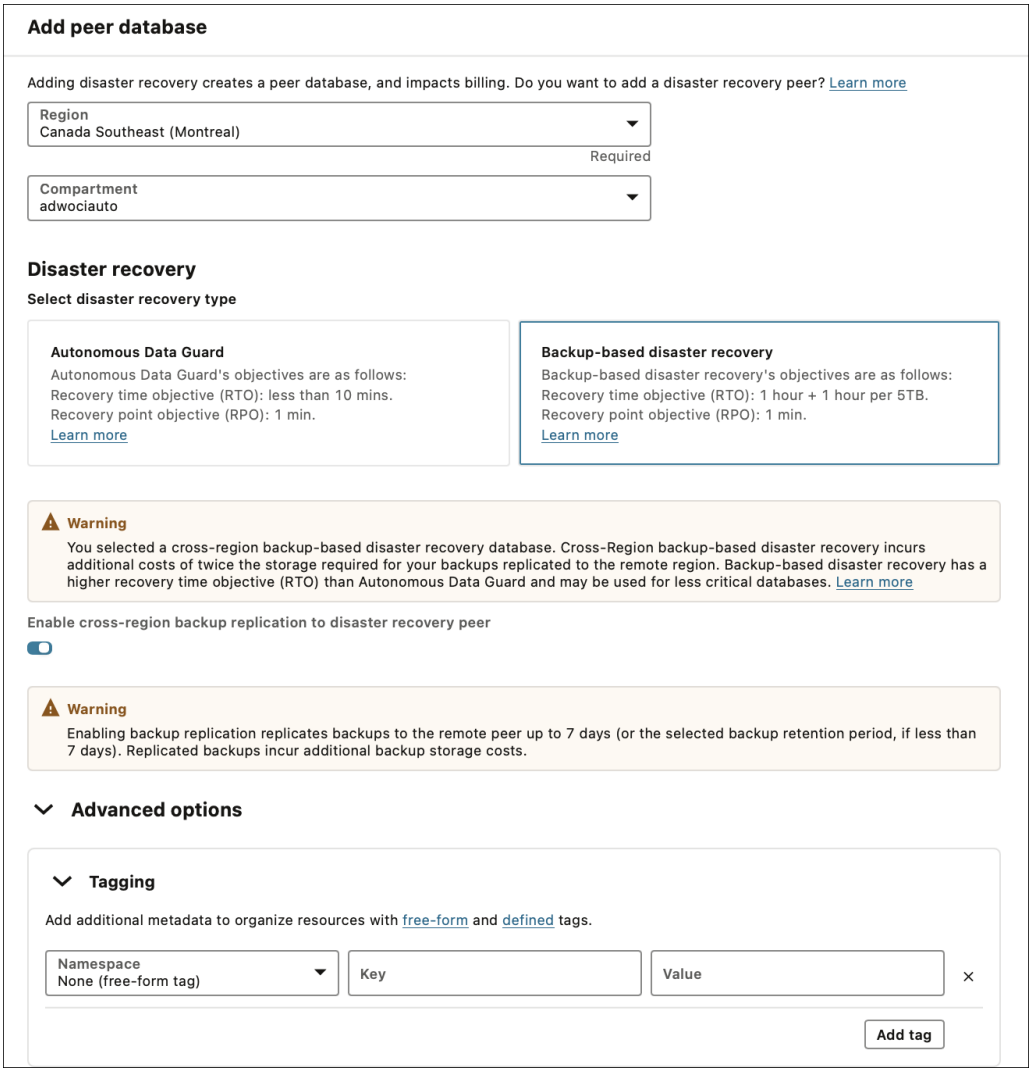
To add a cross-region Backup-Based Disaster Recovery peer, do the following:

1. On the Autonomous Database Details page, select the **Disaster recovery** tab.

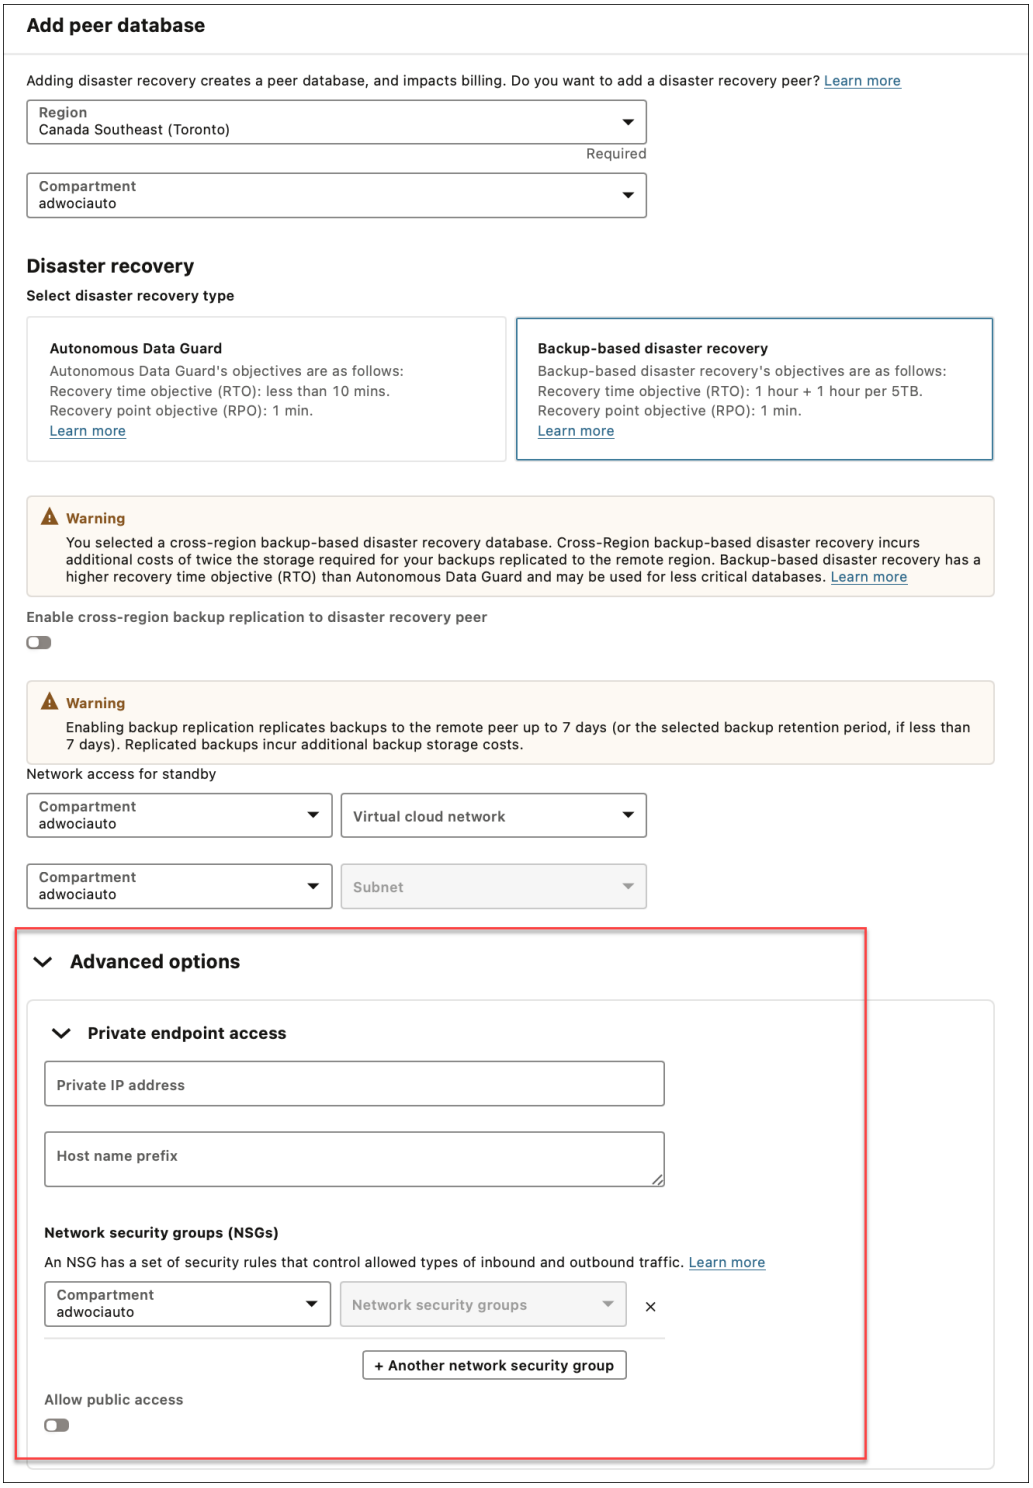


2. Click **Add peer database**.
3. In the **Region** drop-down list, select a region.

   The region list shows the available remote regions where you can create a cross-region peer. When you add a peer database, the list of available regions only shows a remote region if your tenancy is subscribed to the remote region (you must be subscribed to the paired remote region). See Autonomous Database Cross-Region Paired Regions for more information.
4. In the **Select a compartment** drop-down list, select a compartment.
5. Select the disaster recovery type. In addition, when the source database is configured with a private endpoint, enter the private endpoint information for the peer.
   a. Select the disaster recovery type: **Backup-based disaster recovery**.
   b. If you want to enable Cross-Region Backup Replication select the **Enable cross-region backup replication to disaster recovery peer** check-box. See Replicating Backups to a Cross-Region Backup Based Disaster Recovery Peer for more information.



c. When the source database is configured with a private endpoint, in the **Network access for standby** area enter the **Virtual cloud network** and the **Subnet**.



In these Network access for standby fields you specify the private endpoint's VCN and Subnet on the remote region where the standby is created. Configure Private Endpoints.

> **Note:**
>
> If you change your network access on the source database to enable a private endpoint after the standby is created, you must manually access the standby to enable a private endpoint on the peer.

6. Click **Add peer database**.

   The Autonomous Database Lifecycle state changes to **Updating**. In the **Resources** area, the number next to **Disaster recovery** increments to show that you have another disaster recovery peer, and the **State** field shows **Provisioning** for the new cross-region peer.

   > **Note:**
   >
   > While you add a new peer, the primary database is available for read/write operations. There is no downtime on the primary database.

   Autonomous Database generates a work request when you add a cross-region peer. To view the work request, select the **Work requests** tab.

See Notes for Cross-Region Backup-Based Disaster Recovery Peer Operations for more information.

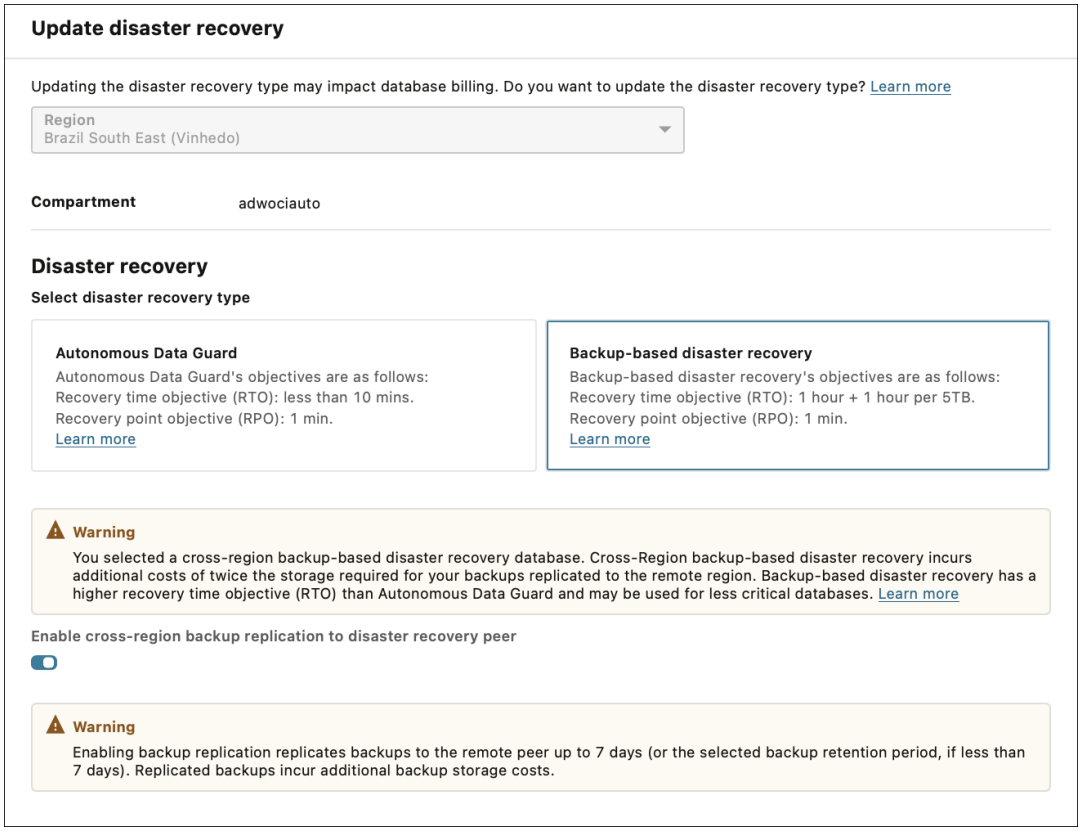
Enable or Disable Backup Replication for an Existing Cross-Region Peer

You can enable or disable backup replication on a Backup-Based Disaster Recovery cross-region peer.

To enable or disable backup replication for an existing cross-region Autonomous Data Guard standby:

1. On the **Autonomous Database Details** page, select the **Disaster recovery** tab.
2. In a row that lists a cross-region standby, click ... at the end of the row and select **Update disaster recovery**.

   This shows the Update disaster recovery page.



3. Enable or disable backup replication.
   a. If cross-region backup replication is disabled, select **Enable cross-region backup replication to disaster recovery peer** to enable the option.
   b. If cross-region backup replication is enabled, deselect **Enable cross-region backup replication to disaster recovery peer** to disable the option.
4. Click **Submit**.

   The Autonomous Database Lifecycle state changes to **Updating**.

If you select **Enable cross-region backup replication to disaster recovery peer**, it can take between several minutes and several hours to replicate the backups to the remote region, depending on the size of the backups. After backups are replicated, when you select the **Backups** tab on the peer database's Oracle Cloud Infrastructure Console Autonomous Database details page, you will see the list of replicated backups.

Convert Cross-Region Backup-Based Disaster Recovery Peer to Snapshot Standby

A cross-region Backup-Based Disaster Recovery peer can be converted to a snapshot standby. This converts the peer to a read-write database for up to two days (48 hours).

See Convert Cross-Region Peer to Snapshot Standby for more information.

Disconnect a Cross-Region Backup-Based Disaster Recovery Peer

Shows you the steps to disconnect a cross-region Backup-Based Disaster Recovery peer from the Primary database.

> **Note:**
>
> The disconnect operation for a cross-region Backup-Based Disaster Recovery peer can only be performed on an Autonomous Database instance that uses the ECPU compute model.

When you disconnect a cross-region peer, the peer database is disassociated from the primary database. This converts the database from a peer database to a standalone database. Following the disconnect operation you are not allowed to reconnect to the Primary.

The steps to disconnect a Backup-Based Disaster Recovery peer standby are the same as those to disconnect a standby database. See Disconnect a Peer Database for more information.

Notes for disconnecting a remote peer.

- The disconnect operation for a remote peer can only be performed on an Autonomous Database instance that uses the ECPU compute model.
- After the disconnect operation, the standalone database is no longer associated with the database that was the Primary database. To use the database as a standalone database, you must know the name of the database that was disconnected from the Primary database.
- There is no reconnect operation. After you disconnect a snapshot standby you are not allowed to reconnect to the Primary.
- After the disconnect operation, the standalone database is no longer associated with the database that was the Primary database. To use the database as a standalone database, you must know the name of the database that was disconnected from the Primary database.
- After the disconnect operation, the standalone database starts taking new backups as a standalone database.

Disable a Cross-Region (Remote) Peer

Describes the steps to terminate a cross-region (remote) peer.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To terminate a cross-region (remote) peer:

1. On the Primary database, on the Autonomous Database Details page select the **Disaster recovery** tab.

2. Access the Oracle Cloud Infrastructure Console for the remote region peer.

   The **Disaster recovery** information area shows the **Peer Autonomous Database**. The remote peer has the same display name as the primary database, with an "*_region*" extension. Where *region* is the region name, such as `IAD` or `BOM`.

   If you created the cross-region peer before the introduction of support for multiple cross-region peers, the remote peer has the same display name as the primary database, with an "`_Remote`" extension.

   Under **Peer Autonomous Database**, click the link for the remote peer to access the cross-region peer.

3. On the Oracle Cloud Infrastructure Console for the remote peer, on the **Details** page, from the **More actions** drop-down list, select **Terminate**.

4. On the **Terminate Autonomous Database** page, enter the database name to confirm that you want to terminate the cross-region peer.

5. Click **Terminate Autonomous Database**.

   While the peer is terminating, the **Lifecycle state** changes to **Terminating**.

There are limitations for disabling when an instance has a cross-region Backup-Based Disaster Recovery peer, as follows:

- A peer in the remote region cannot be disabled from the primary database.
- When Backup-Based Disaster Recovery is enabled with a cross-region peer, you must terminate all cross-region disaster recovery peers before you terminate the primary role database. If you attempt to terminate the primary, the system gives you an error.

  In this case, after you terminate all cross-region (remote) peers, you can terminate the primary database.

Update Remote Peer Network ACLs for a Backup-Based Disaster Recovery Peer

You can independently modify network ACLs on a remote disaster recovery peer database.

By default the disaster recovery primary and remote peer databases use the same network Access Control Lists (ACLs). Optionally, you can configure ACLs independently on remote peer databases. This provides an option to use different ACLs on remote peer databases.

If you modify the ACLs on a remote peer, Autonomous Database no longer keeps the ACL configuration synchronized between the primary and the remote peer. After you modify the ACLs on a remote peer, Autonomous Database manages the ACLs on the remote peer independently.

To use different network ACLs on a remote Autonomous Database peer:

1. On the primary database, on the Autonomous Database Details page, select the **Disaster recovery** tab.

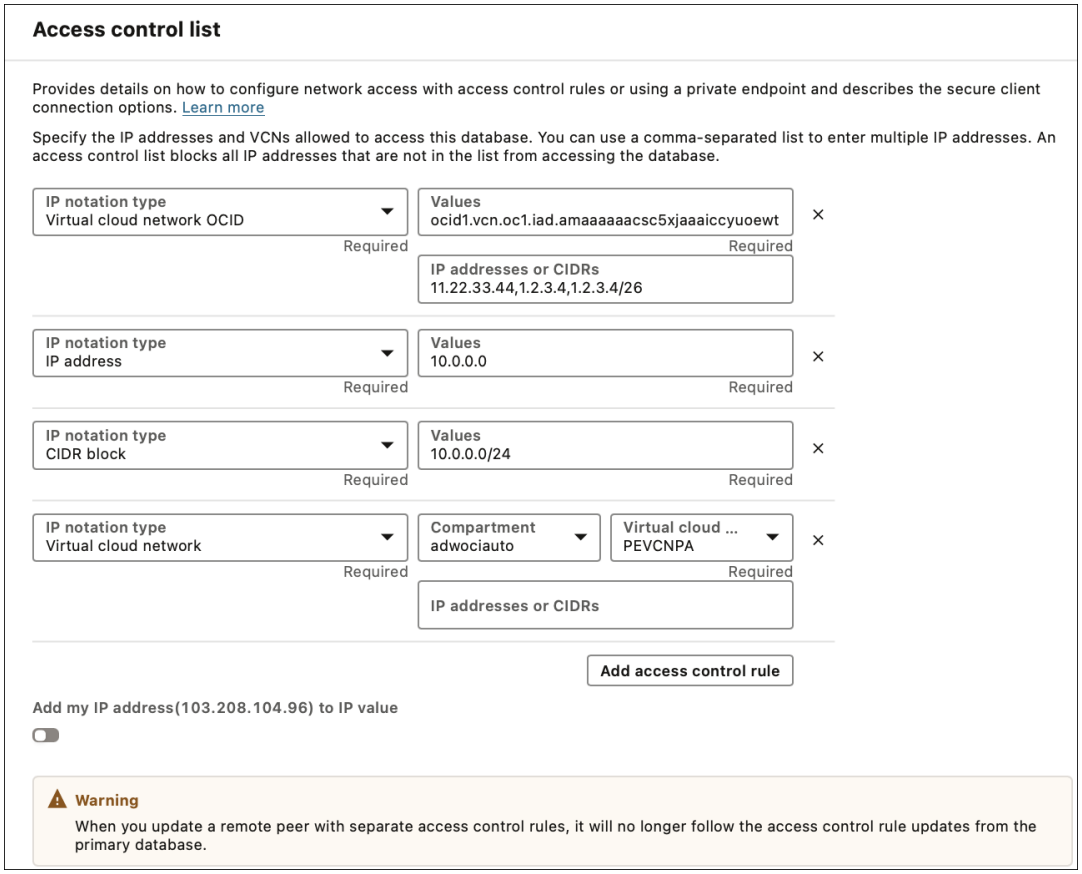
2. Access the remote peer.

   The **Disaster recovery** information area shows the **Peer Autonomous Database**. The remote peer database by default has the same display name as the primary database, with an extension. For example, `DBNAME_remote`.

   Under **Peer Autonomous Database**, click the link to access a cross-region peer.

3. On the remote peer database, edit the access control list.

   Before you change ACL the dialog shows a message indicating that ACLs on the peer database are syncing from the Primary database. For example:



See Configure Access Control Lists for an Existing Autonomous Database Instance for more information.

4. Add, remove, or modify one or more ACLs.
5. Click **Save**.

After you modify ACLs, the ACLs on the primary and on the remote peer are managed separately.

If you want to restart the synchronization of ACLs between the primary and the remote peer, you have two options:

- Terminate the peer Autonomous Database and create a new cross-region disaster recovery peer database.

  See Disable a Cross-Region (Remote) Peer for details on terminating a remote peer database.

- Contact Oracle Cloud Support and file a service request or contact your support representative.

Notes for Cross-Region Backup-Based Disaster Recovery Peer Operations

Lists notes and restrictions for adding and managing a cross-region Backup-Based Disaster Recovery peer.

- After you add a cross-region (remote) peer, the wallet and connection string from the primary database will contain only the hostname of the primary database, and the wallet and connection string from the remote database will contain only the hostname of the remote database. This applies to both instance and regional wallets.

See Cross-Region Disaster Recovery Connection Strings and Wallets for more information.

- If you switch on the **Enable cross-region backup replication to disaster recovery peer** toggle, replicating the backups to the remote region can take between several minutes and several hours, depending on the size of the backups. After backups are replicated, on the peer's Autonomous Database details page select the **Backups** tab to show a list of the replicated backups.

  See Enable or Disable Backup Replication for an Existing Cross-Region Peer for more information.

- When you add a cross region peer there are special considerations when the primary instance is using customer-managed keys, or if you want to switch to use customer-managed keys. See Autonomous Data Guard with Customer Managed Keys for more information.
- When you add a Backup-Based Disaster Recovery peer, while the **Lifecycle state** field shows **Updating**, the following actions are disabled on the Primary database:
  - Move Resource. See Move an Autonomous Database to a Different Compartment for information on moving an instance.
  - Stop. See Stop Autonomous Database for information on stopping an instance.
  - Restart. See Restart Autonomous Database for information on restarting an instance.
  - Restore. See Restore and Recover your Autonomous Database for information on restoring.

Backup-Based Disaster Recovery Events

You can use Oracle Cloud Infrastructure events to respond when Autonomous Database changes its state due to a Backup-Based Disaster Recovery related event.

Autonomous Database events include the following:

- Begin manual failover
- End manual failover with failover result of success or failure.
- Begin switchover
- End switchover with switchover result of success or failure.

Based on events you can perform actions or send notifications. See Events and Notifications for a Standby Database for more information on using events and producing notifications.

Use the API

Provides links for details on using API operations to manage Backup-Based Disaster Recovery.

For information about using the API and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Disaster Recovery:

- To enable or disable Backup-Based Disaster Recovery, use UpdateAutonomousDatabase.
- To initiate a manual failover operation, use FailOverAutonomousDatabase.
- To initiate a switchover operation, use SwitchOverAutonomousDatabase.

Use these Terraform APIs to manage Autonomous Database resources:

For information about Terraform, see Terraform Provider and for information about Terraform APIs, see Data Source: oci_database_autonomous_database.

Track Table Changes with Flashback Time Travel

Use Flashback Time Travel to view past states of database objects or to return database objects to a previous state without using point-in-time media recovery.

- About Flashback Time Travel
  Flashback Time Travel lets you track and store transactional changes to a table over its lifetime. Flashback Time Travel is useful for compliance with record stage policies and audit reports. You can also use Flashback Time Travel in various scenarios such as enforcing digital shredding, accessing historical data, and selective data recovery.
- Enable Flashback Time Travel for a Table
  Describes steps to enable Flashback Time Travel for a table in Autonomous Database.
- Disable Flashback Time Travel for a Table
  Describes procedure to disable Flashback Time Travel for a table in Autonomous Database.
- Modify the Retention Time for Flashback Time Travel
  Describes procedure to modify the retention time for Flashback Time Travel in Autonomous Database.
- Purge Historical Data for Flashback Time Travel
  Describes procedure to purge historical data for Flashback Time Travel in Autonomous Database.
- View Flashback Time Travel Information
  Describes data dictionary views to view information about Flashback Time Travel files in Autonomous Database.
- Notes for Flashback Time Travel
  Provides notes and restrictions for using Flashback Time Travel on Autonomous Database.

About Flashback Time Travel

Flashback Time Travel lets you track and store transactional changes to a table over its lifetime. Flashback Time Travel is useful for compliance with record stage policies and audit reports. You can also use Flashback Time Travel in various scenarios such as enforcing digital shredding, accessing historical data, and selective data recovery.

Flashback Time Travel was called Flashback Data Archive in previous Oracle Database versions. The Flashback Time Travel APIs and some Flashback Time Travel terms such as the `FLASHBACK ARCHIVE` privilege retain the Flashback Data Archive naming.

Each Autonomous Database instance has one Flashback Archive named `flashback_archive` that supports Flashback Time Travel operations. The default retention time for `flashback_archive` is 60 days. See Modify the Retention Time for Flashback Time Travel for information on changing the default retention time.

There are restrictions to enable Flashback Time Travel for a table, including the following:

- You must have the `FLASHBACK ARCHIVE` object privilege for `flashback_archive`. By default the `ADMIN` user has this privilege.
- The table must not be any of the following:

  - A nested table
  - A temporary table
  - A remote table
  - An external table
- The table cannot contain `LONG` columns.
- The table cannot contain nested columns.

See Notes for Flashback Time Travel for a list of additional Flashback Time Travel restrictions.

See Using Oracle Flashback Technology for more information on Flashback Technology.

Enable Flashback Time Travel for a Table

Describes steps to enable Flashback Time Travel for a table in Autonomous Database.

By default, Flashback Time Travel is disabled for new and existing tables.

The following is the prerequisite to enable Flashback Time Travel:

- You must be logged in as the `ADMIN` user or have the `FLASHBACK ARCHIVE` object privilege.

  The `ADMIN` user or the user having the `FLASHBACK ARCHIVE` privilege `WITH GRANT OPTION` can grant the `FLASHBACK ARCHIVE` object privilege to another user.

  For example:

  ```
  GRANT FLASHBACK ARCHIVE ON FLASHBACK_ARCHIVE TO <username>
  ```

  ```
  GRANT FLASHBACK ARCHIVE ON FLASHBACK_ARCHIVE TO <username> WITH GRANT
  OPTION
  ```

  See Manage User Roles and Privileges on Autonomous Database for more information.

You can enable Flashback Time Travel for an existing table or a new table that you are creating.

1. To enable Flashback Time Travel when you create a table:

   ```
   CREATE TABLE employee (EMPNO NUMBER(4) NOT NULL, ENAME VARCHAR2(10), JOB
   VARCHAR2(9), MGR NUMBER(4)) FLASHBACK ARCHIVE;
   ```

2. To enable the Flashback Time Travel for an existing table:

   ```
   ALTER TABLE departments FLASHBACK ARCHIVE;
   ```

After you enable Flashback Time Travel for a table you can disable Flashback Time Travel. See Disable Flashback Time Travel for a Table for more information.

Disable Flashback Time Travel for a Table

Describes procedure to disable Flashback Time Travel for a table in Autonomous Database.

After Flashback Time Travel is enabled for a table you can disable it as the `ADMIN` user or if you have the `FLASHBACK ARCHIVE` object privilege.

For example, to disable Flashback Time Travel for the `employee` table:

```
ALTER TABLE employee NO FLASHBACK ARCHIVE;
```

Modify the Retention Time for Flashback Time Travel

Describes procedure to modify the retention time for Flashback Time Travel in Autonomous Database.

You can modify the retention time for Flashback Time Travel if you are logged in as `ADMIN` user or if you have `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

For example, to set the retention time to 365 days:

```
BEGIN
  DBMS_CLOUD_ADMIN.SET_FLASHBACK_ARCHIVE_RETENTION
   (retention_days => 365);
END;
/
```

See SET_FLASHBACK_ARCHIVE_RETENTION Procedure for detailed information about the procedure.

Purge Historical Data for Flashback Time Travel

Describes procedure to purge historical data for Flashback Time Travel in Autonomous Database.

You can purge historical data for Flashback Time Travel if you are logged in as the `ADMIN` user or if you have `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

For example, to purge all Flashback Time Travel historical data:

```
BEGIN
  DBMS_CLOUD_ADMIN.PURGE_FLASHBACK_ARCHIVE
   (scope => 'ALL');
END;
/
```

Example to purge the historical Flashback Time Travel data before a specified timestamp:

```
BEGIN
  DBMS_CLOUD_ADMIN.PURGE_FLASHBACK_ARCHIVE
   (scope => 'TIMESTAMP', before_timestamp => '12-JUL-2023 10:24:00');
END;
/
```

Example to purge Flashback Time Travel historical data older than 1 day:

```
BEGIN
  DBMS_CLOUD_ADMIN.PURGE_FLASHBACK_ARCHIVE
   (scope => 'TIMESTAMP', before_timestamp => SYSTIMESTAMP - INTERVAL '1'
DAY);
```

```
END;
/
```

Example to purge the historical Flashback Time Travel data before the specified scn:

```
BEGIN
  DBMS_CLOUD_ADMIN.PURGE_FLASHBACK_ARCHIVE
   (scope => 'SCN',before_scn=> '5928826');
END;
/
```

See PURGE_FLASHBACK_ARCHIVE Procedure for detailed information about the procedure.

View Flashback Time Travel Information

Describes data dictionary views to view information about Flashback Time Travel files in Autonomous Database.

You can view information about Flashback Time Travel files in static data dictionary views.

View	Description
*_FLASHBACK_ARCHIVE	Displays information about Flashback Time Travel files.
*_FLASHBACK_ARCHIVE_TS	Displays tablespaces of Flashback Time Travel files.
*_FLASHBACK_ARCHIVE_TABLES	Displays information about tables that have Flashback Time Travel enabled.

Notes for Flashback Time Travel

Provides notes and restrictions for using Flashback Time Travel on Autonomous Database.

Note the following Flashback Time Travel restrictions:

- You cannot enable Flashback Time Travel on tables with LONG data type or nested table columns.
- You cannot enable Flashback Time Travel on a nested table, temporary table, external table, materialized view, Advanced Query (AQ) table, hybrid partitioned tables, or non-table object.
- Flashback Time Travel does not support DDL statements that move, split, merge, or coalesce partitions or sub partitions, move tables, or convert LONG columns to LOB columns.
- Adding or enabling a Constraint, including Foreign Key Constraint, on a table that has been enabled for Flashback Time Travel fails with ORA-55610.

  Dropping or disabling a Constraint (including Foreign Key Constraint) on a table that has been enabled for Flashback Time Travel is supported.
- After enabling Flashback Time Travel on a table, Oracle recommends initially waiting at least 20 seconds before inserting data into the table and waiting up to 5 minutes before using Flashback Query on the table.
- There is one Flashback Data Archive per Autonomous Database instance, named flashback_archive, and you cannot create additional Flashback Data Archives.
- You cannot drop the Flashback Data Archive, flashback_archive, within an Autonomous Database instance.

- You cannot create, modify, or drop tablespaces for the Flashback Data Archive. Hence, you cannot run these statements:
  - `ALTER FLASHBACK ARCHIVE flashback_archive ADD TABLESPACE;`
  - `ALTER FLASHBACK ARCHIVE flashback_archive MODIFY TABLESPACE;`
  - `ALTER FLASHBACK ARCHIVE flashback_archive REMOVE TABLESPACE;`
- If you enable Flashback Time Travel on a table, but Automatic Undo Management (AUM) is disabled, error ORA-55614 occurs when you try to modify the table.
- To enable Flashback Time Travel on a table, the table cannot use any of the following Flashback Time Travel reserved words as column names:
  - `STARTSCN`
  - `ENDSCN`
  - `RID`
  - `XID`
  - `OP`
  - `OPERATION`

Use OCI Full Stack Disaster Recovery with Autonomous Database

You can enable the Oracle Cloud Infrastructure Full Stack Disaster Recovery on Autonomous Database.

When you enable the OCI Full Stack Disaster Recovery (Full Stack Disaster Recovery) you can use Full Stack Disaster Recovery to perform switchover/failover operations or optionally perform database only cross-region Autonomous Database switchover/failover operations.

> **Note:**
>
> Full Stack Disaster Recovery can only be enabled on an Autonomous Database instance that uses the ECPU compute model.

See Full Stack Disaster Recovery for more information.

Topics

- Prerequisite Steps for Autonomous Database with Full Stack Disaster Recovery
  If you enable Full Stack Disaster Recovery and you want your disaster recovery topology to contain an Autonomous Database instance, first perform these prerequisite steps.
- Enable Full Stack Disaster Recovery with Autonomous Database
  Enable Full Stack Disaster Recovery by adding an Autonomous Database instance to a Disaster Recovery Protection Group.
- Use Full Stack Disaster Recovery to Perform Switchover or Failover Operations
  After you enable Full Stack Disaster Recovery, when you perform a cross-region switchover or failover you have the option to use Full Stack Disaster Recovery.

- Notes for Full Stack Disaster Recovery
  Note the following for using Autonomous Database with Full Stack Disaster Recovery enabled.

Prerequisite Steps for Autonomous Database with Full Stack Disaster Recovery

If you enable Full Stack Disaster Recovery and you want your disaster recovery topology to contain an Autonomous Database instance, first perform these prerequisite steps.

1. Add one or more cross-region Autonomous Data Guard peers to your Autonomous Database instance.

   See Add a Cross-Region Standby Database for more information.

2. Set up Full Stack Disaster Recovery and configure the required OCI Identity and Access Management policies.

   See Prerequisites for Full Stack Disaster Recovery and Policies for Full Stack Disaster Recovery for more information.

Enable Full Stack Disaster Recovery with Autonomous Database

Enable Full Stack Disaster Recovery by adding an Autonomous Database instance to a Disaster Recovery Protection Group.

1. Create Disaster Recovery Protection Groups in a primary region and in one or more standby regions.

   You can create a Disaster Recovery Protection Group from the Oracle Cloud Infrastructure Console. To access Full Stack Disaster Recovery, on the Autonomous Database details page click **Configure** in the **Full Stack DR** field under Disaster recovery.

   See Manage Disaster Recovery Protection Groups for more information.

2. Add an Autonomous Database instance to the Disaster Recovery Protection Group in primary region.

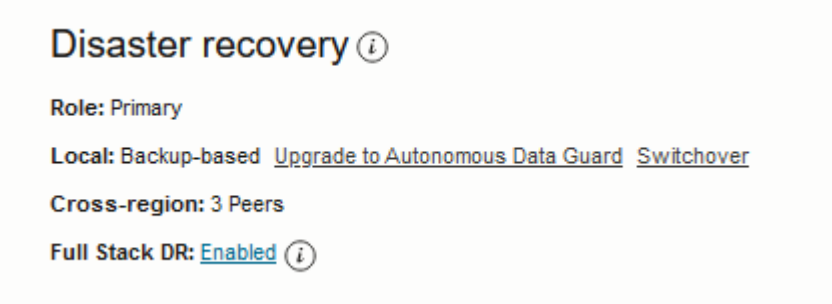
   See Add Members to a Disaster Recovery Protection Group for more information.

3. Add at least one Autonomous Data Guard cross-region standby database to a Disaster Recovery Protection Group in a remote (standby) region.

   > **Note:**
   >
   > Full Stack Disaster Recovery does not support using a local, same region, Autonomous Data Guard standby.

   See Add Members to a Disaster Recovery Protection Group for more information.

After you create a Disaster Recovery Protection Group that includes an Autonomous Database, the Oracle Cloud Infrastructure Console shows that Full Stack Disaster Recovery is enabled.



Click **Enabled** in the **Full Stack DR** field to view the Disaster Recovery Protection Group details.

Use Full Stack Disaster Recovery to Perform Switchover or Failover Operations

After you enable Full Stack Disaster Recovery, when you perform a cross-region switchover or failover you have the option to use Full Stack Disaster Recovery.

For a cross-region switchover or failover you must initiate the operation from a Standby database. You have several options to access a Standby database:

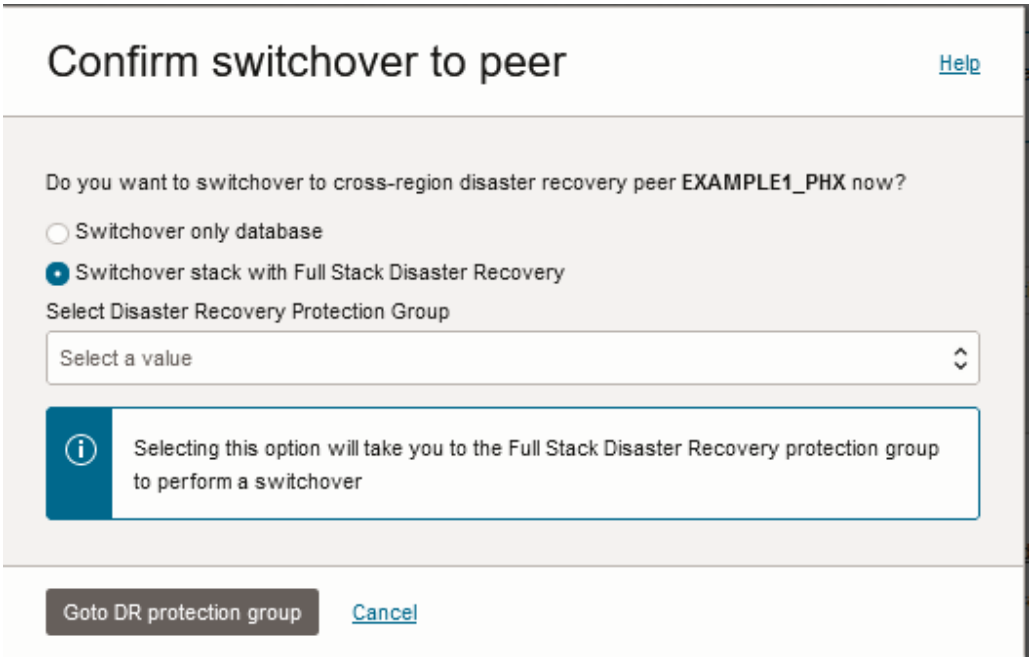
- Select the remote region in Oracle Cloud Infrastructure Console and then access the Standby database.
- On the Primary database you can access a standby database from the Oracle Cloud Infrastructure Console. To access a standby database, from the Autonomous Database details page select the **Disaster recovery** tab and click a link for a standby database in the **Peer Autonomous Database** column.

To perform a switchover or a failover:

1. Access the cross-region standby database and from the Autonomous Database details page, under **Disaster recovery** click **Switchover**(or **Failover** when the Primary is not available) in the **Role** field.

   As an alternative, to initiate a switchover you can select **More actions** and **Switchover**(or **Failover** when the Primary is not available).

   This shows the Confirm switchover to peer dialog.
2. Select an option and confirm the operation.
   a. Select **Switchover stack with Full Stack Disaster Recovery**.



b. In the **Select Disaster Recovery Protection Group** field, select a value.

c. Click **Goto DR protection group**.

This brings you to the Disaster Recovery DR protection group details page. From this page you can perform disaster recovery actions. See Manage Disaster Recovery Plan Executions for more information.

Notes for Full Stack Disaster Recovery

Note the following for using Autonomous Database with Full Stack Disaster Recovery enabled.

- When Full Stack Disaster Recovery is enabled, depending on the configuration of the Disaster Recovery Protection Group, a cross-region Standby database should be part of a larger disaster recovery configuration. If you perform disaster recovery operations just on the database, this can impact other Oracle Cloud Infrastructure resources that are part of the Disaster Recovery Protection Group. For example, if you select the **Switchover only database option**, Full Stack Disaster Recovery receives an event indicating that a database switchover has occurred. In this case Full Stack Disaster Recovery can automatically trigger a switchover of the remaining stack. The action that Full Stack Disaster Recovery takes when it receives the database switchover event is configurable with Full Stack Disaster Recovery.
- Full Stack Disaster Recovery can only be enabled on an Autonomous Database instance that uses the ECPU compute model.

  See Compute Models in Autonomous Database for more information.
- Full Stack Disaster Recovery does not support disaster recovery using Autonomous Database Backup-Based Disaster Recovery peers.

  See Use Backup-Based Disaster Recovery for more information.

Security

Autonomous Database stores all data with inbuilt security. Only authenticated users and applications can access the data when they connect to the database.

- Security Features Overview
  Describes some of the robust security features that Autonomous Database provides.
- Security and Authentication in Oracle Autonomous Database
  Oracle Autonomous Database stores all data in encrypted format in the database. Only authenticated users and applications can access the data when they connect to the database.
- Security Testing Policies on Autonomous Database
  Autonomous Database is subject to the Oracle Cloud Security Testing policy which describes when and how you may conduct certain types of security testing of Oracle Cloud Infrastructure services, including vulnerability and penetration tests, as well as tests involving data scraping tools.
- Manage Encryption Keys on Autonomous Database
  Describes how to use customer-managed encryption keys with Autonomous Database, and if you are using customer-managed encryption keys, shows how to rotate the keys, switch to Oracle-managed encryption keys, or view the encryption key history.
- Configure Network Access with Access Control Rules (ACLs) and Private Endpoints
  Provides details on how to configure network access with access control rules or using a private endpoint and describes the secure client connection options. Also describes how to enable support for TLS connections (require mutual TLS only or allow both mutual TLS and TLS authentication).
- Audit Autonomous Database
  Autonomous Database provides auditing that allows you to monitor Oracle database activities.
- Rotate Wallets for Autonomous Database
- Use Oracle Database Vault with Autonomous Database
  Oracle Database Vault implements powerful security controls for your database. These unique security controls restrict access to application data by privileged database users, reducing the risk of insider and outside threats and addressing common compliance requirements.
- IAM Policies for Autonomous Database
  Provides information on IAM policies required for API operations on Autonomous Database.
- Use Oracle Data Safe with Autonomous Database
  Provides information on using Oracle Data Safe on Autonomous Database.
- Break Glass Access for SaaS on Autonomous Database
  Autonomous Database supports break glass access for SaaS providers. Break glass access allows a SaaS operations team, when explicitly authorized by a SaaS customer, to access a customer's database to perform critical or emergency operations.
- Encrypt Data While Exporting or Decrypt Data While Importing
  For greater security you can encrypt data that you export to Object Storage. When data on Object Storage is encrypted you can decrypt the data you import or when you use the data in an external table.
- Manage Oracle Cloud Operator Access
  Describes how to grant temporary access to your database for an Oracle Cloud Operator.

Security Features Overview

Describes some of the robust security features that Autonomous Database provides.

Autonomous Database security features include:

- Autonomous Database meets a broad set of international and industry-specific compliance standards, and as part of Oracle Cloud Infrastructure Autonomous Database has achieved attestations for the common compliance frameworks providing an independent assessment of the service's security, privacy, and compliance controls.

  See Regulatory Compliance Certification for more information.

- Autonomous Database applies security patches automatically as soon as they become available.

  See Configuration Management for more information.

- Autonomous Database is governed by the Oracle Cloud Hosting and Delivery Policies which explain the Oracle Cloud Security Policy. See the Delivery Policies area on Oracle Contracts for more information.

- Autonomous Database is subject to the Oracle Cloud Security Testing policy, which describes when and how you may conduct certain types of security testing of Oracle Cloud Infrastructure services, including vulnerability and penetration tests and tests involving data scraping tools.

  See Security Testing Policies on Autonomous Database for more information.

- Autonomous Database provides end-to-end encryption out of the box for the database, backups, and all network communication. All your data, including backups, are encrypted with AES256. You can use Oracle-managed or customer-managed keys to encrypt your data.

  See Manage Encryption Keys on Autonomous Database for more information.

- All network connections are encrypted using TLS 1.2. You can use mutual TLS or one-way TLS connections.

- Autonomous Database provides several options to control client access to your database. You can use public endpoints with access control lists to specify which clients can connect. You can also use private endpoints to place the database in your VCN and use security lists and network security groups to control access to the database.

  See Client Access Control for more information.

- Autonomous Database provides fully automated immutable backups that cannot be tampered with by the users in your tenancy.

  See About Backup and Recovery on Autonomous Database for more information.

- Autonomous Database provides several user authentication methods. You can use local database user names and passwords or external authentication methods, including:

  – Oracle Cloud Infrastructure Identity and Access Management

  – Microsoft Active Directory

  – Azure Active Directory

  – Kerberos

  See Manage Users for more information.

- You can configure Oracle Database Vault to control access to specific schemas from privileged database users such as the ADMIN user.

  See Use Oracle Database Vault with Autonomous Database for more information,

- Autonomous Database provides robust auditing capabilities that enable you to track who did what on the service and on specific databases. You can configure database auditing to audit all actions, such as access to specific objects, schema changes, logons by specific users, and much more.

  See Auditing Overview on Autonomous Database for more information.

- Oracle Cloud Operators do not have authorization to access your data or any other information in your database schemas. When access to your database schemas is required to troubleshoot or mitigate an issue, you can allow a cloud operator to access your Autonomous Database schemas for a limited time.

  See Manage Oracle Cloud Operator Access for more information.

See Security and Authentication in Oracle Autonomous Database for more information.

Security and Authentication in Oracle Autonomous Database

Oracle Autonomous Database stores all data in encrypted format in the database. Only authenticated users and applications can access the data when they connect to the database.

> **Note:**
>
> Oracle Autonomous Database supports the standard security features of the Oracle Database including privilege analysis, network encryption, centrally managed users, secure application roles, transparent sensitive data protection, and others. Additionally, Oracle Autonomous Database adds Label Security, Database Vault, Data Safe, and other advanced security features at no additional cost.

- Configuration Management
  Oracle Autonomous Database provides standard, hardened security configurations that reduce the time and money managing configurations across your databases.
- Data Encryption
  Oracle Autonomous Database uses always-on encryption that protects data at rest and in transit. Data at rest and in motion is encrypted by default. Encryption cannot be turned off.
- Data Access Control
  Securing access to your Oracle Autonomous Database and your data uses several different kinds of access control:
- Auditing Overview on Autonomous Database
  Oracle Autonomous Database provides robust auditing capabilities that enable you to track who did what on the service and on specific databases. Comprehensive log data allows you to audit and monitor actions on your resources, which helps you to meet your audit requirements while reducing security and operational risk.
- Assessing the Security of Your Database and its Data
  Oracle Autonomous Database integrates with Oracle Data Safe to help you assess and secure your databases.
- Regulatory Compliance Certification
  Oracle Autonomous Database meets a broad set of international and industry-specific compliance standards.

Configuration Management

Oracle Autonomous Database provides standard, hardened security configurations that reduce the time and money managing configurations across your databases.

Security patches and updates are done automatically, so you don't spend time, money, or attention to keeping security up to date. These capabilities protect your databases and data from costly and potentially disastrous security vulnerabilities and breaches.

Data Encryption

Oracle Autonomous Database uses always-on encryption that protects data at rest and in transit. Data at rest and in motion is encrypted by default. Encryption cannot be turned off.

Encryption of Data at Rest

Data at rest is encrypted using TDE (Transparent Data Encryption), a cryptographic solution that protects the processing, transmission, and storage of data. Using AES256 tablespace encryption, each database has its own encryption key, and any backups have their own different encryption keys.

By default, Oracle Autonomous Database creates and manages all the master encryption keys used to protect your data, storing them in a secure PKCS 12 keystore on the same systems where the database resides. If your company security policies require, Oracle Autonomous Database can instead use keys you create and manage in the Oracle Cloud Infrastructure Vault service. For more information, see About Master Encryption Key Management on Autonomous Database.

Additionally, customer-managed keys can be rotated when needed in order to meet your organization's security policies.

Note: When you clone a database, the new database gets its own new set of encryption keys.

Encryption of Data in Transit

Clients (applications and tools) connect to Oracle Autonomous Database using supported protocols including SQL*Net, JDBC, and ODBC.

TCPS (Secure TCP) database connection services use the industry-standard TLS 1.2 (Transport Layer Security) protocol for connections and symmetric-key data encryption.

- With mTLS connections, Oracle Autonomous Database users download a connection wallet that contains all necessary files for a client to connect using TCPS. Distribute this wallet only to those users who need and are permitted to have database access. The client-side configuration uses information in the wallet to perform symmetric-key data encryption.
- Autonomous Database by default supports Mutual TLS (mTLS) connections. You have the option to configure an Autonomous Database instance to allow both mTLS and TLS connections. Using TLS connections, some clients, such as JDBC Thin Driver clients, do not need to download a wallet if you use a TLS connection string and TLS is enabled for the Autonomous Database instance.

See Secure Connections to Autonomous Database with mTLS or with TLS for more information.

Data Access Control

Securing access to your Oracle Autonomous Database and your data uses several different kinds of access control:

- Client Access Control
  Client access control for an Autonomous Database instance is enforced by network access control policies, through client connection protocols, and by the access rights of the database user the client uses to connect.
- Database User Access Control
  The Oracle Autonomous Database is configured with an administrative account, ADMIN, that is used to create and manage other database accounts. Oracle Autonomous Database provides a robust set of features and controls including system and object privileges and roles. User profiles allows you to customize password policies to define and implement a secure database user access strategy.
- Oracle Cloud User Access Control
  You use Identity and Access Management (IAM) services to control the privileges of your Oracle Cloud users by specifying the actions those users can perform on your Oracle Autonomous Database.
- Authorized Access on Autonomous Database
  Only authorized users are allowed access to an Autonomous Database instance.
- Autonomous Database Fully Managed Service
  Autonomous Database is a fully managed service and Oracle uses its own Oracle Cloud Infrastructure tenancies to run the Autonomous Database service.

Client Access Control

Client access control for an Autonomous Database instance is enforced by network access control policies, through client connection protocols, and by the access rights of the database user the client uses to connect.

Network Access Control

You define network access control when you set up and configure your Oracle Autonomous Database. There are two options to consider.

- **Private Endpoints and Security Lists:** This is the recommended option. Create your Oracle Autonomous Database in your virtual cloud network (VCN) using private endpoints. You control access to your database using security lists and network security groups allowing you to specify who can create connections to your database.

  For detailed information about creating these resources, see Configure Network Access with Private Endpoints.
- **Public Endpoints and Access Control Lists:** Create your Oracle Autonomous Database using public endpoints allowing access from any client with client credentials. You control access to your database using network access control lists (ACLs) allowing you to specify IP addresses, CIDR blocks, or VCNs that can connect to your database. Public IPs are easier to discover and attack, and Private Endpoints are recommended where possible.

  For detailed information about setting up an ACL, see Configure Access Control Lists for an Existing Autonomous Database Instance.

Client Connection Control

Clients connect through a TCPS (Secure TCP) database connection using standard TLS 1.2 to secure the connection. Oracle Autonomous Database uses self-signed certificates. You can rotate the self-signed certificates from the Oracle Cloud Infrastructure console to meet your organization's security compliance needs. See Rotate Wallets with Immediate Rotation.

The access the client has to the database is restricted by the access rights of the database user the client uses to connect.

Database User Access Control

The Oracle Autonomous Database is configured with an administrative account, ADMIN, that is used to create and manage other database accounts. Oracle Autonomous Database provides a robust set of features and controls including system and object privileges and roles. User profiles allows you to customize password policies to define and implement a secure database user access strategy.

For basic information about standard user management, see User Accounts in *Oracle Database Concepts*. For detailed information and guidance, see Managing Security for Oracle Database Users in *Oracle Database Security Guide*.

If your database user access strategy demands more controls than are provided by standard user management, you can configure your Oracle Autonomous Database to use Database Vault to meet more rigorous requirements.

Using Microsoft Active Directory to Manage Database Users

If you use Microsoft Active Directory as a user repository, you can configure your database to authenticate and authorize Microsoft Active Directory users. This integration enables you to consolidate your user repository while still implementing a rigorous database user access strategy, regardless of whether you use standard user management or Database Vault.

For more information about integrating Microsoft Active Directory with your databases, see Use Microsoft Active Directory with Autonomous Database.

Database Vault

Oracle Database Vault comes preconfigured and ready to use. You can use its powerful security controls to restrict access to application data by privileged database users, reducing the risk threats, and addressing common compliance requirements.

You configure controls to block privileged account access to application data and control sensitive operations inside the database. You configure trusted paths to add additional security controls to authorized data access, database objects, and database commands. Database Vault secures existing database environments transparently, eliminating costly and time consuming application changes.

Before using Database Vault, be sure to review Use Oracle Database Vault with Autonomous Database to gain an understanding of the impact of configuring and enabling Database Vault.

For detailed information on implementing Database Vault features, refer to *Oracle Database Vault Administrator's Guide*.

Oracle Cloud User Access Control

You use Identity and Access Management (IAM) services to control the privileges of your Oracle Cloud users by specifying the actions those users can perform on your Oracle Autonomous Database.

The IAM service provides several kinds of components to help you define and implement a secure cloud user access strategy:

- **Compartment**: A collection of related resources. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating your cloud resources.
- **Group**: A collection of users who all need the same type of access to a particular set of resources or compartment.
- **Dynamic Group**: A special type of group that contains resources that match rules that you define. Thus, the membership can change dynamically as matching resources are created or deleted.
- **Policy**: A group of statements that specify who can access which resources, and how. Access is granted at the group and compartment level, which means you write a policy statement that gives a specific group a specific type of access to a specific type of resource within a specific compartment.

Of these, the policy is the primary tool you use to control access because it provides the "Who", "How", "What" and "Where" of a single access constraint. A policy statement has this format:

The format of a policy statement is:

```
Allow
  group <group-name>
  to <control-verb>
  <resource-type>
  in compartment <compartment-name>
```

- **`group <group-name>`** specifies the "Who" by providing the name of an existing IAM group.
- **`to <control-verb>`** specifies the "How" using one of these predefined control verbs:
  - **`inspect`**: the ability to list resources of the given type, without access to any confidential information or user-specified metadata that may be part of that resource.
  - **`read`**: `inspect` plus the ability to get user-specified metadata and the actual resource itself.
  - **`use`**: `read` plus the ability to work with existing resources, but not to create or delete them. Additionally, "work with" means different operations for different resource types.
  - **`manage`**: all permissions for the resource type, including creation and deletion.
- **`<resource-type>`** specifies the "What" using a predefined resource-type. The resource-type values for infrastructure resources are:
  - **`autonomous-databases`**
  - **`autonomous-backups`**

  You may create policy statements that refer to the **`tag-namespaces`** resource-type value if tagging is used in your tenancy.

- **`in compartment <compartment-name>`** specifies the "Where" by providing the name of an existing IAM compartment.

For information about how the IAM service and its components work and how to use them, see Overview of Oracle Cloud Infrastructure Identity and Access Management. For quick answers to common questions about IAM, see the Identity and Access Management FAQ.

Authorized Access on Autonomous Database

Only authorized users are allowed access to an Autonomous Database instance.

Oracle Cloud Operators do not have authorization to access your Autonomous Database. When access to your database is required to troubleshoot or mitigate an issue, you can allow a Cloud Operator to access a database for a limited time.

You allow a Cloud Operator to access the database by running the procedure `DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS`. This means if you file a service request with Oracle Cloud Support or by contacting your support representative and Oracle Cloud Operators need to access your database, you must also enable operator access by running `DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS`.

Each database access by Oracle Cloud Operators is logged with a request ID and reason.

See Manage Oracle Cloud Operator Access and View Oracle Cloud Infrastructure Operations Actions for more information.

Autonomous Database Fully Managed Service

Autonomous Database is a fully managed service and Oracle uses its own Oracle Cloud Infrastructure tenancies to run the Autonomous Database service.

Oracle Cloud Operators do not have access to customer tenancies and cloud operators cannot access the network.

Auditing Overview on Autonomous Database

Oracle Autonomous Database provides robust auditing capabilities that enable you to track who did what on the service and on specific databases. Comprehensive log data allows you to audit and monitor actions on your resources, which helps you to meet your audit requirements while reducing security and operational risk.

- Auditing Service Level Activities
  All actions Oracle Cloud users perform on the resources that make up your deployment of Oracle Autonomous Database are logged by the Audit service, regardless of the interface used: the Oracle Cloud Infrastructure Console, REST API, Command Line Interface (CLI), Software Development Kits (SDK) and so on.
- Auditing Database Activities
  Oracle Autonomous Database configures the autonomous databases you create to use the unified auditing feature of Oracle Database.

Auditing Service Level Activities

All actions Oracle Cloud users perform on the resources that make up your deployment of Oracle Autonomous Database are logged by the Audit service, regardless of the interface used: the Oracle Cloud Infrastructure Console, REST API, Command Line Interface (CLI), Software Development Kits (SDK) and so on.

You can use the Audit service to perform diagnostics, track resource usage, monitor compliance, and collect security-related events. For more information about the Audit service, see Overview of Audit in *Oracle Cloud Infrastructure Documentation*.

Additionally, when users perform operations on your Oracle Autonomous Database, the database publishes *events* to the Oracle Cloud Events service. The Oracle Cloud Events service allows you to create rules to capture these events and perform actions.

For more information about how the Events service works and how to set up the rules and actions it uses, see Overview of Events. For listings of the Oracle Autonomous Database operations that generate events, see Autonomous Database Event Types.

Auditing Database Activities

Oracle Autonomous Database configures the autonomous databases you create to use the unified auditing feature of Oracle Database.

This feature captures audit records from the following sources and gathers them in a single audit trail in a uniform format:

- Audit records (including `SYS` audit records) from unified audit policies and `AUDIT` settings
- Fine-grained audit records from the `DBMS_FGA` PL/SQL package
- Oracle Database Real Application Security audit records
- Oracle Recovery Manager audit records
- Oracle Database Vault audit records
- Oracle Label Security audit records
- Oracle Data Mining records
- Oracle Data Pump
- Oracle SQL*Loader Direct Load

Audit information is retained for up to 14 days, after which it is automatically purged. To retain audit information for longer, and to easily analyze and report on database activity, use Oracle Data Safe (included with your Oracle Autonomous Database subscription).

See About Auditing Autonomous Database for more information.

Assessing the Security of Your Database and its Data

Oracle Autonomous Database integrates with Oracle Data Safe to help you assess and secure your databases.

Oracle Data Safe helps you understand the sensitivity of your data, evaluate risks to data, mask sensitive data, implement and monitor security controls, assess user security, monitor user activity, and address data security compliance requirements in your databases.

You use Oracle Data Safe to identify and protect sensitive and regulated data your Oracle Autonomous Database by registering your database with Data Safe. Then, you use the Data Safe console directly from the Details page of your database.

For more information about using Data Safe, see Use Oracle Data Safe Features.

Regulatory Compliance Certification

Oracle Autonomous Database meets a broad set of international and industry-specific compliance standards.

Certification	Description
C5	The Cloud Computing Compliance Controls Catalog (C5)
CSA STAR	The Cloud Security Alliance (CSA) Security Trust, Assurance and Risk (STAR)
Cyber Essentials (UK) Cyber Essentials Plus (UK)	Oracle Cloud Infrastructure has achieved Cyber Essentials and Cyber Essentials Plus certification in these regions: • UK Gov South (London) • UK Gov West (Newport)
DESC (UAE)	Dubai Electronic Security Center CSP Security Standard
DoD IL4/IL5	DISA Impact Level 5 authorization in these regions: • US DoD East (Ashburn) • US DoD North (Chicago) • US DoD West (Phoenix)
ENS High (Spain)	The Esquema Nacional de Seguridad with the level of accreditation High.
FedRAMP High	Federal Risk and Authorization Management Program (U.S. Government Regions only)
FSI (S. Korea)	The Financial Security Institute
HDS	The French Public Health Code requires healthcare organizations that control, process, or store health or medical data to use infrastructure, hosting, and platform service providers that are Hébergeur de Données de Santé (HDS) accredited and certified
HIPAA	Health Insurance Portability and Accountability Act
HITRUST	The Health Information Trust Alliance
IRAP (Australia)	The Infosec Registered Assessors Program. Sydney and Melbourne regions
ISMS (S. Korea)	The Information Security Management System
ISO/IEC 27001:2013	International Organization for Standardization 27001
ISO/IEC 27017:2015	Code of Practice for Information Security Controls Based on ISO/IEC 27002 for Cloud Services
ISO/IEC 27018:2014	Code of Practice for Protection of Personally Identifiable Information (PII) In Public Clouds Acting as PII Processors
MeitY (India)	The Ministry of Electronics and Information Technology
MTCS (Singapore)	Multi-Tier Cloud Service (MTCS) Level 3
PASF (UK OC4)	Police Assured Secure Facilities (PASF) in these regions: • UK Gov South (London) • UK Gov West (Newport)
PCI DSS	Payment Card Industry Data Security Standard is a set of requirements intended to ensure that all companies that process, store, or transmit credit card information maintain a secure environment
SOC 1	System and Organization Controls 1
SOC 2	System and Organization Controls 2

For more information and a complete list of certifications, see Oracle Cloud Compliance.

Security Testing Policies on Autonomous Database

Autonomous Database is subject to the Oracle Cloud Security Testing policy which describes when and how you may conduct certain types of security testing of Oracle Cloud Infrastructure services, including vulnerability and penetration tests, as well as tests involving data scraping tools.

Oracle regularly performs penetration and vulnerability testing and security assessments against Oracle Cloud Infrastructure, platforms, and applications. These tests are intended to validate and improve the overall security of Oracle Cloud services. You can also conduct your own testing as per the rules explained in the policy.

See Oracle Cloud Security Testing Policies for more information.

Manage Encryption Keys on Autonomous Database

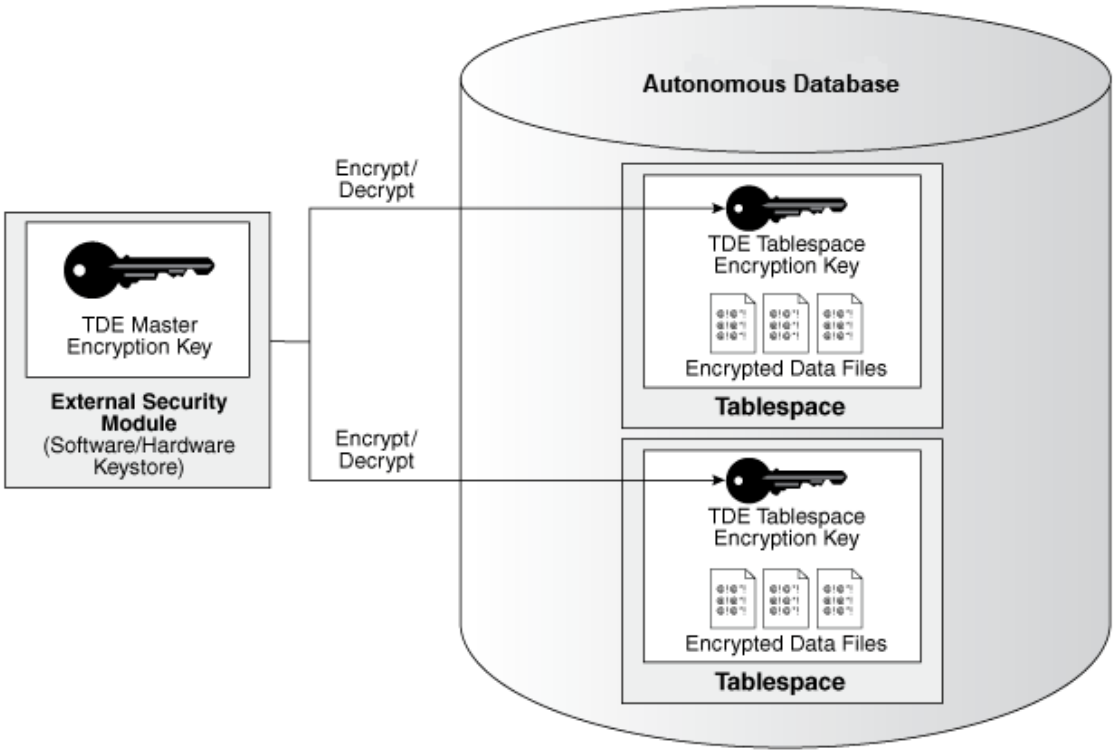
Describes how to use customer-managed encryption keys with Autonomous Database, and if you are using customer-managed encryption keys, shows how to rotate the keys, switch to Oracle-managed encryption keys, or view the encryption key history.

- About Master Encryption Key Management on Autonomous Database
  Autonomous Database provides two options for Transparent Data Encryption (TDE) to encrypt your database: Oracle-managed encryption keys and Customer-managed encryption keys.
- Manage Master Encryption Keys in OCI Vault
  If your organization's security policies require customer-managed encryption keys, you can configure Autonomous Database to use an Oracle Cloud Infrastructure Vault master encryption key. With customer-managed master encryption keys, Autonomous Database uses the master encryption key to generate the TDE master key.
- Manage Master Encryption Keys in Azure Key Vault
  Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in Azure Key Vault.
- Manage Master Encryption Keys in AWS Key Management Service
  Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in AWS Key Management Service (KMS).
- Manage Master Encryption Keys in Oracle Key Vault
  Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in Oracle Key Vault (OKV).
- Switch to Oracle-Managed Encryption Keys on Autonomous Database
  Shows the steps to switch to Oracle-managed master encryption keys on Autonomous Database if you are using customer-managed encryption keys.
- View History for Customer-Managed Encryption Keys on Autonomous Database
  You can view the key history from the Oracle Cloud Infrastructure Console or by selecting from the `V$ENCRYPTION_KEYS` view.
- Notes for Using Customer-Managed Keys with Autonomous Database
  Provides additional information and notes for using customer-managed keys with Autonomous Database

About Master Encryption Key Management on Autonomous Database

Autonomous Database provides two options for Transparent Data Encryption (TDE) to encrypt your database: Oracle-managed encryption keys and Customer-managed encryption keys.

Autonomous Database uses Transparent Data Encryption, including a TDE master key and TDE tablespace keys to encrypt data in the database. As shown in the following figure, the TDE master key generates and encrypts/decrypts the TDE tablespace keys, and the TDE tablespace keys encrypt the data files.



Oracle-Managed Master Encryption Keys on Autonomous Database

By default, Autonomous Database uses Oracle-managed encryption keys.

Using Oracle-managed keys, Autonomous Database creates and manages the encryption keys that protect your data and Oracle handles rotation of the TDE master key.

Customer-Managed Master Encryption Keys on Autonomous Database

With customer-managed master encryption keys, Autonomous Database uses the master encryption key in a customer-managed key vault to generate the TDE master key. If your organization's security policies require customer-managed encryption keys, you can configure Autonomous Database to use a master encryption key in the following key management systems:

- Oracle Cloud Infrastructure (OCI) Vault
  See Manage Master Encryption Keys in OCI Vault for more information.
- Microsoft Azure Key Vault
  See Manage Master Encryption Keys in Azure Key Vault for more information.
- Amazon Web Services (AWS) Key Management Service (KMS)

See Manage Master Encryption Keys in AWS Key Management Service for more information.

- Oracle Key Vault (OKV)
  See Manage Master Encryption Keys in Oracle Key Vault for more information.

Manage Master Encryption Keys in OCI Vault

If your organization's security policies require customer-managed encryption keys, you can configure Autonomous Database to use an Oracle Cloud Infrastructure Vault master encryption key. With customer-managed master encryption keys, Autonomous Database uses the master encryption key to generate the TDE master key.

- About Customer-Managed Keys on Autonomous Database in OCI Vault
  Using customer-managed encryption keys on Autonomous Database in Oracle Cloud Infrastructure (OCI) Vault involves creating a master key in your OCI Vault and configuring your Autonomous Database instance to use encryption keys in the OCI Vault.
- Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault
  Perform these prerequisite steps to use customer-managed keys on Autonomous Database in OCI Vault:
- Use Customer-Managed Encryption Keys with Vault Located in Local Tenancy
  Shows the steps to select customer-managed master encryption keys on Autonomous Database. If you are using customer-managed master encryption keys, follow these steps to rotate the master keys.
- Use Customer-Managed Encryption Key Located in a Remote Tenancy
  Shows the steps to select customer-managed master encryption keys from a Vault on a remote tenancy.
- Rotate Customer-Managed Encryption Keys on Autonomous Database in OCI Vault
  Describes how to rotate customer-managed encryption keys on Autonomous Database in OCI Vault.

About Customer-Managed Keys on Autonomous Database in OCI Vault

Using customer-managed encryption keys on Autonomous Database in Oracle Cloud Infrastructure (OCI) Vault involves creating a master key in your OCI Vault and configuring your Autonomous Database instance to use encryption keys in the OCI Vault.

Follow these general steps:

1. Create a master encryption key in your OCI Vault.

   See Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault for more information.
2. Select customer-managed encryption keys from the Oracle Cloud Infrastructure Console:
   - For an existing database, select **Manage Encryption Key** on the Oracle Cloud Infrastructure Console.
   - While provisioning, under **Advanced Options**, on the **Encryption Key** tab select either **Encrypt using customer-managed key in this tenancy** or **Encrypt using a customer-managed key located in a remote tenancy**.
   - While cloning, under **Advanced Options**, on the **Encryption Key** tab select either **Encrypt using customer-managed key in this tenancy** or **Encrypt using a customer-managed key located in a remote tenancy**.

See Use Customer-Managed Encryption Keys with Vault Located in Local Tenancy, Use Customer-Managed Encryption Key Located in a Remote Tenancy and Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault

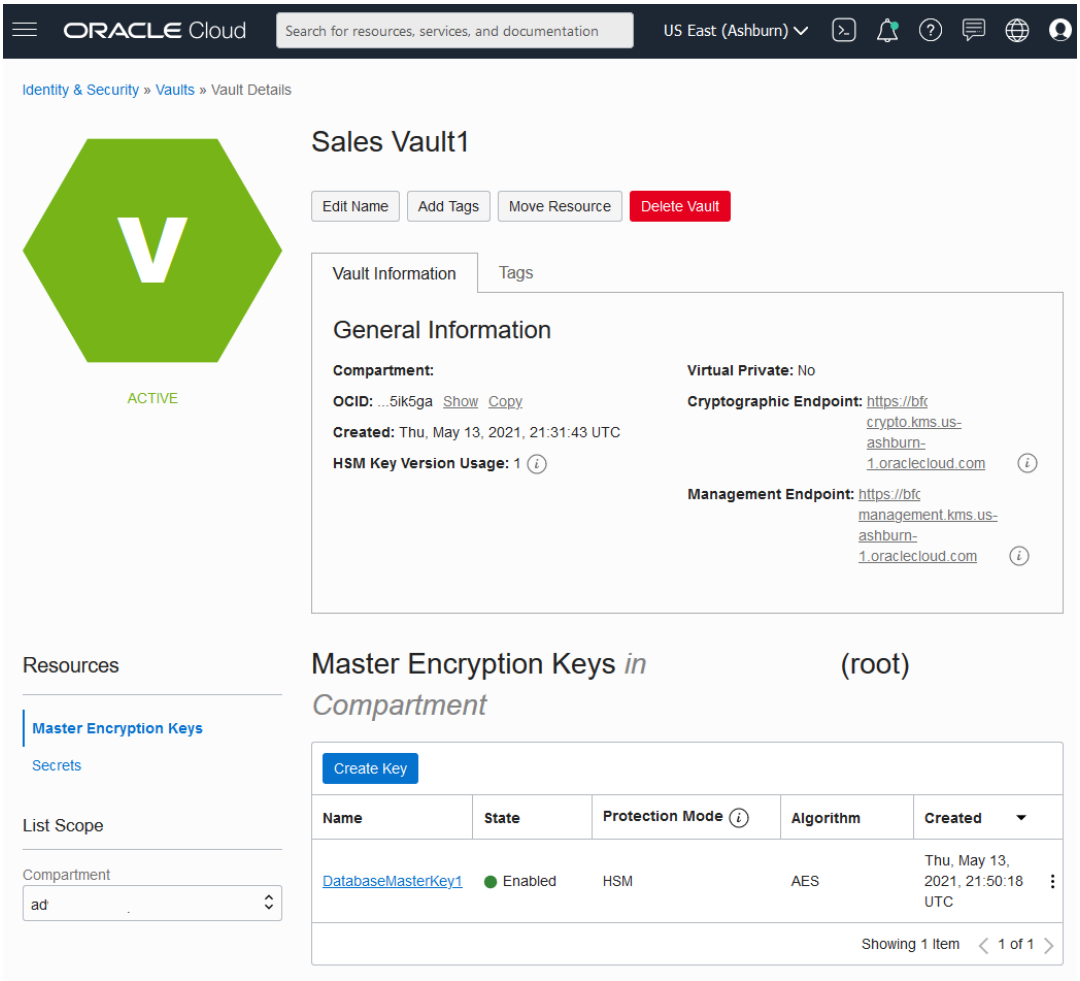
Perform these prerequisite steps to use customer-managed keys on Autonomous Database in OCI Vault:

1. Create an Oracle Cloud Infrastructure Vault.
   a. Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Oracle Cloud.
   b. From the Oracle Cloud Infrastructure left navigation menu click **Identity and Security**.
   c. Under **Key Management & Secret Management** click **Vault**.
   d. Select an existing Vault or create a new Vault.

      For more details, see Creating a Vault.
2. Create a Master Encryption Key in the Vault.

> **Note:**
>
> You must use these options when you create the key:
>
> - **Key Shape: Algorithm**: AES (Symmetric key used for Encrypt and Decrypt)
> - **Key Shape: Length**: 256 bits

For more information, see Creating a Master Encryption Key and Overview of Key Management.



3. Create dynamic group and policy statements for the dynamic group to enable access to Oracle Cloud Infrastructure resources (Vaults and Keys).

   This step depends on whether the vault is on the same tenancy as the Autonomous Database instance or on a different tenancy:

   - Vault and keys are in the same tenancy as the Autonomous Database instance. See Create Dynamic Group and Policies for Customer Managed Keys with Vault in Same Tenancy as Database for more information.
   - Vault and keys are in a different tenancy. See Create Dynamic Group and Policies for Customer Managed Keys with Vault in Different Tenancy than the Database for more information.

You must replicate the vault and keys to use customer-managed encryption keys with Autonomous Data Guard with a remote Standby database. Customer-Managed Encryption Keys are only supported with a single cross-region Autonomous Data Guard standby. Multiple cross-region standbys are not supported because Oracle Cloud Infrastructure Vault only supports replication to one remote region.

See the following for more information:

- To Replicate a Vault and Its Keys
- Autonomous Data Guard with Customer Managed Keys

- Create Dynamic Group and Policies for Customer Managed Keys with Vault in Same Tenancy as Database
  Create dynamic group and policies to provide access to the vault and keys for customer-managed keys when the vault and keys are in the same tenancy as the Autonomous Database instance.
- Create Dynamic Group and Policies for Customer Managed Keys with Vault in Different Tenancy than the Database
  Perform these steps to use customer-managed keys when the Autonomous Database instance and vaults and keys are in different tenancies.

Create Dynamic Group and Policies for Customer Managed Keys with Vault in Same Tenancy as Database

Create dynamic group and policies to provide access to the vault and keys for customer-managed keys when the vault and keys are in the same tenancy as the Autonomous Database instance.

1. Create a dynamic group to make the master encryption key accessible to the Autonomous Database instance.
   a. In the Oracle Cloud Infrastructure console click **Identity & Security**.
   b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).
   c. Under **Identity domain**, click **Dynamic groups**.
   d. Click **Create dynamic group** and enter a **Name**, a **Description**, and a rule.
      - **Create Dynamic Group for an existing database:**

        You can specify that an Autonomous Database instance is part of the dynamic group. The dynamic group in the following example includes only the Autonomous Database whose OCID is specified in the `resource.id` parameter:

        ```
        resource.id = '<your_Autonomous_Database_instance_OCID>'
        ```

      - **Create a Dynamic Group for a database that has not been provisioned yet:**

        When you are creating the dynamic group before you provision or clone an Autonomous Database instance, the OCID for the new database is not yet available. For this case, create a dynamic group that specifies the resources in a given compartment:

        ```
        resource.compartment.id = '<your_Compartment_OCID>'
        ```

   e. Click **Create**.
2. Write policy statements for the dynamic group to enable access to Oracle Cloud Infrastructure resources (vaults and keys).
   a. In the Oracle Cloud Infrastructure console click **Identity & Security** and click **Policies**.
   b. To write policies for a dynamic group, click **Create Policy**, and enter a **Name** and a **Description**.
   c. Use the **Policy Builder** to create a policy for vault and keys in the local tenancy.

For example, the following allows the members of the dynamic group `DGKeyCustomer1` to access the vaults and keys in the compartment named `training`:

```
Allow dynamic-group DGKeyCustomer1 to use vaults in compartment training
Allow dynamic-group DGKeyCustomer1 to use keys in compartment training
```

This sample policy applies for a single compartment. You can specify that a policy applies for your tenancy, a compartment, a resource, or a group of resources.

To use customer-managed keys with Autonomous Data Guard with a remote standby, the following policy is also required:

```
Allow dynamic-group DGKeyCustomer1 to manage vaults in compartment
training
Allow dynamic-group DGKeyCustomer1 to manage keys in compartment
training
```

d. Click **Create** to save the policy.

See the following for more information:

- Managing Policies
- Autonomous Data Guard with Customer Managed Keys
- Replicating Vaults and Keys

Create Dynamic Group and Policies for Customer Managed Keys with Vault in Different Tenancy than the Database

Perform these steps to use customer-managed keys when the Autonomous Database instance and vaults and keys are in different tenancies.

In this case, you need to supply OCID values when you change to customer-managed keys. In addition, you need to define dynamic groups and policies that allow the Autonomous Database instance to use vaults and keys in a different tenancy.

1. Copy the master encryption key OCID.
2. Copy the vault OCID.
3. Copy the tenancy OCID (the remote tenancy that contains vaults and keys).
4. On the tenancy with the Autonomous Database instance, create a dynamic group.
   a. In the Oracle Cloud Infrastructure console, on the tenancy with the Autonomous Database instance, click **Identity & Security**.
   b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).
   c. Under **Identity domain**, click **Dynamic groups**.
   d. Click **Create dynamic group** and enter a **Name**, a **Description**, and a rule.
      - **Create Dynamic Group for an existing database:**

        You can specify that an Autonomous Database instance is part of the dynamic group. The dynamic group in the following example includes only the Autonomous Database whose OCID is specified in the `resource.id` parameter:

        ```
        resource.id = '<your_Autonomous_Database_instance_OCID>'
        ```

- **Create a Dynamic Group for a database that has not been provisioned yet:**

  When you are creating the dynamic group before you provision or clone an Autonomous Database instance, the OCID for the new database is not yet available. For this case, create a dynamic group that specifies the resources in a given compartment:

  ```
  resource.compartment.id = '<your_Compartment_OCID>'
  ```

e. Click **Create**.

5. On the tenancy with the Autonomous Database instance, define the policies to allow access to vaults and keys (where the vaults and keys are on a different tenancy).

   a. In the Oracle Cloud Infrastructure console click **Identity & Security**.

   b. Under **Identity** click **Policies**.

   c. To write a policy, click **Create Policy**.

   d. On the Create Policy page, enter a Name and a Description.

   e. On the Create Policy page, select **Show manual editor**.

   f. In the policy builder, add policies so that the Autonomous Database instance is able to access vaults and keys located in the different tenancy. Also add policies for the IAM group that the IAM user belongs to so that the Oracle Cloud Infrastructure Console for the Autonomous Database instance can show details about the key that resides in a different tenancy.

   For example, in the generic policy, call the tenancy with the Autonomous Database instance Tenancy-1 and the tenancy with vaults and keys, Tenancy-2:

   Copy the following policy and replace the variables and names with the values you define, where the dynamic group name `ADB-DynamicGroup` is the dynamic group you created in Step 4:

   ```
   define tenancy REMTEN as <ocid of tenancy-2>
   endorse dynamic-group ADB-DynamicGroup to use vaults in tenancy REMTEN
   ```

```
endorse dynamic-group ADB-DynamicGroup to use keys in tenancy REMTEN
endorse group MyUserGroup to use vaults in tenancy REMTEN
endorse group MyUserGroup to use keys in tenancy REMTEN
```

For example, the following allows the members of the dynamic group `DGKeyCustomer1` to access the remote vaults and keys in the tenancy named `training2`:

```
define tenancy training2 as ocid1.tenancy.oc1..aaa_example_rcyx2a
endorse dynamic-group DGKeyCustomer1 to use vaults in tenancy training2
endorse dynamic-group DGKeyCustomer1 to use keys in tenancy training2
endorse group MyUserGroup to use vaults in tenancy training2
endorse group MyUserGroup to use keys in tenancy training2
```

g. Click **Create** to save the policy.

6. Copy the tenancy OCID (the tenancy that contains the Autonomous Database instance).
7. Copy the Dynamic Group OCID (for the Dynamic Group you created in Step 4).
8. On the remote tenancy with vaults and keys, define a dynamic group and policies to allow the Autonomous Database instance to access vaults and keys.
   a. In the Oracle Cloud Infrastructure console, click **Identity & Security**.
   b. Under **Identity** click **Policies**.
   c. To create a policy, click **Create Policy**.
   d. On the Create Policy page, enter a Name and a Description.
   e. On the Create Policy page, select **Show manual editor**.
   f. In the policy builder, add policies and a dynamic group to provide access to the dynamic group on the tenancy with the Autonomous Database instance (Tenancy-1), such that the Autonomous Database instance can use the vaults and keys in Tenancy-2. Also need to add policies to allow the user group to access the vault and keys to display information on the Oracle Cloud Infrastructure Console for the Autonomous Database instance in a different tenancy.

      Use the **Policy Builder** to create a dynamic group and a policy for vaults and keys.

```
define tenancy ADBTEN as <ocid of tenancy-1>
define dynamic-group REM-ADB-DG as <ocid of the Dynamic Group in
tenancy-1>
define group REMGROUP as <group-ocid>
admit dynamic-group REM-ADB-DG of tenancy ADBTEN to use vaults in
tenancy
admit dynamic-group REM-ADB-DG of tenancy ADBTEN to use keys in tenancy
admit group REMGROUP of tenancy ADBTEN to use vaults in tenancy
admit group REMGROUP of tenancy ADBTEN to use keys in tenancy
```

For example define the following on the remote tenancy to allow the members of the dynamic group `DGKeyCustomer1` and the group `REMGROUP` to access the remote vaults and keys in the tenancy named `training2`:

```
define tenancy adbdemo5 as ocid1.tenancy.oc1..aaa_example_4cnl5q
define dynamic-group REM-ADB-DG as
ocid1.dynamicgroup.oc1..aaa_example_526bia
define group REMGROUP as ocid1.group.oc1..aaa_example_6vctn6xsaq
admit dynamic-group REM-ADB-DG of tenancy adbdemo5 to use vaults in
```

```
tenancy
admit dynamic-group REM-ADB-DG of tenancy adbdemo5 to use keys in
tenancy
admit group REMGROUP of tenancy ADBTEN to use vaults in tenancy
admit group REMGROUP of tenancy ADBTEN to use keys in tenancy
```

g. Click **Create** to save the policy.

Use Customer-Managed Encryption Keys with Vault Located in Local Tenancy

Shows the steps to select customer-managed master encryption keys on Autonomous Database. If you are using customer-managed master encryption keys, follow these steps to rotate the master keys.

> **Caution:**
>
> The customer-managed encryption key is stored in Oracle Cloud Infrastructure Vault, external to the database host. If the customer-managed encryption key is disabled or deleted, the database will be inaccessible.

For details on using customer-managed keys where the Vault is located in a remote tenancy, see Use Customer-Managed Encryption Key Located in a Remote Tenancy.

On Autonomous Database you can choose customer-managed keys as follows:

- While provisioning, under **Advanced Options**, on the **Encryption Key** tab.
- While cloning, under **Advanced Options**, on the **Encryption Key** tab

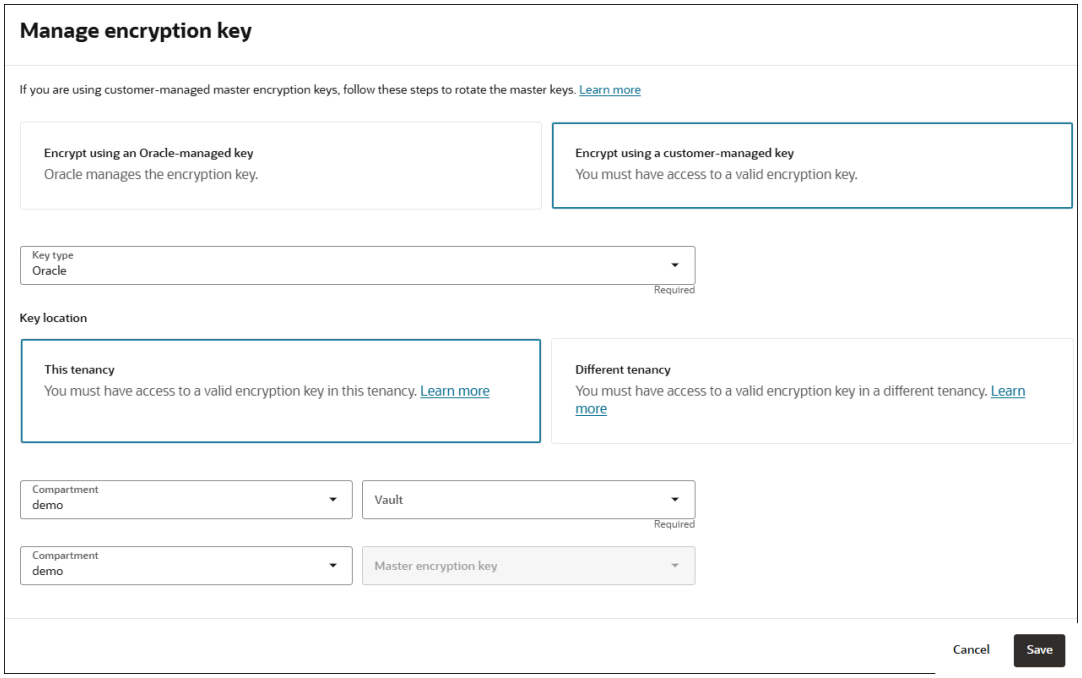
Follow these steps if your Autonomous Database is using Oracle-managed keys and you want to switch to customer-managed encryption keys with the vault in the local tenancy, or if you are using customer-managed encryption keys and you want to rotate the master key.

1. Perform the required customer-managed encryption key prerequisite steps as necessary. See Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault for more information.
2. On the **Details** page, from the **More actions** drop-down list, select **Manage encryption key**.
3. On the **Manage encryption key** page, select **Encrypt using customer-managed key**.

   If you are already using customer-managed keys and you want to rotate the TDE keys, follow these steps and select a different key (select a key that is different from the currently selected master encryption key).
4. For **Key type**, select **Oracle**.
5. For **Key location**, click **This tenancy**.
6. Select a Vault.

   Click **Change compartment** to select a vault in a different compartment.
7. Select a Master encryption key.

   Click **Change Compartment** to select a master encryption key in a different compartment.



When cross-region Autonomous Data Guard is enabled the **Vault** and **Master encryption key** values show the keys that are replicated in both the primary and the remote standby region.

8. Click **Save**.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

After the request completes, on the Oracle Cloud Infrastructure Console, the key information shows on the Autonomous Database Information page under the heading **Encryption**. This area shows the **Encryption Key** field with a link to the Master Encryption Key and the **Encryption Key OCID** field with the Master Encryption Key OCID.

See Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Use Customer-Managed Encryption Key Located in a Remote Tenancy

Shows the steps to select customer-managed master encryption keys from a Vault on a remote tenancy.

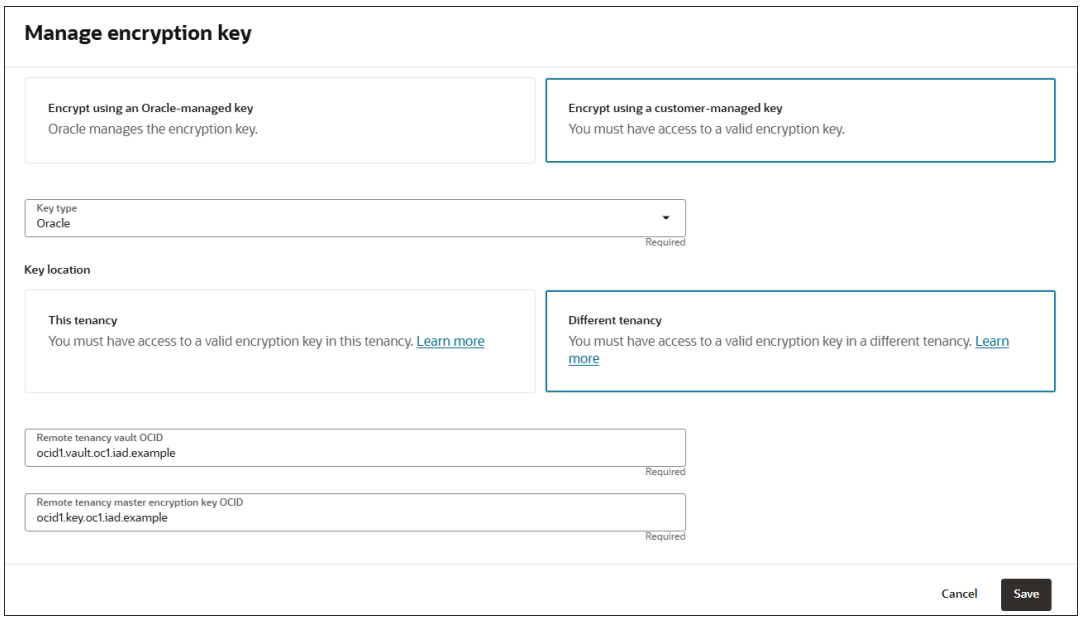
When you use customer-managed master encryption keys with a Vault in a remote tenancy, the Vault and the Autonomous Database instance must be in the same region. To change the tenancy, on the sign-on page click **Change tenancy**. After you change the tenancy, make sure to select the same region for both the Vault and the Autonomous Database instance.

1. Perform the required customer-managed encryption key prerequisite steps as necessary. See Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault for more information.
2. On the **Details** page, from the **More actions** drop-down list, select **Manage encryption key**.
3. On the **Manage encryption key** page, select the **Encrypt using a customer-managed key** option.

   If you are already using customer-managed keys and you want to rotate the TDE keys, follow these steps and use a different key OCID with the same vault OCID, or use a new

vault OCID and a new key OCID. This lets you use a key that is different from the current master encryption key.

4. For **Key type**, select **Oracle**.
5. For **Key location**, click **Different tenancy**.
6. Enter a remote tenancy vault OCID.
7. Enter a remote tenancy master encryption key OCID.



8. Click **Save**.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

After the request completes, on the Oracle Cloud Infrastructure Console, the key information shows on the Autonomous Database Information page under the heading **Encryption**. This area shows the **Encryption Key** field with a link to the Master Encryption Key and the **Encryption Key OCID** field with the Master Encryption Key OCID.

Rotate Customer-Managed Encryption Keys on Autonomous Database in OCI Vault

Describes how to rotate customer-managed encryption keys on Autonomous Database in OCI Vault.

When you rotate the customer-managed master encryption key, Autonomous Database generates a new TDE master key and uses the new TDE master key to re-encrypt the tablespace encryption keys that encrypt and decrypt your data. This operation is fast and does not require database downtime. It does not change the tablespace keys and does not re-encrypt customer data.

> **Note:**
>
> Using the Oracle Cloud Infrastructure Console you can rotate an Oracle Cloud Infrastructure Vault master encryption key with the **Rotate Key** command. This is a separate action and does not result in a new master encryption key for your Autonomous Database. To rotate the master encryption key of your Autonomous Database, create a new master encryption key in Oracle Cloud Infrastructure Vault and follow the steps described below.

To rotate customer-managed encryption keys:

1. Create a new master encryption key in your Oracle Cloud Infrastructure Vault. If you already have multiple master encryption keys, then select a master encryption key that is different than the key you are using as your master encryption key for your Autonomous Database instance.

   See Prerequisites to Use Customer-Managed Encryption Keys on Autonomous Database in OCI Vault for more information.

2. Rotate the master encryption key from the Oracle Cloud Infrastructure Console:

   See Use Customer-Managed Encryption Keys with Vault Located in Local Tenancy for more information.

Manage Master Encryption Keys in Azure Key Vault

Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in Azure Key Vault.

- Prerequisites to Use Customer-Managed Encryption Keys in Azure Key Vault
  Describes prerequisite steps to use customer-managed master encryption keys on Autonomous Database that reside in Azure Key Vault.
- Use Customer-Managed Encryption Keys on Autonomous Database with Azure Key Vault
  Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in Azure Key Vault.

Prerequisites to Use Customer-Managed Encryption Keys in Azure Key Vault

Describes prerequisite steps to use customer-managed master encryption keys on Autonomous Database that reside in Azure Key Vault.

Limitations:

- Azure Key Vault is only supported in commercial regions.
- Cross-tenancy access, where the Autonomous Database instance and the Azure Key Vault are in different tenancies, is not supported.
- Azure Key Vault is not supported in cross-region standbys.
- Azure Key Vault is not supported in refreshable clones.
- Supported key shapes and sizes are the following:
  - RSA 2048, 3072, and 4096
  - EC-P256, EC-P256K, EC-P384, EC-P521

Follow these steps:

1. Create an Autonomous Database instance that uses the default Encryption key setting of **Encrypt using an Oracle-managed key**. See Provision an Autonomous Database Instance for more information.

> **Note:**
>
> Encryption key settings for customer-managed keys in Azure Key Vault are not available during the creation process. The options are available post provisioning, when editing the instance.

2. Create an Azure Key Vault with a Transparent Data Encryption (TDE) master key.

   See About Azure Key Vault for more information.

3. Enable Azure service principal authentication with the Azure Directory `tenant_id` to allow your Autonomous Database instance access to the Azure Key Vault.

   a. Obtain your Microsoft Azure Active Directory tenant ID.

   See How to find your Azure Active Directory tenant ID for more information.

   b. Connect to your instance as ADMIN.

   c. Enable Azure service principal with `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH`. The value of `azure_tenantid` is the Azure Directory ID you obtained in the previous step.

   For example:

```
BEGIN
 DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
         provider => 'AZURE',
         params   => JSON_OBJECT('azure_tenantid' value
'azure_directoryID'));
 END;
 /
```

   This enables Azure service principal authentication and creates an Azure application for Autonomous Database on the Azure portal. See Enable Azure Service Principal for more information.

4. Provide the Azure application consent to access Azure resources from Autonomous Database.

   a. On Autonomous Database query `CLOUD_INTEGRATIONS`.

      For example:

      ```
      SELECT * FROM CLOUD_INTEGRATIONS;

      PARAM_NAME        PARAM_VALUE
      ---------------
      ------------------------------------------------------------------------
      ------------------------------------------------------------------
      azure_tenantid    29...eb
      azure_consent_url https://login.microsoftonline.com/f8...5a/oauth2/v2.0/
      authorize?client_id=d4f5...d5&response_type=code&scope=User.read
      azure_app_name    ADBS_APP_OCID1.AUTONOMOUSDATABASE...
      ```

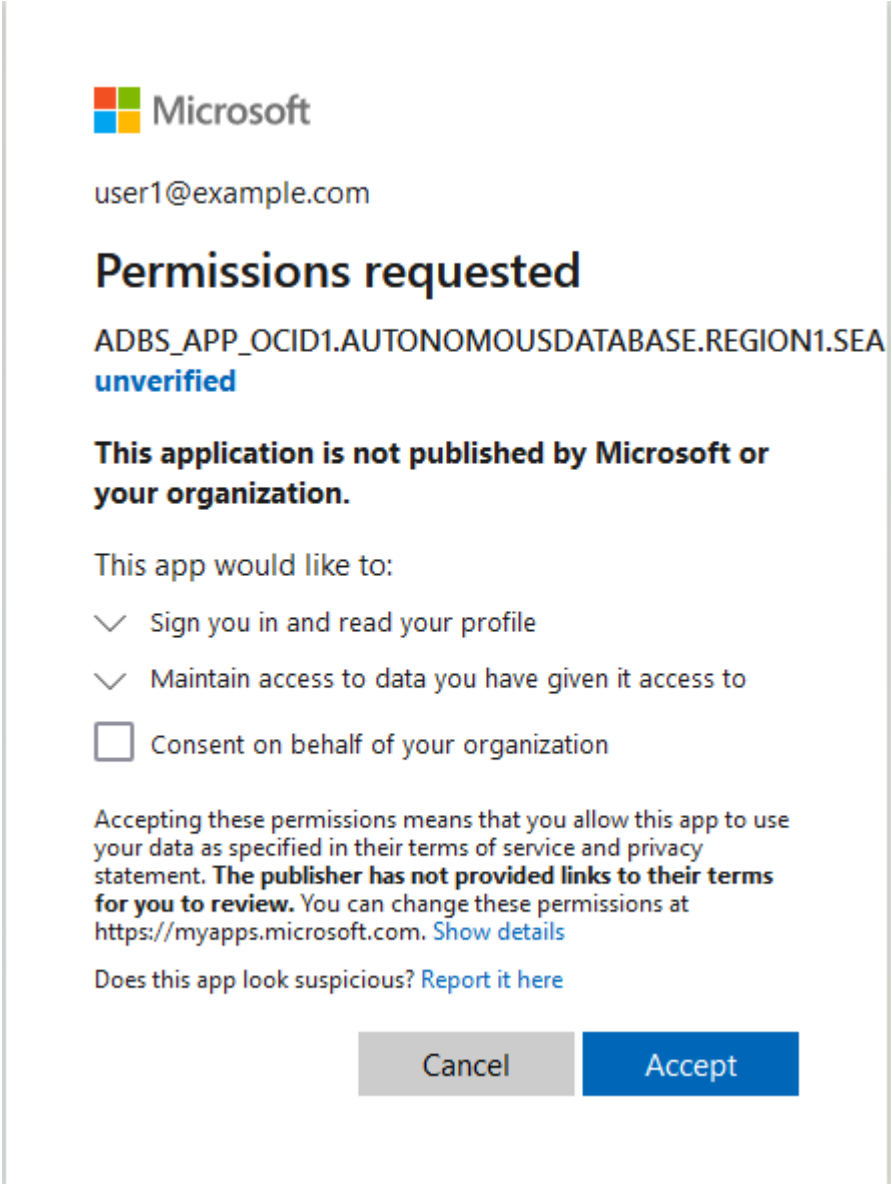
      The view `CLOUD_INTEGRATIONS` is available to the `ADMIN` user or to a user with `DWROLE` role.

   b. In a browser, open the Azure consent URL specified by the `azure_consent_url` parameter.

      For example, copy the `azure_consent_url` from the query results and enter the URL into your browser:

      ```
      https://login.microsoftonline.com/f8...5a/oauth2/v2.0/authorize?
      client_id=d4f5...d5&response_type=code&scope=User.read
      ```

      The **Permissions requested** page opens and shows a consent request, similar to the following:



5. Obtain the Azure application name.
   a. On Autonomous Database query `CLOUD_INTEGRATIONS`.

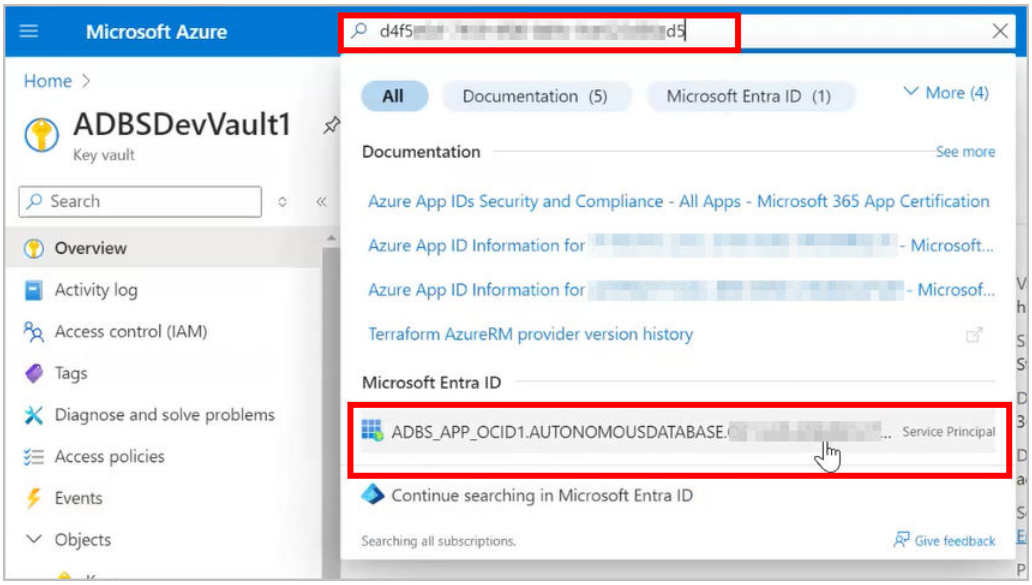
      For example:

      ```
      SELECT * FROM CLOUD_INTEGRATIONS;
      ```

   b. Copy the `client_id` value included in the `consent_url`.

      ```
      PARAM_NAME        PARAM_VALUE
      --------------
      ------------------------------------------------------------------------
      ------------------------------------------------------------------
      azure_tenantid    29...eb
      azure_consent_url https://login.microsoftonline.com/f8...5a/oauth2/v2.0/
      authorize?client_id=d4f5...d5&response_type=code&scope=User.read
      azure_app_name    ADBS_APP_OCID1.AUTONOMOUSDATABASE...
      ```

c. Search on the `client_id` in the Azure portal. The application ID is displayed under Microsoft Entra ID.



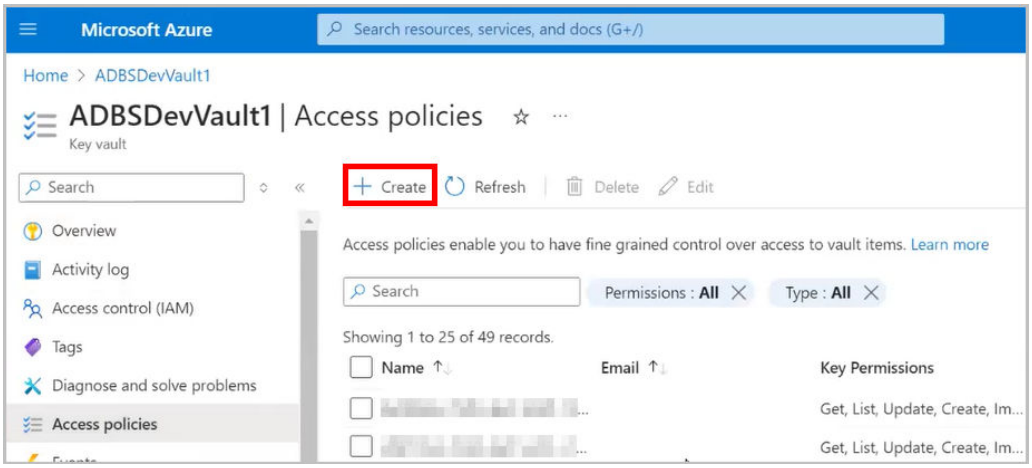
d. Copy the application ID. This value is used in subsequent steps to allow this application access to keys in the Azure Key Vault.

6. Assign necessary roles for the Azure application to access the Azure Key Vault.

a. In the Azure portal, navigate to the Access policies for the Azure Key Vault.

The list of applications with access to this vault are displayed.

b. On the Access policies page, click **+ Create** to create an access policy for the application to access this key vault.



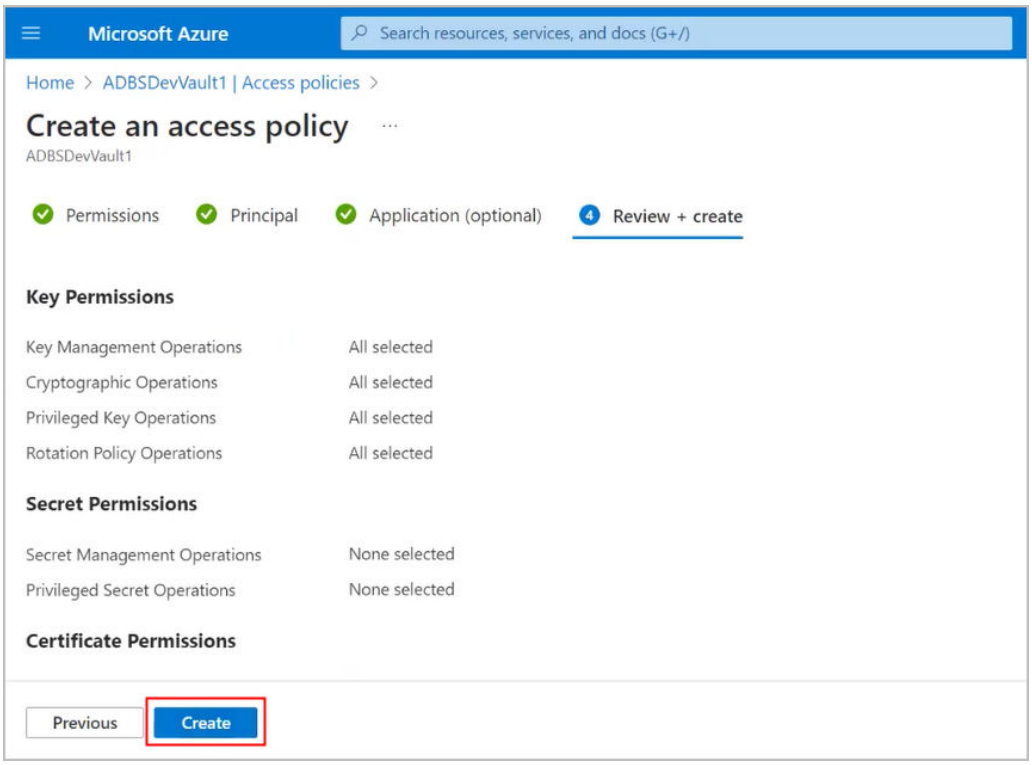
c. For Permissions on the Create an access policy page, select all Key permissions, including: Key Management Operations, Cryptography Operations, Privileged Key Operations, and Rotation Policy Operations and click **Next**.

d. For Principal, search the application name.

e. Select the displayed application name and click **Next**.

f. For Application (optional), select **Next**.

g. For Review + create, review the policy details and click **Create**.



h. On the Azure Key Vault details page, click Refresh and search for the application name. It is included in the displayed list of applications with permission to access keys in this Azure Key Vault.

See Assign a Key Vault access Policy for more information.

Use Customer-Managed Encryption Keys on Autonomous Database with Azure Key Vault

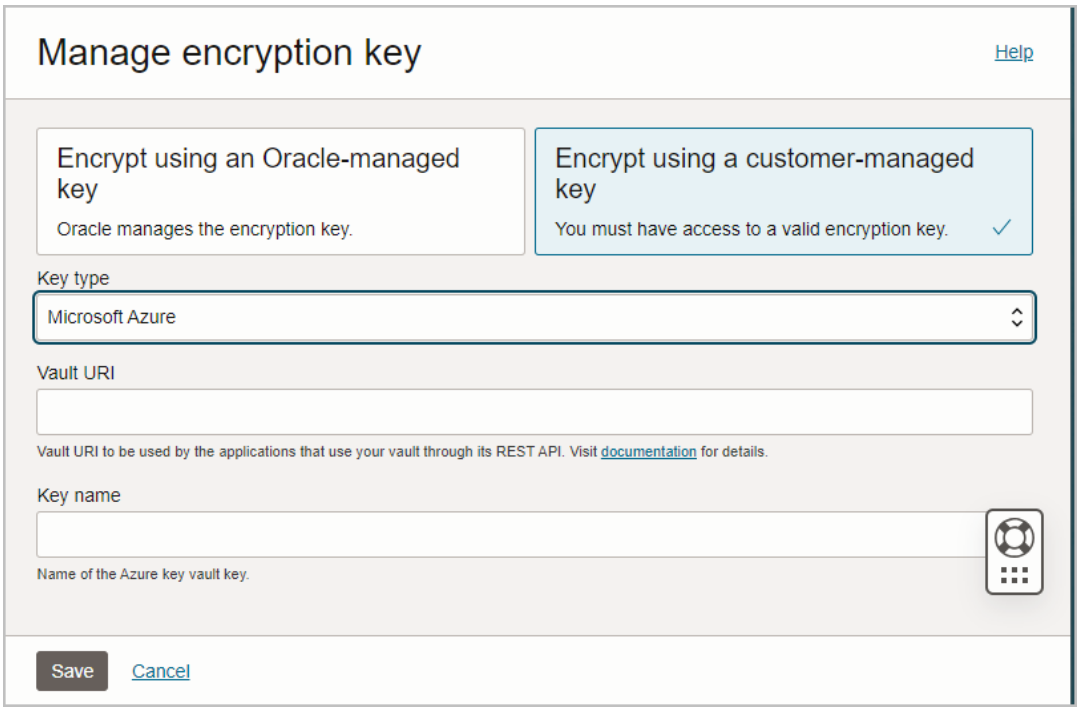
Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in Azure Key Vault.

Follow these steps:

1. Perform the required customer-managed master key prerequisite steps. See Prerequisites to Use Customer-Managed Encryption Keys in Azure Key Vault.
2. On the **Details** page, from the **More actions** drop-down list, select **Manage encryption key**.

> **Note:**
>
> If you are already using customer-managed Transparent Data Encryption (TDE) keys stored in Azure Key Vault and you want to rotate the keys, follow these steps and select a different key (select a key that is different from the currently selected master TDE key).

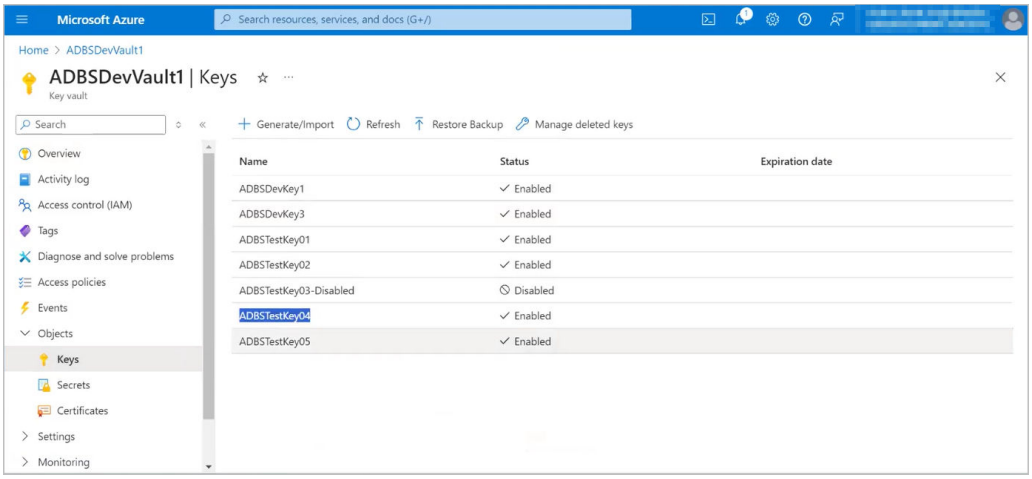
3. On the **Manage encryption key** page, select **Encrypt using a customer-managed key**.
4. From the **Key type** drop-down, select **Microsoft Azure**.



5. In the **Vault URI** field, enter the **Azure Vault URI**.
   a. In the Azure portal, navigate to the Azure Key Vault.
   b. Select the Azure Key Vault **Overview** page and copy the displayed **Vault URI**.

   c. Enter the copied Azure Vault URI into the **Vault URI** field in the Autonomous Database Manage encryption key page.
6. In the **Key name** field, enter the name of the **Azure Key Name**.
   a. In the Azure portal, navigate to the Azure Key Vault and select **Keys**. A list of keys for this vault is displayed.

b. From the list of displayed keys, copy the **Key Name** you want to use.



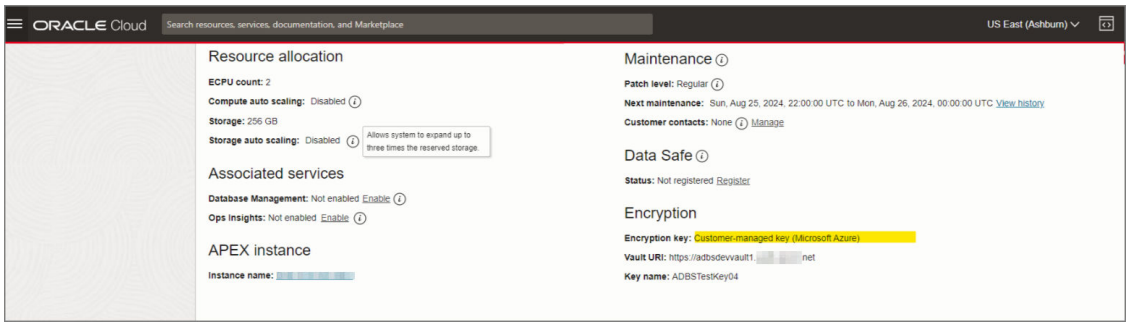
c. Enter the copied Azure key name into the **Key name** field in the Autonomous Database Manage encryption key page.

7. Click **Save**.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

After the request completes, on the Oracle Cloud Infrastructure Console, the key information shows on the Autonomous Database Information page under the heading **Encryption**. This area shows the **Encryption Key** is **Customer-managed key (Microsoft Azure)**, and displays the **Vault URI** and **Key name**.

For example:



See Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Manage Master Encryption Keys in AWS Key Management Service

Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in AWS Key Management Service (KMS).

- Prerequisites to Use Customer-Managed Encryption Keys in AWS Key Management Service
  Describes prerequisite steps to use customer-managed master encryption keys that reside in Amazon Web Services (AWS) Key Management Service (KMS) on Autonomous Database.
- Use Customer-Managed Encryption Keys on Autonomous Database with AWS Key Management Service
  Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in AWS Key Management Service (KMS).

Prerequisites to Use Customer-Managed Encryption Keys in AWS Key Management Service

Describes prerequisite steps to use customer-managed master encryption keys that reside in Amazon Web Services (AWS) Key Management Service (KMS) on Autonomous Database.

Limitations:

- AWS KMS is only supported in commercial regions.
- Cross-tenancy access, where the Autonomous Database instance and AWS KMS are in different tenancies, is not supported.
- AWS KMS is not supported in cross-region standbys.
- AWS KMS is not supported in refreshable clones.

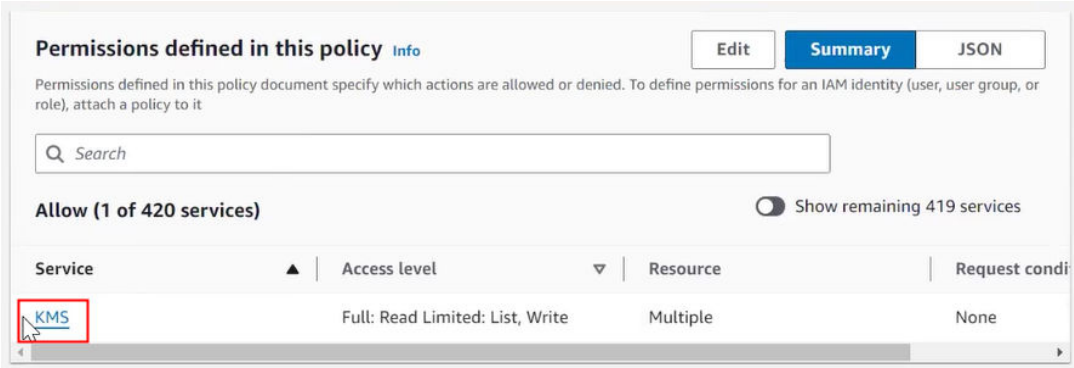
Follow these steps:

1. Create an AWS policy that grants read access to AWS KMS.

   See Creating an IAM policy to access AWS KMS for instructions, and Perform AWS Management Prerequisites to Use Amazon Resource Names (ARNs) for more information.

   For example, the `ADBS_AWS_Policy1` policy has been created:

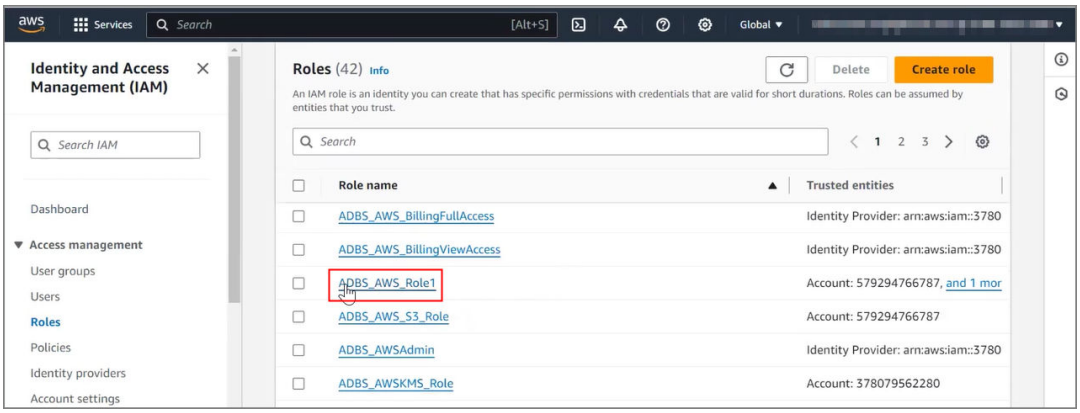
   The `ADBS_AWS_Policy1` policy includes permission to access **KMS**.



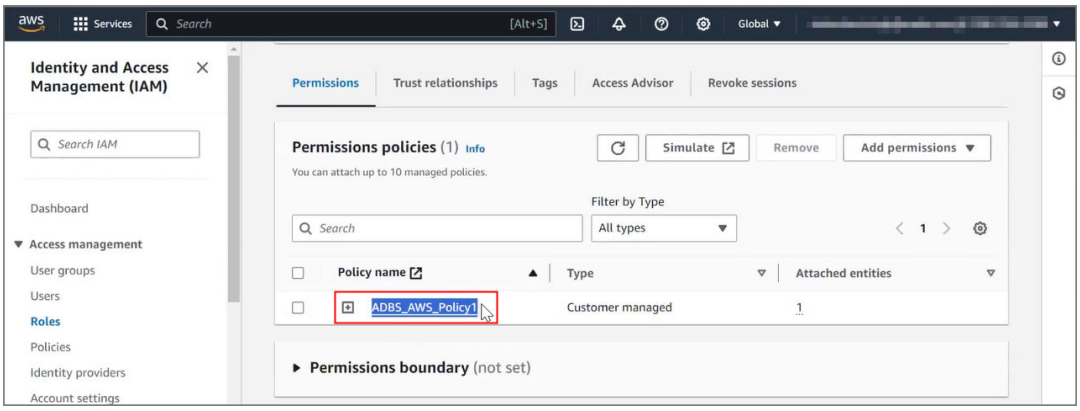
2. Create an AWS role and attach the policy to the role.

   See Creating an IAM role to access AWS services for instructions.

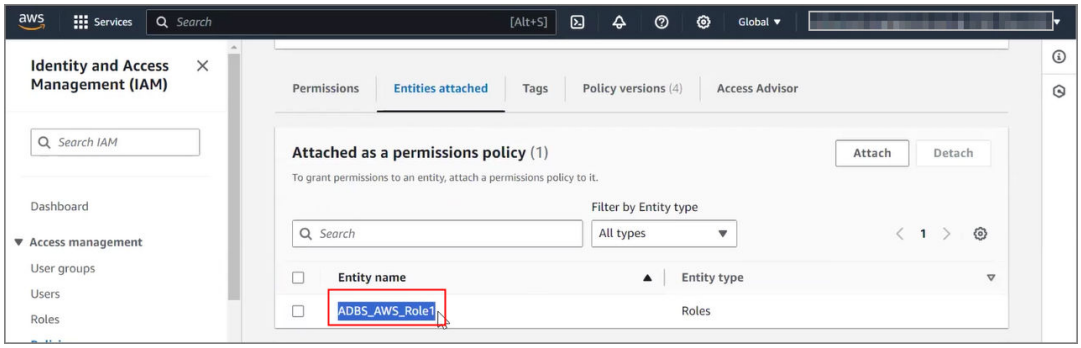
   For example, an `ADBS_AWS_Role1` role has been created:



In this example, the `ADBS_AWS_Policy1` policy is attached to the `ADBS_AWS_Role1` role:



On the policy details page, for this example, the role is listed under **Attached as permissions policy**:



3. Specify a Trust Relationship for the role.

   Edit the AWS Role's Trust Relationship to include Oracle's User ARN, and an External ID (tenancy OCID) for additional security.

   a. On Autonomous Database query `CLOUD_INTEGRATIONS`.

      For example:

```
SELECT * FROM CLOUD.INTEGRATIONS;

SELECT * FROM CLOUD_INTEGRATIONS;

PARAM_NAME          PARAM_VALUE
---------------
--------------------------------------------------------------------------------
------------------------------------------------------------------
aws_arn             arn:aws:iam:…:user/oraclearn
```

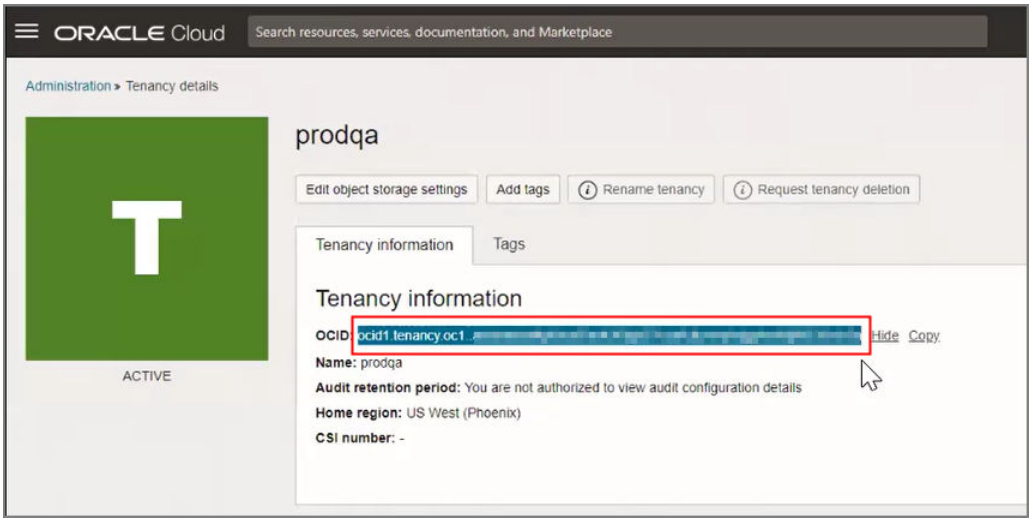
      The view `CLOUD_INTEGRATIONS` is available to the `ADMIN` user or to a user with `DWROLE` role.

   b. Copy the `PARAM_VALUE` for `aws_user_arn` and save the value for a subsequent step.

   c. Get the tenancy OCID, needed for the External ID.

      In the OCI console, click on your **Profile**, and select **Tenancy** to go to the tenancy details page. Copy the tenancy OCID and save it for a subsequent step.

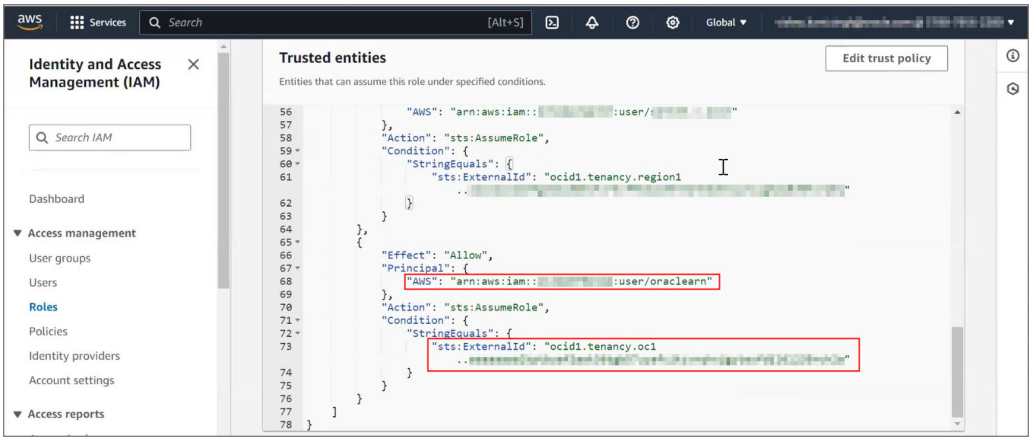
      For example:



d. On the AWS portal, navigate to the **Trusted entities** for the role, and scroll to the **"Principal"** statement.

e. For `"Principal"` specify **"AWS"** as the saved Oracle User ARN and for `"Condition"` specify **"sts:ExternalId"** as the saved OCID.

For example:



Use Customer-Managed Encryption Keys on Autonomous Database with AWS Key Management Service

Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in AWS Key Management Service (KMS).

Follow these steps:

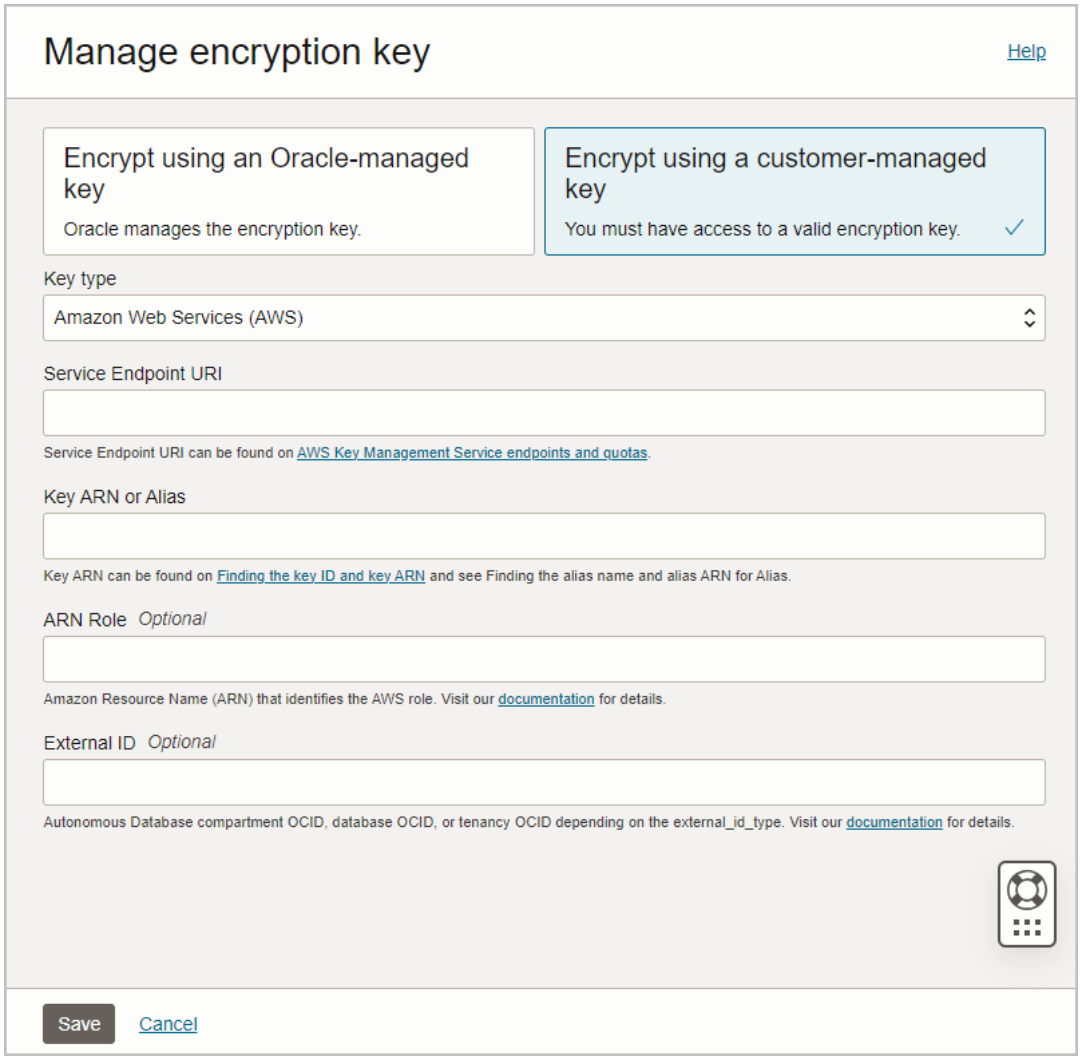
1. Perform the required customer-managed encryption key prerequisite steps as necessary. See Prerequisites to Use Customer-Managed Encryption Keys in AWS Key Management Service for details.
2. Create an Autonomous Database instance that uses the default Encryption key setting of **Encrypt using an Oracle-managed key**. See Provision an Autonomous Database Instance for more information.

> **Note:**
>
> Encryption key settings for customer-managed keys in AWS Key Vault are not available during the Autonomous Database instance creation process. The options are available post provisioning, when editing the instance.

3. On the **Details** page for the Autonomous Database instance, click **More actions**, and select **Manage encryption key**.

> **Note:**
>
> If you are already using customer-managed keys in AWS KMS and you want to rotate the TDE keys, follow these steps and select a different key (select a key that is different from the currently selected master encryption key).

4. On the **Manage encryption key** page, select **Encrypt using a customer-managed key**.
5. From the **Key type** drop-down, select **Amazon Web Services (AWS)**.



6. Enter the Service Endpoint URI.

   The Service Endpoint URI is the AWS region where the AWS KMS is located.

   a. Go to the AWS portal, navigate to the KMS where your key is located.

   b. Find the region name listed in the top bar of the portal.

      For example, this KMS is in the region named **Ohio**:

   c. Look up the endpoint corresponding to the region. Go to AWS Key Management Service endpoints and quotas and find the endpoint for the AWS region name where your AWS KMS is located.

      For example, if the AWS region name is `Ohio` the endpoint is `kms.us-east-2.amazonaws.com`.

   d. Enter the endpoint for the **Service Endpoint URI**.

7. Enter the Key ARN or Alias.

   a. Navigate to the key details page on the AWS portal. Copy the key's Alias or ARN.

      For example, the alias for `ADBS_TestAWSKMSKey` is selected:

   b. Enter the key's Alias or ARN into the **Key ARN or Alias** field.

      If entering the Alias, prefix the entry with `alias/`. For example, if the alias is `ADBS_TestAWSKMSKey` enter:

      ```
      alias/ADBS_TestAWSKMSKey
      ```

      If entering the ARN, no prefix is needed. For example, if the ARN is `arn.aws.kms.us-east-2:37807956...bd154` enter:

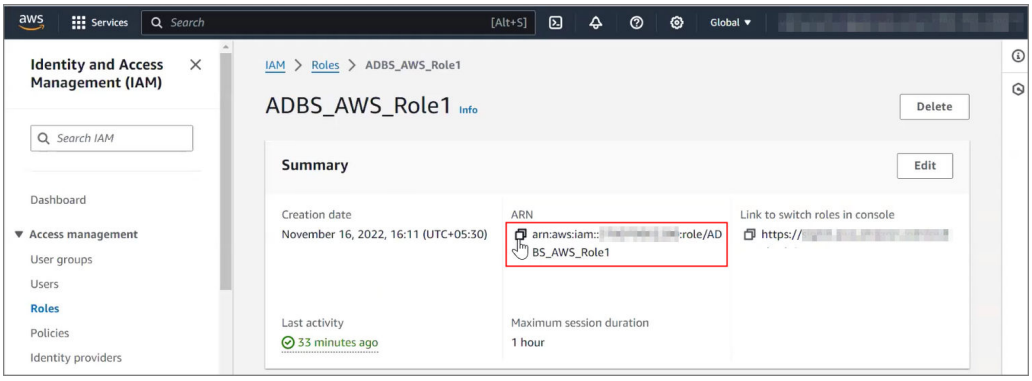
      ```
      arn.aws.kms.us-east-2:37807956...bd154
      ```

8. Enter ARN Role (Optional).

a. Navigate to the role details page on the AWS portal.

b. Copy the role's ARN.

For example, the ARN for `ADBS_AWS_Role1` is copied:



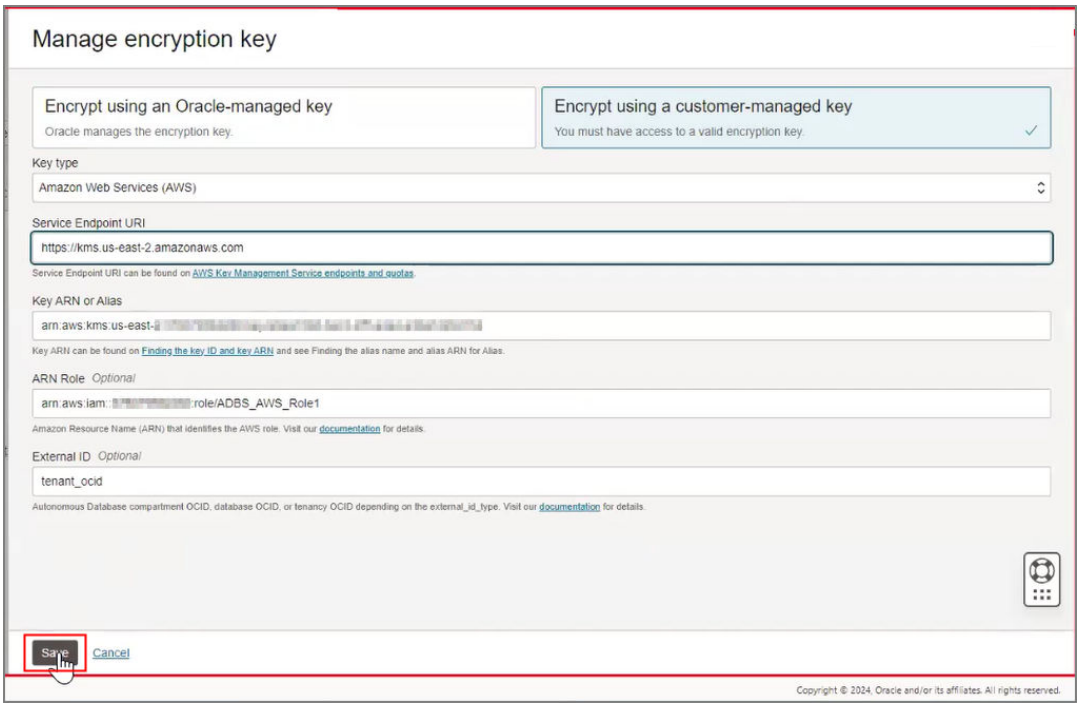
c. Enter the copied ARN into the **ARN Role field**.

9. Enter External ID (Optional).

For the External ID, enter **`tenant_ocid`**.

10. Click **Save**.

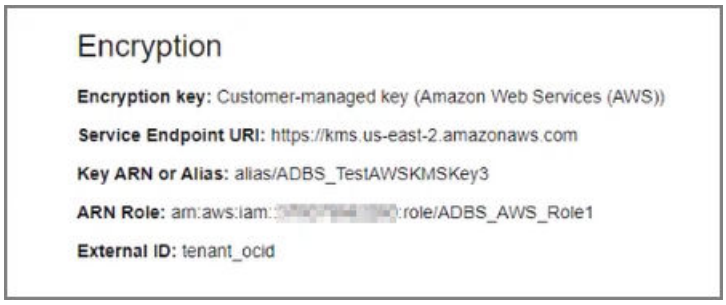
For example:



The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

After the request completes, on the Oracle Cloud Infrastructure Console, the key information shows on the Autonomous Database instance details page under the heading **Encryption**.

For example:



See Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Manage Master Encryption Keys in Oracle Key Vault

Autonomous Database supports customer-managed Transparent Data Encryption (TDE) keys that reside in Oracle Key Vault (OKV).

- Prerequisites to Use Customer-Managed Encryption Keys in Oracle Key Vault
  Describes the prerequisite steps to use customer-managed master encryption keys that reside in Oracle Key Vault (OKV) on Autonomous Database.
- Use Customer-Managed Encryption Keys on Autonomous Database with Oracle Key Vault
  Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in Oracle Key Vault (OKV).

Prerequisites to Use Customer-Managed Encryption Keys in Oracle Key Vault

Describes the prerequisite steps to use customer-managed master encryption keys that reside in Oracle Key Vault (OKV) on Autonomous Database.

Requirements:

- The Autonomous Database instance must use private endpoints.
- Autonomous Database supports OKV instances that are in private networks and are accessible from the same network where the Autonomous Database resides.

  See VCN and Subnet Management and Oracle Key Vault Installation and Configuration, for more information.

Limitations:

- Cross-tenancy access, where the Autonomous Database instance and OKV are in different tenancies, is not supported.
- OKV is not supported in cross-region standbys.
- OKV is not supported in refreshable clones.

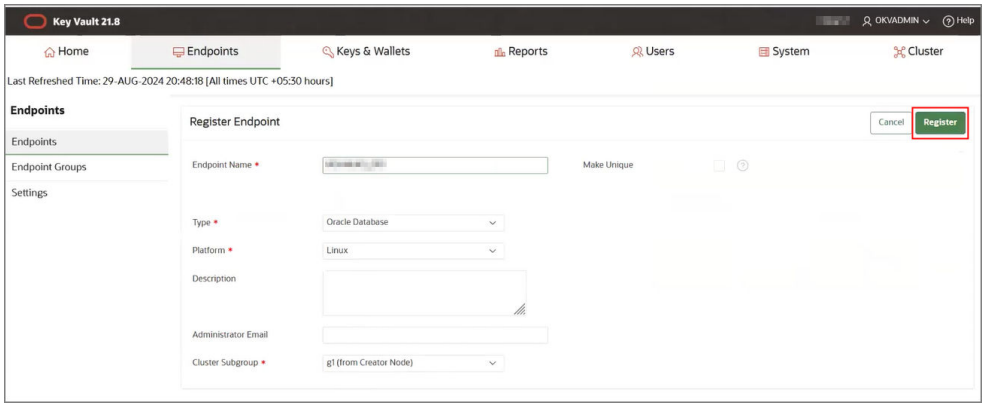
Follow these steps:

1. Create an OKV endpoint, wallet and TDE master key.
   a. Sign into the OKV instance.
      - Copy the **Public IP address**, or **Private IP address** on the OKV instance details page and paste into a browser.

- On the OKV instance login page, enter the username and password.

b. Create and register an OKV endpoint.

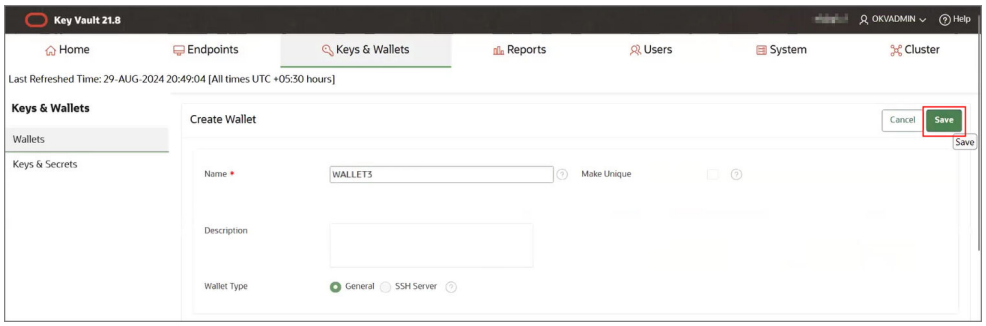
- Click **Endpoints**, on the OKV home page.
- Click **Add**, on the Endpoints details page and enter a name for the endpoint.
- Allow all other settings to default and click **Register**.
  For example:



See Adding, Deleting, or Reenroling Endpoints for more information.

c. Create a wallet.
The OKV wallet holds the TDE master encryption key.

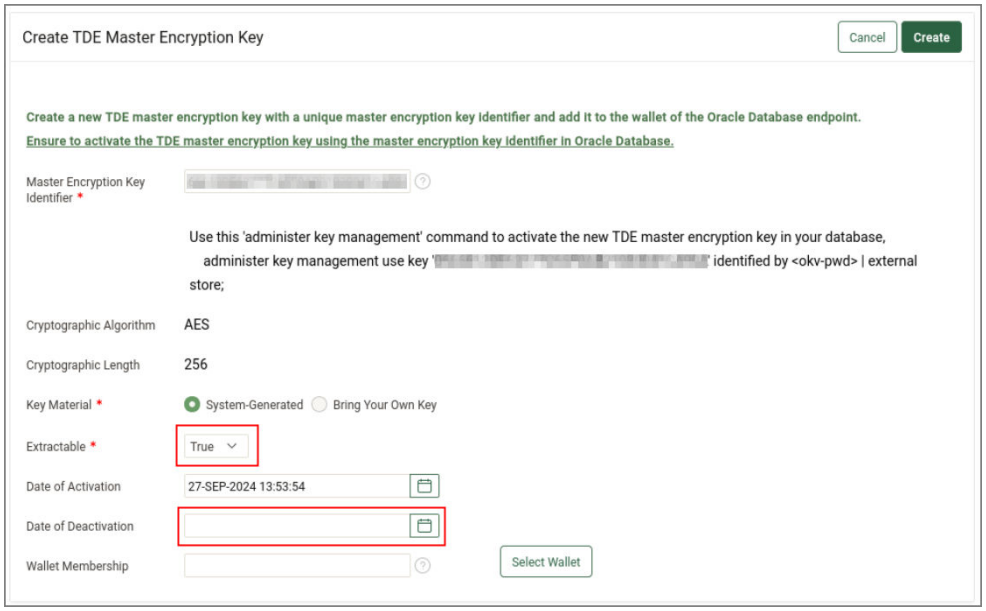
- From the OKV home page, navigate to the **Keys & Wallets** page.
- For **Wallets** on the **Keys & Wallets** page, click **Create**.
- Enter the name of the wallet in the **Name** field and click **Save**.
  For example:



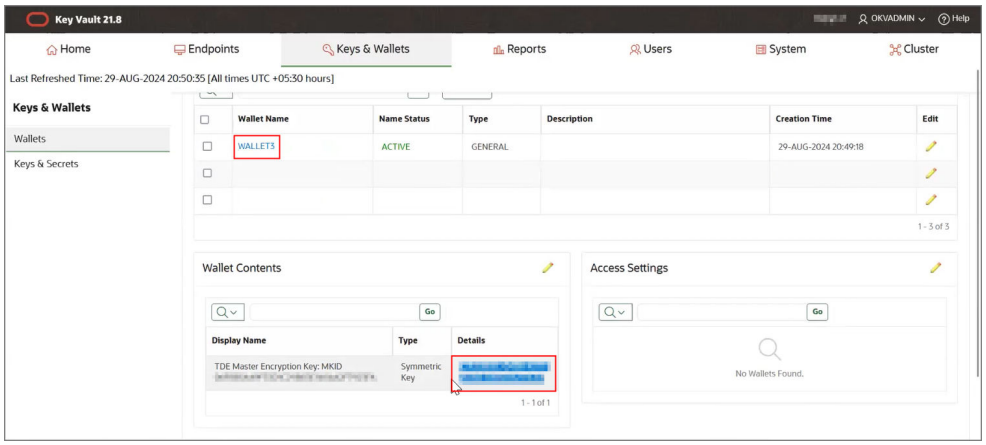
See Creating a Virtual Wallet for more information.

d. Create a TDE Master Encryption Key in the wallet.

- Select **Keys & Secrets**, and click **Create**.
- For **Application Keys**, select **TDE Master Encryption Key**.
- For **Extractable**, select **True**.
- Make sure the **Date of Deactivation** is empty.
  For example:



- For **Wallet Membership**, click **Select Wallet**.
- From the displayed list of wallets, select the wallet created in the previous step and click **Close**.
- Click **Create**. The TDE Master Encryption Key is created and displayed under **Wallet Contents**.
  For example:



e. Modify the endpoint to make the previously created wallet the default wallet.
   - Navigate to the endpoint's details page.
   - On the Default Wallet pane, select **Choose Wallet**.
   - On the Choose Wallet page, select the previously created wallet and click **Select**.
   - Click **Save**.

f. Enable Restful services.

> **Note:**
>
> Restful services must be enabled on the OKV instance to successfully run the curl command, in a subsequent step, to download the wallet.

- From the OKV home page, select the **System** tab.
- On the left navigation pane, click **Setting** .
- Under System Configuration, select **Restful services**.
- Click **All**, then **Save**.

2. Provision an Autonomous Database instance, with the following required settings:
   a. For **Choose network access**, select **Private endpoint access only**.
   b. For **Virtual cloud network**, select the VCN where this database instance is running.
   c. For **Subnet**, select the private subnet where this database instance is running.
   d. For **Network security groups (NSGs)**, select the security group.
   e. For **Encryption key** settings, default to **Encryption using an Oracle-managed key**. These settings are changed to customer managed keys in OKV, after these prerequisite steps are completed. The customer managed keys are disabled during instance provisioning. See Use Customer-Managed Encryption Keys on Autonomous Database with Oracle Key Vault for details.
3. Connect to the Autonomous Database instance and create a directory for the OKV wallet.
   a. Connect to the Private Endpoint Autonomous Database instance as the ADMIN user.

      For example, connect to the OKVDEMO1 database instance:

      ```
      SQL> connect ADMIN/<password>@OKVDEMO1_low
      ```

   b. Create a directory object in the Autonomous Database instance.

      For example:

      ```
      SQL> create directory okv_dir as 'okvdir';
      ```

   c. Check to make sure the directory is created.

      For example, the following statements create the `OKV_DIR` directory object and the statement results display the directory name (`OKV_DIR`) and directory path (`/u03/dbfs/<path data>/data/okvdir`).

      ```
      SQL> connect ADMIN/<admin password>#@OKVDEMO1_low
      Connected
      SQL>
      SQL> create directory okv_dir as 'okvdir';
      Directory created.
      SQL> select * from dba_directories where directory_name = 'OKV_DIR';
      OWNER
      ------------------------------------------------------------------------
      DIRECTORY_NAME
      ------------------------------------------------------------------------
      DIRECTORY_PATH
      ------------------------------------------------------------------------
      ```

```
ORIGIN_CON_ID
-------------
SYS
OKV_DIR
/u03/dbfs/<path data>/data/okvdir
SQL>
```

4. Download the OKV wallet to the directory object created in the Autonomous Database instance.

   a. Download the wallet for the endpoint from the OKV instance.

      Run the following command from the client:

      ```
      curl -k -X POST
       --location https://<OKV server>:5695/okv/cloud/utility/endpoint/
      download/sso
       --data "token=<Enrollment Token>"
       --output cwallet.sso
      ```

      Where:

      - `OKV server`: is the Internal Fully Qualified Domain Name (FQDN) or Private IP found on the OKV instance details page.
      - `Enrollment Token`: is the enrollment token for the endpoint found on the Endpoints page.

      After the wallet is downloaded, the endpoint on the OKV instance shows a status of enrolled. Alternatively, you can also download the wallet by selecting the endpoint name and clicking "Download (wallet)".

   b. Upload the wallet to Object Storage.

      Upload the wallet file from your local machine to your Object Storage bucket using Upload Object. See Uploading an Object to a Bucket, for more information.

   c. In Object Storage, generate a Pre-Authenticated Request (PAR) URL for the uploaded wallet file. See Creating a Pre-Authenticated Request in Object Storage for more information.

   d. From the VM, connect to the database instance as ADMIN user.

   e. In the database instance, run the `DBMS_CLOUD.GET_OBJECT` procedure to download the wallet from Object Storage to the database instance wallet directory.

      For example:

      ```
      BEGIN
          DBMS_CLOUD.GET_OBJECT(
              object_uri => '<PAR URL>',
              directory_name => '<wallet_dir>');
      END;
      /
      ```

      - Where:
        - `object_uri` is the PAR URL generated for the wallet file in Object Storage.
        - `directory_name` is the name of the wallet directory created in the database instance.

See GET_OBJECT Procedure and Function for more information.

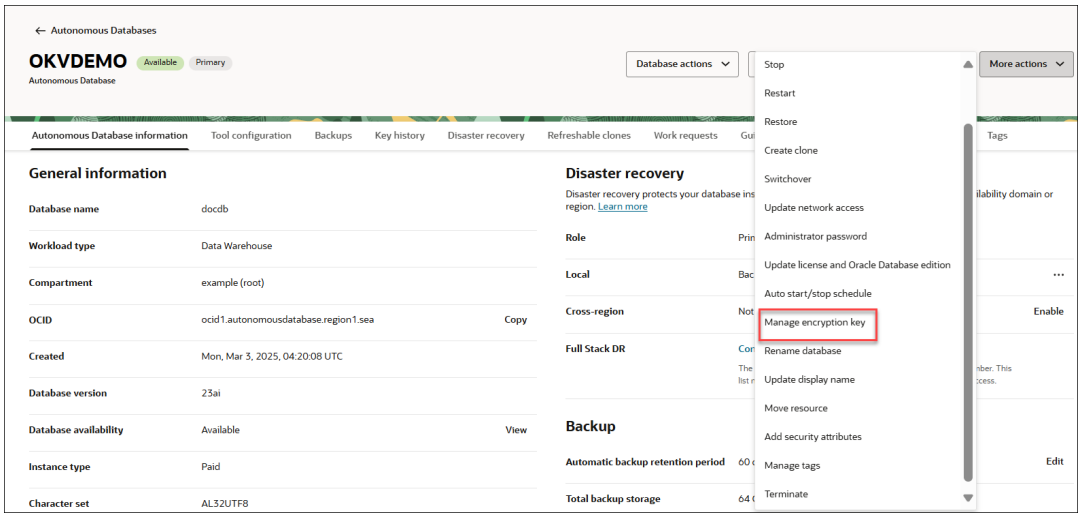
f. Delete the wallet from Object Storage.

Use Customer-Managed Encryption Keys on Autonomous Database with Oracle Key Vault

Shows the steps to encrypt your Autonomous Database using customer-managed master encryption keys that reside in Oracle Key Vault (OKV).

Follow these steps:

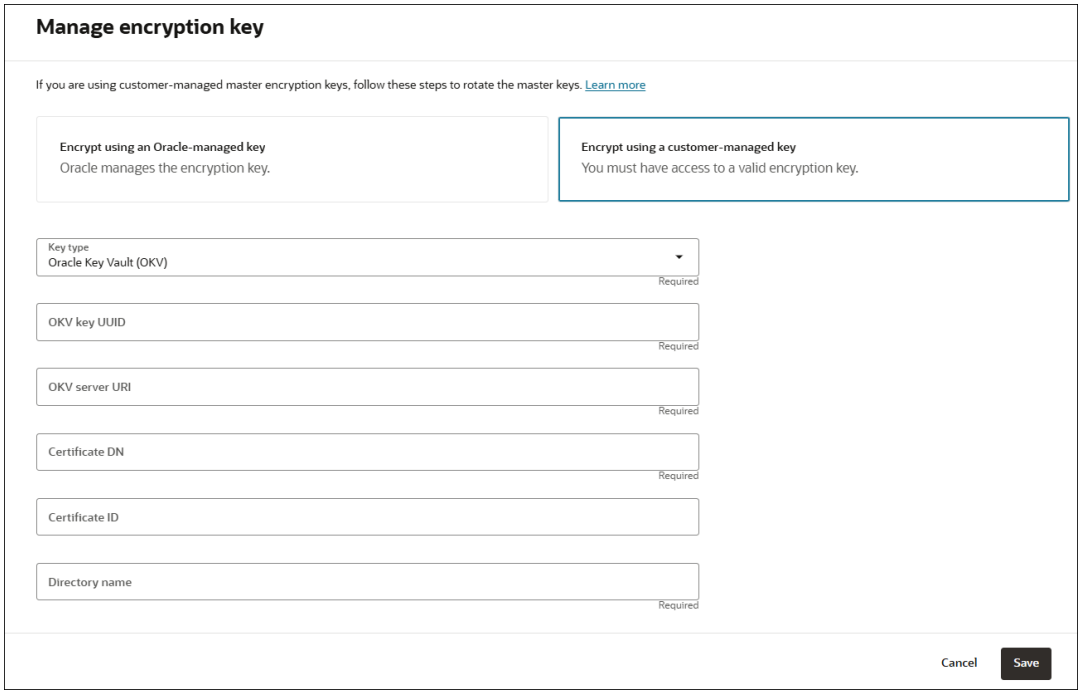
1. Perform the required customer-managed encryption key prerequisite steps as necessary. See Prerequisites to Use Customer-Managed Encryption Keys in Oracle Key Vault for details.
2. On the **Details** page for the Autonomous Database instance, click **More actions**, and select **Manage encryption key**.



> **Note:**
>
> If you are already using customer-managed keys in OKV and you want to rotate the TDE keys, follow these steps and select a different key (select a key that is different from the currently selected master encryption key). However, you cannot use an OKV key that has been used previously on the same Autonomous Database instance.

3. On the **Manage encryption key** page, select **Encrypt using a customer-managed key**.
4. On the **Key type** drop-down, select **Oracle Key Vault (OKV)**.

   The Manage encryption key dialog displays the Oracle Key Vault (OKV) options.



5. Enter the following information:

   - **OKV UUID**: Enter the TDE master key's Unique Identifier for the key located in the OKV instance.

     To find this value:

     a. Sign into the OKV instance and select **Keys & Wallets**.

     b. Click the **name of the default wallet** for the Autonomous Database endpoint.

     c. Scroll to **Wallet Contents** and copy the **Unique Identifier** from the **Details** column.

        For example:

        ```
        BC63511B-4B4A-411C-A71C-4AA90005F632
        OKV Server URI: ok
        Certificate DN:
        ```

        Click the endpoint name, then click the green **Download (PEM format)**; this downloads the “CA.pem” to your computer.

        Extract the certificate DN with a command such as:

        ```
        $ openssl x509 -in ./CA.pem -noout -subject -nameopt RFC2253 | sed
        's|subject=||'
        ```

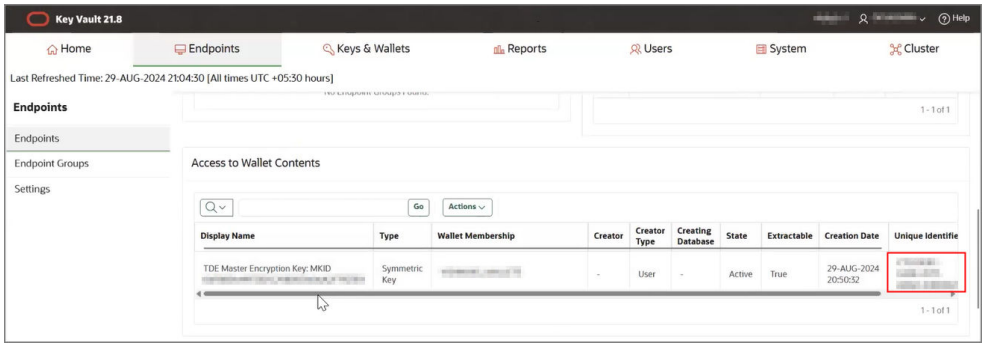
        For example:

        ```
        CN=CA,OU=Key_Vault,O=Oracle,L=Redwood_City,ST=California,C=us
        ```

     d. Click the name of the default wallet for your Autonomous Database endpoint.

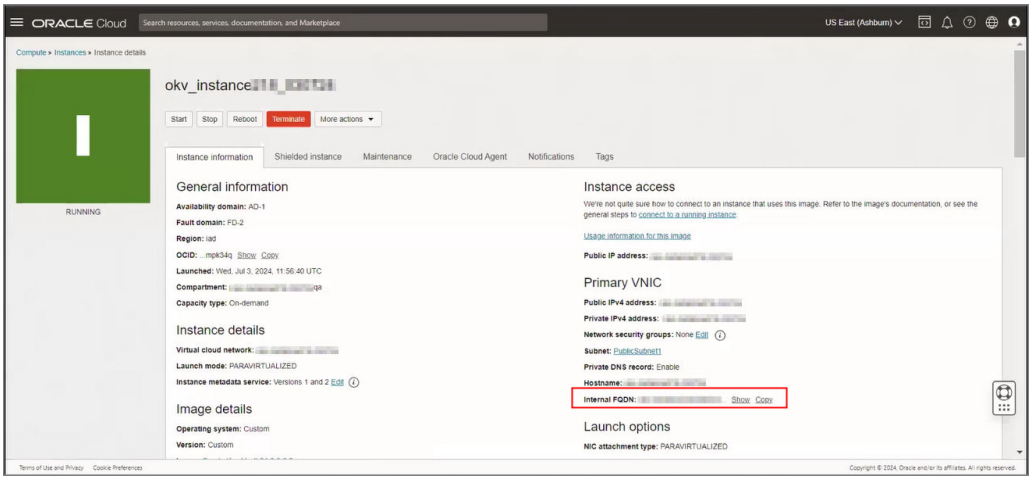
     e. Scroll to **Access to Wallet Contents**, and copy the **Unique Identifier**.

.



f. Paste the Unique Identifier into the **OKV UUID** field.

- **OKV Server URI** - Enter the **Internal Fully Qualified Domain Name** or the Private IP found on the OKV instance details page.
  For example, if using an OCI VM to host OKV, this value can be found on the OKV instance details page under **Primary VNIC**:



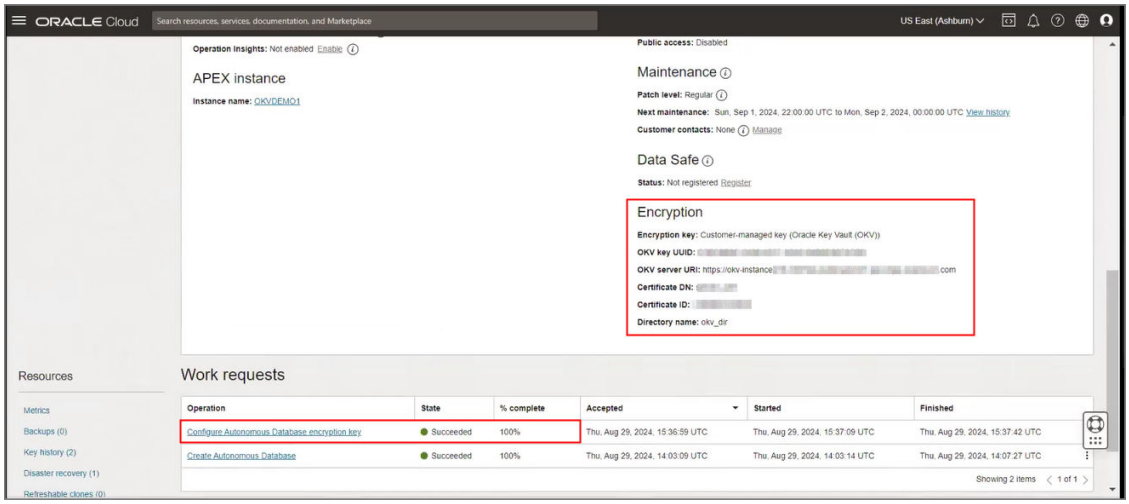
- **Certificate DN** - Enter your certificate Distinguished Name (DN).
- **Certificate ID** (*Optional*) - Enter your certificate ID or leave blank.

> **Note:**
>
> This field is optional if using OKV versions 21.9 and above. If using OKV versions below 21.9, the certificate ID is required.

- **Directory name** - Enter the directory name where the wallet is saved on the Autonomous Database instance.

6. Click **Save**.

When the save completes successfully, encryption settings for the Autonomous Database instance are updated to show **Customer-managed key (Oracle Key Vault (OKV))** and the work request state shows succeeded.



See Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Switch to Oracle-Managed Encryption Keys on Autonomous Database

Shows the steps to switch to Oracle-managed master encryption keys on Autonomous Database if you are using customer-managed encryption keys.

If your Autonomous Database is using customer-managed keys and you want to switch to Oracle-managed keys:

1. On the **Details** page, from the **More actions** drop-down list, select **Manage Encryption Key**.
2. On the **Manage Encryption Key** page, select **Encrypt using Oracle-managed keys**.
3. Click **Save Changes**.

The **Lifecycle state** changes to **Updating**. When the request completes, the **Lifecycle state** shows **Available**.

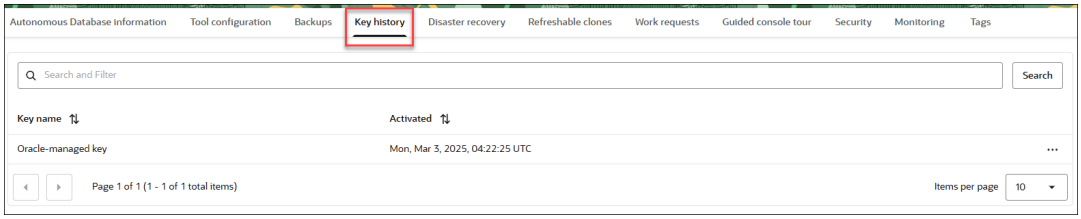
View History for Customer-Managed Encryption Keys on Autonomous Database

You can view the key history from the Oracle Cloud Infrastructure Console or by selecting from the `V$ENCRYPTION_KEYS` view.

To view the key history from the Oracle Cloud Infrastructure Console:

1. On the Autonomous Database Details page, select the **Key History** tab.
2. This shows the Key History.

   For example:



To view the key history by selecting from the `V$ENCRYPTION_KEYS` view:

1. Connect to the Autonomous Database as the ADMIN user.
2. As the ADMIN user, issue the following command:

```
SELECT activation_time, tag FROM V$ENCRYPTION_KEYS;
```

For example:

```
SELECT activation_time, tag FROM V$ENCRYPTION_KEYS;
ACTIVATION_TIME                TAG
-------------------------      -------------------------
2020-02-19T17:21:57.821Z       {"credential_name":"OCI$RESOURCE_PRINCIPAL",
                                "oci_management_url":"https://aqm-
management.kms.ca-toronto-1.oraclecloud.com/20180608/keys/",
                                "master_key_id":"ocid1.key.oc1.ca-
toronto-1","username":"\"ADMIN\"",
                                "vault_id":"ocid1.vault.oc1.ca-toronto-1"}
```

See Notes for Using Customer-Managed Keys with Autonomous Database for more information.

Notes for Using Customer-Managed Keys with Autonomous Database

Provides additional information and notes for using customer-managed keys with Autonomous Database

- Caution for Customer-Managed Encryption Keys when the Key is Unreachable
  After you switch to customer-managed keys, some database operations might be affected when the key is unreachable.
- Caution for Using Customer-Managed Encryption Keys When the Master Key is Disabled or Deleted
  After you switch to customer-managed keys, some database operations might be affected if the master key is disabled or deleted.
- Caution for Using Customer-Managed Encryption Keys History and Backups
  After you switch to customer-managed keys, some database operations might be affected if the master key is rotated, disabled, or deleted and you do not have a valid key to restore your data from a previously saved backup or from a clone.
- Notes for Customer-Managed Keys in OCI Vault with Autonomous Data Guard
  Autonomous Data Guard is supported when using customer-managed keys with the key provider Oracle Cloud Infrastructure Vault.
- Notes for Customer-Managed Encryption Keys with Cloning
  Autonomous Database does not support using customer-managed encryption keys with a refreshable clone.
- Notes for Customer-Managed Keys with Vault in Remote Tenancy
  To use customer-managed master encryption keys with a Vault in a remote tenancy, note the following:

Caution for Customer-Managed Encryption Keys when the Key is Unreachable

After you switch to customer-managed keys, some database operations might be affected when the key is unreachable.

If the database is unable to access your key for some reason, such as a network outage, then Autonomous Database handles the outage as follows:

- There is a 2-hour grace period where the database remains up and running.
- If the key is not reachable at the end of the 2-hour grace period, the database Lifecycle state is set to **Inaccessible**. In this state existing connections are dropped and new connections are not allowed.
- If Autonomous Data Guard is enabled when using Oracle Cloud Infrastructure Vault, during or after the 2-hour grace period you can manually try to perform a failover operation. Autonomous Data Guard automatic failover is not triggered when you are using customer-managed encryption keys and the Oracle Cloud Infrastructure Vault is unreachable.

  > **Note:**
  >
  > Only Oracle Cloud Infrastructure Vault is supported with Autonomous Data Guard.

- If Autonomous Database is stopped, then you cannot start the database when the keys are unreachable.

  For this case, the work request shown when you click the **Work requests** tab on the Autonomous Database details page on the Oracle Cloud Infrastructure Console shows:

  ```
  The Vault service is not accessible.
  Your Autonomous Database could not be started. Please contact Oracle
  Support.
  ```

Caution for Using Customer-Managed Encryption Keys When the Master Key is Disabled or Deleted

After you switch to customer-managed keys, some database operations might be affected if the master key is disabled or deleted.

- For disable/delete key operations where the Master Encryption Key **State** is any of the following:

Key Vault	Key State
Oracle Cloud Infrastructure (OCI) Vault	– `DISABLING` – `DISABLED` – `DELETING` – `DELETED` – `SCHEDULING_DELETION` – `PENDING_DELETION`
AWS Key Management System (KMS)	– `Disabled` – `PendingDeletion`
Azure Key Vault	– `DISABLED` – `DELETED`
Oracle Key Vault (OKV)	– `COMPROMISED` – `DEACTIVATED` – `DESTROYED`

The database becomes **Inaccessible** after the key Lifecycle state goes into one of these states. When the key is in any of these states, Autonomous Database drops existing connections and does not allow new connections.

The database becoming inaccessible can take up to 15 min after the key operations (Autonomous Database checks the key provider at 15 minute intervals).

- If you disable or delete the Oracle Cloud Infrastructure Vault key used by your Autonomous Database while Autonomous Data Guard is enabled, Autonomous Data Guard will not perform an automatic failover.

> **Note:**
>
> Only Oracle Cloud Infrastructure Vault is supported with Autonomous Data Guard.

- If you enable a disabled key, the database automatically goes into the Available state.
- If you delete the master key you can check the key history in the Oracle Cloud Infrastructure Console to find the keys that were used for the database. The history shows you the key name, along with an activation timestamp. If one of the older keys from the history list is still available, then you can restore the database to the time when the database was using that key, or you can clone from a backup to create a new database with that timestamp.

See View History for Customer-Managed Encryption Keys on Autonomous Database for more information.

Caution for Using Customer-Managed Encryption Keys History and Backups

After you switch to customer-managed keys, some database operations might be affected if the master key is rotated, disabled, or deleted and you do not have a valid key to restore your data from a previously saved backup or from a clone.

- It is recommended that you create a new key that hasn't been used for rotation in the last 60 days and use that key for rotation. This makes sure that you can go back to a backup if the current key is deleted or disabled.
- When you perform multiple encryption key rotations within 60 days, it is recommended that you either create a new key for each master encryption key rotation operation or specify a key that has not been used in the last 60 days. This helps to save at least one key you can use to recover your data from a backup, in the case where a customer-managed master encryption key is disabled or deleted.

See View History for Customer-Managed Encryption Keys on Autonomous Database for more information.

Notes for Customer-Managed Keys in OCI Vault with Autonomous Data Guard

Autonomous Data Guard is supported when using customer-managed keys with the key provider Oracle Cloud Infrastructure Vault.

> **Note:**
>
> When you are using Oracle-managed keys you can only switch to customer-managed keys from the primary database. Likewise, when you are using customer-managed keys you can only rotate keys or switch to Oracle-managed keys from the primary database. The **Manage encryption key** option under **More actions** is disabled on a standby database.

Note the following when you are using Autonomous Data Guard with a standby database with customer-managed keys:

- In order for a remote standby to use the same master encryption key as primary, the master encryption key must be replicated to the remote region.

  Customer-Managed Encryption Keys are only supported with a single cross-region Autonomous Data Guard standby. Multiple cross-region standbys are not supported because Oracle Cloud Infrastructure Vault only supports replication to one remote region.
- The primary database and the standby database use the same key. In the event of a switchover or failover to the standby, you can continue to use the same key.
- When you rotate the customer-managed key on the primary database, this is reflected on the standby database.
- When you switch from customer-managed keys to Oracle-managed keys the change is reflected on the standby database.
- When the Oracle Cloud Infrastructure Vault is unreachable, there is a 2-hour grace period before the database goes into the `INACCESSIBLE` state. You can perform a failover during or after this 2-hour grace period.
- If you disable or delete the Oracle Cloud Infrastructure master encryption key that your Autonomous Database is using with customer-managed keys while Autonomous Data Guard is enabled, Autonomous Data Guard does not perform an automatic failover.
- Customer-Managed Encryption Keys are not supported with Cross Tenancy Autonomous Data Guard.

See the following for more information:

- To Replicate a Vault and Its Keys
- Autonomous Data Guard with Customer Managed Keys
- Overview of Vault

Notes for Customer-Managed Encryption Keys with Cloning

Autonomous Database does not support using customer-managed encryption keys with a refreshable clone.

- You cannot create a refreshable clone from a source database that uses customer-managed encryption keys. Additionally, you cannot switch to a customer-managed encryption key on a source database that has one or more refreshable clones.

Notes for Customer-Managed Keys with Vault in Remote Tenancy

To use customer-managed master encryption keys with a Vault in a remote tenancy, note the following:

When you use customer-managed master encryption keys with a Vault in a remote tenancy, the Vault and the Autonomous Database instance must be in the same region. To change the tenancy, on the sign-on page click **Change tenancy**. After you change the tenancy, make sure to select the same region for both the Vault and the Autonomous Database instance.

Configure Network Access with Access Control Rules (ACLs) and Private Endpoints

Provides details on how to configure network access with access control rules or using a private endpoint and describes the secure client connection options. Also describes how to enable support for TLS connections (require mutual TLS only or allow both mutual TLS and TLS authentication).

- Configuring Network Access with Access Control Rules (ACLs)
  Specifying an access control list blocks all IP addresses that are not in the ACL list from accessing the database. After you specify an access control list, the Autonomous Database only accepts connections from addresses on the access control list and the database rejects all other client connections.
- Configure Network Access with Private Endpoints
  You can specify that Autonomous Database uses a private endpoint inside your Virtual Cloud Network (VCN) in your tenancy. You can configure a private endpoint during provisioning or cloning your Autonomous Database, or you can switch to using a private endpoint in an existing database that uses a public endpoint. This allows you to keep all traffic to and from your database off of the public internet.
- Use Zero Trust Packet Routing on Autonomous Database
  Oracle Cloud Infrastructure Zero Trust Packet Routing (ZPR) protects sensitive data from unauthorized access through intent-based security policies that you write for resources, such as an Autonomous Database on a private endpoint, that you assign security attributes to.
- Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database
  Describes how to update the secure client connection authentication options, Mutual TLS (mTLS) and TLS.

Configuring Network Access with Access Control Rules (ACLs)

Specifying an access control list blocks all IP addresses that are not in the ACL list from accessing the database. After you specify an access control list, the Autonomous Database only accepts connections from addresses on the access control list and the database rejects all other client connections.

- Configure Access Control Lists When You Provision or Clone an Instance
  When you provision or clone Autonomous Database with the **Secure access from allowed IPs and VCNs only** option, you can restrict network access by defining Access Control Lists (ACLs).
- Configure Access Control Lists for an Existing Autonomous Database Instance
  You can control and restrict access to your Autonomous Database by specifying network access control lists (ACLs). On an existing Autonomous Database instance with a public endpoint you can add, change, or remove ACLs.
- Change from Private to Public Endpoints with Autonomous Database
  If your Autonomous Database instance is configured to use a private endpoint you can change the configuration to use a public endpoint.

- Access Control List Restrictions and Notes
  Describes restrictions and notes for access control rules on Autonomous Database.

Configure Access Control Lists When You Provision or Clone an Instance

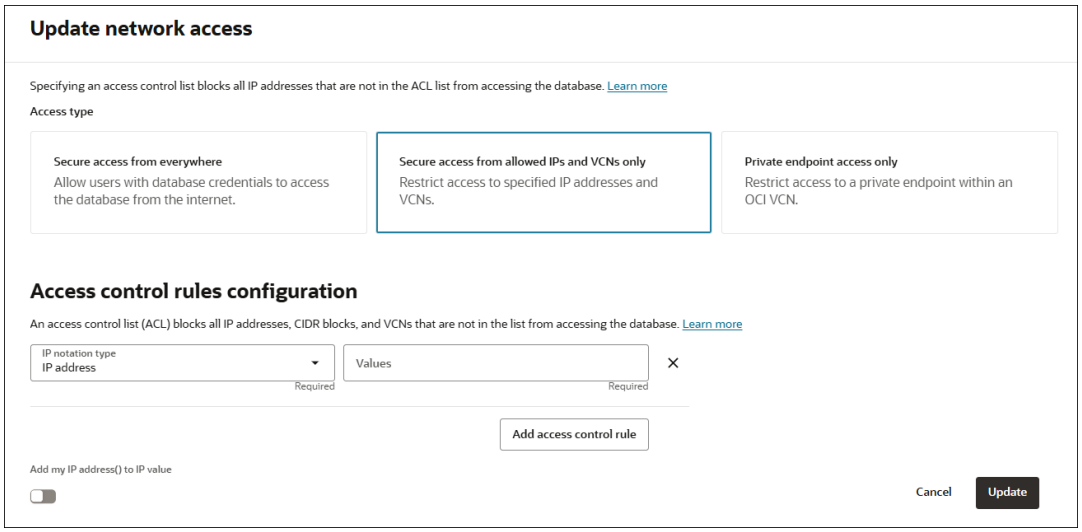
When you provision or clone Autonomous Database with the **Secure access from allowed IPs and VCNs only** option, you can restrict network access by defining Access Control Lists (ACLs).

See Provision an Autonomous Database Instance for information on provisioning your Autonomous Database.

Configure ACLs as follows:

1. In the Choose network access area, select **Secure access from allowed IPs and VCNs only**.

   With **Secure access from allowed IPs and VCNs only** selected, the console shows the fields and options to specify ACLs:



2. In the Choose network access area, specify access control rules by selecting an **IP notation type** and entering **Values** appropriate for the type you select:

   - **IP address**:
     In **Values** field enter values for the **IP address**. An IP address specified in a network ACL entry is the public IP address of the client that is visible on the public internet that you want to grant access. For example, for an Oracle Cloud Infrastructure VM, this is the IP address shown in the **Public IP** field on the Oracle Cloud Infrastructure console for that VM.

     > **Note:**
     >
     > Optionally select **Add my IP address** to add your current IP address to the ACL entry.

   - **CIDR block**:
     In **Values** field enter values for the **CIDR block**. The CIDR block specified is the public CIDR block of the clients that are visible on the public internet that you want to grant access.
   - **Virtual cloud network**:

Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

Use this option to specify the VCN for use with an Oracle Cloud Infrastructure Service Gateway:

- In **Virtual cloud network** field select the VCN that you want to grant access from. If you do not have the privileges to see the VCNs in your tenancy this list is empty. In this case use the selection **Virtual cloud network (OCID)** to specify the OCID of the VCN.
- Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

- **Virtual cloud network (OCID)**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.
  - In the **Values** field enter the OCID of the VCN you want to grant access from.
  - Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

3. Click **Add access control rule** to add a new value to the access control list.
4. Click **x** to remove an entry.

   You can also clear the value in the **IP addresses** or **CIDR blocks** field to remove an entry.
5. Require mutual TLS (mTLS) authentication.

   After you enter an IP notation type and a value, you have the option to select this option. The options are:

   - When **Require mutual TLS (mTLS) authentication** is selected, only mTLS connections are allowed (TLS authentication is not allowed).
   - When **Require mutual TLS (mTLS) authentication** is deselected, TLS and mTLS connections are allowed. This is the default configuration.

   See Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database for more information.
6. Complete the remaining provisioning or cloning steps, as specified in Provision an Autonomous Database Instance, Clone an Autonomous Database Instance, or Clone an Autonomous Database from a Backup.

After provisioning completes, you can update public endpoint ACLs or you can change the Autonomous Database configuration to use a private endpoint.

See Configure Access Control Lists for an Existing Autonomous Database Instance for information on updating ACLs.

See Change from Public to Private Endpoints with Autonomous Database for information on changing to a private endpoint.

Configure Access Control Lists for an Existing Autonomous Database Instance

You can control and restrict access to your Autonomous Database by specifying network access control lists (ACLs). On an existing Autonomous Database instance with a public endpoint you can add, change, or remove ACLs.

Configure ACLs, or add, remove, or update existing ACLs for an Autonomous Database instance as follows:

1. On the **Details** page, in the Network area, next to the **Access control list field**, click **Edit**.

   This shows the Update network access pane.

   As an alternative you can click **More actions** and select select **Update network access**, and in the pane, under **Access type**, select **Secure access from allowed IPs and VCNs only**.

2. Specify the access control rules by selecting an **IP notation type** and values:

   Select one of:

   - **IP address**:
     In **Values** field enter values for the **IP address**. An IP address specified in a network ACL entry is the public IP address of the client that is visible on the public internet that you want to grant access. For example, for an Oracle Cloud Infrastructure VM, this is the IP address shown in the **Public IP** field on the Oracle Cloud Infrastructure console for that VM.

     > **Note:**
     >
     > Optionally select **Add my IP address** to add your current IP address to the ACL entry.

   - **CIDR block**:

In **Values** field enter values for the **CIDR block**. The CIDR block specified is the public CIDR block of the clients that are visible on the public internet that you want to grant access.

- **Virtual cloud network**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  Use this option to specify the VCN for use with an Oracle Cloud Infrastructure Service Gateway:

  – In **Virtual cloud network** field select the VCN that you want to grant access from. If you do not have the privileges to see the VCNs in your tenancy this list is empty. In this case use the selection **Virtual cloud network (OCID)** to specify the OCID of the VCN.

  – Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

- **Virtual cloud network (OCID)**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  – In the **Values** field enter the OCID of the VCN you want to grant access from.

  – Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

3. Click **Add access control** to add a new value to the access control list.
4. Click **x** to remove an entry.

   You can also clear the value in the **IP addresses** or **CIDR blocks** field to remove an entry.
5. Click **Update**.

If the Lifecycle state is **Available** when you click **Update** the Lifecycle state changes to **Updating** until the ACL is set. The database is still up and accessible, there is no downtime. When the update is complete the Lifecycle state returns to **Available** and the network ACLs from the access control list are in effect.

Change from Private to Public Endpoints with Autonomous Database

If your Autonomous Database instance is configured to use a private endpoint you can change the configuration to use a public endpoint.

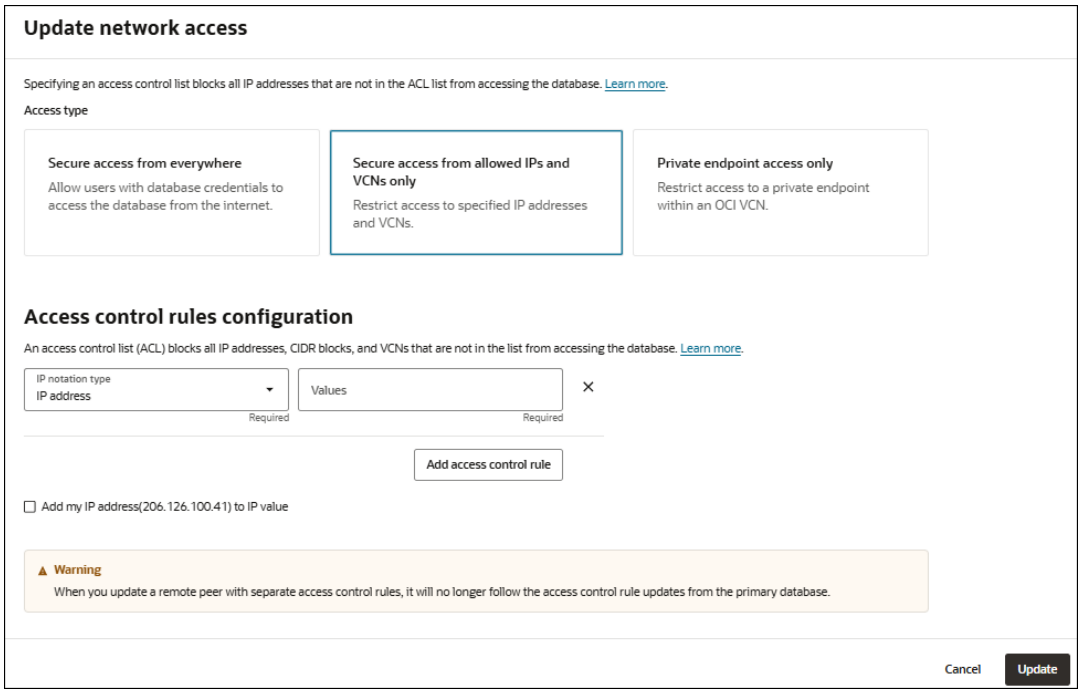
There are several prerequisites to change an instance from a private to a public endpoint, as follows:

- The Autonomous Database instance must be in the available state (Lifecycle state: **Available**).
- Before changing the network configuration from a private endpoint to a public endpoint, you must change the configuration to not allow TLS connections. This closes any existing TLS connections. See Update your Autonomous Database Instance to Require mTLS and Disallow TLS Authentication for more information.

To specify a public endpoint for your Autonomous Database do the following:

1. On the **Details** page, from the **More actions** drop-down list, select **Update network access**.
2. In the **Update network access** dialog, select one of **Secure access from everywhere** or **Secure access from allowed IPs and VCNs only**.

   For example, if you select **Secure access from allowed IPs and VCNs only** the dialog shows fields to configure access control rules:



3. In the dialog, under Configure access control rules specify rules by selecting an **IP notation type** and values:

   - **IP address**:
     In **Values** field enter values for the **IP address**. An IP address specified in a network ACL entry is the public IP address of the client that is visible on the public internet that you want to grant access. For example, for an Oracle Cloud Infrastructure VM, this is the IP address shown in the **Public IP** field on the Oracle Cloud Infrastructure console for that VM.

     > **Note:**
     >
     > Optionally select **Add my IP address** to add your current IP address to the ACL entry.

   - **CIDR block**:
     In **Values** field enter values for the **CIDR block**. The CIDR block specified is the public CIDR block of the clients that are visible on the public internet that you want to grant access.
   - **Virtual cloud network**:
     Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.
     – In **Virtual cloud network** field select the VCN that you want to grant access from. If you do not have the privileges to see the VCNs in your tenancy this list is empty.

In this case use the selection **Virtual cloud network (OCID)** to specify the OCID of the VCN.

  - Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

- **Virtual cloud network (OCID)**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  - In the **Values** field enter the OCID of the VCN you want to grant access from.
  - Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

4. Click **Add access control rule** to add a new value to the access control list.
5. Click **x** to remove an entry.

   You can also clear the value in the **IP addresses** or **CIDR blocks** field to remove an entry.
6. Click **Update**.
7. In the **Confirm** dialog, type the Autonomous Database name to confirm the change.
8. In the **Confirm** dialog, click **Update**.

The Lifecycle state changes to **Updating** until the operation completes.

Notes for changing from private endpoint to public endpoint network access:

- After updating the network access type all database users must obtain a new wallet and use the new wallet to access the database. See Download Client Credentials (Wallets) for more information.
- After the update completes, you can change or define new access control rules ACLs for the public endpoint. See Configure Access Control Lists for an Existing Autonomous Database Instance for more information.
- The URL for Database Actions and for the Database Tools are different when a database uses a private endpoint compared to using a public endpoint. Click Database Actions on the Oracle Cloud Infrastructure Console to find the updated Database Actions URL and in Database Actions click the appropriate cards to find the updated Database Tools URLs, after changing from a private endpoint to a public endpoint.

Access Control List Restrictions and Notes

Describes restrictions and notes for access control rules on Autonomous Database.

- See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.
- If you want to only allow connections coming through a service gateway you need to use the IP address of the service gateway in your ACL definition. To do this you need to add an ACL definition with the CIDR source type with the value `240.0.0.0/4`. Note that this is not recommended, instead of this you can specify individual VCNs in your ACL definition for the VCNs you want to allow access from.

  See Access to Oracle Services: Service Gateway for more information.

- When you restore a database the existing ACLs are not overwritten by the restore.
- The network ACLs apply to the database connections and Oracle Machine Learning notebooks. If an ACL is defined, if you try to login to Oracle Machine Learning Notebooks from a client whose IP is not specified on the ACL this shows the "login rejected based on access control list set by the administrator" error.
- The following Autonomous Database tools are subject to ACLs. You can use Virtual Cloud Network, Virtual Cloud Network (OCID), IP address, or CIDR block ACLs to control access to these tools:
  - Database Actions
  - Oracle APEX
  - Oracle Graph Studio
  - Oracle Machine Learning Notebooks
  - Oracle REST Data Services
- If you have a private subnet in your VCN that is configured to access the public internet through a NAT Gateway, you need to enter the public IP address of the NAT Gateway in your ACL definition. Clients in the private subnet do not have public IP addresses. See NAT Gateway for more information.
- If you are using ACLs and TLS connections are allowed, you must change your network configuration to not allow TLS connections before removing all ACLs. See Update your Autonomous Database Instance to Require mTLS and Disallow TLS Authentication for more information.
- To view the network information for your instance, see View Network Information on the OCI Console.

Configure Network Access with Private Endpoints

You can specify that Autonomous Database uses a private endpoint inside your Virtual Cloud Network (VCN) in your tenancy. You can configure a private endpoint during provisioning or cloning your Autonomous Database, or you can switch to using a private endpoint in an existing database that uses a public endpoint. This allows you to keep all traffic to and from your database off of the public internet.

Specifying the virtual cloud network configuration allows traffic only from the virtual cloud network you specify and blocks access to the database from all public IPs or VCNs. This allows you to define security rules with Security Lists or at the Network Security Group (NSG) level to specify ingress/egress for your Autonomous Database instance. Using a private endpoint and defining Security Lists or NSGs allows you to control traffic to and from your Autonomous Database instance.

> **Note:**
>
> If you configure your Autonomous Database instance to use a private endpoint and you also want to allow connections from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway, select the **Allow public access** option. This adds a public endpoint for a database that is configured with a private endpoint. See Use a Private Endpoint with Public Access Allowed for more information.
> The **Allow public access option** is available only when the database uses the ECPU compute model.

Topics

- Configure Private Endpoints
  You can specify that Autonomous Database uses a private endpoint and configure a Virtual Cloud Network (VCN) in your tenancy to use with the private endpoint.
- Enhanced Security for Outbound Connections with Private Endpoints
  When you use a private endpoint with your Autonomous Database instance you can provide enhanced security by setting the `ROUTE_OUTBOUND_CONNECTIONS` database property to the value `PRIVATE_ENDPOINT`.
- Private Endpoints Notes
  Describes restrictions and notes for private endpoints on Autonomous Database.
- Private Endpoints Configuration Examples on Autonomous Database
  Shows several Private Endpoint (VCN) configuration samples for Autonomous Database.

Configure Private Endpoints

You can specify that Autonomous Database uses a private endpoint and configure a Virtual Cloud Network (VCN) in your tenancy to use with the private endpoint.

- Prerequisite Steps to Configure Private Endpoints
  Describes the prerequisite steps you need to perform before you configure a private endpoint for an Autonomous Database instance.
- IAM Policies Required to Manage Private Endpoints
  In addition to the policies required to provision and manage an Autonomous Database, some network policies are needed to use private endpoints.
- Configure Private Endpoints When You Provision or Clone an Instance
  You can configure a private endpoint when you provision or clone an Autonomous Database instance.
- Change from Public to Private Endpoints with Autonomous Database
  If your Autonomous Database instance is configured to use a public endpoint you can change the configuration to a private endpoint.
- Update the Configuration for a Private Endpoint
  You can change some options in the configuration of a private endpoint on an existing Autonomous Database instance.
- Configure Private Endpoint Advanced Options
  The private endpoint access advanced options allow you to enter a user specified private IP address and host name, select one or more network security groups, or specify details to allow public access to a private endpoint database.
- Use a Private Endpoint with Public Access Allowed
  Select the **Allow public access** option when you want to configure an Autonomous Database to use a private endpoint and you also want to allow connections from specific public IP addresses or from specific VCNs (if the VCNs are configured to privately connect to Autonomous Database using a Service Gateway).

Prerequisite Steps to Configure Private Endpoints

Describes the prerequisite steps you need to perform before you configure a private endpoint for an Autonomous Database instance.

Perform the following prerequisite steps before configuring a private endpoint:

- Set required policies for the resources you are working with. See IAM Policies Required to Manage Private Endpoints for more information.
- Create a VCN within the region that will contain your Autonomous Database. See VCNs and Subnets for more information.
- Configure a subnet within your VCN configured with default DHCP options. See DNS in Your Virtual Cloud Network for more information.
- (Optional) Perform the following optional step before configuring a private endpoint:

  Specify a Network Security Group (NSG) within your VCN. The NSG specifies rules for connections to your Autonomous Database. See Network Security Groups for more information.

IAM Policies Required to Manage Private Endpoints

In addition to the policies required to provision and manage an Autonomous Database, some network policies are needed to use private endpoints.

The following table lists the IAM policies required for a cloud user to add a private endpoint. The listed policies are the minimum requirements to add a private endpoint. You can also use a policy rule that is broader. For example, if you set the policy rule:

```
Allow group MyGroupName to manage virtual-network-family in tenancy
```

This rule also works because it is a superset that contains all the required policies.

Operation	Required IAM Policies
Configure a private endpoint	`use vcns` for the compartment which the VCN is in `use subnets` for the compartment which the VCN is in `use network-security-groups` for the compartment which the network security group is in `manage private-ips` for the compartment which the VCN is in `manage vnics` for the compartment which the VCN is in `manage vnics` for the compartment which the database is provisioned or is to be provisioned in

Autonomous Database relies on the IAM (Identity and Access Management) service to authenticate and authorize cloud users to perform operations that use any of the Oracle Cloud Infrastructure interfaces (the Console, REST API, CLI, SDK, or others).

The IAM service uses **groups**, **compartments** and **policies** to control which cloud users can access which resources. In particular, a policy defines what kind of access a group of users has to a particular kind of resource in a particular compartment. For more information, see Getting Started with Policies.

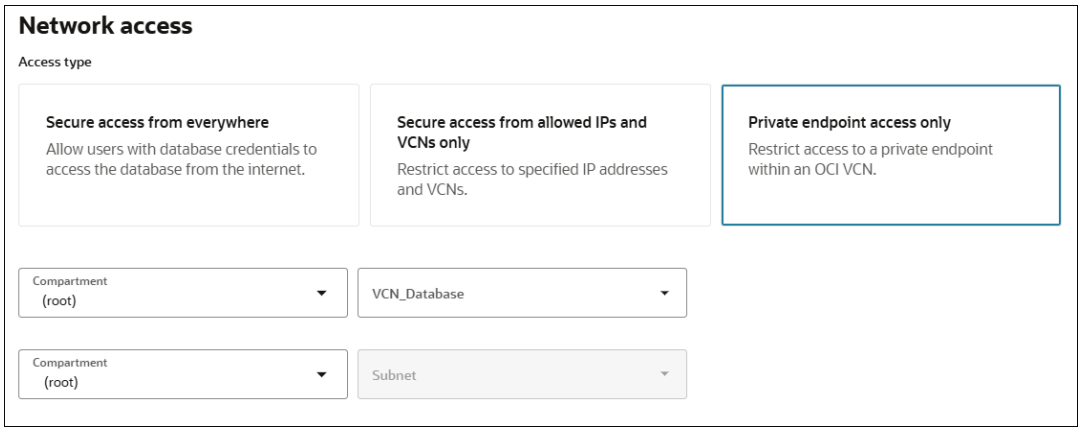
Configure Private Endpoints When You Provision or Clone an Instance

You can configure a private endpoint when you provision or clone an Autonomous Database instance.

These steps assume you are provisioning or cloning an instance and you have completed the prerequisite steps, and you are at the **Choose network access** step of the provisioning or cloning steps:

1. Select **Private endpoint access only**.

This expands the Virtual cloud network private access configuration area.



If you select **Private endpoint access only**, this only allows connections from the specified private network (VCN), from peered VCNs, and from on-prem networks connected to your VCN. You can configure an Autonomous Database instance on a private endpoint to allow connections from on-prem networks. See Example: Connecting from Your Data Center to Autonomous Database for an example.

If you want to allow connections from public IP addresses or from allowed IPs and VCNs, you have the following options:

- Select **Secure access from everywhere**.
- Select **Secure access from allowed IPs and VCNs only**.
- If you select **Private endpoint access only**, expand **Show advanced options** and select **Allow public access**. See Configure Private Endpoint Advanced Options for more information.

2. Select a **Virtual cloud network** in your compartment or if the VCN is in a different compartment click **Change Compartment** and select the compartment that contains the VCN and then select a virtual cloud network.

   See VCNs and Subnets for more information.

3. Select the **Subnet** in your compartment to attach the Autonomous Database to or if the Subnet is in a different compartment click **Change Compartment** and select the compartment that contains the Subnet and then select a subnet.

   See VCNs and Subnets for more information.

4. (Optional) Click **Show advanced options** to show additional private endpoint options.

   See Configure Private Endpoint Advanced Options for details on the advanced options.

5. Require mutual TLS (mTLS) authentication.

   The **Require mutual TLS (mTLS) authentication** options are:

   - When **Require mutual TLS (mTLS) authentication** is deselected, TLS and mTLS connections are allowed. This is the default configuration.
   - When **Require mutual TLS (mTLS) authentication** is selected, only mTLS connections are allowed (TLS authentication is not allowed).

   See Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database for more information.

6. Complete the remaining provisioning or cloning steps, as specified in Provision an Autonomous Database Instance, Clone an Autonomous Database Instance, or Clone an Autonomous Database from a Backup.

See Private Endpoints Notes for more information.

Change from Public to Private Endpoints with Autonomous Database

If your Autonomous Database instance is configured to use a public endpoint you can change the configuration to a private endpoint.

1. On the **Details** page, from the **More actions** drop-down list, select **Update network access**.

   To change an instance from a public to a private endpoint, the Autonomous Database instance must be in the **Available** state (Lifecycle state: **Available**).

2. In the **Update network access** dialog, select **Private endpoint access only**.

   This expands the Virtual cloud network private access configuration area.

   If you select **Private endpoint access only**, this only allows connections from the specified private network (VCN), from peered VCNs, and from on-prem networks connected to your VCN. You can configure an Autonomous Database instance on a private endpoint to allow connections from on-prem networks. See Example: Connecting from Your Data Center to Autonomous Database for an example.

   If you want to allow connections from public IP addresses or from allowed IPs and VCNs, you have the following options:

   - Select **Secure access from everywhere**.
   - Select **Secure access from allowed IPs and VCNs only**.
   - If you select **Private endpoint access only**, expand **Show advanced options** and select **Allow public access**. See Configure Private Endpoint Advanced Options for more information.

3. Select a **Virtual cloud network** in your compartment or if the VCN is in a different compartment click **Change Compartment** and select the compartment that contains the VCN and then select a virtual cloud network.

   See VCNs and Subnets for more information.

4. Select the **Subnet** in your compartment to attach the Autonomous Database to or if the Subnet is in a different compartment click **Change Compartment** and select the compartment that contains the Subnet and then select a subnet.

   See VCNs and Subnets for more information.

5. (Optional) Click **Show advanced options** to see additional options.

   See Configure Private Endpoint Advanced Options for details on the advanced options.

6. Click **Update**.
7. In the **Confirm** dialog, type the Autonomous Database name to confirm the change.
8. In the **Confirm** dialog, click **Update**.

The Lifecycle state changes to **Updating** until the operation completes.

Notes for changing from public to private network access:

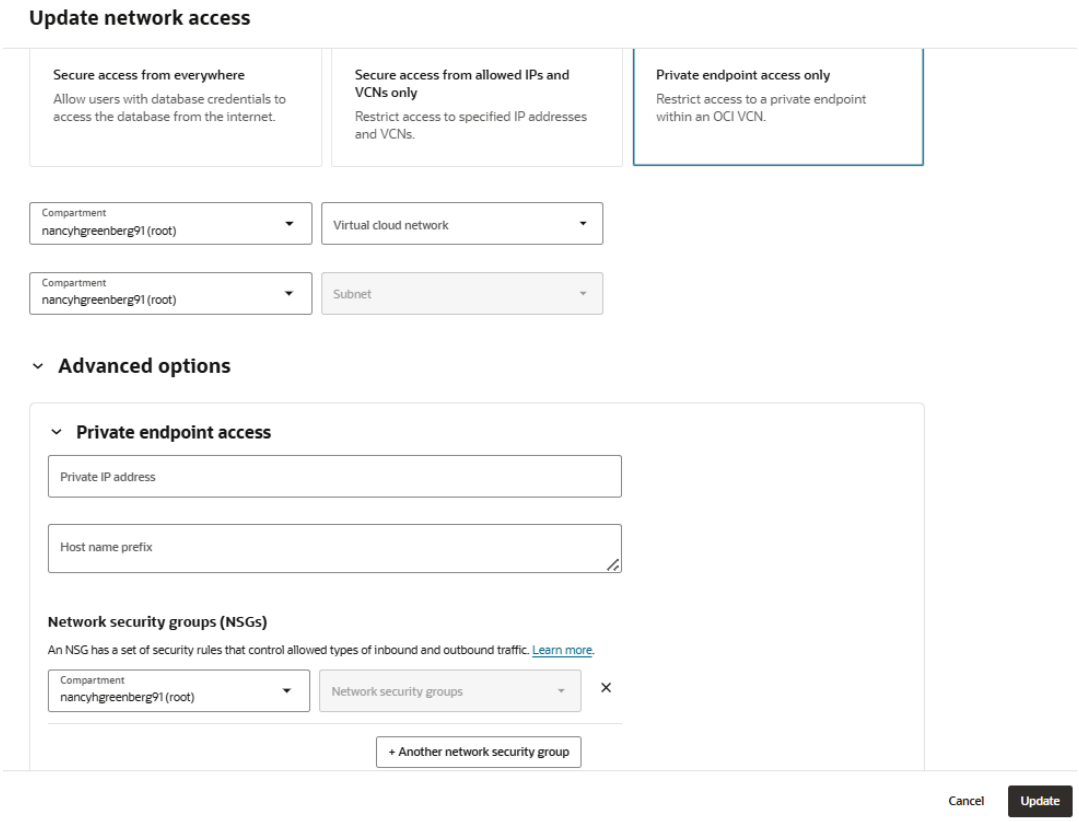
- After updating the network access type all database users must obtain a new wallet and use the new wallet to access the database. See Download Client Credentials (Wallets) for more information.
- If you had ACLs defined for the public endpoint, the ACLs do not apply for the private endpoint.
- After you update the network access to use a private endpoint, the URL for the Database Tools is different compared to using a public endpoint. You can find the updated URLs on the console, after changing from a public endpoint to a private endpoint.

Update the Configuration for a Private Endpoint

You can change some options in the configuration of a private endpoint on an existing Autonomous Database instance.

1. On the **Details** page, from the **More actions** drop-down list, select **Update network access**.

   This shows the Update network access panel.



2. Select **Private endpoint access only**.

   If you want to allow connections from public IP addresses or from allowed IPs and VCNs, you have the following options:

   - Select **Secure access from everywhere**.
   - Select **Secure access from allowed IPs and VCNs only**.
   - When you select **Private endpoint access only** show advanced options and select **Allow public access**. This defines a private endpoint database that includes both a private endpoint and a public endpoint.

   a. Optionally add **Network security groups (NSGs)**.

      Optionally, to allow connections to the Autonomous Database instance define security rules in an NSG; this creates a virtual firewall for your Autonomous Database.

      - Select a Network Security Group in your compartment to attach the Autonomous Database to, or if the Network Security Group is in a different compartment, click **Change Compartment** and select a different compartment and then select a Network Security Group in that compartment.
      - Click **+ Another Network Security Group** to add another Network Security Group.
      - Click **x** to remove a Network Security Group entry.

      For the NSG you select for the private endpoint define a security rule as follows:

      - For mutual TLS (mTLS) authentication, add a stateful ingress rule with the source set to the address range you want to allow to connect to your database, the IP Protocol set to TCP, and the Destination Port Range set to 1522.

- For TLS authentication, add a stateful ingress rule with the source set to the address range you want to allow to connect to your database, the IP Protocol set to TCP, and the Destination Port Range set to either 1521 or 1522.
- To use Oracle APEX, Database Actions, and Oracle REST Data Services, add port 443 to the NSG rule.

> **Note:**
>
> Incoming and outgoing connections are limited by the combination of ingress and egress rules defined in NSGs and the Security Lists defined with the VCN. When there are no NSGs, ingress and egress rules defined in the Security Lists for the VCN still apply. See Security Lists for more information on working with Security Lists.

See Secure Connections to Autonomous Database with mTLS or with TLS for more information.

See Private Endpoints Configuration Examples on Autonomous Database for examples.

See Network Security Groups for more information.

b. Optionally, select **Allow public access** or if this is already selected, you can configure access control rules to the public endpoint that is configured with the private endpoint database.

The **Allow public access option** is available only when the database uses the ECPU compute model.

When you select **Allow public access**, this shows the Configure access control options to enter the allowed IP addresses, CIDR blocks, or Virtual cloud networks that can connect to the database.

Select one of:

- **IP address**:
  In **Values** field enter values for the **IP address**. An IP address specified in a network ACL entry is the public IP address of the client that is visible on the public internet that you want to grant access. For example, for an Oracle Cloud Infrastructure VM, this is the IP address shown in the **Public IP** field on the Oracle Cloud Infrastructure console for that VM.

  Optionally select **Add my IP address** to add your current IP address to the ACL entry.
- **CIDR block**:
  In **Values** field enter values for the **CIDR block**. The CIDR block specified is the public CIDR block of the clients that are visible on the public internet that you want to grant access.
- **Virtual cloud network**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  Use this option to specify the VCN for use with an Oracle Cloud Infrastructure Service Gateway:

  – In **Virtual cloud network** field select the VCN that you want to grant access from. If you do not have the privileges to see the VCNs in your tenancy this list

is empty. In this case use the selection **Virtual cloud network (OCID)** to specify the OCID of the VCN.

- Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

- **Virtual cloud network (OCID)**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.
  - In the **Values** field enter the OCID of the VCN you want to grant access from.
  - Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

  If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

3. Click **Update**.

If the Lifecycle state is **Available** when you click **Update**, the Lifecycle state changes to **Updating** until the changes are applied. The database is still up and accessible, there is no downtime. When the update is complete the Lifecycle state returns to **Available**.

See Private Endpoints Notes for more information.

Configure Private Endpoint Advanced Options

The private endpoint access advanced options allow you to enter a user specified private IP address and host name, select one or more network security groups, or specify details to allow public access to a private endpoint database.

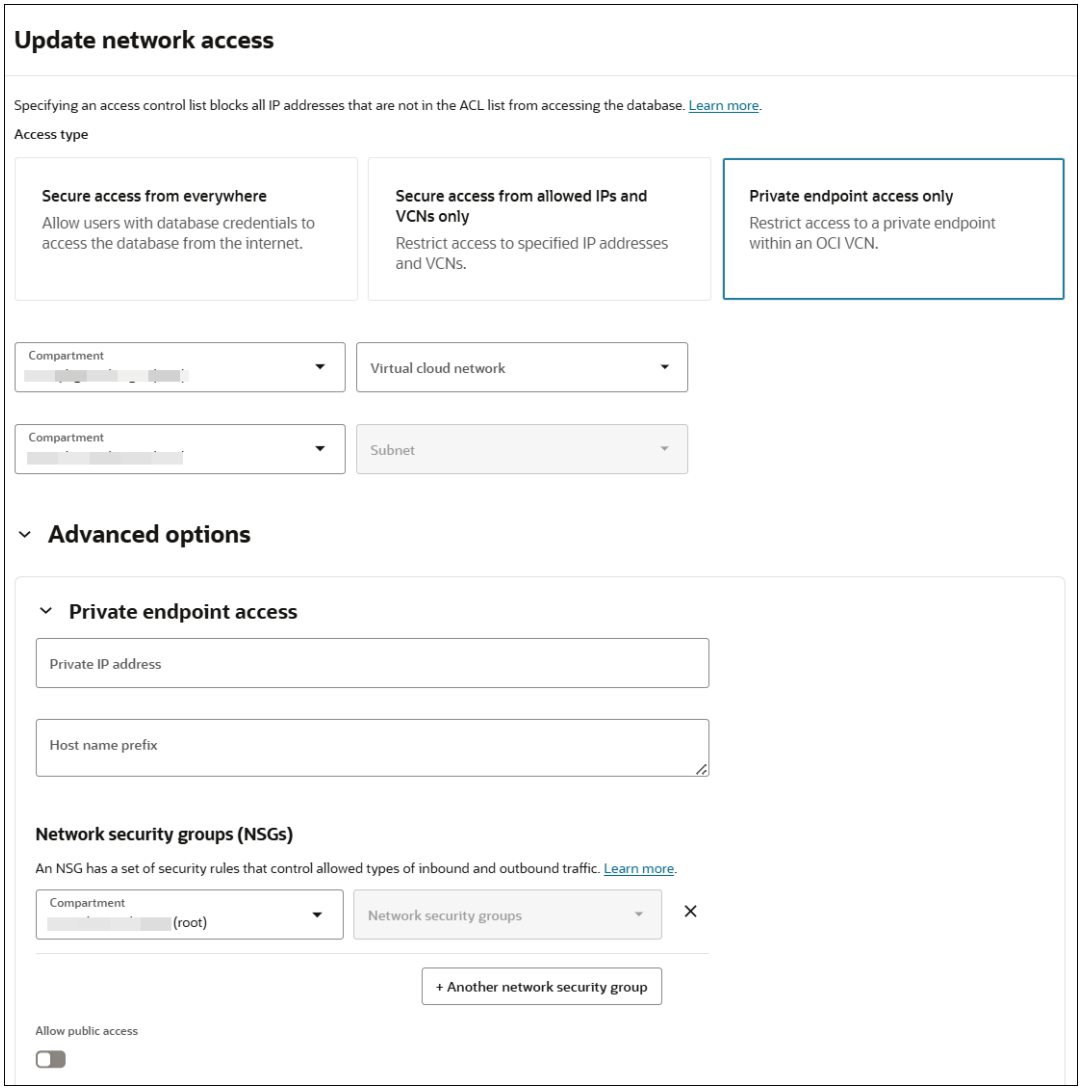
These steps assume you are provisioning or cloning an Autonomous Database instance or changing from public access to private access for an existing Autonomous Database instance and you are at the **Choose network access** step.

1. Select **Private endpoint access only**.

   This shows the Virtual cloud network private access configuration area.

2. (Optional) Click **Show advanced options** to show additional private endpoint options.

   This displays the advanced options.



a. Optionally enter a **Private IP address**.

   Use this field to enter a custom private IP address. The private IP address you enter must be within the selected subnet's CIDR range.

   If you do not provide a custom private IP address the IP address is automatically assigned.

b. Optionally enter a **Hostname prefix**.

   This specifies a hostname prefix for the Autonomous Database and associates a DNS name with the database instance, in the following form:

   ```
   hostname_prefix.adb.region.oraclecloud.com
   ```

   If you do not specify a hostname prefix, a system generated hostname prefix is supplied.

c. Optionally add **Network security groups (NSGs)**.

   Optionally, to allow connections to the Autonomous Database instance define security rules in an NSG; this creates a virtual firewall for your Autonomous Database.

- Select a Network Security Group in your compartment to attach the Autonomous Database to, or if the Network Security Group is in a different compartment, click **Change Compartment** and select a different compartment and then select a Network Security Group in that compartment.
- Click **+ Another Network Security Group** to add another Network Security Group.
- Click **x** to remove a Network Security Group entry.

For the NSG you select for the private endpoint define a security rule as follows:

- For mutual TLS (mTLS) authentication, add a stateful ingress rule with the source set to the address range you want to allow to connect to your database, the IP Protocol set to TCP, and the Destination Port Range set to 1522.
- For TLS authentication, add a stateful ingress rule with the source set to the address range you want to allow to connect to your database, the IP Protocol set to TCP, and the Destination Port Range set to either 1521 or 1522.
- To use Oracle APEX, Database Actions, and Oracle REST Data Services, add port 443 to the NSG rule.

> **Note:**
>
> Incoming and outgoing connections are limited by the combination of ingress and egress rules defined in NSGs and the Security Lists defined with the VCN. When there are no NSGs, ingress and egress rules defined in the Security Lists for the VCN still apply. See Security Lists for more information on working with Security Lists.

See Secure Connections to Autonomous Database with mTLS or with TLS for more information.

See Private Endpoints Configuration Examples on Autonomous Database for examples.

See Network Security Groups for more information.

d. Optionally, select **Allow public access** and configure access control rules to add a public endpoint for the private endpoint database.

The **Allow public access option** is available only when the database uses the ECPU compute model.

When you select **Allow public access**, this shows the Configure access control options to enter the allowed IP addresses, CIDR blocks, or Virtual cloud networks that can connect to the database.

Select one of:

- **IP address**:
  In **Values** field enter values for the **IP address**. An IP address specified in a network ACL entry is the public IP address of the client that is visible on the public internet that you want to grant access. For example, for an Oracle Cloud Infrastructure VM, this is the IP address shown in the **Public IP** field on the Oracle Cloud Infrastructure console for that VM.

  Optionally select **Add my IP address** to add your current IP address to the ACL entry.

Optionally select **Add my IP address** to add your current IP address to the ACL entry.

- **CIDR block**:
  In **Values** field enter values for the **CIDR block**. The CIDR block specified is the public CIDR block of the clients that are visible on the public internet that you want to grant access.
- **Virtual cloud network**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  Use this option to specify the VCN for use with an Oracle Cloud Infrastructure Service Gateway:

  – In **Virtual cloud network** field select the VCN that you want to grant access from. If you do not have the privileges to see the VCNs in your tenancy this list is empty. In this case use the selection **Virtual cloud network (OCID)** to specify the OCID of the VCN.

  – Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.
- **Virtual cloud network (OCID)**:
  Use this option when the network route from the client to the database is going through an Oracle Cloud Infrastructure Service Gateway. See Access to Oracle Services: Service Gateway for more information.

  – In the **Values** field enter the OCID of the VCN you want to grant access from.

  – Optionally, in the **IP addresses or CIDRs** field enter private IP addresses or private CIDR blocks as a comma separated list to allow specific clients in the VCN.

If you want to specify multiple IP addresses or CIDR ranges within the same VCN, do not create multiple ACL entries. Use one ACL entry with the values for the multiple IP addresses or CIDR ranges separated by commas.

3. Complete the remaining private endpoint configuration steps.

Use a Private Endpoint with Public Access Allowed

Select the **Allow public access** option when you want to configure an Autonomous Database to use a private endpoint and you also want to allow connections from specific public IP addresses or from specific VCNs (if the VCNs are configured to privately connect to Autonomous Database using a Service Gateway).

This option adds a public endpoint for a database that is configured on a private endpoint. You configure a private endpoint for your Autonomous Database instance when you provision or clone the instance, or when you update the network configuration for an existing Autonomous Database. See the following for details on the steps to configure an Autonomous Database instance with a private endpoint:

- Configure Private Endpoints When You Provision or Clone an Instance
- Change from Public to Private Endpoints with Autonomous Database

When public access is enabled with **Allow public access** on a private endpoint database, the instance has both a private endpoint and a public endpoint:

- The private hostname, endpoint URL, and private IP address allow you to connect to the database from the VCN where the database resides.
- The public hostname allows you to connect to the database from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway.

Autonomous Database Connection String Additions for a Private Endpoint Database with Allow Public Access Enabled

When **Allow public access** is enabled for a private endpoint database, there are additional connection strings that allow you to connect to the database from the public endpoint:

- The connection strings in `tnsnames.ora` in the Autonomous Database wallet zip include the public connection strings to use with connections coming from the public internet. The connection strings for the public endpoint use the following naming convention:

  dbname`_public_`*consumerGroup*

  For example:

  ```
  adbfinance_public_low
  ```

  See Download Client Credentials (Wallets) for more information.
- You can view the connection strings for both the public endpoint and the private endpoint from the Oracle Cloud Infrastructure Console (or using the API).

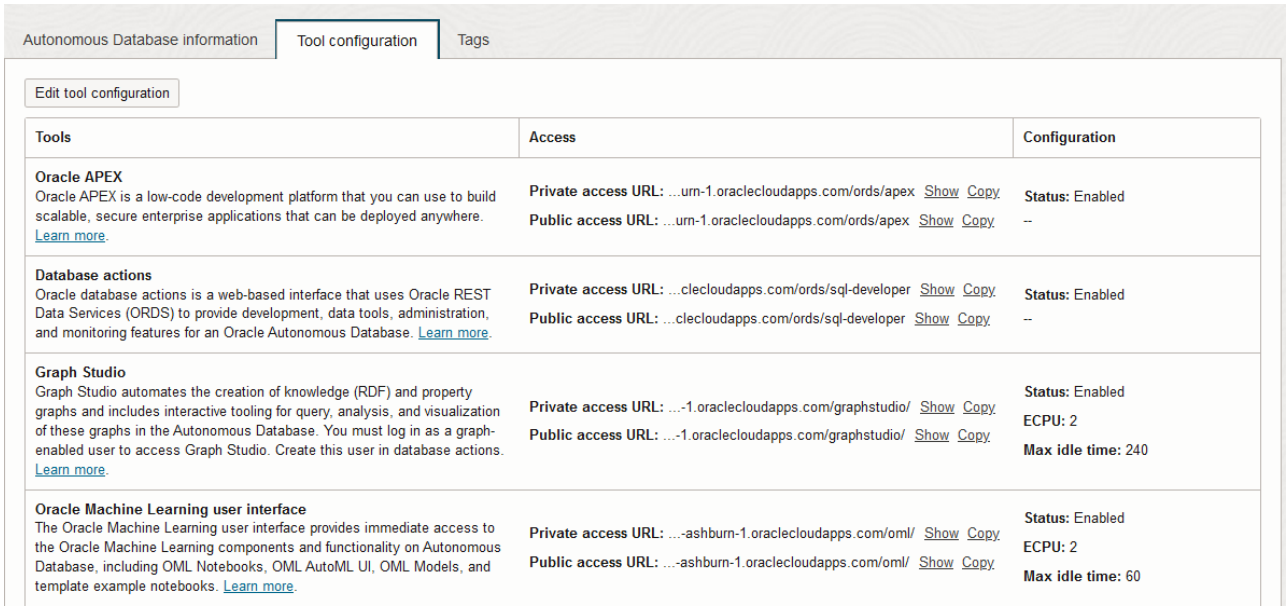
  See View TNS Names and Connection Strings for an Autonomous Database Instance for more information.

Autonomous Database Tools Additions for a Private Endpoint Database with Allow Public Access Enabled

When **Allow public access** is enabled for a private endpoint database, the database tools allow you to connect from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway:

- Each tool has a private access URL and a public access URL displayed in the Tool configuration table. Use the public access URL to access the tool from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway.

  For example:



See View Autonomous Database Built-in Tools Status for more information.

- The `README` file in the wallet zip file provides both an Access Link for the private endpoint for each database tool and a Public Access Link.

  See Wallet README File for more information.

Enhanced Security for Outbound Connections with Private Endpoints

When you use a private endpoint with your Autonomous Database instance you can provide enhanced security by setting the `ROUTE_OUTBOUND_CONNECTIONS` database property to the value `PRIVATE_ENDPOINT`.

Setting the `ROUTE_OUTBOUND_CONNECTIONS` database property to the value `PRIVATE_ENDPOINT` enforces that all outgoing connections to a target host are subject to and limited by the private endpoint's egress rules. You define egress rules in the Virtual Cloud Network (VCN) security list or in the Network Security Group (NSG) associated with the Autonomous Database instance private endpoint.

Before you set the `ROUTE_OUTBOUND_CONNECTIONS` database property, configure your Autonomous Database instance to use a private endpoint. See Configure Private Endpoints for more information.

Set the `ROUTE_OUTBOUND_CONNECTIONS` database property to `PRIVATE_ENDPOINT` to specify that all outgoing connections are subject to the Autonomous Database instance private endpoint VCN's egress rules. With the value `PRIVATE_ENDPOINT` the database restricts outgoing connections to locations specified by the private endpoint's egress rules and also changes DNS resolution such that hostnames are resolved using your VCN's DNS resolver (not using a public DNS resolver).

> **Note:**
>
> With `ROUTE_OUTBOUND_CONNECTIONS` not set to `PRIVATE_ENDPOINT`, all outgoing connections to the public internet pass through the Network Address Translation (NAT) Gateway of the service VCN. In this case, if the target host is on a public endpoint the outgoing connections are not subject to the Autonomous Database instance private endpoint VCN or NSG egress rules.

When you configure a private endpoint for your Autonomous Database instance and set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, this setting changes the handling of outbound connections and DNS resolution for the following:

- Database links
- APEX_LDAP, APEX_MAIL, and APEX_WEB_SERVICE
- UTL_HTTP, UTL_SMTP, and UTL_TCP
- DBMS_LDAP
- CMU with Microsoft Active Directory

  See Use Microsoft Active Directory with Autonomous Database for more information.

When you configure a private endpoint for your Autonomous Database instance and set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, this setting does not change the handling of outbound connections and DNS resolution for the following:

- Oracle REST Data Services (ORDS)
- Database Actions

To set `ROUTE_OUTBOUND_CONNECTIONS`:

1. Connect to your database.
2. Set the database property `ROUTE_OUTBOUND_CONNECTIONS`.

   For example:

   ```
   ALTER DATABASE PROPERTY SET ROUTE_OUTBOUND_CONNECTIONS =
   'PRIVATE_ENDPOINT';
   ```

Notes for setting `ROUTE_OUTBOUND_CONNECTIONS`:

- Use the following command to restore the default parameter value:

  ```
  ALTER DATABASE PROPERTY SET ROUTE_OUTBOUND_CONNECTIONS = '';
  ```

- Use the following command to query the current parameter value:

  ```
  SELECT * FROM DATABASE_PROPERTIES
          WHERE PROPERTY_NAME = 'ROUTE_OUTBOUND_CONNECTIONS';
  ```

  If the property is not set the query does not return results.

- This property only applies for database links that you create after you set the property to the value `PRIVATE_ENDPOINT`. Thus, database links that you created prior to setting the property continue to use the NAT Gateway of the service VCN and are not subject to the Autonomous Database instance private endpoint's egress rules.

- Only set `ROUTE_OUTBOUND_CONNECTIONS` to the value `PRIVATE_ENDPOINT` when you are using Autonomous Database with a private endpoint.
- When your database is on a private endpoint and you want your outbound connections to be resolved by your VCN, you need to set the `ROUTE_OUTBOUND_CONNECTIONS` parameter to `PRIVATE_ENDPOINT`.

See NAT Gateway for more information on Network Address Translation (NAT) gateway.

Private Endpoints Notes

Describes restrictions and notes for private endpoints on Autonomous Database.

- After you update the network access to use a private endpoint, or after the provisioning or cloning completes where you configure a private endpoint, you can view the network configuration on the Autonomous Database Details page under the **Network** section.

  The **Network** section shows the following information for a private endpoint:

  - **Access type**: Specifies the access type for the Autonomous Database configuration. Private endpoint configurations show the access type: **Virtual cloud network**.
  - **Availability domain**: Specifies the availability domain of your Autonomous Database instance.
  - **Virtual cloud network**: This includes a link for the VCN associated with the private endpoint.
  - **Subnet**: This includes a link for the subnet associated with the private endpoint.
  - **Private endpoint IP**: Shows the private endpoint IP for the private endpoint configuration.
  - **Private endpoint URL**: Shows the private endpoint URL for the private endpoint configuration.
  - **Network security groups**: This field includes links to the NSG(s) configured with the private endpoint.
  - **Public access**: This field indicates whether public access is enabled for the private endpoint. Click the `Edit` link to view or change the allowed ACLs or VCNs.
  - **Public endpoint URL**: This shows when **Allow public access** is enabled on the private endpoint. This is the public endpoint URL that you can use to connect from allowed IPs or VCNs on the public internet.

  For more details on the network information on the Oracle Cloud Infrastructure Console, see View Network Information on the OCI Console.

- After provisioning or cloning completes, you can change the Autonomous Database configuration to use a public endpoint.

  See Change from Private to Public Endpoints with Autonomous Database for information on changing to a public endpoint.

- You can specify up to five NSGs to control access to your Autonomous Database.
- You can change the private endpoint Network Security Group (NSG) for the Autonomous Database.

  To change the NSG for a private endpoint, do the following:

  1. On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

2. On the **Autonomous Database Details** page, under **Network** in the **Network Security Groups** field, click **Edit**.

- You can connect your Oracle Analytics Cloud instance to your Autonomous Database that has a private endpoint using the Data Gateway like you do for an on-premises database. See Configure and Register Data Gateway for Data Visualization for more information.
- The following Autonomous Database tools are supported in databases configured with a private endpoint:
  - Database Actions
  - Oracle APEX
  - Oracle Graph Studio
  - Oracle Machine Learning Notebooks
  - Oracle REST Data Services
  - Oracle Database API for MongoDB

  Additional configuration is required to access these Autonomous Database tools from on-premises environments. See Example: Connecting from Your Data Center to Autonomous Database to learn more.

  Accessing Oracle APEX, Database Actions, Oracle Graph Studio, or Oracle REST Data Services using a private endpoint from on-premises environments without completing the additional private endpoint configuration shows the error:

  ```
  404 Not Found
  ```
- After you update the network access to use a private endpoint, the URL for the Database Tools is different compared to using a public endpoint. You can find the updated URLs on the console, after changing from a public endpoint to a private endpoint.
- In addition to the default Oracle REST Data Services (ORDS) preconfigured with Autonomous Database, you can configure an alternative ORDS deployment that provides more configuration options and that can be used with private endpoints. See About Customer Managed Oracle REST Data Services on Autonomous Database to learn about an alternative ORDS deployment that can be used with private endpoints.
- Modifying a private IP address is not allowed after you provision or clone an instance, whether the IP address is automatically assigned when you enter a value in the **Private IP address** field.

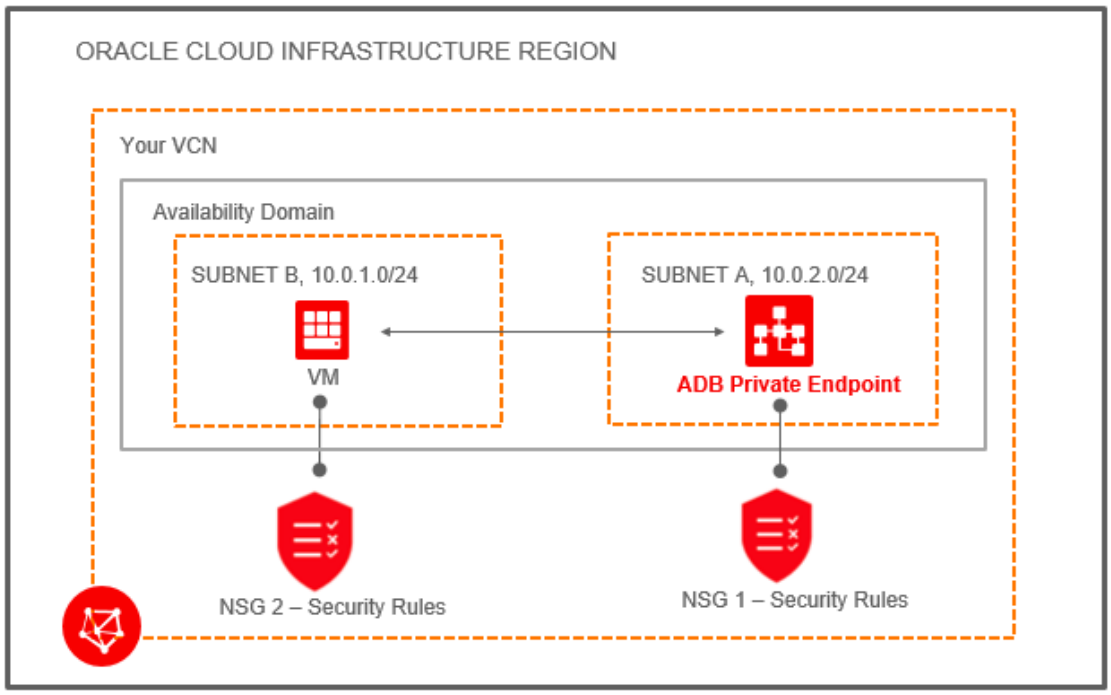
Private Endpoints Configuration Examples on Autonomous Database

Shows several Private Endpoint (VCN) configuration samples for Autonomous Database.

- Example: Connecting from Inside Oracle Cloud Infrastructure VCN
  Demonstrates an application running inside Oracle Cloud Infrastructure on a virtual machine (VM) in the same VCN which is configured with your Autonomous Database.
- Example: Connecting from Your Data Center to Autonomous Database
  Demonstrates how to connect privately to an Autonomous Database from your on-premise data center. In this scenario, traffic never goes over the public internet.

Example: Connecting from Inside Oracle Cloud Infrastructure VCN

Demonstrates an application running inside Oracle Cloud Infrastructure on a virtual machine (VM) in the same VCN which is configured with your Autonomous Database.

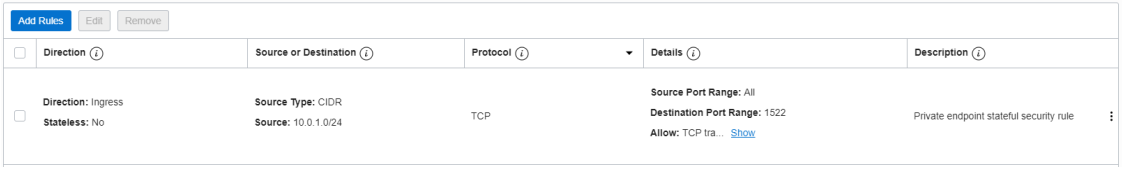


There is an Autonomous Database instance which has a private endpoint in the VCN named "Your VCN". The VCN includes two subnets: "SUBNET B" (CIDR 10.0.1.0/24) and "SUBNET A" (CIDR 10.0.2.0/24).

The Network Security Group (NSG) associated with the Autonomous Database instance is shown as "NSG 1 - Security Rules". This Network Security Group defines security rules that allow incoming and outgoing traffic to and from the Autonomous Database instance. Define a rule for the Autonomous Database instance as follows:

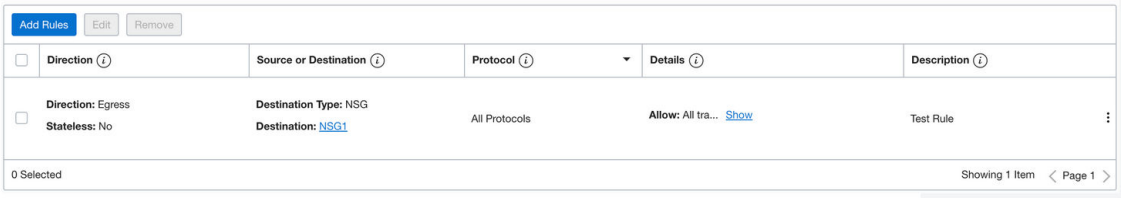
- For Mutual TLS authentication, add a stateful ingress rule to allow connections from the source to the Autonomous Database instance; the source is set to the address range you want to allow to connect to your database, IP Protocol is set to TCP, and the Destination Port Range is set to 1522.
- For TLS authentication, add a stateful ingress rule to allow connections from the source to the Autonomous Database instance; the source is set to the address range you want to allow to connect to your database, IP Protocol is set to TCP, and the Destination Port Range is set to either 1521 or 1522.
- To use Oracle APEX, Database Actions, and Oracle REST Data Services, add port 443 to the NSG rule.

The following figure shows a sample stateful security rule to control traffic for the Autonomous Database instance:



The application connecting to the Autonomous Database is running on a VM in SUBNET B. You also add a security rule to allow traffic to and from the VM (as shown, with label "NSG 2 Security Rules"). You can use a stateful security rule for the VM, so simply add a rule for egress to NSG 2 Security Rules (this allows access to the destination subnet A).

The following figure shows sample security rules that control traffic for the VM:

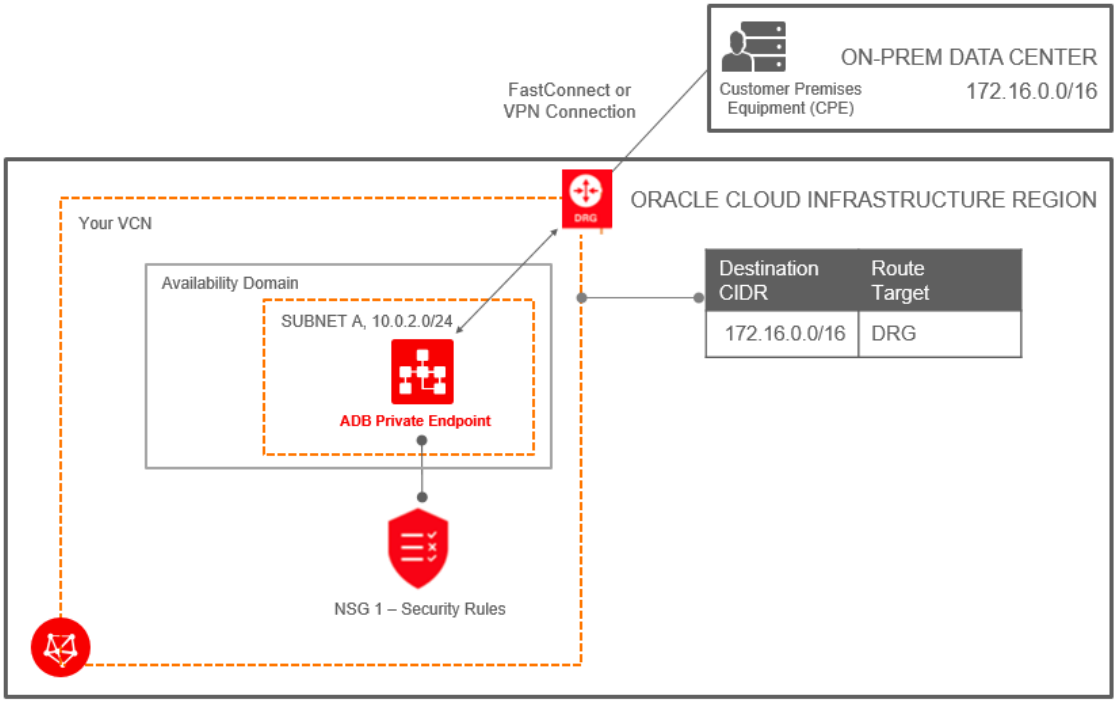


After you configure the security rules, your application can connect to the Autonomous Database instance using the client credentials wallet. See Download Client Credentials (Wallets) for more information.

See Network Security Groups for information on configuring Network Security Groups.

Example: Connecting from Your Data Center to Autonomous Database

Demonstrates how to connect privately to an Autonomous Database from your on-premise data center. In this scenario, traffic never goes over the public internet.



To connect from your data center, you connect the on-premise network to the VCN with FastConnect and then set up a Dynamic Routing Gateway (DRG). To resolve the Autonomous Database private endpoint, a Fully Qualified Domain Name (FQDN), requires that you add an entry in your on-premise client's hosts file. For example, `/etc/hosts` file for Linux machines. For example:

```
/etc/hosts entry -> 10.0.2.7 example.adb.ca-toronto-1.oraclecloud.com
```

To use Oracle APEX, Database Actions, and Oracle REST Data Services, add another entry with the same IP. For example:

```
/etc/hosts entry -> 10.0.2.7 example.adb.ca-toronto-1.oraclecloudapps.com
```

You find the private endpoint IP and the FQDN as follows:

- The Private IP is shown on the Oracle Cloud Infrastructure console Autonomous Database details page for the instance.
- The FQDN is shown in the `tnsnames.ora` file in the Autonomous Database client credential wallet.

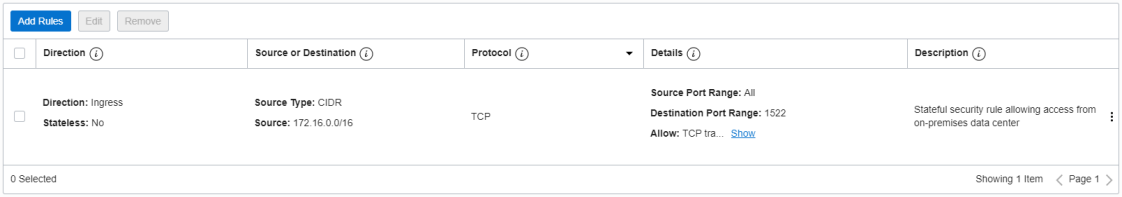
Alternatively you can use Oracle Cloud Infrastructure private DNS to provide DNS name resolution. See Private DNS for more information.

In this example there is a Dynamic Routing Gateway (DRG) between the on-premise data center and "Your VCN". The VCN contains the Autonomous Database. This also shows a route table for the VCN associated with the Autonomous Database, for outgoing traffic to CIDR 172.16.0.0/16 through the DRG.

In addition to setting up the DRG, define a Network Security Group (NSG) rule to allow traffic to and from the Autonomous Database, by adding a rule for the data center CIDR range (172.16.0.0/16). In this example, define a security rule in "NSG 1" as follows:

- For Mutual TLS authentication, create a stateful rule to allow ingress traffic from the data center. This is a stateful ingress rule with the source set to the address range you want to allow to connect to your database, protocol set to TCP, source port range set to CIDR range (172.16.0.0/16), and destination port set to 1522.
- For TLS authentication, create a stateful rule to allow ingress traffic from the data center. This is a stateful ingress rule with the source set to the address range you want to allow to connect to your database, protocol set to TCP, source port range set to CIDR range (172.16.0.0/16), and destination port set to either 1521 or 1522.
- To use Oracle APEX, Database Actions, and Oracle REST Data Services, add port 443 to the NSG rule.

The following figure shows the security rule that controls traffic for the Autonomous Database instance:



After you configure the security rule, your on-premise database application can connect to the Autonomous Database instance using the client credentials wallet. See Download Client Credentials (Wallets) for more information.

Use Zero Trust Packet Routing on Autonomous Database

Oracle Cloud Infrastructure Zero Trust Packet Routing (ZPR) protects sensitive data from unauthorized access through intent-based security policies that you write for resources, such as an Autonomous Database on a private endpoint, that you assign security attributes to.

Security attributes are labels that ZPR uses to identify and organize resources. ZPR enforces policy at the network level each time access is requested regardless of potential network architecture changes or misconfigurations. You can write ZPR based policies in your tenancy to ensure an Autonomous Database instance on a private endpoint is only accessed by authorized users/resources. ZPR is built on top of existing network security group (NSG) and security control list (SCL) rules. For a packet to reach a target, it must pass all NSG and SCL rules, and ZPR policies. If any NSG, SCL, or ZPR rule or policy doesn't allow traffic, the request is dropped.

> **Note:**
>
> On Autonomous Database Zero Trust Packet Routing (ZPR) applies only for incoming connections when the instance is configured with a private endpoint. See Configure Private Endpoints for more information.

You can secure networks with Zero Trust Packet Routing (ZPR) in three steps:

1. Create and manage security attribute namespaces and security attributes
2. Write policies using security attributes to control access to resources
3. Apply security attributes to specified resources

Avoid entering confidential information when assigning descriptions, tags, security attributes, or friendly names to cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

You have the following options to apply Zero Trust Packet Routing (ZPR) security attributes to a private endpoint on Autonomous Database:

- Apply security attributes when you provision an Autonomous Database instance and you choose **Private endpoint access only** network access during provisioning. See Provision an Autonomous Database Instance for more information.
- Apply security attributes when you clone an Autonomous Database instance and you choose **Private endpoint access only** network access during cloning. See Clone an Autonomous Database Instance for more information.
- Apply security attributes to a private endpoint on an existing Autonomous Database instance. See Configure Zero Trust Packet Routing (ZPR) for a Private Endpoint for more information.

See Getting Started with Zero Trust Packet Routing for more information.

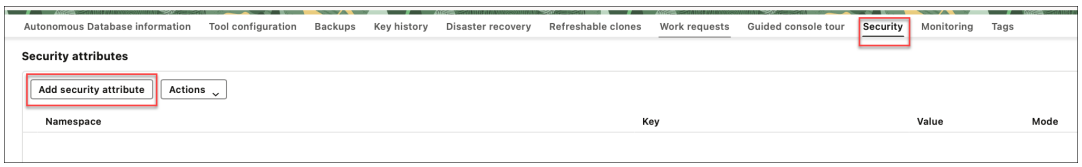
- Configure Zero Trust Packet Routing (ZPR) for a Private Endpoint
  Shows the steps to configure Zero Trust Packet Routing (ZPR) for a private endpoint.

Configure Zero Trust Packet Routing (ZPR) for a Private Endpoint

Shows the steps to configure Zero Trust Packet Routing (ZPR) for a private endpoint.

Set or change the values for ZPR security attributes on an existing Autonomous Database instance configured with a private endpoint as follows:

1. From the Oracle Cloud Infrastructure Console, on the Autonomous Database Details page, select the **Security** tab.



2. Click **Add security attributes**.
3. In the Add security attributes dialog, select a **Namespace** and enter a **Key** and a **Value**.
4. Optionally click **Add security attribute** to add additional security attributes.

5. Click **Add security attributes** to confirm.

Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database

Describes how to update the secure client connection authentication options, Mutual TLS (mTLS) and TLS.

- Network Access Prerequisites for TLS Connections
  Describes the network access configuration prerequisites for TLS connections.
- Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication
- Update your Autonomous Database Instance to Require mTLS and Disallow TLS Authentication
  If your Autonomous Database instance is configured to allow TLS connections, you can update the instance to require mTLS connections and disallow TLS connections.

Network Access Prerequisites for TLS Connections

Describes the network access configuration prerequisites for TLS connections.

To allow an Autonomous Database instance to use TLS connections, either ACLs must be defined or a private endpoint must be configured:

- When an Autonomous Database instance is configured to operate over the public internet, one or more Access Control Lists (ACLs) must be defined before you use TLS authentication to connect to the database. To validate that ACLs are defined, in the **Network** area on the Autonomous Database Details page view the **Access Control List** field. This field shows **Enabled** when ACLs are defined and shows **Disabled** when ACLs are not defined.

  See Configuring Network Access with Access Control Rules (ACLs) for more information.
- When an Autonomous Database instance is configured with a private endpoint you can use TLS authentication to connect to the database. To validate that a private endpoint is defined, in the **Network** area on the Autonomous Database Details page view the **Access type** field. This field shows **Virtual Cloud Network** when a private endpoint is defined.

  See Configure Network Access with Private Endpoints for more information.

> **Note:**
>
> When an Autonomous Database instance is configured with the network access type: **Secure access from everywhere**, you can only use TLS connections to connect to the database if you specify ACLs to restrict access.

Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication

If your Autonomous Database instance is configured to only allow mTLS connections, you can update the instance to allow both mTLS and TLS connections.

When you update your configuration to allow both mTLS and TLS, you can use both authentication types at the same time and connections are no longer restricted to require mTLS authentication.

You can allow TLS connections when network access is configured as follows:

- With network access configured with ACLs defined.
- With network access configured with a private endpoint defined.

> **Note:**
>
> When you configure your Autonomous Database instance network access with ACLs or a private endpoint, the ACLs or the private endpoint apply for both mTLS and TLS connections.

Perform the network access configuration prerequisites. See Network Access Prerequisites for TLS Connections for more information.

Perform the following steps as necessary:

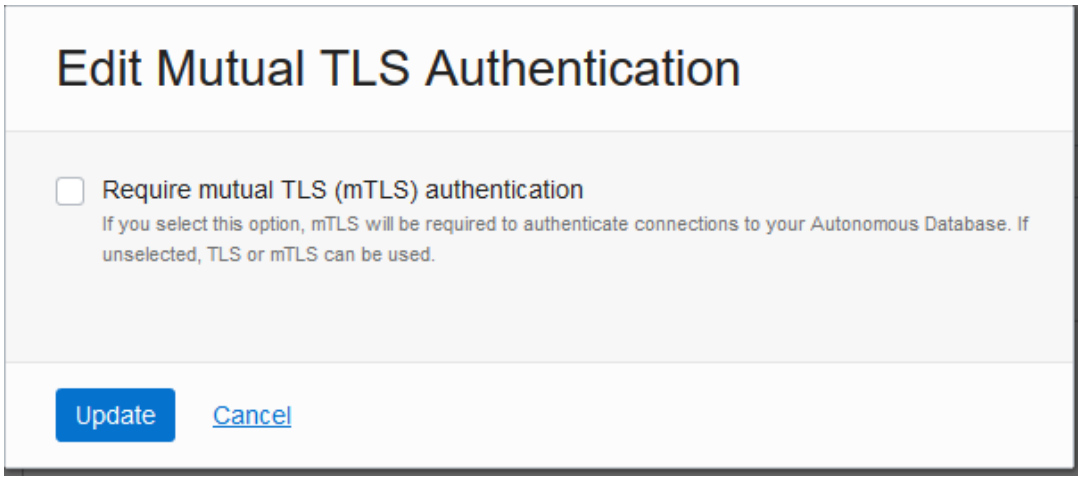
- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To change the Autonomous Database instance to allow TLS authentication, do the following:

1. On the **Autonomous Database Details** page, under **Network**, click **Edit** in the **Mutual TLS (mTLS) Authentication** field.

   This shows the Edit Mutual TLS Authentication page.

2. To change the value to allow TLS authentication, deselect **Require mutual TLS (mTLS) authentication**.



3. Click **Update**.

   The Autonomous Database Lifecycle state changes to **Updating**.

   After some time, the **Lifecycle state** shows **Available** and the **Mutual TLS (mTLS) Authentication** field changes to show **Not Required**.

After you define ACLs or configure a private endpoint and the **Mutual TLS (mTLS) Authentication** field shows **Not Required**, the ACLs or the private endpoint you specify apply to all connection types (mTLS and TLS).

Depending on the type of client, TLS connections have the following support with Autonomous Database:

- If the client is connecting with JDBC Thin using TLS authentication, the client can connect without providing a wallet. See Connect with JDBC Thin Driver for more information.
- If the client is connecting with managed ODP.NET or ODP.NET Core versions 19.13 or 21.4 (or above) using TLS authentication, the client can connect without providing a wallet. See Connect Microsoft .NET, Visual Studio Code, and Visual Studio Without a Wallet for more information.
- If the client is connecting with SQLNet and Oracle Call Interface (OCI), and for certain other connection types with TLS authentication, the clients must provide the CA certificate in a wallet. See Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication and Connect SQL*Plus Without a Wallet for more information.

Update your Autonomous Database Instance to Require mTLS and Disallow TLS Authentication

If your Autonomous Database instance is configured to allow TLS connections, you can update the instance to require mTLS connections and disallow TLS connections.

> **Note:**
>
> When you update an Autonomous Database instance to require Mutual TLS (mTLS) connections, existing TLS connections are disconnected.

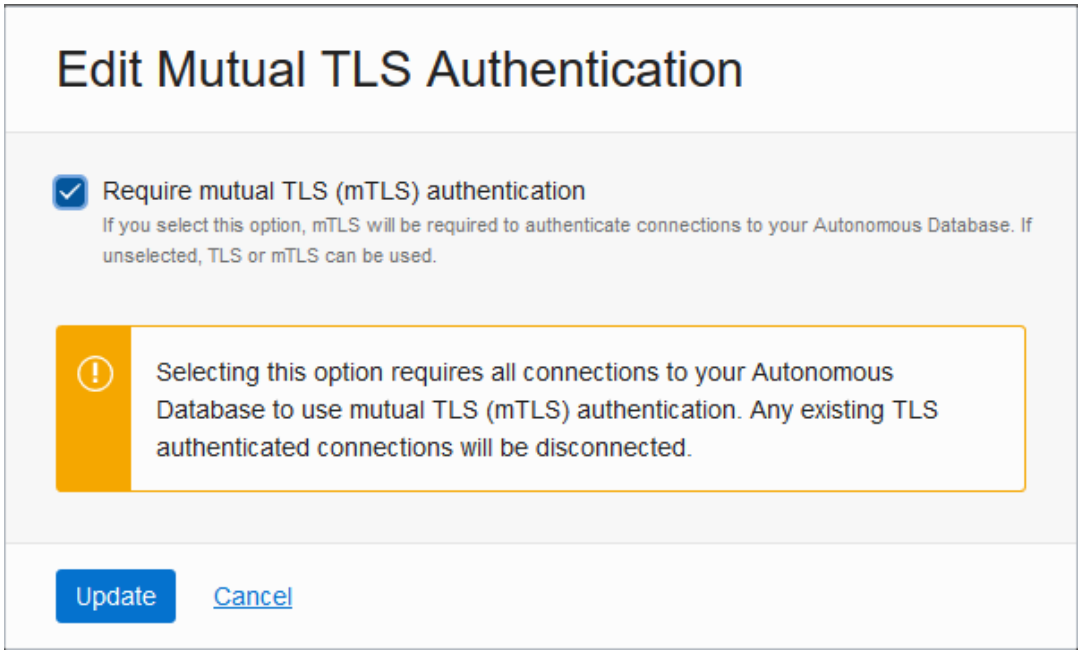
Perform the following steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To change the Autonomous Database instance to require mTLS authentication and to not allow TLS authentication, do the following:

1. On the **Autonomous Database Details** page, under **Network**, click **Edit** in the **Mutual TLS (mTLS) Authentication** field.

   This shows the Edit Mutual TLS Authentication page.
2. Select **Require mutual TLS (mTLS) authentication**.



3. Click **Update**.

   The Autonomous Database Lifecycle state changes to **Updating**.

   After some time, the **Lifecycle state** shows **Available** and the **Mutual TLS (mTLS) Authentication** field changes to show **Required**.

Audit Autonomous Database

Autonomous Database provides auditing that allows you to monitor Oracle database activities.

- About Auditing Autonomous Database
  Autonomous Database provides auditing to track, monitor, and record database actions. Auditing can help you detect security risks and improve regulatory compliance for your database.
- Register Oracle Data Safe on Autonomous Database
  Use Oracle Data Safe to apply auditing policies for database users, for administrative users, to apply predefined auditing policies or to extend the audit data record retention for your Autonomous Database instance.
- Extend Audit Record Retention with Oracle Data Safe on Autonomous Database
  Use Oracle Data Safe to extend the audit data record retention to a specified number of months.
- View and Manage Oracle Data Safe Audit Trails on Autonomous Database
  Data Safe uses audit trails to define where to retrieve the audit data and to collect Autonomous Database audit records. During the registration process, Oracle Data Safe discovers the audit trails and creates an audit trail resource.
- View and Manage Audit Policies with Oracle Data Safe on Autonomous Database
  Use Oracle Data Safe to set audit policies for your Autonomous Database instance.
- Generate Audit Reports with Data Safe on Autonomous Database
  Data Safe includes out-of-box audit data reports, and you can create custom reports to suit your needs.

About Auditing Autonomous Database

Autonomous Database provides auditing to track, monitor, and record database actions. Auditing can help you detect security risks and improve regulatory compliance for your database.

- Audit Features on Autonomous Database
  Autonomous Database includes extensive, sophisticated audit capabilities that allow you capture the audit information you need for your organization. Autonomous Database provides default auditing.
- Audit Data on Autonomous Database
  Autonomous Database protects audit data and writes its audit trail to the `UNIFIED_AUDIT_TRAIL` data dictionary view.
- Default Audit Policies on Autonomous Database
  Autonomous Database provides auditing to track, monitor, and record activities on your database.

Audit Features on Autonomous Database

Autonomous Database includes extensive, sophisticated audit capabilities that allow you capture the audit information you need for your organization. Autonomous Database provides default auditing.

In addition, you can use either of the following to apply auditing policies:

- Use Oracle Data Safe to apply auditing policies for database users, for administrative users, and to apply predefined auditing policies or to apply customized auditing policies. See Activity Auditing Overview for more information.
- Configure Oracle Database Audit Policies. See Configuring Audit Policies for more information.

You can configure auditing to accomplish the following:

- Enable accountability for actions. These include actions taken in a particular schema, table, or row, or affecting specific content.
- Deter users, or others, such as intruders, from inappropriate actions based on their accountability.
- Investigate suspicious activity. For example, if a user is logging into the database using the application's database credentials, then auditing connections to the database lets you determine that the login came from a user's workstation instead of from the application server.
- Notify an auditor of the actions of an unauthorized user. For example, notify an auditor when an unauthorized user attempts to delete data from a table.
- Monitor and gather data about specific database activities. For example, you can gather statistics about which tables are being updated, the number of failed logins, or how many concurrent users connect at peak times.
- Detect problems with an authorization or access control implementation. For example, you can create audit policies that you expect will never generate an audit record because the data is protected in other ways. However, if these policies generate audit records, then you will know the other security controls are not properly implemented.
- Address auditing requirements for compliance. Regulations such as the following have common auditing-related requirements:

- European Union General Data Protection Regulation (GDPR)
- Sarbanes-Oxley Act
- Health Insurance Portability and Accountability Act (HIPAA)
- International Convergence of Capital Measurement and Capital Standards: a Revised Framework (Basel II)
- Japan Privacy Law
- European Union Directive on Privacy and Electronic Communications

Audit Data on Autonomous Database

Autonomous Database protects audit data and writes its audit trail to the `UNIFIED_AUDIT_TRAIL` data dictionary view.

The underlying table storing audit data on Autonomous Database is `AUDSYS.AUD$UNIFIED`. This table is protected and does not allow users to perform DML/DDL operations or to purge the table (any attempt to perform these actions automatically produces an audit record). After an audit record is written, the only activity allowed is for the ADMIN user to perform a `PURGE`. The ADMIN has the AUDIT_ADMIN role that is required to run a `PURGE`. If you assign the AUDIT_ADMIN role to another user, then that user could also perform a `PURGE`.

Depending on the number and type of audit policies you use and the amount of activity, over time the audit trail can grow to use a large amount of storage. Autonomous Database provides the following ways to limit the storage required for audit data:

- Each Autonomous Database instance runs an automated purge job once a day to remove all audit records older than fourteen (14) days.
- Users with the AUDIT_ADMIN role can purge audit records manually using the `DBMS_AUDIT_MGMT.CLEAN_AUDIT_TRAIL` procedure. See DBMS_AUDIT_MGMT for more information.

If you need a longer audit data retention period than 14 days, use Oracle Data Safe to retain audit data. See Extend Audit Record Retention with Oracle Data Safe on Autonomous Database for more information.

Autonomous Database audits and logs every operation carried out in your database by the Oracle Cloud Infrastructure Operations teams. See View Oracle Cloud Infrastructure Operations Actions for more information on how to audit Operations activities.

Default Audit Policies on Autonomous Database

Autonomous Database provides auditing to track, monitor, and record activities on your database.

By default, Autonomous Database applies audit policies to audit the following database activities:

- All activity by Oracle Cloud Operations
- All login failures to the database
- All password changes
- Attempts to create or alter procedures
- Execution of certain procedures, including procedures in the packages: `UTL_HTTP` or `UTL_SMTP` that connect to the network

In addition, you can use either of the following to apply additional auditing policies:

- Use Oracle Data Safe to apply auditing policies for database users, for administrative users, and to apply predefined auditing policies or to apply customized auditing policies. For more information, see:
  - View and Manage Audit Trails
  - View and Manage Audit Policies
- Configure Oracle Database Audit Policies. See Configuring Audit Policies for more information.

Register Oracle Data Safe on Autonomous Database

Use Oracle Data Safe to apply auditing policies for database users, for administrative users, to apply predefined auditing policies or to extend the audit data record retention for your Autonomous Database instance.

Register your Autonomous Database instance with Oracle Data Safe as follows:

1. Access your Autonomous Database instance from the Oracle Cloud Infrastructure Console.
   a. Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Oracle Cloud.
   b. From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
   c. On the Autonomous Databases page select an Autonomous Database from the links under the **Display Name** column.
2. Register your Autonomous Database instance with Oracle Data Safe.
   a. On the Autonomous Database Details page, under **Data Safe**, click **Register**.

   b. In the Register database with Data Safe dialog, click **Confirm**.

   The Data Safe status shows: **Registering**. This step takes about 15 to 20 minutes.

After Oracle Data Safe is registered, the Data Safe status shows **Registered** and two links: **View** and **Deregister**.

Click **View** to show the Data Safe register database details page.

Click **Deregister** to disable Oracle Data Safe.

Extend Audit Record Retention with Oracle Data Safe on Autonomous Database

Use Oracle Data Safe to extend the audit data record retention to a specified number of months.

First register your Autonomous Database instance with Oracle Data Safe. See Register Oracle Data Safe on Autonomous Database for more information.

After your Autonomous Database instance is registered, you can specify the Data Safe retention period.

See Update Retention Periods for a Target Database for more information.

View and Manage Oracle Data Safe Audit Trails on Autonomous Database

Data Safe uses audit trails to define where to retrieve the audit data and to collect Autonomous Database audit records. During the registration process, Oracle Data Safe discovers the audit trails and creates an audit trail resource.

Oracle Data Safe lists resources on the Audit Trails page. To access the Audit Trails page, under Security Center in Data Safe click **Activity Auditing**, and then, on the Activity Auditing page under **Related Resources** click **Audit Trails**. You can discover new audit trails at any time and remove audit trail resources in Oracle Data Safe as needed.

First register your Autonomous Database instance with Oracle Data Safe. See Register Oracle Data Safe on Autonomous Database for more information.

When the Autonomous Database is stopped or restarted, the following happens:

- The audit trail switches to a retrying state and Data Safe makes multiple attempts to reconnect for four (4) hours. The Audit Trail **Collection State** field shows: **RETRYING**.

  In this case, if the Autonomous Database (target database) starts, the audit trail automatically resumes.

- After four hours, the audit trail switches to a stopped state. The Audit Trail **Collection State** field shows: **STOPPED_NEEDS_ATTN**.

  In this case, when the Autonomous Database (target database) starts and the audit trail collection state is **STOPPED_NEEDS_ATTN**, you can manually resume the audit trail.

You can also manually stop or delete the audit trail. Deleting the audit trail does not remove audit records that have already been collected. Those records remain in Data Safe until the retention period is reached.

See View and Manage Audit Trails for more information.

View and Manage Audit Policies with Oracle Data Safe on Autonomous Database

Use Oracle Data Safe to set audit policies for your Autonomous Database instance.

First register your Autonomous Database instance with Oracle Data Safe. See Register Oracle Data Safe on Autonomous Database for more information.

After your Autonomous Database instance is registered, access Oracle Data Safe to set audit policies.

See View and Manage Audit Policies for more information.

Generate Audit Reports with Data Safe on Autonomous Database

Data Safe includes out-of-box audit data reports, and you can create custom reports to suit your needs.

After you enable and register Oracle Data Safe, and you add a trail to collect audit data from your Autonomous Database instance, then you can use the reports to monitor activity for your database.

See View and Manage Audit Reports for more information.

Rotate Wallets for Autonomous Database

Wallet rotation lets you invalidate existing client certification keys for a database instance or for all Autonomous Database instances that a cloud account owns in a region.

- About Wallet Rotation
  You have the option to perform one of two types of wallet rotation: immediate or with a grace period.
- Rotate Wallets with Immediate Rotation
  Immediate wallet rotation lets you invalidate existing client certification keys for an Autonomous Database instance or for all Autonomous Database instances that a cloud account owns in a region.
- Rotate Wallets with Grace Period

About Wallet Rotation

You have the option to perform one of two types of wallet rotation: immediate or with a grace period.

- **Immediate** wallet rotation initiates immediately, without delay.
- **After a grace period** wallet rotation occurs with a grace period. During the grace period the old client certification keys remain valid for a selected time of 1 hour to 24 hours. After the grace period expires only the new client certification keys are valid.

You may want to rotate wallets for any of the following reasons:

- If your organization's policies require regular client certification key rotation.
- When a client certification key or a set of keys is suspected to be compromised.

Rotate Wallets with Immediate Rotation

Immediate wallet rotation lets you invalidate existing client certification keys for an Autonomous Database instance or for all Autonomous Database instances that a cloud account owns in a region.

There are two options for immediate client certification key rotation:

- Per-database with **Instance wallet** selected:

  - For the database whose certification key is rotated, any existing database specific instance wallets will be void. After you rotate a wallet you have to download a new wallet to connect to the database.
  - Regional wallets containing all database certification keys continue to work.
  - All user sessions are terminated for the database whose wallet is rotated. User session termination begins after wallet rotation completes, however this process does not happen immediately.

> **Note:**
>
> If you want to terminate all connections immediately after the wallet rotation completes, Oracle recommends that you restart the Autonomous Database instance. This provides the highest level of security for your database.

- Regional level with **Regional wallet** selected:
  - For the region whose certification key is rotated, both regional and database specific instance wallets will be void. After you rotate a wallet you have to download new regional or instance wallets to connect to any database in the region.
  - All user sessions are terminated for the databases in the region whose wallet is rotated. User session termination begins after wallet rotation completes, however this process does not happen immediately.

> **Note:**
>
> If you want to terminate all connections immediately after the wallet rotation completes, Oracle recommends that you restart the Autonomous Database instances in the region. This provides the highest level of security for your database.

To immediately rotate the client certification key for a given database or for all Autonomous Database instances that a cloud account owns in a region:

1. Navigate to the Autonomous Database details page.
2. Click **Database connection**.
3. On the **Database connection** page select the **Wallet type**:
   - **Instance wallet**: Wallet rotation for a single database only; this provides a database-specific wallet rotation.
   - **Regional wallet**: Wallet rotation for all Autonomous Databases for a given tenant and region (this option rotates the client certification key for all service instances that a cloud account owns).
4. Click **Rotate wallet**.
5. Enter the name as shown in the dialog to confirm the wallet rotation.
6. In the Rotate Wallet dialog, click **Rotate**.

The Database Connection page shows: **Rotation in Progress**.

After the rotation completes, the **Wallet last rotated** field shows the last rotation date and time.

Oracle recommends you provide a database-specific instance wallet to end users and for application use whenever possible, with Wallet type set to **Instance wallet** when you use **Download wallet**. Regional wallets should only be used for administrative purposes that require potential access to all Autonomous Databases within a region.

You can also use the Autonomous Database API to rotate wallets using `UpdateAutonomousDatabaseRegionalWallet` and `UpdateAutonomousDatabaseWallet`. See Autonomous Database Wallet Reference for more information.

Rotate Wallets with Grace Period

Autonomous Database allows you to rotate wallets for an Autonomous Database instance or for all instances that a cloud account owns in a region. with a grace period of 1 hour to 24 hours.

Setting a grace period allows you to perform wallet rotation without down time. During the grace period you can inform users to download the new wallet and to update their applications to use the new wallet. During the grace period both the old and new client certification keys are valid. When the grace period expires, Autonomous Database invalidates the old client certification keys and only the new client certification keys are valid.

There are two options for client certification key rotation with a grace period:

- Per-database with **Instance wallet** selected:
  - For the database whose certification key is rotated, database specific instance wallets that were in use before the wallet rotation be void after the grace period expires.
  - After you perform client certification key rotation with a grace period, you can immediately download a wallet and use the new wallet to connect to the database.
  - Regional wallets containing all database certification keys continue to work.
  - After the grace period expires, existing connections using the old wallet continue to work.

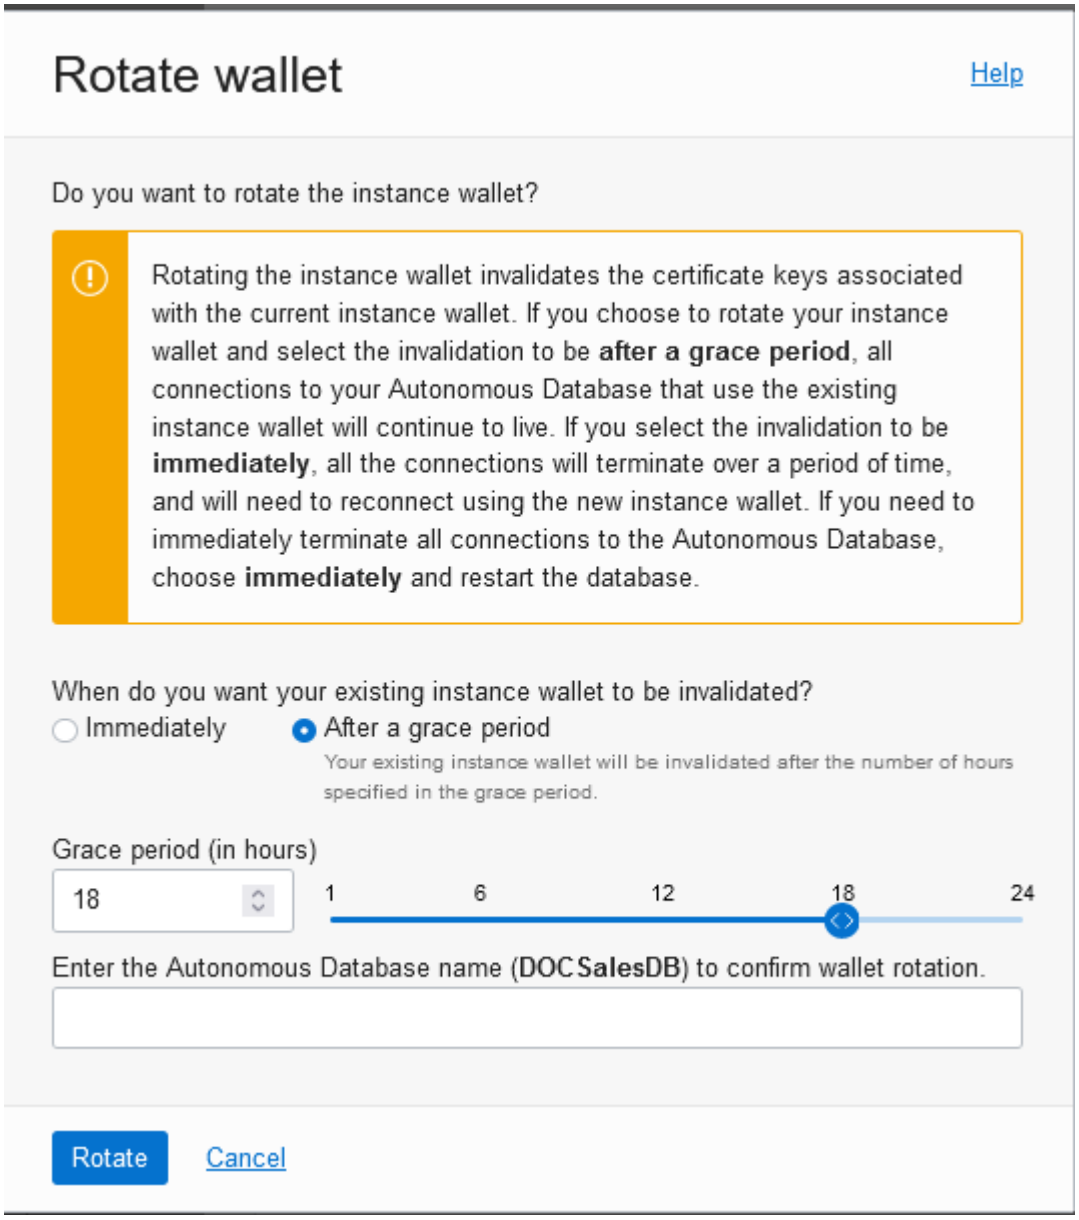
> **Note:**
>
> After the grace period completes, if you want to terminate any connections using the old wallet, Oracle recommends that you restart the Autonomous Database instance.

- Regional level with **Regional wallet** selected:
  - For the region whose certification key is rotated, both regional and database specific instance wallets will be void. After the grace period expires you have to download new regional or instance wallets to connect to any database in the region.
  - After the grace period expires, existing connections using the old wallets continue to work.

> **Note:**
>
> After the grace period completes, if you want to terminate any connections using the old wallets, Oracle recommends that you restart every Autonomous Database instance in the region.

To rotate the client certification key with a grace period for a given database or for all for all Autonomous Database instances that a cloud account owns in a region:

1. Navigate to the Autonomous Database details page.
2. Click **Database connection**.
3. On the **Database connection** page select the **Wallet type**:
   - **Instance wallet**: Wallet rotation for a single database only; this provides a database-specific wallet rotation.
   - **Regional wallet**: Wallet rotation for all Autonomous Databases for a given tenant and region (this option rotates the client certification key for all service instances in the region that a cloud account owns).
4. Click **Rotate wallet**.
5. Select **After a grace period**.
6. In the **Grace period (in hours)** area, either enter a value in the text field or use the slider to select a value.



7. Enter the name as shown in the dialog to confirm the wallet rotation.
8. In the Rotate Wallet dialog, click **Rotate**.

The Database Connection page shows: **Rotation in Progress**.

After the rotation completes, the **Wallet last rotated** field shows the last rotation date and time.

Notes for wallet rotation with a grace period:

- Always Free Autonomous Databases only support immediate wallet rotation (wallet rotation with a grace period is not supported).
- Oracle recommends you provide a database-specific instance wallet to end users and for application use whenever possible, with Wallet type set to **Instance wallet** when you use **Download wallet**. Regional wallets should only be used for administrative purposes that require potential access to all Autonomous Databases within a region.

You can also use the Autonomous Database API to rotate wallets using `UpdateAutonomousDatabaseRegionalWallet` and `UpdateAutonomousDatabaseWallet`. See Autonomous Database Wallet Reference for more information.

Use Oracle Database Vault with Autonomous Database

Oracle Database Vault implements powerful security controls for your database. These unique security controls restrict access to application data by privileged database users, reducing the risk of insider and outside threats and addressing common compliance requirements.

See What Is Oracle Database Vault? for more information.

- Oracle Database Vault Users and Roles on Autonomous Database
  Oracle Database Vault provides powerful security controls to help protect application data from unauthorized access, and to implement separation of duties between administrators and data owners to comply with privacy and regulatory requirements.
- Enable Oracle Database Vault on Autonomous Database
  Shows the steps to enable Oracle Database Vault on Autonomous Database.
- Disable Oracle Database Vault on Autonomous Database
  Shows the steps to disable Oracle Database Vault on Autonomous Database.
- Disable User Management with Oracle Database Vault on Autonomous Database
  Shows how to disallow user management related operations for specified components on Autonomous Database with Oracle Database Vault enabled.
- Enable User Management with Oracle Database Vault on Autonomous Database
  Shows the steps to allow user management for a specified component on Autonomous Database with Oracle Database Vault enabled.

Oracle Database Vault Users and Roles on Autonomous Database

Oracle Database Vault provides powerful security controls to help protect application data from unauthorized access, and to implement separation of duties between administrators and data owners to comply with privacy and regulatory requirements.

By default the ADMIN user has the `DV_OWNER` and `DV_ACCTMGR` roles. If you want to set up separate users for `DV_OWNER` and `DV_ACCTMGR` accounts. See Oracle Database Vault Schemas, Roles, and Accounts for more information.

The user management is by default enabled for the APEX component when Oracle Database Vault is enabled. When user management is enabled, the APEX users who have the necessary roles to `CREATE | ALTER | DROP` users have the needed privileges to perform these operations when Database Vault is enabled. To change this, see Disable User Management with Oracle Database Vault on Autonomous Database.

On Autonomous Database with Oracle Database Vault enabled, grant the following privileges:

- When using Oracle GoldenGate, grant the `GGADMIN` user `DV_GOLDENGATE_ADMIN` and `DV_GOLDENGATE_REDO_ACCESS`.
- The ADMIN user must grant the `BECOME USER` privilege to users who need to use Oracle Data Pump. To perform some Oracle Data Pump operations additional Oracle Database Vault authorization may be needed. For example to run a full database export or to export a realm protected schema requires using `DBMS_MACADM.AUTHORIZE_DATAPUMP_USER`.

  See AUTHORIZE_DATAPUMP_USER Procedure for more information.

- In order for `DBMS_CLOUD` credential related APIs to work when Oracle Database Vault is enabled and the credential owner's schema is protected using a Database Vault realm, you must add authorizations for the `C##CLOUD$SERVICE` user to the Database Vault realm.

  For example:

  ```
  BEGIN
      DBMS_MACADM.ADD_AUTH_TO_REALM(realm_name    => 'PROTECT_ADMIN',
          grantee       => 'C##CLOUD$SERVICE',
          rule_set_name => 'Enabled',
          auth_options  => DBMS_MACUTL.G_REALM_AUTH_PARTICIPANT);
  END;
  /
  ```

  Where *PROTECT_ADMIN* is your Oracle Database Vault realm.

  See ADD_AUTH_TO_REALM Procedure for more information.

Enable Oracle Database Vault on Autonomous Database

Shows the steps to enable Oracle Database Vault on Autonomous Database.

Oracle Database Vault is disabled by default on Autonomous Database. To configure and enable Oracle Database Vault on Autonomous Database, do the following:

1. Configure Oracle Database Vault using the following command:

   ```
   EXEC DBMS_CLOUD_MACADM.CONFIGURE_DATABASE_VAULT('adb_dbv_owner',
   'adb_dbv_acctmgr');
   ```

   Where:

   - *adb_dbv_owner* is the Oracle Database Vault owner.
   - *adb_dbv_acctmgr* is the account manager.

   See CONFIGURE_DATABASE_VAULT Procedure for more information.

2. Enable Oracle Database Vault:

   ```
   EXEC DBMS_CLOUD_MACADM.ENABLE_DATABASE_VAULT;
   ```

   See ENABLE_DATABASE_VAULT Procedure for more information.

3. Restart the Autonomous Database instance.

   See Restart Autonomous Database for more information.

Use the following command to check if Oracle Database Vault is enabled or disabled:

```
SELECT * FROM DBA_DV_STATUS;
```

Output similar to the following appears:

```
NAME                 STATUS
-------------------- -----------
```

```
DV_CONFIGURE_STATUS  TRUE
DV_ENABLE_STATUS     TRUE
```

The `DV_ENABLE_STATUS` value `TRUE` indicates Oracle Database Vault is enabled.

> **Note:**
>
> Autonomous Database maintenance operations such as backups and patching are not affected when Oracle Database Vault is enabled.

See Disable Oracle Database Vault on Autonomous Database for information on disabling Oracle Database Vault.

Disable Oracle Database Vault on Autonomous Database

Shows the steps to disable Oracle Database Vault on Autonomous Database.

To disable Oracle Database Vault on Autonomous Database, do the following:

1. Disable Oracle Database Vault.

   ```
   EXEC DBMS_CLOUD_MACADM.DISABLE_DATABASE_VAULT;
   ```

   See DISABLE_DATABASE_VAULT Procedure for more information.
2. Restart the Autonomous Database instance.

   See Restart Autonomous Database for more information.

Use the following command to check if Oracle Database Vault is enabled or disabled:

```
SELECT * FROM DBA_DV_STATUS;
```

Output similar to the following appears:

```
NAME                 STATUS
-------------------- -----------
DV_CONFIGURE_STATUS  TRUE
DV_ENABLE_STATUS     FALSE
```

The `DV_ENABLE_STATUS` value `FALSE` indicates Oracle Database Vault is disabled.

Disable User Management with Oracle Database Vault on Autonomous Database

Shows how to disallow user management related operations for specified components on Autonomous Database with Oracle Database Vault enabled.

Autonomous Database with Oracle Database Vault enabled has user management, by default, enabled for the Oracle APEX console. If you want to enforce stricter separation of duty and disallow user management from this console, use `DBMS_CLOUD_MACADM.DISABLE_USERMGMT_DATABASE_VAULT`.

1. As a user granted `DV_ACCTMGR` and `DV_ADMIN` roles you can disable user management for specified components.

2. To disable user management for a specified component, for example for the APEX component, use the following command:

```
EXEC DBMS_CLOUD_MACADM.DISABLE_USERMGMT_DATABASE_VAULT('APEX');
```

See DISABLE_USERMGMT_DATABASE_VAULT Procedure for more information.

Enable User Management with Oracle Database Vault on Autonomous Database

Shows the steps to allow user management for a specified component on Autonomous Database with Oracle Database Vault enabled.

Autonomous Database with Oracle Database Vault enabled has user management, by default, enabled for the Oracle APEX console. This allows user management for operations such as `CREATE USER`, `ALTER USER`, and `DROP USER` from the specified component in Autonomous Database.

Use `DBMS_CLOUD_MACADM.ENABLE_USERMGMT_DATABASE_VAULT` to allow specified user accounts to perform user management when Oracle Database Vault is enabled. Use this procedure if user management is disabled and you want to enable it again.

1. A user granted `DV_ACCTMGR` and `DV_ADMIN` roles can enable user management for specified components.
2. To enable user management for a specified component, for example for the APEX component, use the following command:

```
EXEC DBMS_CLOUD_MACADM.ENABLE_USERMGMT_DATABASE_VAULT('APEX');
```

See ENABLE_USERMGMT_DATABASE_VAULT Procedure for more information.

IAM Policies for Autonomous Database

Provides information on IAM policies required for API operations on Autonomous Database.

Oracle Autonomous Database relies on the IAM (Identity and Access Management) service to authenticate and authorize cloud users to perform operations that use any of the Oracle Cloud Infrastructure interfaces (the console, REST API, CLI, or SDK).

The IAM service uses **groups**, **compartments,** and **policies** to control which cloud users can access which resources.

- Policy Details for Autonomous Database
  This topic covers details for writing policies to control access to Autonomous Database resources.
- IAM Permissions and API Operations for Autonomous Database
  This topic covers the available IAM permissions for operations on Autonomous Database.
- Provide Specific Privileges in IAM Policies to Manage Autonomous Database
  Lists IAM policies that you can use with an authorization verb and a condition to grant more granular operations to a group.

Policy Details for Autonomous Database

This topic covers details for writing policies to control access to Autonomous Database resources.

A policy defines what kind of access a group of users has to a specific resource in an individual compartment. For more information, see Getting Started with Policies.

Resource-Types

An aggregate resource-type covers the list of individual resource-types that directly follow. For example, writing one policy to allow a group to have access to the `autonomous-database-family` is equivalent to writing four separate policies for the group that would grant access to the `autonomous-databases`, `autonomous-backups` resource-types. For more information, see Resource-Types.

Resource-Types for Autonomous Database
Aggregate Resource-Type:

`autonomous-database-family`

Individual Resource-Types:

`autonomous-databases`

`autonomous-backups`

Details for Verb + Resource-Type Combinations

The level of access is cumulative as you go from `inspect > read > use > manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `autonomous-databases` resource-type covers the same permissions and API operations as the `inspect` verb, plus the `AUTONOMOUS_DATABASE_CONTENT_READ` permission. The `read` verb partially covers the `CreateAutonomousDatabaseBackup` operation, which also needs manage permissions for `autonomous-backups`.

The following tables show the Permissions and API operations covered by each verb. For information about permissions, see Permissions.

> **Note:**
>
> The resource family covered by **autonomous-database-family** can be used to grant access to database resources associated with all the Autonomous Database workload types.

autonomous-databases Resource Types

Verbs	Permissions	APIs Fully Covered	APIs Partially Covered
inspect	AUTONOMOUS_DATABASE_INSPECT	GetAutonomousDatabase, GetAutonomousDatabaseBackupConfig, GetAutonomousDatabaseCapability, ListAutonomousDatabases, ListAutonomousDatabaseClones, ListAutonomousDatabasePeers, ListAutonomousDatabaseRefreshableClones, ResourcePoolShapes	*none*
read	*INSPECT* + AUTONOMOUS_DATABASE_CONTENT_READ	GenerateAutonomousDatabasePerformanceData, GenerateAutonomousDatabaseWallet, GetAutonomousDatabaseRegionalWallet, GetAutonomousDatabaseWallet, RetrieveDatabasePerformanceBulkData	CreateAutonomousDatabaseBackup (also needs manage autonomous-backups)

Verbs	Permissions	APIs Fully Covered	APIs Partially Covered
use	*READ* + AUTONOMOUS_DATABASE_CONTENT_WRITE AUTONOMOUS_DATABASE_UPDATE	AutonomousDatabaseManualRefresh, CancelAutonomousDatabaseSession, ChangeDisasterRecoveryConfiguration, ConfigureAutonomousDatabaseVaultKey, DeregisterAutonomousDatabaseDataSafe, DisableAutonomousDatabaseOperationsInsights, DisableDatabaseManagement, EnableAutonomousDatabaseOperationsInsights, EnableDatabaseManagement, FailOverAutonomousDatabase, GetAutonomousDatabaseConsoleToken, RegisterAutonomousDatabaseDataSafe, RestartAutonomousDatabase, RotateAutonomousDatabaseEncryptionKey, ShrinkAutonomousDatabase, StartAutonomousDatabase, StopAutonomousDatabase, SwitchOverAutonomousDatabase, UpdateAutonomousDatabaseRegionalWallet, UpdateAutonomousDatabase	RestoreAutonomousDatabase (also needs read autonomous-backups) ChangeAutonomousDatabaseCompartment (also needs read autonomous-backups)
manage	*USE* + AUTONOMOUS_DATABASE_CREATE AUTONOMOUS_DATABASE_DELETE	CreateAutonomousDatabase, DeleteAutonomousDatabase	*none*

List of Operations and Required IAM Policies to Manage an Autonomous Database Instance

Operation	Required IAM Policies
Add peer database	use autonomous-databases
Add security attributes	use autonomous-databases

Operation	Required IAM Policies
Change compute model	`use autonomous-databases`
Change database mode	`use autonomous-databases`
Change Network	`use autonomous-databases`
Change workload type	`use autonomous-databases`
Clone an Autonomous Database	`manage autonomous-databases` See IAM Permissions and API Operations for Autonomous Database for additional cloning permissions on Autonomous Database.
Create an Autonomous Database	`manage autonomous-databases` `read autonomous-databases`
Edit Database Tools Configuration	`use autonomous-databases`
Edit start/stop schedule	`use autonomous-databases`
Enable elastic pool	`use autonomous-databases`
Enable or disable auto scaling for an Autonomous Database	`use autonomous-databases`
Join elastic pool	`use autonomous-databases`
Manage customer contacts	`use autonomous-databases`
Manage encryption key	`use autonomous-databases`
Move an Autonomous Database to another compartment	`use autonomous-databases` in the database's current compartment and in the compartment you are moving it to `read autonomous-backups`
Rename an Autonomous Database	`use autonomous-databases`
Restart an Autonomous Database	`use autonomous-databases`
Restore an Autonomous Database	`use autonomous-databases` `read autonomous-backups`
Scale the ECPU count or storage of an Autonomous Database	`use autonomous-databases`
Set ADMIN user password	`use autonomous-databases`
Stop or start an Autonomous Database	`use autonomous-databases`
Switchover	`use autonomous-databases`
Terminate an Autonomous Database	`manage autonomous-databases`
Update disaster recovery	`use autonomous-databases`
Update display name	`use autonomous-databases`
Update license and Oracle Database Edition	`use autonomous-databases`
Update network access for ACLs	`use autonomous-databases`
Update network access for a private endpoint	`use autonomous-databases`
View a list of an Autonomous Databases	`inspect autonomous-databases`
View details of an Autonomous Database	`inspect autonomous-databases`

autonomous-backups

Verbs	Permissions	APIs Fully Covered	APIs Partially Covered
inspect	`AUTONOMOUS_DB_BACKUP_INSPECT`	`ListAutonomousDatabaseBackups`, `GetAutonomousDatabaseBackup`	*none*
manage	*`USE`* + `AUTONOMOUS_DB_BACKUP_CREATE` `AUTONOMOUS_DB_BACKUP_DELETE`	`DeleteAutonomousDatabaseBackup`	`CreateAutonomousDatabaseBackup` (also needs `read autonomous-databases`)
read	*`INSPECT`* + `AUTONOMOUS_DB_BACKUP_CONTENT_READ`	*no extra*	`RestoreAutonomousDatabase` (also needs `use autonomous-databases`) `ChangeAutonomousDatabaseCompartment` (also needs `use autonomous-databases`)
use	*READ* + *no extra*	*no extra*	*none*

Supported Variables

All of the general OCI Identity and Access Management variables are supported. See General Variables for All Requests for more information.

Additionally, you can use the `target.id` variable with the OCID of a database after creation of a database and the `target.workloadType` variable with a value as shown in the following table:

target.workloadType Value	Description
`OLTP`	Online Transaction Processing, used for Autonomous Databases with Transaction Processing workload.
`DW`	Data Warehouse, used for Autonomous Databases with Data Warehouse workload.
`AJD`	Autonomous JSON Database used for Autonomous Databases with JSON workload.
`APEX`	APEX Service used for Autonomous Database APEX Service.

Example policy using the `target.id` variable:

```
Allow group ADB-Admins to manage autonomous-databases in tenancy where
target.id = 'OCID'
```

Example policy using the `target.workloadType` variable:

```
Allow group ADB-Admins to manage autonomous-databases in tenancy where
target.workloadType = 'AJD'
```

IAM Permissions and API Operations for Autonomous Database

This topic covers the available IAM permissions for operations on Autonomous Database.

The following are the IAM permissions for Autonomous Database:

- AUTONOMOUS_DATABASE_CONTENT_READ
- AUTONOMOUS_DATABASE_CONTENT_WRITE
- AUTONOMOUS_DATABASE_CREATE

  See Cloning Permissions for additional cloning limitations.
- AUTONOMOUS_DATABASE_DELETE
- AUTONOMOUS_DATABASE_INSPECT
- AUTONOMOUS_DATABASE_UPDATE
- AUTONOMOUS_DB_BACKUP_CONTENT_READ
- AUTONOMOUS_DB_BACKUP_CREATE
- AUTONOMOUS_DB_BACKUP_INSPECT
- NETWORK_SECURITY_GROUP_UPDATE_MEMBERS
- VNIC_ASSOCIATE_NETWORK_SECURITY_GROUP

Example policy for a group to have permissions to create Autonomous Database in a compartment:

```
Allow group group-name to manage autonomous-database in compartment id
compartment-ocid
    where all{request-permission = 'AUTONOMOUS_DATABASE_UPDATE'}
```

Permissions Required to Use Operation	API Operation
AUTONOMOUS_DATABASE_CONTENT_READ	GenerateAutonomousDatabaseWallet GetAutonomousDatabaseRegionalWallet GetAutonomousDatabaseWallet RetrieveDatabasePerformanceBulkData
AUTONOMOUS_DATABASE_CREATE	CreateAutonomousDatabase
AUTONOMOUS_DATABASE_DELETE	DeleteAutonomousDatabase
AUTONOMOUS_DATABASE_INSPECT	GetAutonomousDatabase ListAutonomousDatabaseClones ListAutonomousDatabasePeers ListAutonomousDatabaseRefreshableClones ListAutonomousDatabases ResourcePoolShapes

Permissions Required to Use Operation	API Operation
AUTONOMOUS_DATABASE_UPDATE	AutonomousDatabaseManualRefresh ConfigureAutonomousDatabaseVaultKey DeregisterAutonomousDatabaseDataSafe DisableAutonomousDatabaseOperationsInsights DisableDatabaseManagement EnableAutonomousDatabaseOperationsInsights EnableDatabaseManagement FailOverAutonomousDatabase RegisterAutonomousDatabaseDataSafe RestartAutonomousDatabase RotateAutonomousDatabaseEncryptionKey ShrinkAutonomousDatabase StartAutonomousDatabase StopAutonomousDatabase SwitchOverAutonomousDatabase UpdateAutonomousDatabaseWallet UpdateAutonomousDatabaseRegionalWallet
AUTONOMOUS_DB_BACKUP_INSPECT	GetAutonomousDatabaseBackup ListAutonomousDatabaseBackups
AUTONOMOUS_DB_BACKUP_UPDATE	UpdateAutonomousDatabaseBackup
AUTONOMOUS_DB_BACKUP_CREATE AUTONOMOUS_DATABASE_CONTENT_READ	CreateAutonomousDatabaseBackup
AUTONOMOUS_DB_BACKUP_INSPECT AUTONOMOUS_DB_BACKUP_DELETE	DeleteAutonomousDatabaseBackup
AUTONOMOUS_DB_BACKUP_INSPECT AUTONOMOUS_DB_BACKUP_CONTENT_READ AUTONOMOUS_DATABASE_CONTENT_WRITE	RestoreAutonomousDatabase
Required on the source and the target compartment: AUTONOMOUS_DATABASE_UPDATE AUTONOMOUS_DB_BACKUP_INSPECT AUTONOMOUS_DB_BACKU_CREATE AUTONOMOUS_DATABASE_CONTENT_WRITE Required in both the source and the target compartment when Private Endpoint is enabled: WNIC_ASSOCIATE_NETOWRK_SECURITY_GROUP NETWORK_SECURITY_GROUP_UPDATE_MEMBERS	ChangeAutonomousDatabaseCompartment

Permissions Required to Use Operation	API Operation

Three possible cases:
• If Workload is `NULL`:
`AUTONOMOUS_DATABASE_UPDATE`
• If Workload is not `NULL`:
`AUTONOMOUS_DATABASE_CREATE`
`AUTONOMOUS_DATABASE_UPDATE`
• If Tagging is enabled:
`AUTONOMOUS_DATABASE_UPDATE`
`AUTONOMOUS_DATABASE_INSPECT`
	`UpdateAutonomousDatabase`: Use this API for changes or updates for any of the following operations:
	• set admin password (`adminPassword`)
	• auto start/stop schedule (`scheduledOperations`)
	• manage customer contacts (`customerContacts`)
	• edit tool configuration (`dbToolsDetails`)
	• update BYOL license options (`licenseModel` and `byolComputeCountLimit`)
	• update display name (`displayName`)
	• join an elastic pool
	• update elastic pool options
	• manage encryption keys
	• update to autonomous data guard for disaster recovery (`isLocalDataGuardEnabled` and `disasterRecoveryType`)
	• change database operation mode read/write read-only (`openMode`)
	• update network access with ACLs (`whitelistedIps`)
	• update network access with private endpoint (`privateEndpointLabel`)
	• rename database (`dbName`)
	• scale compute limits (`computeCount`)
	• manage compute auto scaling option (`isAutoScalingEnabled`)
	• scale storage limits (`dataStorageSizeInTBs`)
	• manage storage auto scaling options (`isAutoScalingForStorageEnabled`)
	• change workload type (`dbWorkload`)

requires `changeAutonomousDatabaseSubscription`	`ChangeAutonomousDatabaseSubscription`
requires `getSaasAdminUser`	`SaasAdminUserStatus`

requires `updateSaasAdminUser`	`ConfigureSaasAdminUser`
	`ListAutonomousDatabaseCharacterSets`
	`ListAutonomousDatabaseMaintenanceWindows`

Cloning Permissions

General IAM permissions are supported for Autonomous Database. In addition you can use `target.autonomous-database.cloneType` with the supported permission values to control the level of access, as shown in the following table.

target.autonomous-database.cloneType Value	Description
`CLONE-FULL`	Allow full clone only.

target.autonomous-database.cloneType Value	Description
CLONE-METADATA	Allow metadata clone only.
CLONE-REFRESHABLE	Allow refreshable clone only.
/CLONE*/	Allow any kind of clone.

Example policies with the supported `target.autonomous-database.cloneType` permission values:

```
Allow group group-name to manage autonomous-databases in compartment id
compartment-ocid
    where all {request.permission =  'AUTONOMOUS_DATABASE_CREATE',
target.autonomous-database.cloneType = 'CLONE-FULL'}
```

```
Allow group group-name to manage autonomous-databases in compartment id
compartment-ocid
    where all {request.permission =  'AUTONOMOUS_DATABASE_CREATE',
target.autonomous-database.cloneType = 'CLONE-METADATA'}
```

```
Allow group group-name to manage autonomous-databases in compartment id
compartment-ocid
    where all {request.permission =  'AUTONOMOUS_DATABASE_CREATE',
target.autonomous-database.cloneType = 'CLONE-REFRESHABLE'}
```

```
Allow group group-name to manage autonomous-databases in compartment id
compartment-ocid
    where all {request.permission =  'AUTONOMOUS_DATABASE_CREATE',
target.autonomous-database.cloneType = /CLONE*/}
```

See Permissions for more information.

Provide Specific Privileges in IAM Policies to Manage Autonomous Database

Lists IAM policies that you can use with an authorization verb and a condition to grant more granular operations to a group.

For example, to allow the group `MyGroup` to start Autonomous Databases using the `StartAutonomousDatabase` API:

```
Allow MyGroup to manage autonomous-databases where request.operation =
'StartAutonomousDatabase'
```

See Verbs and Conditions for more information.

Authorization Verb List
autonomousDatabaseManualRefresh
changeAutonomousDatabaseCompartment

Authorization Verb List
changeAutonomousDatabaseSubscription
changeDisasterRecoveryConfiguration
configureAutonomousDatabaseVaultKey
configureSaasAdminUser
createAutonomousDatabase
createAutonomousDatabaseBackup
deleteAutonomousDatabase
deleteAutonomousDatabaseBackup
deregisterAutonomousDatabaseDataSafe
disableAutonomousDatabaseManagement
disableAutonomousDatabaseOperationsInsights
enableAutonomousDatabaseManagement
enableAutonomousDatabaseOperationsInsights
failOverAutonomousDatabase
generateAutonomousDatabaseWallet
getAutonomousDatabase
getAutonomousDatabaseBackup
getAutonomousDatabaseRegionalWallet
getAutonomousDatabaseWallet
listAutonomousDatabaseBackups
listAutonomousDatabaseCharacterSets
listAutonomousDatabaseClones
listAutonomousDatabaseMaintenanceWindows
listAutonomousDatabasePeers
listAutonomousDatabaseRefreshableClones
listAutonomousDatabases
registerAutonomousDatabaseDataSafe
resourcePoolShapes
restartAutonomousDatabase
restoreAutonomousDatabase
rotateAutonomousDatabaseEncryptionKey
SaasAdminUserStatus
shrinkAutonomousDatabase
startAutonomousDatabase
stopAutonomousDatabase
switchoverAutonomousDatabase
updateAutonomousDatabase
updateAutonomousDatabaseBackup
updateAutonomousDatabaseRegionalWallet
updateAutonomousDatabaseWallet

The Authorization Verb `updateAutonomousDatabase` groups together privileges to use several API operations.

Operation
DeregisterAutonomousDatabaseDataSafe
DisableAutonomousDatabaseOperationsInsights
DisableDatabaseManagement
EnableAutonomousDatabaseOperationsInsights
RegisterAutonomousDatabaseDataSafe

For example:

```
Allow MyGroup to manage autonomous-databases where request.operation =
'updateAutonomousDatabase'
```

Use Oracle Data Safe with Autonomous Database

Provides information on using Oracle Data Safe on Autonomous Database.

- About Oracle Data Safe with Autonomous Database
  Oracle Data Safe, which is included with Autonomous Database, provides a unified control center that helps you manage the day-to-day security and compliance requirements of Oracle Databases.
- Register Autonomous Database with Oracle Data Safe
  To use Oracle Data Safe you first need to register your database with Oracle Data Safe.
- Use Oracle Data Safe Features
  After you register Autonomous Database with Oracle Data Safe you can use the Data Safe features.

About Oracle Data Safe with Autonomous Database

Oracle Data Safe, which is included with Autonomous Database, provides a unified control center that helps you manage the day-to-day security and compliance requirements of Oracle Databases.

Data Safe helps you to evaluate security controls, assess user security, monitor user activity, mitigate risk from compromised accounts, and address data security compliance requirements for your database. Data Safe accomplishes this by evaluating the sensitivity of your data and assisting you when you need to mask sensitive data for non-production databases.

Oracle Data Safe provides features to assist you when:

- Your organization's policies require that you monitor your databases and retain audit records.
- You need to protect against common database attacks coming from risks such as compromised accounts.
- Your developers need to use copies of production data for work on a new application and you're wondering what kinds of sensitive information the production data contains.
- You need to make sure that staff changes haven't left dormant user accounts on your databases.

Oracle Data Safe provides the following:

- **Security Assessment**: Configuration errors and configuration drift are significant contributors to data breaches. Use security assessment to evaluate your database's configuration and compare it to Oracle and industry best practices. Security assessment provides reports on areas of risk and notifies you when configurations change.
- **User Assessment**: Many breaches start with a compromised user account. User Assessment helps you spot the riskiest database accounts, those accounts which if compromised could cause the most damage. User Assessment helps you take proactive steps to secure these accounts. User Assessment Baselines make it easy to know when new accounts are added, or when an account's privileges are modified. You can use Oracle Cloud Infrastructure Events to receive proactive notifications when a database deviates from its baseline.
- **Data Discovery**: Provides support to locate and to manage sensitive data in your applications. Data discovery scans your database for over 150 different types of sensitive data and helps you to understand what types and how much sensitive data you are storing. Use the data discovery reports to formulate audit policies, develop data masking templates, and create effective access control policies.
- **Data Masking** Minimize the amount of sensitive data your organization maintains to help you meet compliance requirements and satisfy data privacy regulations. Data masking helps you remove risk from your non-production databases by replacing sensitive information with masked data. With reusable masking templates, over 50 included masking formats, and the ability to easily create custom formats for your organization's unique requirements, data masking can streamline your application development and testing operations.
- **Activity Auditing** Activity auditing collects audit records from databases and helps you manage audit policies. Understanding and reporting on user activity, data access, and changes to database structures supports regulatory compliance requirements and can aid in post-incident investigations. Audit insights make it easy to identify inefficient audit policies, while alerts based on audit data proactively notify you of risky activity.

  > **Note:**
  >
  > One (1) million audit records per database per month are included for your Autonomous Database if using the audit collection for Activity Auditing in Oracle Data Safe.

- **SQL Firewall Management** Protect against risks such as SQL injection attacks or compromised accounts. Oracle SQL Firewall is a security capability available with Oracle Database 23ai that offers best-in-class protection against these risks. The SQL Firewall feature in Oracle Data Safe lets you centrally manage and monitor the SQL Firewall policies for your target databases. Data Safe lets you collect authorized SQL activities of a database user, generate and enable the policy with allowlists of approved SQL statements and database connection paths and provides a comprehensive view of any SQL Firewall violations across the fleet of your target databases.

See Oracle Data Safe Overview for more information.

Register Autonomous Database with Oracle Data Safe

To use Oracle Data Safe you first need to register your database with Oracle Data Safe.

To get started, register your database:

[1] SQL Firewall is only available with Oracle Database 23ai.

1. Apply the necessary Identity and Access Management (IAM) permissions to register your target database.

   See Permissions to register an Autonomous Database for more information.

2. If you are registering an Autonomous Database that is configured to use a private IP address, then you need to create an Oracle Data Safe private endpoint either before or during registration.

   See Create an Oracle Data Safe Private Endpoint for more information.

3. Use the Oracle Data Safe Wizard to register your Autonomous Database instance.

   See Register an Autonomous Database for details on the registration steps.

Use Oracle Data Safe Features

After you register Autonomous Database with Oracle Data Safe you can use the Data Safe features.

Data Safe Feature	More Information
Security Assessment	Security Assessments are automatically scheduled once a week. Start by reviewing the security assessment report for your database: View the latest assessment for a target database. See Security Assessment Overview for more information.
User Assessment	User Assessments are automatically scheduled once a week. Start by reviewing the user assessment report for your database: View the latest user assessment for a target database See User Assessment Overview for more information.
Data Discovery	Start by discovering sensitive data in your database: Create Sensitive Data Models See Data Discovery Overview for more information.
Data Masking	To determine where sensitive data is stored in your database, run Data Discovery. After you know where sensitive data is stored in your database, you can create a masking policy: Create Masking Policies For example, after you create a masking policy you can make a copy of a production database and apply the masking policy to the non-production database: Mask Sensitive Data on a Target Database See Data Masking Overview for more information.
Activity Auditing	To use activity auditing, start the audit trail for your target database in Data Safe: Start an Audit Trail After the audit trail is started you can monitor and analyze your audit data with pre-defined audit reports: View a Predefined or Custom Audit Report See Activity Auditing Overview for more information.

Data Safe Feature	More Information
SQL Firewall	SQL Firewall[1] in Oracle Data Safe lets you centrally manage the SQL Firewalls and provides a comprehensive view of SQL Firewall violations across the fleet of your target databases. Data Safe lets you collect authorized SQL activities of a database user you wish to protect, monitor the progress of the collection, generate and enable the policy with allowlists of approved SQL statements and database connection paths. Start by enabling the SQL Firewall in your 23ai target database: Enable SQL Firewall On Your Target Database Next, you need to generate and enable a SQL Firewall policy with allowlists for the database user you wish to protect: Generate and Enforce SQL Firewall Policies. After you start enforcing the SQL Firewall policy, you can monitor and analyze the violations in the predefined violation reports: View and Manage Violations Reports. You can find more details on SQL Firewall at SQL Firewall Overview.

Break Glass Access for SaaS on Autonomous Database

Autonomous Database supports break glass access for SaaS providers. Break glass access allows a SaaS operations team, when explicitly authorized by a SaaS customer, to access a customer's database to perform critical or emergency operations.

- About Break Glass Access on Autonomous Database
  Break glass access on Autonomous Database supports SaaS providers, where the SaaS organization defines procedures to permit a SaaS operations team member to access a customer's database when they are explicitly authorized by the customer.
- Enable Break Glass Access
  After authorization to access a database with `SAAS_ADMIN` is approved through procedures defined by your organization, use the Autonomous Database CLI or API to enable the `SAAS_ADMIN` user.
- Disable Break Glass Access
  Use the Autonomous Database CLI or API to disable `SAAS_ADMIN` user access.
- Notes for Break Glass Access
  Provides notes for break glass access.

About Break Glass Access on Autonomous Database

Break glass access on Autonomous Database supports SaaS providers, where the SaaS organization defines procedures to permit a SaaS operations team member to access a customer's database when they are explicitly authorized by the customer.

Break Glass Sample Use Case with Example.com

Consider a SaaS provider named `example.com` that is using Autonomous Database for their product. In usual operations the SaaS provider, `example.com`, creates an Autonomous Database instance for each SaaS customer. In this model a SaaS customer, for example a customer named Scott, is an end-user for the `example.com` product (and a SaaS customer whose data is stored in an Autonomous Database instance). The provider `example.com` creates and stores all of Scott's data in an Autonomous Database instance, and the customer, Scott, has no direct access to the database.

This SaaS model is summarized as follows:

- The Oracle customer creating Autonomous Database instances is the SaaS organization, (example.com).
- The SaaS provider is example.com.
- The SaaS customer is Scott.

If and when something goes wrong with regards to application performance, or there is some other critical issue that requires troubleshooting by the SaaS operations team, the customer Scott, can grant access so that the operations team can access Scott's database for troubleshooting. The SaaS operations team is only authorized to establish direct access to Scott's Autonomous Database instance through a SaaS defined approval process (in other words, after example.com receives permission from their customer, Scott).

Break Glass and the Autonomous Database SAAS_ADMIN User

When a SaaS invokes the break glass API on a customer's Autonomous Database instance, this enables the SAAS_ADMIN user. The SaaS operations team can then access the instance using the SAAS_ADMIN user with a specified set of roles, for a limited time.
By default the SAAS_ADMIN user is locked. Using an approval process defined by the SaaS organization, the SAAS_ADMIN user can be enabled to allow access to an Autonomous Database instance. The break glass name comes from manual fire alarms that require their users to break a small glass window pane before activating the alarm (the glass must be broken to prevent the alarm from being triggered by mistake). Similarly, the SAAS_ADMIN user doesn't normally access the database and access requires a predefined approval process.

Depending on the type of access granted, when enabled, the SAAS_ADMIN user can access the database to investigate issues or to make changes associated with an emergency or other unusual event. When break glass access expires or when access is explicitly disabled, the SAAS_ADMIN account password/secrets are immediately rotated and SAAS_ADMIN user access is revoked. All the actions that the SAAS_ADMIN user performs are audited.

The SAAS_ADMIN user is enabled with one of three access types:

- read-only: provides read only access to the instance. This is the default access type and includes default roles: CREATE SESSION, SELECT ANY TABLE, SELECT ANY DICTIONARY, SELECT_CATALOG_ROLE.
- read/write: provides read/write access to the instance. The default roles for this type are: CREATE SESSION, SELECT ANY TABLE, SELECT ANY DICTIONARY, SELECT_CATALOG_ROLE, INSERT ANY TABLE, and UPDATE ANY TABLE.
- admin: provides admin access to the instance. The default roles for this type are: CREATE SESSION and PDB_DBA.

Break Glass API

The SAAS_ADMIN user is enabled and disabled only through the Command Line Interface (CLI) or using the Autonomous Database REST APIs.

For information about using the REST APIs and signing requests, see REST APIs and Security Credentials.

For information about SDKs, see Software Development Kits and Command Line Interface.

Use these APIs for Break Glass operations:

- To enable or disable SAAS_ADMIN, use configureSaasAdminUser.
- To check if the SAAS_ADMIN user is enabled use getSaasAdminUserStatus.

Enable Break Glass Access

After authorization to access a database with `SAAS_ADMIN` is approved through procedures defined by your organization, use the Autonomous Database CLI or API to enable the `SAAS_ADMIN` user.

You must have the manage autonomous database privilege to enable the `SAAS_ADMIN` user.

Before you enable the `SAAS_ADMIN` user to access a database you must obtain values for the required parameters.

Parameter	Description
`isEnabled`	Specifies a Boolean value. Use `TRUE` to enable.
`password`	Specifies the password for the `SAAS_ADMIN` user. If you specify `secretId` you cannot specify `password`. The password you provide as a parameter must conform to the Autonomous Database password requirements. See About User Passwords on Autonomous Database for more information.
`secretId`	Specifies the value of a secret's Oracle Cloud Infrastructure Vault secret OCID. If you specify `password` you cannot specify `secretId`. See Overview of Vault for more information. The password you provide as a secret in the Oracle Cloud Infrastructure Vault must conform to the Autonomous Database password requirements. See About User Passwords on Autonomous Database for more information.
`secretVersionNumber`	Specifies the version number of the secret specified with the `secretId`. This parameter is optional. The default is to use the latest secret version. This parameter only applies when `secretId` is also specified.
`accessType`	One of: `read-only`, `read/write`, or `admin`. The default is `read-only`.
`duration`	Specifies the duration in hours, in the range of 1 hour to 24 hours. The default is 1 hour.

To enable the `SAAS_ADMIN` user on an Autonomous Database instance you must define the required access using OCI Identity and Access Management policy statements written by an administrator.

The following policy is required:

```
Allow group Group_Name to manage autonomous-databases in compartment
Compartment_Name
```

See IAM Policies for Autonomous Database and Getting Started with Policies for more information.

Topics

- Enable Break Glass Access with a Password
  Use the Autonomous Database CLI or API to enable `SAAS_ADMIN` with a password.
- Enable Break Glass Access with a Vault Secret
  Use the Autonomous Database CLI or API to enable `SAAS_ADMIN` with a `secretId`, when the secret is stored in Oracle Cloud Infrastructure Vault.

Enable Break Glass Access with a Password

Use the Autonomous Database CLI or API to enable `SAAS_ADMIN` with a password.

1. Use the API or the CLI and specify a value for the password to enable `SAAS_ADMIN` with a `password`.

   For example:

   ```
   POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
   ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/configureSaasAdminUser

   {  "isEnabled": true,
      "password": password,
      "accessType": "READ_ONLY",
      "duration": 17
   }
   ```

   See configureSaasAdminUser for more information.

2. Verify that `SAAS_ADMIN` user is enabled.

   ```
   POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
   ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/getSaasAdminUserStatus

   {    "isEnabled": true,
        "accessType": "READ_ONLY",
        "timeSaasAdminUserEnabled": "2023-11-23T01:59:07.032Z"
   }
   ```

   This response shows that the `SAAS_ADMIN` user is enabled and that access type is `READ_ONLY`. The timestamp shows the time when `SAAS_ADMIN` was enabled (time is in UTC).

   See getSaasAdminUserStatus for more information.

Enable Break Glass Access with a Vault Secret

Use the Autonomous Database CLI or API to enable `SAAS_ADMIN` with a `secretId`, when the secret is stored in Oracle Cloud Infrastructure Vault.

When you specify a `secretId`, in order for Autonomous Database to reach the secret in the Oracle Cloud Infrastructure Vault, the following conditions must apply:

- The secret must be in `current` or `previous` state.
- You must have the proper user group policy that allows `READ` access to the specific secret in a given compartment. For example:

  ```
  Allow userGroup1 to read secret-bundles in compartment training
  ```

To enable `SAAS_ADMIN` with a `secretId` with the secret stored in Oracle Cloud Infrastructure Vault:

1. Use the API or the CLI and specify an OCID value for the `secretId`.

For example:

```
POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/configureSaasAdminUser

{  "isEnabled": true,
   "secretId": "ocid1.key.co1.ap-
mumbai-1.example..aaaaaaaauq5ok5nq3bf2vwetkpqsoa",
   "accessType": "READ_ONLY",
   "duration": 20
}
```

Specifying a secret version is optional. If you specify a secret version in the API call with `secretVersionNumber`, the specified secret version is used. If you do not specify a secret version the call uses the latest secret version.

See configureSaasAdminUser for more information.

2. Verify that `SAAS_ADMIN` user is enabled.

   For example:

```
POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/getSaasAdminUserStatus

{    "isEnabled": true,
     "accessType": "READ_ONLY",
     "timeSaasAdminUserEnabled": "2023-11-23T01:59:07.032Z"
}
```

   This response shows that the `SAAS_ADMIN` user is enabled and the access type is `READ_ONLY`. The timestamp shows the time when the user was enabled (time is in UTC).

   See getSaasAdminUserStatus for more information.

Disable Break Glass Access

Use the Autonomous Database CLI or API to disable `SAAS_ADMIN` user access.

By default access expires after one hour if the `duration` parameter is not set when `SAAS_ADMIN` is enabled. If the `duration` parameter is set when `SAAS_ADMIN` is enabled, then access expires after the specified `duration` number of hours. As an alternative to letting the access expire based on the either the default expiration time or the duration you specify, you can use configureSaasAdminUser to explicitly disable `SAAS_ADMIN` user access.

To disable the `SAAS_ADMIN` user on an Autonomous Database instance you must define the required access using OCI Identity and Access Management policy statements written by an administrator.

The following policy is required:

```
Allow group Group_Name to manage autonomous-databases in compartment
Compartment_Name
```

See IAM Policies for Autonomous Database and Getting Started with Policies for more information.

1. Disable `SAAS_ADMIN` user access.

   For example:

   ```
   POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
   ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/configureSaasAdminUser
   {
     "isEnabled": false
   }
   ```

   See configureSaasAdminUser API for more information.

2. Verify that `SAAS_ADMIN` user is disabled.

   For example:

   ```
   POST https://dbaas-api.svc.ad3.us-phoenix-1/20160918/autonomousDatabases/
   ocid1.autonomousdatabase.oc1.phx.uniqueId/actions/getSaasAdminUserStatus

   {    "isEnabled": false
   }
   ```

   This response indicates that the `SAAS_ADMIN` user is disabled.

   See getSaasAdminUserStatus for more information.

When you disable the `SAAS_ADMIN` user, access to the database is revoked and Autonomous Database rotates the password or the secret that was used to access the database.

Notes for Break Glass Access

Provides notes for break glass access.

Notes for break glass access:

- The `duration` you specify when you enable `SAAS_ADMIN` applies either until the specified time expires or until you explicitly disable the `SAAS_ADMIN` user. You cannot change this value after you enable the `SAAS_ADMIN` user.
- Always Free Autonomous Database does not support access with the `SAAS_ADMIN` user.
- The `DBA_CLOUD_CONFIG` view provides information on the `SAAS_ADMIN` user.

  For example, the use the following query to obtain information on the status for the `SAAS_ADMIN` user:

  ```
  SELECT PARAM_VALUE FROM DBA_CLOUD_CONFIG WHERE
              param_name ='saas_admin_access' order by 1;
  ```

  The presence of a value for `auth_revoker` means the access has been revoked and shows the user who revoked access.

  The `auth_end` shows a `planned` time. After authorization is revoked, if the authorization expired at the time end of the `duration` specified when `SAAS_ADMIN` user was enabled, the `planned` time will be the same as the `actual` time. If the `planned` and the `actual` time are different, this means that `SAAS_ADMIN` authorization was revoked before the `duration` expired.

For example, if `SAAS_ADMIN` is enabled with a duration of 2 hours, and after 1 hour access is disabled by calling the API configureSaasAdminUser to disable the `SAAS_ADMIN` user, the `auth_end planned` and `actual` times will be different.

If this query shows no rows, then the `SAAS_ADMIN` user does not exist. It may have been created and dropped or it was never created.

Encrypt Data While Exporting or Decrypt Data While Importing

For greater security you can encrypt data that you export to Object Storage. When data on Object Storage is encrypted you can decrypt the data you import or when you use the data in an external table.

- Encrypt Data While Exporting to Object Storage
  You can encrypt table data while exporting to Object Storage.
- Decrypt Data While Importing from Object Storage
  You can decrypt and load data from encrypted files stored in Object Storage. You can also decrypt encrypted data on Object Storage that you use in an external table.

Encrypt Data While Exporting to Object Storage

You can encrypt table data while exporting to Object Storage.

Use the `format` parameter and the `encryption` option with `DBMS_CLOUD.EXPORT_DATA` to encrypt data when you export from Autonomous Database to Object Storage.

Note the following when you export encrypted data to Object Storage:

- The `encryption` option is only supported when exporting data from Autonomous Database to Object Storage as CSV, JSON, or XML.
- When the export includes both encryption and compression, the order of operations is: first the data is compressed, next the data is encrypted, and then it is uploaded to Object Storage.
- There are two supported encryption methods:
  - Using a user-defined function.
  - Using a `DBMS_CRYPTO` specified encryption algorithm.

    See DBMS_CRYPTO for information on the cryptographic functions and procedures for encryption and decryption.

Topics

- Encrypt Data Using DBMS_CRYPTO Encryption Algorithms
  Shows the steps to encrypt data using `DBMS_CRYPTO` encryption algorithms while exporting to Cloud Object Storage.
- Encrypt Data with a User Defined Encryption Function
  Shows the steps to encrypt data using a user-defined encryption function while exporting to Cloud Object Storage.

Encrypt Data Using DBMS_CRYPTO Encryption Algorithms

Shows the steps to encrypt data using `DBMS_CRYPTO` encryption algorithms while exporting to Cloud Object Storage.

Perform the following steps to encrypt data while exporting to Cloud Object Storage (this example exports table data to a CSV file):

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'OBJ_STORE_CRED',
       username        => 'user1@example.com',
       password        => 'password'
     );
   END;
   /
   ```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   See CREATE_CREDENTIAL Procedure for more information.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a credential to store the encryption key (the encryption key to be used for encrypting data).

   When you encrypt data using `DBMS_CRYPTO` encryption algorithms you store the encryption key in a credential. The key is specified in the `password` field in a credential you create with `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'ENC_CRED_NAME',
       username        => 'Any_username',
       password        => 'password'
     );
   END;
   /
   ```

   As an alternative you can create a credential to store the key in a vault. For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name  => 'ENC_CRED_NAME',
       params           => JSON_OBJECT ('username' value 'Any_username',
   ```

```
                                        'region'    value 'Region',
                                        'secret_id' value 'Secret_id_value'));
END;
/
```

> **Note:**
>
> The `username` parameter you specify in the credential that stores the key can be any string.

This creates the `ENC_CRED_NAME` credential which is a vault secret credential, where the secret (decryption/encryption key) is stored as a secret in Oracle Cloud Infrastructure Vault.

See CREATE_CREDENTIAL Procedure for more information.

4. Run `DBMS_CLOUD.EXPORT_DATA`.

   Use the `format` parameter with the `encryption` option. The `encryption` type specifies the `DBMS_CRYPTO` encryption algorithm to use to encrypt the table data and the `credential_name` value is credential that specifies the secret (encryption key).

   For example:

```
BEGIN
    DBMS_CLOUD.EXPORT_DATA (
        credential_name => 'OBJ_STORE_CRED',
        file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/encrypted.csv',
        query           => 'SELECT * FROM ADMIN.employees',
        format          => json_object(
               'type' value 'csv',
               'encryption' value  json_object(
                      'type' value DBMS_CRYPTO.ENCRYPT_AES256 +
DBMS_CRYPTO.CHAIN_CBC + DBMS_CRYPTO.PAD_PKCS5,
                      'credential_name' value 'ENC_CRED_NAME'))
      );
END;
/
```

   This encrypts and exports the data from the `EMPLOYEES` table into a CSV file.

   See DBMS_CRYPTO Algorithms for more information on encryption algorithms.

   In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

   See EXPORT_DATA Procedure and DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.

After you encrypt files with `DBMS_CLOUD.EXPORT_DATA`, when you use `DBMS_CRYPTO` encryption algorithms to encrypt the files, you have these options for using or importing the files you exported:

- You can use `DBMS_CLOUD.COPY_DATA` or `DBMS_CLOUD.COPY_COLLECTION` with the same encryption algorithm options and the key to decrypt the files.

See Decrypt and Load Data Using DBMS_CRYPTO Algorithms for more information.

- You can query the data in an external table by supplying the same encryption algorithm options and the key to decrypt the files, with any of the following procedures:
  - `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`
  - `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`
  - `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`

    For `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` this option is only applicable to the Object Storage files.

  See Decrypt and Load Data Using DBMS_CRYPTO Algorithms for more information.
- On a system that is not an Autonomous Database you can use the `DBMS_CRYPTO` package with the same algorithm options and the key to decrypt the files.

  Note that the key is stored as a `VARCHAR2` in the credential in Autonomous Database but `DBMS_CRYPTO` uses `RAW` type for the key parameter.

  See DBMS_CRYPTO Algorithms for more information on encryption algorithms.

Encrypt Data with a User Defined Encryption Function

Shows the steps to encrypt data using a user-defined encryption function while exporting to Cloud Object Storage.

Perform the following steps to encrypt data while exporting to Cloud Object Storage (this example exports table data to a CSV file):

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.
2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'OBJ_STORE_CRED',
    username        => 'user1@example.com',
    password        => 'password'
  );
END;
/
```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   See CREATE_CREDENTIAL Procedure for more information.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.
3. Create a user-defined callback function to encrypt data.

For example:

```
CREATE OR REPLACE FUNCTION encryption_func (data IN BLOB)
  RETURN BLOB
  IS
      l_encrypted_data BLOB;
       BEGIN
     DBMS_LOB.CREATETEMPORARY (l_encrypted_data, TRUE, DBMS_LOB.CALL);
     DBMS_CRYPTO.ENCRYPT (
         dst => l_encrypted_data,
         src => data,
         typ => DBMS_CRYPTO.ENCRYPT_AES256 + DBMS_CRYPTO.CHAIN_CBC +
DBMS_CRYPTO.PAD_PKCS5,
         key => 'encryption key'
      );
     RETURN l_encrypted_data;
END encryption_func;
/
```

This creates the `ENCRYPTION_FUNC` encryption function. This function encrypts data using a stream or block cipher with a user supplied key.

> **Note:**
>
> You must create an encryption key to be used as a value in the `KEY` parameter. See DBMS_CRYPTO Operational Notes for more information on generating the encryption key.

4. Run `DBMS_CLOUD.EXPORT_DATA` with the `format` parameter, include the `encryption` option and specify a `user_defined_function`.

   For example:

```
BEGIN
      DBMS_CLOUD.EXPORT_DATA (
        credential_name => 'OBJ_STORE_CRED',
        file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/encrypted.csv',
        query           => 'SELECT * FROM ADMIN.emp',
        format          => json_object(
                               'type' value 'csv',
                               'encryption' value
json_object('user_defined_function' value 'admin.encryption_func'))
      );
END;
/
```

This encrypts the data from the specified query the on `EMP` table and exports the data as a CSV file on Cloud Object Storage. The `format` parameter with the `encryption` value specifies the user-defined encryption function to use to encrypt the data.

> **Note:**
>
> You must have `EXECUTE` privilege on the encryption function.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

See EXPORT_DATA Procedure and DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.

Decrypt Data While Importing from Object Storage

You can decrypt and load data from encrypted files stored in Object Storage. You can also decrypt encrypted data on Object Storage that you use in an external table.

This option is useful when migrating from an on-premises database to an Autonomous Database if the data in your source files is encrypted.

> **Note:**
>
> This option is only supported for Object Storage files less than 4 GB.

This option is applicable for the following procedures:

- `DBMS_CLOUD.COPY_DATA`
- `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`
- `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`
- `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`

  For `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` this option is only applicable to the Object Storage files.
- `DBMS_CLOUD.COPY_COLLECTION`

Topics

- Decrypt and Load Data Using DBMS_CRYPTO Algorithms
  Shows the steps to decrypt encrypted files from Object Storage and load the data into a table on Autonomous Database (the decrypt step uses `DBMS_CRYPTO` algorithms).
- Decrypt and Load Data with a User Defined Function
  Shows the steps to decrypt files in Object Storage and load the data into tables using a user-defined decryption function.

Decrypt and Load Data Using DBMS_CRYPTO Algorithms

Shows the steps to decrypt encrypted files from Object Storage and load the data into a table on Autonomous Database (the decrypt step uses `DBMS_CRYPTO` algorithms).

As a prerequisite you must have encrypted files and uploaded the files into Object Storage. This example uses a CSV file and it is assumed that the file is encrypted using

`DBMS_CRYPTO.ENCRYPT_AES256 + DBMS_CRYPTO.CHAIN_CBC + DBMS_CRYPTO.PAD_PKCS5` algorithm and uploaded to your Cloud Object Storage.

See ENCRYPT Function for more information on the `ENCRYPT` function.

See DBMS_CRYPTO Operational Notes for more information on generating an encryption key.

To decrypt and load data into an existing table on Autonomous Database from Object Storage:

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'OBJ_STORE_CRED',
       username        => 'user1@example.com',
       password        => 'password'
     );
   END;
   /
   ```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   See CREATE_CREDENTIAL Procedure for more information.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a credential to store the key using `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'ENC_CRED_NAME',
       username        => 'Any_username',
       password        => 'password'
     );
   END;
   /
   ```

   As an alternative you can create credentials to store the key in a vault. For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name  => 'ENC_CRED_NAME',
       params           => JSON_OBJECT ('username' value 'Any_username',
                                        'region'    value 'Region',
                                        'secret_id' value 'Secret_id_value'));
   END;
   /
   ```

> **Note:**
>
> The `username` parameter you specify in the credential that stores the key can be any string.

This creates the `ENC_CRED_NAME` credential which is a vault secret credential, where the secret (decryption/encryption key) is stored as a secret in the Oracle Cloud Infrastructure Vault.

See CREATE_CREDENTIAL Procedure for more information.

4. Run `DBMS_CLOUD.COPY_DATA` and specify `DBMS_CRYPTO` encryption algorithm as decryption method.

```
BEGIN
 DBMS_CLOUD.COPY_DATA (
   table_name       => 'CSV_COPY_DATA',
   credential_name  => 'OBJ_STORE_CRED',
   file_uri_list    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/encrypted.csv',
   format           => json_object( 'type' value 'csv', 'encryption' value
json_object('type' value DBMS_CRYPTO.ENCRYPT_AES256 +
DBMS_CRYPTO.CHAIN_CBC + DBMS_CRYPTO.PAD_PKCS5,'credential_name' value
'ENC_CRED_NAME'))
  );
END;
/
```

This decrypts the `ENCRYPTED.CSV` file in the Object Storage. The data is then loaded into the `CSV_COPY_DATA` table. The `format` parameter `encryption` option value specifies a `DBMS_CRYPTO` encryption algorithm to be used to decrypt data.

See DBMS_CRYPTO Algorithms for more information on encryption algorithms.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see COPY_DATA Procedure.

For detailed information about the available `format` parameters, you can use with `DBMS_CLOUD.COPY_DATA`, see DBMS_CLOUD Package Format Options.

Decrypt and Load Data with a User Defined Function

Shows the steps to decrypt files in Object Storage and load the data into tables using a user-defined decryption function.

As a prerequisite for these steps you must have encrypted files and uploaded the files into Object Storage. This example uses a CSV file and it is assumed that the file is encrypted using `DBMS_CRYPTO.ENCRYPT_AES256 + DBMS_CRYPTO.CHAIN_CBC + DBMS_CRYPTO.PAD_PKCS5` algorithm and uploaded to your Cloud Object Storage.

See ENCRYPT Function for more information on the `ENCRYPT` function.

See DBMS_CRYPTO Operational Notes for more information on generating an encryption key.

To decrypt and load data into an existing table on Autonomous Database from Object Storage:

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'OBJ_STORE_CRED',
    username        => 'user1@example.com',
    password        => 'password'
  );
END;
/
```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   See CREATE_CREDENTIAL Procedure for more information.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a user-defined function decryption callback function.

   For example:

```
CREATE OR REPLACE FUNCTION decryption_func (data IN BLOB)
RETURN BLOB
IS
  l_decrypted_data     BLOB;
  response             DBMS_CLOUD_TYPES.resp;
  l_response_json      JSON_ARRAY_T;
  l_response_json_obj  JSON_OBJECT_T;
  l_secret_id          VARCHAR2(4000) := '<secret_ocid>';
  l_key                VARCHAR2(4000);
BEGIN
   response := DBMS_CLOUD.send_request (
               credential_name => 'OCI$RESOURCE_PRINCIPAL',
               uri             => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/' ||
l_secret_id,
               method          => 'GET');
  l_response_json_obj := JSON_OBJECT_T.parse
(DBMS_CLOUD.get_response_text(response));
  l_key := UTL_RAW.cast_to_varchar2
(UTL_ENCODE.base64_decode(UTL_RAW.cast_to_raw
(l_response_json_obj.get_object('secretBundleContent').get_string('content'
))));

  DBMS_LOB.createtemporary (l_decrypted_data, TRUE, DBMS_LOB.CALL);
  DBMS_CRYPTO.decrypt (
      dst => l_decrypted_data,
      src => data,
```

```
      typ => DBMS_CRYPTO.ENCRYPT_AES256 + DBMS_CRYPTO.CHAIN_CBC +
DBMS_CRYPTO.PAD_PKCS5,
      key => l_key
    );
  RETURN l_decrypted_data;
END decryption_func;
/
```

This creates the `DECRYPTION_FUNC` decryption function. This function decrypts data using a stream or block cipher with a user supplied key. The user supplied key in the example is stored in Oracle Cloud Infrastructure Vault and is retrieved dynamically by making a REST call to Oracle Cloud Infrastructure Vault service.

4. Run `DBMS_CLOUD.COPY_DATA` and specify the `format` option `encryption` and specify the user-defined function you created to decrypt the data.

```
BEGIN
 DBMS_CLOUD.COPY_DATA (
    table_name      => 'CSV_COPY_DATA',
    credential_name => 'OBJ_STORE_CRED',
    file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/encrypted.csv',
    format          => json_object(
                         'type' value 'csv',
                         'encryption' value
json_object('user_defined_function' value 'admin.decryption_func'))
  );
end;
/
```

This decrypts the `ENCRYPTED.CSV` file in the Object Storage. The data is then loaded into the `CSV_COPY_DATA` table. The `format` parameter `encryption` option value specifies a user-defined function name to use to decrypt data.

> **Note:**
>
> You must have the `EXECUTE` privilege on the user-defined function.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see COPY_DATA Procedure.

For detailed information about the available `format` parameters, you can use with `DBMS_CLOUD.COPY_DATA`, see DBMS_CLOUD Package Format Options.

Manage Oracle Cloud Operator Access

Describes how to grant temporary access to your database for an Oracle Cloud Operator.

Oracle Cloud Operators do not have authorization to access your data or any other information in your database schemas. When access to your database schemas is required to

troubleshoot or mitigate an issue, you can allow a cloud operator to access your Autonomous Database schemas for a limited time.

You allow a cloud operator to access the database schemas by running the procedure `DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS`. This means if you file a service request with Oracle Cloud Support and Oracle Cloud Operators need to access your database schemas, you must also enable operator access by running `DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS`.

Topics

- Enable Cloud Operator Access
  Describes the steps to enable Cloud Operator access on an Autonomous Database instance.
- Disable Cloud Operator Access
  Describes the steps to disable Cloud Operator access on an Autonomous Database instance.

Enable Cloud Operator Access

Describes the steps to enable Cloud Operator access on an Autonomous Database instance.

1. Enable operator access.

   For example:

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS(
          auth_duration => 12 );
   END;
   /
   ```

   The `auth_duration` parameter specifies the number of Hours for which the Cloud Operator is granted access. The value must be a whole number in the range of 1 to 24 and the default is 1 (Hour).

   See ENABLE_OPERATOR_ACCESS Procedure for more information.

2. Verify that operator access is enabled.

   For example:

   ```
   SELECT param_name, param_value FROM DBA_CLOUD_CONFIG
         WHERE LOWER(param_name) = 'operator_access';

   PARAM_NAME PARAM_VALUE
   ---------------
   ------------------------------------------------------------------------
   -
   operator_access {"auth_grantor":"\"ADMIN\"","auth_begin":"26-FEB-24
   07.34.37.144846 PM UTC",
   "auth_duration":"12 hour", "planned_auth_end":"27-FEB-24 07.34.37.146297
   AM UTC"}
   ```

`DBMS_CLOUD_ADMIN.ENABLE_OPERATOR_ACCESS` allows access only to the Cloud Operator and does not enable access for any other user.

All operations performed by the Cloud Operator are stored in the view `DBA_OPERATOR_ACCESS`. See View Oracle Cloud Infrastructure Operations Actions for more information.

Disable Cloud Operator Access

Describes the steps to disable Cloud Operator access on an Autonomous Database instance.

1. Disable operator access.

   For example

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.DISABLE_OPERATOR_ACCESS;
   END;
   /
   ```

   See DISABLE_OPERATOR_ACCESS Procedure for more information.

2. Verify that operator access is disabled.

   For example:

   ```
   SELECT param_name, param_value FROM DBA_CLOUD_CONFIG
         WHERE LOWER(param_name) = 'operator_access';

   No data found
   ```

Performance Monitor and Management

Oracle Autonomous Database Serverless includes several features that automatically monitor, analyze and optimize the performance of your Autonomous Database.

- Use OCI Ops Insights on Autonomous Database
  OCI Ops Insights is a cloud-native service that enables users to make informed, data-driven, Autonomous Database resource and performance management decisions.
- Manage Optimizer Statistics on Autonomous Database
  Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints.
- Manage Automatic Indexing on Autonomous Database
  Automatic indexing automates the index management tasks in Autonomous Database. Auto Indexing is disabled by default in Autonomous Database.
- Manage Automatic Partitioning on Autonomous Database

Use OCI Ops Insights on Autonomous Database

OCI Ops Insights is a cloud-native service that enables users to make informed, data-driven, Autonomous Database resource and performance management decisions.

See Get Started with Ops Insights for information about enabling and disabling Ops Insights. In particular, see Enable Autonomous Databases & Full Feature Support for Autonomous Database configuration options.

Manage Optimizer Statistics on Autonomous Database

Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints.

There are differences in the commands to run to gather optimizer statistics or enable optimizer hints, depending on your workload: Data Warehouse, Transaction Processing, or JSON Database.

- Manage Optimizer Statistics and Hints with Data Warehouse Workloads
  Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints with Data Warehouse workloads.
- Manage Optimizer Statistics and Hints with Transaction Processing and JSON Database Workloads
  Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints.

Manage Optimizer Statistics and Hints with Data Warehouse Workloads

Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints with Data Warehouse workloads.

Manage Optimizer Statistics with Data Warehouse Workloads

Autonomous Database with Data Warehouse workloads gathers optimizer statistics automatically for tables loaded with direct path operations issued in SQL (direct path load operations that bypass the SQL data processing, such as SQL*Loader direct path, do not collect statistics). For example, for loads using the `DBMS_CLOUD` package the database gathers optimizer statistics automatically.

If you have tables modified using conventional DML operations you can run commands to gather optimizer statistics for those tables. For example, for the `SH` schema you can gather statistics for all tables in the schema using the following command:

```
BEGIN
  DBMS_STATS.GATHER_SCHEMA_STATS('SH', options=>'GATHER AUTO');
END;
/
```

This example gathers statistics for all tables that have stale statistics in the `SH` schema.

For more information about direct-path loads see *Loading Tables*.

For more information on optimizer statistics see *Database Concepts*.

Manage Optimizer Hints with Data Warehouse Workloads

Autonomous Database with Data Warehouse ignores optimizer hints and `PARALLEL` hints in SQL statements by default. If your application relies on hints you can enable optimizer hints by setting the parameter `OPTIMIZER_IGNORE_HINTS` to `FALSE` at the session or system level using `ALTER SESSION` or `ALTER SYSTEM`. For example, the following command enables hints in your session:

```
ALTER SESSION
   SET OPTIMIZER_IGNORE_HINTS=FALSE;
```

You can also enable `PARALLEL` hints in your SQL statements by setting `OPTIMIZER_IGNORE_PARALLEL_HINTS` to `FALSE` at the session or system level using `ALTER SESSION` or `ALTER SYSTEM`. For example, the following command enables `PARALLEL` hints in your session:

```
ALTER SESSION
   SET OPTIMIZER_IGNORE_PARALLEL_HINTS=FALSE;
```

Manage Optimizer Statistics and Hints with Transaction Processing and JSON Database Workloads

Describes Autonomous Database commands to run when you need to gather optimizer statistics or enable optimizer hints.

Manage Optimizer Statistics with Transaction Processing and JSON Database Workloads

Autonomous Database gathers optimizer statistics automatically so that you do not need to perform this task manually and this helps to ensure your statistics are current. Automatic statistics gathering is enabled in Autonomous Database and runs in a standard maintenance window.

> **Note:**
>
> The automatic statistics gathering maintenance window is different than the maintenance window on the Oracle Cloud Infrastructure console. The Oracle Cloud Infrastructure maintenance window shows system patching information.

For more information on automatic statistics gathering maintenance window times and automatic optimizer statistics collection, see *Database Administrator's Guide*.

For more information on optimizer statistics see *SQL Tuning Guide*.

Manage Optimizer Hints with Transaction Processing and JSON Database Workloads

Autonomous Database with Transaction Processing and JSON Database workloads honors optimizer hints and `PARALLEL` hints in SQL statements by default. You can disable optimizer hints by setting the parameter `OPTIMIZER_IGNORE_HINTS` to `TRUE` at the session or system level using `ALTER SESSION` or `ALTER SYSTEM`. For example, the following command disables hints in your session:

```
ALTER SESSION
   SET OPTIMIZER_IGNORE_HINTS=TRUE;
```

You can also disable `PARALLEL` hints in your SQL statements by setting `OPTIMIZER_IGNORE_PARALLEL_HINTS` to `TRUE` at the session or system level using `ALTER SESSION` or `ALTER SYSTEM`.

```
ALTER SESSION
   SET OPTIMIZER_IGNORE_PARALLEL_HINTS=TRUE;
```

Manage Automatic Indexing on Autonomous Database

Automatic indexing automates the index management tasks in Autonomous Database. Auto Indexing is disabled by default in Autonomous Database.

Creating indexes manually requires deep knowledge of the data model, application, and data distribution. In the past, DBAs were responsible for making choices about which indexes to create, and then sometimes the DBAs did not revise their choices or maintain indexes as the conditions changed. As a result, opportunities for improvement were lost, and use of unnecessary indexes could be a performance liability. The automatic indexing feature in Autonomous Database monitors the application workload and creates and maintains indexes automatically.

To enable automatic indexing:

1. Use the `DBMS_AUTO_INDEX.CONFIGURE` procedure to enable automatic indexing:

   ```
   EXEC DBMS_AUTO_INDEX.CONFIGURE('AUTO_INDEX_MODE','IMPLEMENT');
   ```

   This enables automatic indexing in a database and creates any new auto indexes as visible indexes, so that they can be used in SQL statements.
2. Use the `DBMS_AUTO_INDEX` package to report on the automatic task and to set automatic indexing preferences.

> **Note:**
>
> When automatic indexing is enabled, index compression for auto indexes is enabled by default.

To disable automatic indexing:

1. The following statement disables automatic indexing in a database so that no new auto indexes are created (existing auto indexes remain enabled):

   ```
   EXEC DBMS_AUTO_INDEX.CONFIGURE('AUTO_INDEX_MODE','OFF');
   ```

When you use SODA with Autonomous Database the following restrictions apply:

- Automatic indexing is not supported for SQL and PL/SQL code that uses the SQL/JSON function `json_exists`. See SQL/JSON Condition JSON_EXISTS for more information.
- Automatic indexing is not supported for SODA query-by-example (QBE).

See Managing Auto Indexes for more information.

Manage Automatic Partitioning on Autonomous Database

Automatic partitioning analyzes and automates partition creation for tables and indexes of a specified schema to improve performance and manageability in Autonomous Database.

Automatic partitioning, when applied, is transparent and does not require any user interaction or maintenance.

> **Note:**
>
> Automatic partitioning does not interfere with existing partitioning strategies and is complementary to manual partitioning in Autonomous Database. Manually partitioned tables are excluded as candidates for automatic partitioning.

- About Automatic Partitioning
  Automatic partitioning in Autonomous Database analyzes the application workload and automatically applies partitioning to tables and their indexes to improve performance or to allow better management of large tables.
- How Automatic Partitioning Works
- Configure Automatic Partitioning
  Use the `DBMS_AUTO_PARTITION.CONFIGURE` procedure to configure automatic partitioning options.
- Use Automatic Partitioning
  Describes the flow and general processes for using and managing automatic partitioning in Autonomous Database.
- Generate Automatic Partitioning Reports
  Generate automatic partitioning reports using the `REPORT_ACTIVITY` and `REPORT_LAST_ACTIVITY` functions of the `DBMS_AUTO_PARTITION` package.
- Example Automatic Partitioning Scenarios
  Example scenarios for automatic partitioning using the `DBMS_AUTO_PARTITION` API procedures and functions.
- Data Dictionary Views for Automatic Partitioning
  There are two new views and one updated view in the data dictionary for information about the automatic partitioning configuration and recommendations in your database.

About Automatic Partitioning

Automatic partitioning in Autonomous Database analyzes the application workload and automatically applies partitioning to tables and their indexes to improve performance or to allow better management of large tables.

Finding appropriate partitioning strategies requires deep knowledge of the application workload and the data distribution. When you perform manual partitioning, you must analyze your workload and make choices about how to apply partitioning to tables and indexes to improve the performance of applications. Automatic partitioning enables Autonomous Database users to benefit from partitioning without performing manual schema and workload analysis.

Automatic partitioning uses a single-column partition key combined with single-level partitioning. Automatic partitioning does not support more complex partitioning strategies such as multi-column partitioned tables or composite partitioning.

Automatic partitioning chooses from the following partition methods:

- AUTOMATIC INTERVAL: This choice is best suited for ranges of partition key values.
- LIST AUTOMATIC: This partitioning method applies to distinct partition key values.
- HASH: Applies partitioning on the partition key's hash values.

See Partitioning Concepts for more information.

Automatic partitioning provides the following functionality:

- Analyzes application workload and finds the optimal partitioning strategy to improve query performance for tables eligible for automatic partitioning.
- Provides PL/SQL APIs for configuring automatic partitioning in a database, generating reports about partitioning findings, and generating and applying an identified partitioning strategy for a given workload.

> **Note:**
>
> Automatic partitioning requires explicit calls to the `DBMS_AUTO_PARTITION` PL/SQL APIs to recommend and apply automatic partitioning to an Autonomous Database.

How Automatic Partitioning Works

Unlike automatic indexing, automatic partitioning does not run periodically as a background task. Automatic partitioning only runs when you invoke it using the `DBMS_AUTO_PARTITION.RECOMMEND_PARTITION_METHOD` function.

When invoked, automatic partitioning identifies candidate tables for automatic partitioning, evaluates partition schemes, and implements a partitioning strategy.

When you invoke automatic partitioning it performs the following tasks:

1. Identifies candidate tables for automatic partitioning by analyzing the workload for selected candidate tables.

   By default, automatic partitioning uses the workload information collected in an Autonomous Database for analysis. Depending on the size of the workload, a sample of queries might be considered.

2. Evaluates partition schemes based on workload analysis, quantification, and verification of the performance benefits:
   a. Candidate empty partition schemes with synthesized statistics are created internally and analyzed for performance.
   b. The candidate scheme with the highest estimated IO reduction is chosen as the optimal partitioning strategy and is internally implemented to test and verify performance.
   c. If a candidate partition scheme does not improve performance beyond specified performance and regression criteria, automatic partitioning is not recommended.
3. Implements the optimal partitioning strategy, if configured to do so, for the tables analyzed by the automatic partitioning procedures.

Configure Automatic Partitioning

Use the `DBMS_AUTO_PARTITION.CONFIGURE` procedure to configure automatic partitioning options.

Enable and implement recommendations

```
EXEC DBMS_AUTO_PARTITION.CONFIGURE('AUTO_PARTITION_MODE','IMPLEMENT');
```

Enable recommendations, but do not implement those recommendations

```
EXEC DBMS_AUTO_PARTITION.CONFIGURE('AUTO_PARTITION_MODE','REPORT ONLY');
```

Disable new recommendations and implementation of those new recommendations

```
EXEC DBMS_AUTO_PARTITION.CONFIGURE('AUTO_PARTITION_MODE','OFF');
```

> **Note:**
>
> This mode does not disable existing automatically partitioned tables.

Manage schemas and tables for automatic partitioning

Use the `AUTO_PARTITION_SCHEMA` and `AUTO_PARTITION_TABLE` settings to specify schemas and tables considered for automatic partitioning.

> **Note:**
>
> When automatic partitioning is invoked, all schemas and tables in user-managed schemas are considered for automatic partitioning if both the inclusion and exclusion lists are empty.

- Assuming the inclusion list and the exclusion list are empty, add the `HR` schema and the `SH.SALES` table to the exclusion list, preventing only those objects from automatic partitioning analysis.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_SCHEMA',
         PARAMETER_VALUE => 'HR',
         ALLOW           => FALSE);

    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_TABLE',
         PARAMETER_VALUE => 'SH.SALES',
         ALLOW           => FALSE);
END;
/
```

- After the previous example runs, use the following to remove the `HR` schema from the exclusion list.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_SCHEMA',
         PARAMETER_VALUE => 'HR',
         ALLOW           => NULL);
```

```
END;
/
```

- Use the following command to remove all schemas from the exclusion list.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_SCHEMA',
         PARAMETER_VALUE => NULL,
         ALLOW           => TRUE);
END;
/
```

- Assuming the inclusion and exclusion lists are empty, the following example adds the `HR` schema to the inclusion list. As soon as the inclusion list is no longer empty, only schemas in the inclusion list are considered.

  With this example, only the `HR` schema is a candidate for automatic partitioning.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_SCHEMA',
         PARAMETER_VALUE => 'HR',
         ALLOW           => TRUE);
END;
/
```

Manage Automatic Partitioning Report Retention Period

Set the retention period for automatic partitioning reports to 365 days.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
         PARAMETER_NAME  => 'AUTO_PARTITION_REPORT_RETENTION',
         PARAMETER_VALUE => '365');
END;
/
```

See CONFIGURE Procedure for more information.

Use Automatic Partitioning

Describes the flow and general processes for using and managing automatic partitioning in Autonomous Database.

1. Choose the database for automatic partitioning.
   In general, Oracle recommends using automatic partitioning in cloned or manually created databases rather than production databases. The analysis and verification of automatic partitioning using `RECOMMEND_PARTITION_METHOD` is potentially a resource-intensive and long running operation that can add undesirable processing to your database.

   To use a secondary database for automatic partitioning analysis, the database must have information about your workload in an internally managed SQL workload repository.

   a. Use a cloned database for automatic partitioning.

Autonomous Database automatically collects workload information over time in an internally managed SQL workload repository maintained in the SQL Tuning Set (`SYS_AUTO_STS`). If you clone your production database after having run the workload for a while, the clone will have the necessary workload information. You can use automatic partitioning with such clones without any additional actions.

See Clone an Autonomous Database Instance

b. Use other databases for automatic partitioning.
You can run your workload manually to collect the necessary workload information. If you manually run your workload prior to using automatic partitioning, any Autonomous Database that contains your desired schemas and data can be used for automatic partitioning after your workload was run, regardless of whether it is cloned or manually created.

2. Recommend automatic partitioning.
Use `RECOMMEND_PARTITION_METHOD` to analyze your database, specific schemas, or specific tables to identify the optimal partitioning strategy, if any. The recommendation analyzes your workload and schemas verifying performance benefits by running your workload against an internally created auxiliary table. This can be a resource-intensive and long running operation, requiring CPU and IO to create the auxiliary table and verify performance. You will also temporarily need additional space, of 1 - 1.5 times, your largest candidate table.

3. Apply the recommendation.
Any recommendation can be implemented with the `APPLY_RECOMMENDATION` procedure in the database where the recommendation analysis occurred. Alternatively, any recommendation can be extracted from the database used for analysis and applied to any database, such as a production system. The script needed for manual modification is stored in column `MODIFY_TABLE_DDL` in the `DBA_AUTO_PARTITION_RECOMMENDATION` view.

   Oracle recommends applying automatic partitioning to your database at off-peak time. While your tables will be modified to automatically partitioned tables, the conversion adds additional resource requirements to your system, such as additional CPU and IO. Automatic partitioning requires as much as 1.5 times the size of the table to being modified as additional free space, depending on concurrent ongoing DML operations on those tables.

Generate Automatic Partitioning Reports

Generate automatic partitioning reports using the `REPORT_ACTIVITY` and `REPORT_LAST_ACTIVITY` functions of the `DBMS_AUTO_PARTITION` package.

Generate a report, in plain text format, of automatic partitioning operations for a specific period

This example generates a report containing typical information about the automatic partitioning operations for the last 24 hours. The report is generated in plain text format by default.

```
DECLARE
  Report clob := NULL
BEGIN
    Report := DBMS_AUTO_PARTITION.REPORT_ACTIVITY();
END;
/
```

Generate a report, in HTML format, of automatic partitioning operations for MAY 2021

This example generates a report containing basic information about the automatic partitioning operations for the month of MAY 2021. The report is generated in the HTML format, and it includes only a summary of automatic partitioning operations.

```
DECLARE
  Report clob := NULL
BEGIN
    Report := DBMS_AUTO_PARTITION.REPORT_ACTIVITY(
                      ACTIVITY_START => TO_TIMESTAMP('2021-05-01', 'YYYY-MM-
DD'),
                      ACTIVITY_END   => TO_TIMESTAMP('2021-06-01', 'YYYY-MM-
DD'),
                      TYPE           => 'HTML',
                      SECTION        => 'SUMMARY',
                      LEVEL          => 'BASIC' );
END;
/
```

Generate a report, in plain text format, of the last automatic partitioning operation

This example generates a report containing typical information about the last automatic partitioning operation. The report is generated in the plain text format by default.

```
DECLARE
  Report clob := NULL
BEGIN
    Report := DBMS_AUTO_PARTITION.REPORT_LAST_ACTIVITY();
END;
/
```

See REPORT_ACTIVITY Function for more information.

See REPORT_LAST_ACTIVITY Function for more information.

Example Automatic Partitioning Scenarios

Example scenarios for automatic partitioning using the `DBMS_AUTO_PARTITION` API procedures and functions.

Generate a recommendation for a single table and manually apply the recommendation

1. Set `AUTO_PARTITION_MODE` parameter to `REPORT ONLY` to enable an automatic partitioning recommendation to be made and verified. The recommendation is not applied to the table.

   ```
   BEGIN
       DBMS_AUTO_PARTITION.CONFIGURE(
           PARAMETER_NAME  => 'AUTO_PARTITION_MODE',
           PARAMETER_VALUE => 'REPORT ONLY');
   END;
   /
   ```

2. Validate that `TPCH.LINEITEM` table is a candidate for automatic partitioning. This step is optional and recommended when you are selectively targeting single tables.

```
SELECT DBMS_AUTO_PARTITION.VALIDATE_CANDIDATE_TABLE(
           TABLE_OWNER => 'TPCH',
           TABLE_NAME  => 'LINEITEM')
FROM DUAL;
```

   If the table is a valid candidate, when you invoke automatic partitioning for a recommendation analysis it returns as `VALID`. Otherwise, the violation criteria is shown.

   See VALIDATE_CANDIDATE_TABLE Function for a list of criteria for eligible candidate tables.

3. Invoke the `DBMS_AUTO_PARTITION` API to generate a recommendation for the `TPCH.LINEITEM` table.

```
-- DEFINE SQLPLUS BIND VARIABLE FOR RECOMMENDATION ID
VARIABLE RECOMMENDATION_ID VARCHAR2(32);
BEGIN
  :RECOMMENDATION_ID := DBMS_AUTO_PARTITION.RECOMMEND_PARTITION_METHOD(
                            TABLE_OWNER => 'TPCH',
                            TABLE_NAME  => 'LINEITEM');
END;
/
```

   The recommendation analysis and verification that you perform with `DBMS_AUTO_PARTITION.RECOMMEND_PARTITION_METHOD` can be a resource-intensive and long running operation and might take considerable time. You should perform this step on a database that is not your primary production system. Oracle recommends giving the verification operation sufficient resources by choosing the HIGH service.

4. Check the recommendation. The view `DBA_AUTO_PARTITION_RECOMMENDATIONS` contains the information on the recommendation. In this example, check the recommended partition key and partition method.

```
SELECT PARTITION_METHOD, PARTITION_KEY
  FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
  WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID;
```

   Additionally, query the same view to get the performance analysis report generated for the workload after the table was partitioned according to the recommendation.

```
SELECT REPORT
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID;
```

5. After manual validation of the recommendation, apply the recommendation. If you are applying the recommendation in the database where the recommendation analysis has taken place, apply the recommendation by executing the `APPLY_RECOMMENDATION` procedure.

```
BEGIN
    DBMS_AUTO_PARTITION.APPLY_RECOMMENDATION(
         RECOMMENDATION_ID => :RECOMMENDATION_ID);
```

```
END;
/
```

If you want to apply the recommendation to a different database, such as your production environment, extract the modification DDL. Then, run the extracted modification DDL in your target database. The query to extract the modification DDL is as follows:

```
SELECT MODIFY_TABLE_DDL
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID;
```

Example output of modification DDL:

```
BEGIN
    -- DBMS_AUTO_PARTITION RECOMMENDATION_ID
C3F7A59E085C2F25E05333885A0A55EA
    --   FOR TABLE "TPCH"."LINEITEM"
    --   GENERATED AT 06/04/2021 20:52:29
    DBMS_AUTO_PARTITION.BEGIN_APPLY(EXPECTED_NUMBER_OF_PARTITIONS => 10);

    EXECUTE IMMEDIATE
    'ALTER TABLE "TPCH"."LINEITEM"
    MODIFY PARTITION BYLIST(SYS_OP_INTERVAL_HIGH_BOUND
        ("L_SHIPDATE", INTERVAL ''10'' MONTH, TIMESTAMP ''1992-01-01
00:00:00''))
    AUTOMATIC /* SCORE=23533.11;  */
    (PARTITION P_NULL VALUES(NULL))
    AUTO ONLINE PARALLEL';

    DBMS_AUTO_PARTITION.END_APPLY;
EXCEPTION WHEN OTHERS THEN
    DBMS_AUTO_PARTITION.END_APPLY;
    RAISE;
END;
```

6. Verify that the table was automatically partitioned, query the catalog views.

```
SELECT T.AUTO, T.PARTITIONING_TYPE, C.COLUMN_NAME
    FROM DBA_PART_TABLES T, DBA_PART_KEY_COLUMNS C
    WHERE T.OWNER = 'TPCH' AND T.TABLE_NAME = 'LINEITEM'
        AND T.OWNER = C.OWNER AND T.TABLE_NAME = C.NAME;
```

Use this query to identify when automatic partitioning was applied to a given table.

```
SELECT APPLY_TIMESTAMP_START, APPLY_TIMESTAMP_END
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE TABLE_OWNER = 'TPCH' AND TABLE_NAME = 'LINEITEM';
```

See CONFIGURE Procedure for information.

See VALIDATE_CANDIDATE_TABLE Function for information.

See RECOMMEND_PARTITION_METHOD Function for information.

See APPLY_RECOMMENDATION Procedure for information.

Generate a recommendation for eligible tables and manually apply the recommendation

1. Set `AUTO_PARTITION_MODE` parameter to `REPORT ONLY` to enable an automatic partitioning recommendation to be made and verified. The recommendation is not applied to existing tables.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
        PARAMETER_NAME  => 'AUTO_PARTITION_MODE',
        PARAMETER_VALUE => 'REPORT ONLY');
END;
/
```

2. Invoke the `DBMS_AUTO_PARTITION` API to generate a recommendation table.

```
-- DEFINE SQLPLUS BIND VARIABLE FOR RECOMMENDATION ID
VARIABLE RECOMMENDATION_ID VARCHAR2(32);
BEGIN
  :RECOMMENDATION_ID := DBMS_AUTO_PARTITION.RECOMMEND_PARTITION_METHOD();
END;
/
```

   The recommendation analysis and verification is a resource-intensive and long running operation and might take considerable time. On secondary, non-production databases, Oracle recommends giving the verification sufficient resources by choosing service HIGH.

3. Query the `DBA_AUTO_PARTITION_RECOMMENDATIONS` view to see which tables were analyzed.

```
SELECT TABLE_OWNER, TABLE_NAME, PARTITION_METHOD, PARTITION_KEY
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID
    ORDER BY RECOMMENDATION_SEQ;
```

4. Use this query to drill-down in the report for a specific table that was analyzed in the run, the `TPCH.LINEITEM` table in this example.

```
SELECT REPORT
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID
        AND TABLE_OWNER = 'TPCH'
        AND TABLE_NAME  = 'LINEITEM';
```

5. Apply the recommendation by executing the `APPLY_RECOMMENDATION` procedure.

```
BEGIN
    DBMS_AUTO_PARTITION.APPLY_RECOMMENDATION(
         RECOMMENDATION_ID => :RECOMMENDATION_ID);
END;
/
```

Alternately, apply recommendations for a specific table that was analyzed, the `TPCH.LINEITEM` table in this example.

```
BEGIN
    DBMS_AUTO_PARTITION.APPLY_RECOMMENDATION(
        RECOMMENDATION_ID => :RECOMMENDATION_ID,
        TABLE_OWNER       => 'TPCH',
        TABLE_NAME        => 'LINEITEM');
END;
/
```

See CONFIGURE Procedure for information.

See RECOMMEND_PARTITION_METHOD Function for information.

See APPLY_RECOMMENDATION Procedure for information.

> **Note:**
>
> Recommendations of automatic partitioning generated by the `RECOMMEND_PARTITION_METHOD` function have a time limit, specified by the `TIME_LIMIT` parameter, with a default of 1 day. If you are analyzing a large system with many candidate tables, a single invocation may not generate a recommendation for all tables that can be partitioned. You can safely invoke the recommendation for auto partitioning repeatedly to generate recommendations for additional tables. When the function is invoked and zero rows are in `DBA_AUTO_PARTITION_RECOMMENDATIONS` for the `RECOMMENDATION_ID`, then the function did not find any additional candidate tables for automatic partitioning.

Generate and automatically apply recommendations for eligible tables

1. Set `AUTO_PARTITION_MODE` parameter to `REPORT ONLY` to enable an automatic partitioning recommendation to be made and verified. The recommendation is not applied to existing tables.

```
BEGIN
    DBMS_AUTO_PARTITION.CONFIGURE(
        PARAMETER_NAME  => 'AUTO_PARTITION_MODE',
        PARAMETER_VALUE => 'IMPLEMENT');
END;
/
```

2. Invoke the `DBMS_AUTO_PARTITION` API to generate a recommendation table.

```
-- DEFINE SQLPLUS BIND VARIABLE FOR RECOMMENDATION ID
VARIABLE RECOMMENDATION_ID VARCHAR2(32);
BEGIN
  :RECOMMENDATION_ID := DBMS_AUTO_PARTITION.RECOMMEND_PARTITION_METHOD();
END;
/
```

The recommendation analysis and verification is a resource-intensive and long running operation and might take considerable time. On secondary, non-production databases, Oracle recommends giving the verification sufficient resources by choosing service HIGH.

3. Query the DBA_AUTO_PARTITION_RECOMMENDATIONS view to see which tables were analyzed.

```
SELECT TABLE_OWNER, TABLE_NAME, PARTITION_METHOD, PARTITION_KEY
    FROM DBA_AUTO_PARTITION_RECOMMENDATIONS
    WHERE RECOMMENDATION_ID = :RECOMMENDATION_ID
    ORDER BY RECOMMENDATION_SEQ;
```

4. Use the REPORT_LAST_ACTIVITY function to retrieve the report on the actions taken during the last run.

```
SELECT DBMS_AUTO_PARTITION.REPORT_LAST_ACTIVITY() FROM DUAL;
```

See CONFIGURE Procedure for information.

See RECOMMEND_PARTITION_METHOD Function for information.

See REPORT_LAST_ACTIVITY Function for information.

Data Dictionary Views for Automatic Partitioning

There are two new views and one updated view in the data dictionary for information about the automatic partitioning configuration and recommendations in your database.

- DBMS_AUTO_PARTITION DBA_AUTO_PARTITION_CONFIG View
  Displays the current configuration parameter settings for automatic partitioning.
- DBMS_AUTO_PARTITION DBA_AUTO_PARTITION_RECOMMENDATIONS View
  When you run CONFIGURE or RECOMMEND_PARTITION, the results from those procedures is stored in this view. The RECOMMENDATION_ID is used in several procedures and functions.
- DBMS_AUTO_PARTITION Updates to Existing Views
  Discusses the changes to existing views as a result of the implementation of automatic partitioning.

DBMS_AUTO_PARTITION DBA_AUTO_PARTITION_CONFIG View

Displays the current configuration parameter settings for automatic partitioning.

Column	Description
PARAMETER_NAME	Name of the configuration parameter
PARAMETER_VALUE	Value of the configuration parameter
LAST_MODIFIED	Time, in UTC, at which the parameter value was last modified.
MODIFIED_BY	User who last modified the parameter value

DBMS_AUTO_PARTITION DBA_AUTO_PARTITION_RECOMMENDATIONS View

When you run CONFIGURE or RECOMMEND_PARTITION, the results from those procedures is stored in this view. The RECOMMENDATION_ID is used in several procedures and functions.

Column	Description
TABLE_OWNER	Owner of the table
TABLE_NAME	Owner of the table

Column	Description
PARTITION_METHOD	Recommended partition method. See CONFIGURE Procedure
PARTITION_KEY	Recommended partition key. NULL means that analysis complete and recommendation is not to partition the table.
GENERATE_TIMESTAMP	Time, in UTC, when this recommendation was generated.
RECOMMENDATION_ID	ID used with DBMS_AUTO_PARTITION APIs to get additional information about this recommendation.
RECOMMENDATION_SEQ	When a recommendation ID has recommendations for multiple tables, provides the order in which the recommendations were generated. Performance reports are generated assuming that earlier recommendations have been applied. For example, the report for RECOMMENDATION_SEQ = 2 assumes recommendations have been applied for both RECOMMENDATION_SEQ = 1 and RECOMMENDATION_SEQ = 2.
MODIFY_TABLE_DDL	DDL that would be, or was, used to apply the recommendation.
APPLY_TIMESTAMP_START	Time, in UTC, when application of this recommendation was started. NULL if recommendation was not applied.
APPLY_TIMESTAMP_END	Time, in UTC, when application of this recommendation was finished. NULL if recommendation was not applied or if application has not finished.
REPORT	SQL Performance Analyzer report from SQL execution on database after recommendation is applied.

DBMS_AUTO_PARTITION Updates to Existing Views

Discusses the changes to existing views as a result of the implementation of automatic partitioning.

In *_PART_TABLES, the AUTO column (VARCHAR2(3)) was added. Its values are as follows:

- YES - If the table was partitioned by DBMS_AUTO_PARTITION.
- NO - If the table was not partitioned by DBMS_AUTO_PARTITION.

Using Oracle Graph with Autonomous Database

Oracle Graph with Autonomous Database enables you to create graphs from data in your Autonomous Database. With graphs you can analyze your data based on connections and relationships between data entities.

As an Analyst or a Developer you can use graph algorithms and graph pattern queries for ranking, clustering, and path analysis in a graph model of your data. You can use graph features to detect anomalous patterns, identify communities, and find new connections in your data. Then, you can use graphs in your applications, for example, for fraud detection in banking, improved traceability in smart manufacturing, building linked data applications, and more; all while gaining enterprise-grade security, ease of data ingestion, and support for a wide range of workloads.

Autonomous Database includes Graph Studio, which automates graph data management and simplifies modeling, analysis, and visualization across the graph analytics lifecycle. Autonomous Database includes all the graph capabilities from Oracle Database, except the following:

- When using RDF graphs, querying external data sources using SPARQL federated queries is not supported.
- Triple level security in RDF graphs using Oracle Label Security are not supported. See Fine-Grained Access Control for RDF Data for more information.

Database roles must be set to use Graph Studio on an Autonomous Database instance. See Required Roles to Access Tools from Database Actions for more information.

- About Oracle Graph Studio on Autonomous Database
- Building Applications Using Graph APIs with Autonomous Database
  If you are developing an application using graphs, you can also access Property Graph APIs and RDF Graph APIs with Autonomous Database without Graph Studio.

About Oracle Graph Studio on Autonomous Database

Graph Studio allows you to work with the two popular graph models, property graphs and RDF graphs.

Graph Studio features include automated modeling to create graphs from database tables, an integrated notebook to run graph queries and analytics, and native graph and other visualizations. You can easily create and manage either of the graph models. You can validate the graphs by executing queries and exploring their properties.

See Graph Studio: Interactive, Self-Service User Interface and Access Graph Studio Using Oracle Cloud Infrastructure Console for more information on Graph Studio.

Notes for Graph Studio on Autonomous Database:

- Graph Studio is supported with Data Warehouse and Transaction Processing workloads.

Building Applications Using Graph APIs with Autonomous Database

If you are developing an application using graphs, you can also access Property Graph APIs and RDF Graph APIs with Autonomous Database without Graph Studio.

- **Property Graph**: Create and work with Property Graphs with Python and Java developer APIs and the Property Graph Query Language (PGQL). You can use developer APIs to create a graph, run graph queries, and execute graph algorithms.

  You can use these APIs by deploying Oracle Graph Server and Client from OCI Marketplace.

  See Oracle Database Graph for more information.
- **RDF Graph**: Using RDF Graph Server and Query UI you can manage, store, query, and perform inferencing on RDF graphs in Autonomous Database. You can use a REST API, a SPARQL endpoint, a web UI to run SPARQL queries, and developer APIs for advanced RDF graph data management operations.

  You can use these APIs by deploying Oracle RDF Graph Server and Query UI from OCI Marketplace.

  See Using RDF Graph Server and Query UI for more information.

Use Oracle Machine Learning with Autonomous Database

Oracle Machine Learning components are integrated into Autonomous Database.

One of the Oracle Machine Learning components, Oracle Machine Learning Notebooks is a notebook style application designed for advanced SQL users. Oracle Machine Learning Notebooks provides interactive data analysis that lets you develop, document, share, and automate reports based on sophisticated analytics and data models.
Key features of Oracle Machine Learning Notebooks:

- Allows collaboration among data scientists, developers, business users
- Leverages the scalability and performance of Oracle Platform and its Cloud Services

To use Oracle Machine Learning Notebooks with Autonomous Database you need to add or create Oracle Machine Learning users and then access Oracle Machine Learning Notebooks:

- **OML User Management** lets the **Admin** (user with administrative privileges) create and modify Oracle Machine Learning user accounts. See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for details on accessing **OML User Management**.
- **OML Application** – application **users** access Oracle Machine Learning Notebooks to create, view, and share notebooks for data analytics, data visualization, and other Oracle Machine Learning Notebooks tasks. Users access Oracle Machine Learning Notebooks by clicking the Oracle Machine Learning Home icon on the User Administration page or from the account details mailed to a new user. See Work with Oracle Machine Learning User Interface for Data Access, Analysis, and Discovery for details on using the OML application.

See Machine Learning with Autonomous Database for more information.

- Machine Learning with Autonomous Database
  Oracle Machine Learning enables you to solve key enterprise business problems and accelerates the development and deployment of data science and machine learning-based solutions using scalable, automated, and secure machine learning for model building, evaluation, and deployment.

Machine Learning with Autonomous Database

Oracle Machine Learning enables you to solve key enterprise business problems and accelerates the development and deployment of data science and machine learning-based solutions using scalable, automated, and secure machine learning for model building, evaluation, and deployment.

Certain Oracle Machine Learning products are available on specific Oracle Database platforms.

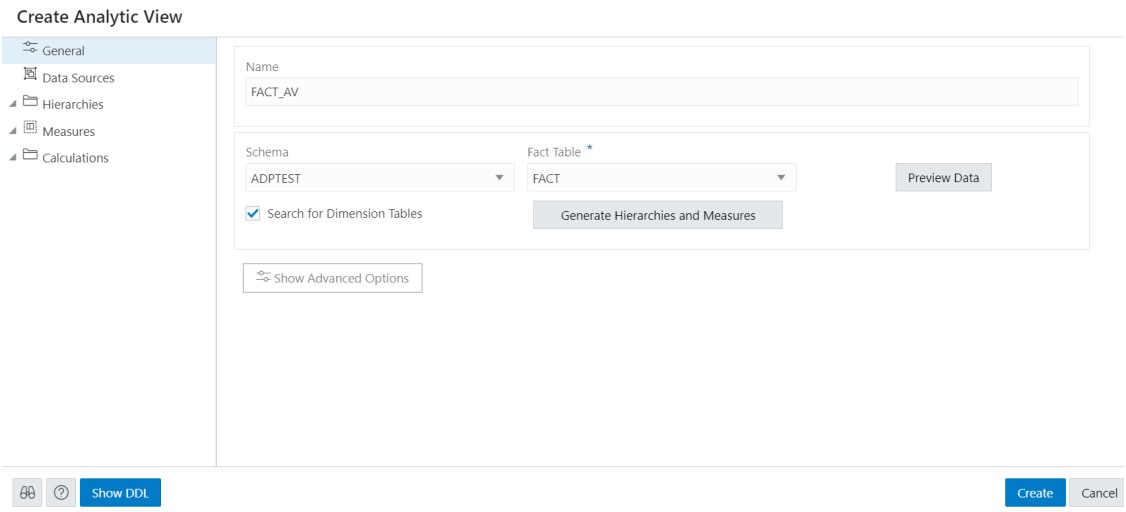
Product Name	Description	Available on:
OML Notebooks	Oracle Machine Learning Notebooks is a collaborative user interface for data scientists, business/data analysts, and SQL, R, and Python users who explore, prepare, and transform data, and who perform machine learning in Oracle Autonomous Database.	Oracle Autonomous Database

Product Name	Description	Available on:
OML AutoML User Interface	AutoML User Interface (AutoML UI) is an Oracle Machine Learning interface that provides you no-code automated machine learning. Business users without extensive data science background can use AutoML UI to create and deploy machine learning models, while data scientists can use it as a productivity tool for quickly assessing algorithms and hyperparameters.	Oracle Autonomous Database
OML for SQL	Oracle Machine Learning for SQL (OML4SQL) provides scalable in-database machine learning algorithms for model building and data scoring.	Oracle Database (on premises and Database Cloud Service) and Oracle Autonomous Database
OML for Python	Oracle Machine Learning for Python (OML4Py) is a Python API for performing statistical and machine learning analysis on data in your Oracle Database. It provides a Python interface to the in-database algorithms and supports deployment of user-defined Python functions with optimal system-supported data-parallel and task-parallel invocation. OML4Py also provides Python functions supporting automated machine learning (AutoML).	Oracle Database and Oracle Database Cloud Service 19c, 21c, 23ai, and Oracle Autonomous Database
Oracle Spatial AI	Oracle Spatial AI is a set of capabilities in OML4Py for detecting patterns and making predictions from geospatial data. It includes features for end-to-end workflows, including spatial machine learning pipelines.	Oracle Autonomous Database
OML for R	Oracle Machine Learning for R (OML4R) is an R API for performing statistical and machine learning analysis on data in your Oracle database. It provides an R interface to the in-database algorithms and supports deployment of user-defined R functions with optional system-supported data-parallel and task-parallel invocation.	Oracle Database and Oracle Database Cloud Service, and Oracle Autonomous Database

Product Name	Description	Available on:
OML Services	The REST API for Oracle Machine Learning Services provides a REST API supporting model management and deployment, data and model monitoring, and cognitive text capabilities. It supports lightweight scoring for real-time and streaming use cases for both in-database models and ONNX-format models.	Oracle Autonomous Database
Oracle Data Miner	An extension to Oracle SQL Developer that enables data scientists and citizen data scientists to explore and prepare data, easily build and compare multiple machine learning models, make predictions, and accelerate model deployment.	Oracle Database and Oracle Autonomous Database

Creating Analytic Views

You can create Analytic Views and view information about them. You can also edit and perform other actions on them.



When you create an Analytic View, you identify a fact table that contains the data to inspect. The **Generate Hierarchies and Measures** button looks at the contents of that table, identifies any hierarchies in the fact table, and searches for other tables that may contain related hierarchies.

While creating an Analytic View, you can enable or disable the following advanced options:

- Autonomous Aggregate Cache, which uses the dimensional metadata of the Analytic View to manage a cache and that improves query response time.

- Analytic View Transparency Views, which presents Analytic Views as regular database views and enables you to use your analytic tools of choice while gaining the benefits of Analytic Views.
- Analytic View Base Table Query Transformation, which enables you to use your existing reports and tools without requiring changes to them.

Create Analytic View

To create Analytic View, click **Create** from the Data Analysis home page and select **Create Analytic View** to begin the process.

Click **Cancel** to cancel the creation of the Analytic View at any time.

Specify Attributes of the Analytic View

On the **General** tab of the **Create Analytic View** pane, specify the following:

- The name for the Analytic View
- The fact table for the view
- Advanced options

You can also preview the data of the fact table and see statistics about that data.

In the **Name** field, specify a name of your choice.

The **Schema** field has the current user's schema. You can only create an Analytic View in that schema.

In the **Fact Table** field, expand the drop-down list and click **More Sources**. The **Select Sources** dialog box has a list of the available tables and views. Select a table or view from the list.

To filter the list, begin typing characters in the Filter field. As you type, the list changes to show the tables or views that contain the characters. Clear the field to show the complete list again. After you select a table or view, click OK.

To enable or disable the advanced options, on the **Create Analytic View** pane, click the **Show Advanced Options** icon at the bottom left. Select or deselect options as desired.

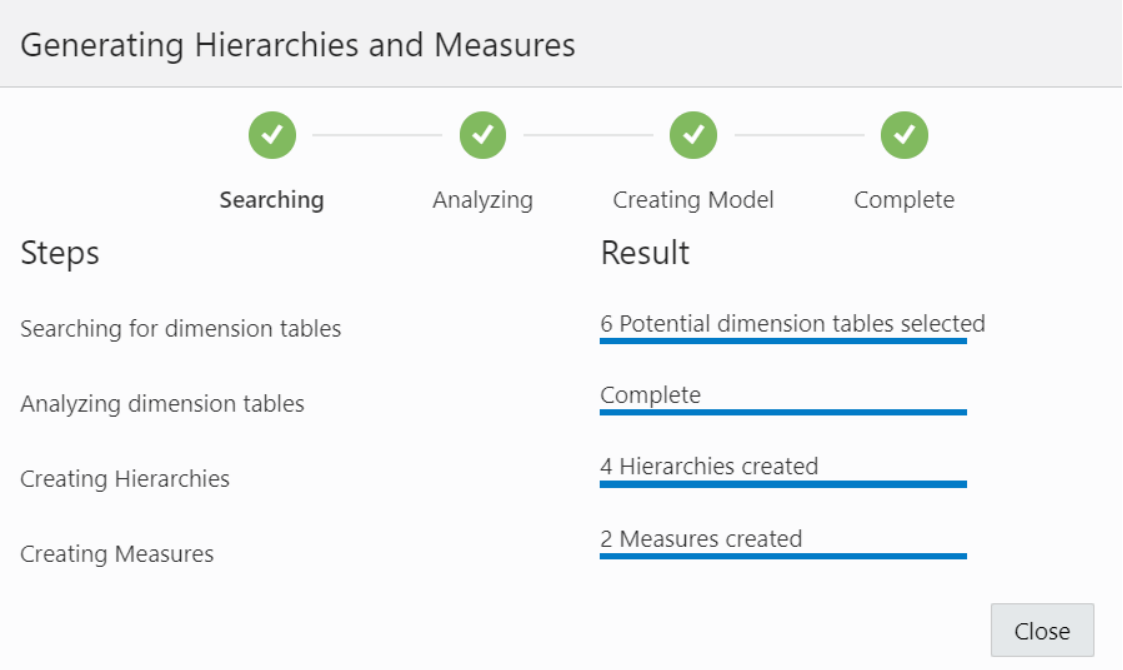
To view the data in the fact table and statistics about the data, click the **Preview Data** button. In the Preview and Statistics pane, the Preview tab shows the columns of the table and the data in the columns.

The Statistics tab shows the size of the table and the number of rows and columns. The statistics may take a few moments to appear, during which time the message, "No statistics available..." may appear. The statistics include the names of the columns, their data types, the number of distinct values and null values, the maximum and minimum values, and other information. The bar graph displays the top unique column values and the number of their occurrences for the selected column. Point to a bar in the graph to see the number of occurrences of the unique value.

Click **Close** to close the Preview and Statistics pane and return to the Create Analytic View pane.

Click on **Generate Hierarchies and Measures** icon.

The Generating Hierarchies and Measures dialog box displays the progress of searching for dimension tables, analyzing the dimension tables and identifying and creating the data sources, joins, hierarchies, and measures to use. When the process completes, click **Close**.



The **Search for Dimension Tables** check box when selected, enables you to search for dimension tables while generating hierarchies and measures.

After the hierarchies and measures are generated, they are displayed under their respective tabs. Review the hierarchies and measures created for you.

Specify the **Name**, **Fact Table** and select **Advanced Options** in the **General** tab of **Create Analytic View** pane. Click **Create** to generate an Analytic View.

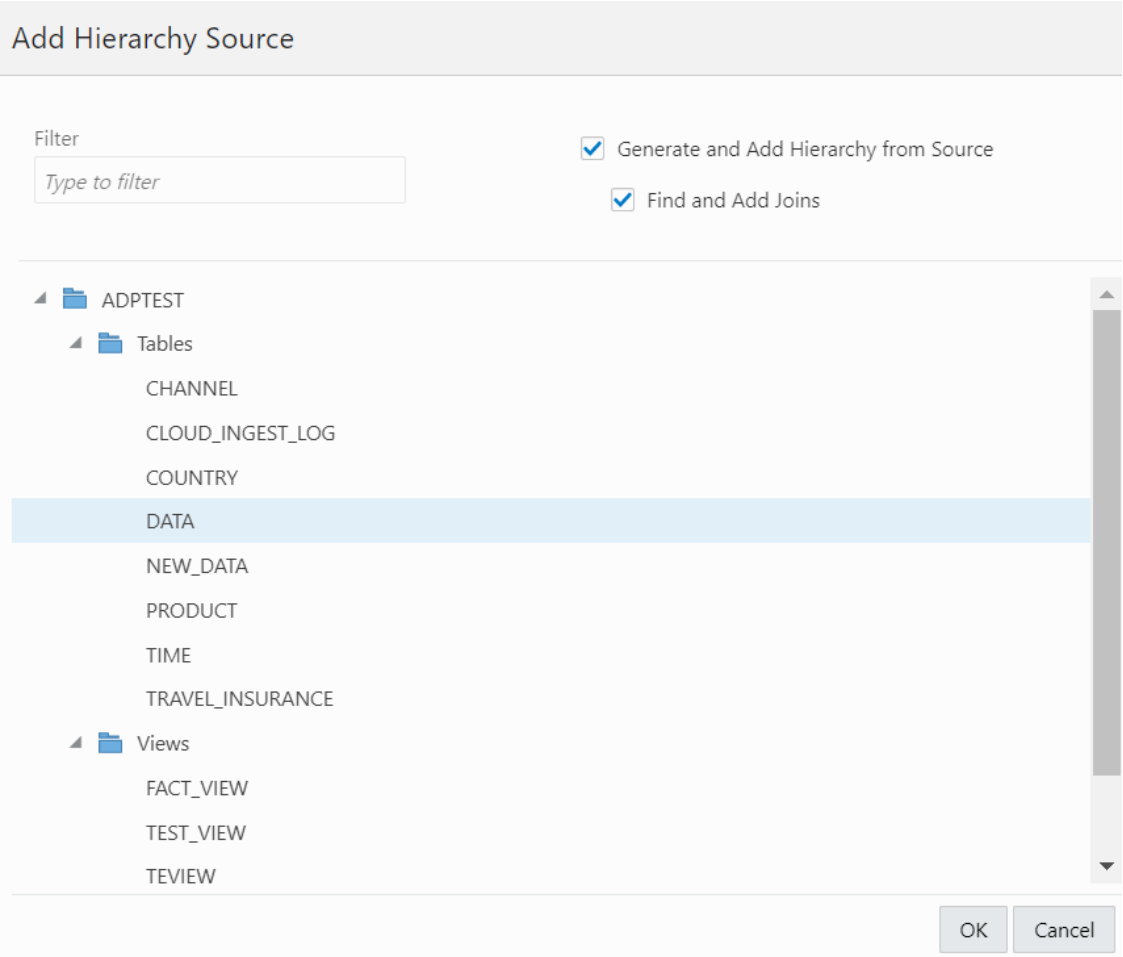
View Data Sources

The Data Sources tab displays the sources of the data and the relationships among them. It has a graphical display of the fact table and the related dimension tables. For example, a fact table of health insurance data might have columns for geography identifiers, income codes, and gender codes. The Data Sources tab would display items for the fact table and for the geography, income, and gender dimension tables.

You can add hierarchies from data sources even after generating hierarchies from the existing fact table. You can add one or more hierarchies to your new or existing analytic view. Multiple hierarchies can be defined and used in an analytical view, however only one will be used by default.

Right-click the Data Sources tab and select **Add Hierarchy Sources** or select **Add Hierarchy Sources**.

Selecting **Add Hierarchy Sources** launches an **Add Hierarchy Source** dialog box.



You can view all the fact tables and views associated with the analytic view.

In the filter field, you can either manually look for the source or start typing to search for the fact table or views from the list of available fact tables and views. After typing the full name of the source, the tool automatically matches the fact table or view.

Select **Generate and Add hierarchy from Source** to generate analysis and hierarchies associated with the source data you select.

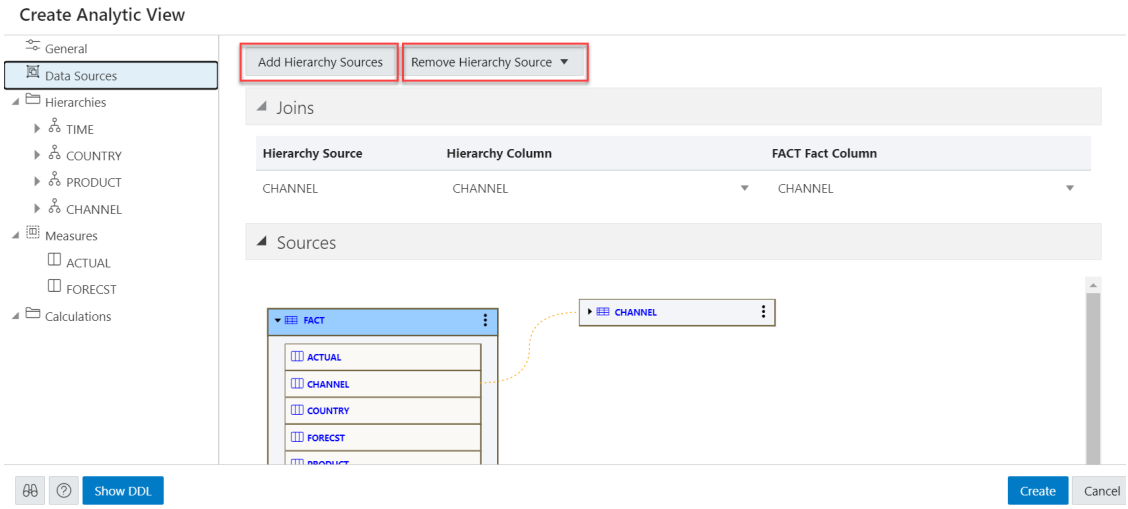
Select **Find and Add Joins** to link all the data sources with the fact table. You can add multiple join entries for a single hierarchy.

Click **OK** to select the source.

The Generating Hierarchies and Measures dialog box displays the progress of analyzing the dimension tables and creating the hierarchies. When the process completes, click **Close**.

> **Note:**
>
> When you add a hierarchy from the data source, you see the new hierarchy in the list of hierarchies in the Hierarchies tab. You can navigate between the Data Sources tab, the Hierarchies tab, the Measures tab, the Calculations tab. You can add a hierarchy from a source that is not connected by navigating back to the Data Sources tab.

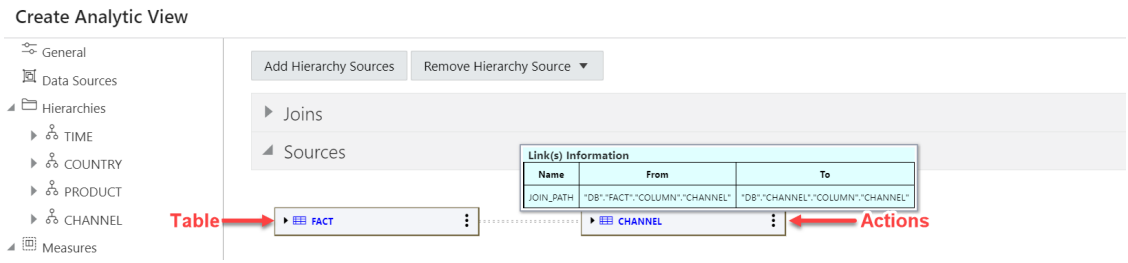
Select **Remove Hierarchy Source** to remove the hierarchies you create from the data sources. You cannot remove hierarchies generated from the fact table you select from this option.



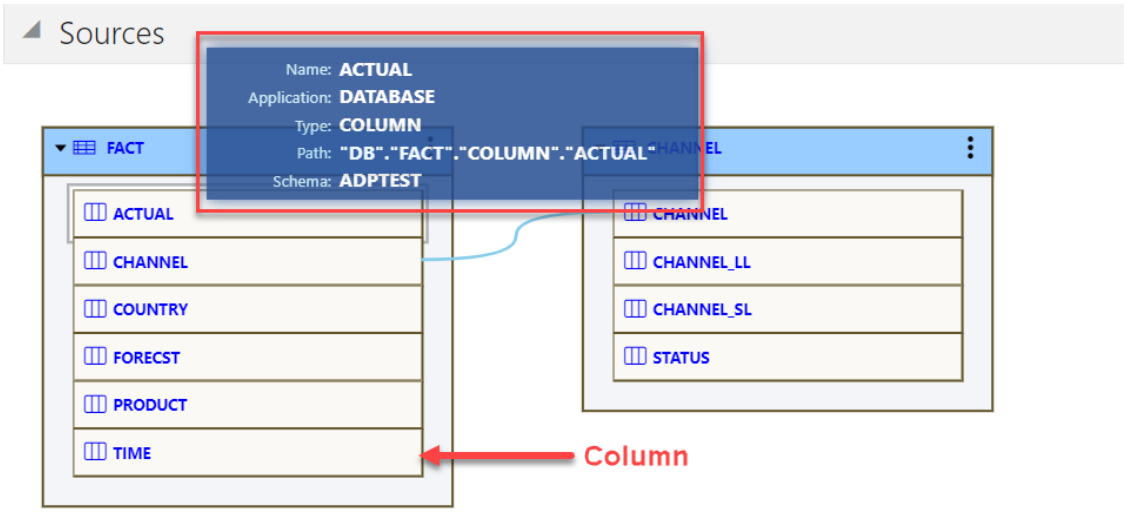
Expand **Joins** to view the **Hierarchy Source**, **Hierarchy Column** and the **Fact column** mapped with the Analytic View. The **Joins** is visible only when the hierarchy table differs from the fact table. You can add multiple join entries for a single hierarchy.

Expand **Sources** to view the fact table associated with the Analytic View. The data model expands to include the data from the source that you added.

Pointing to an item displays the name, application, type, path and the schema of the table. Click the **Actions** (three vertical dots) icon at the right of the item to display a menu to expand or collapse the view of the table.



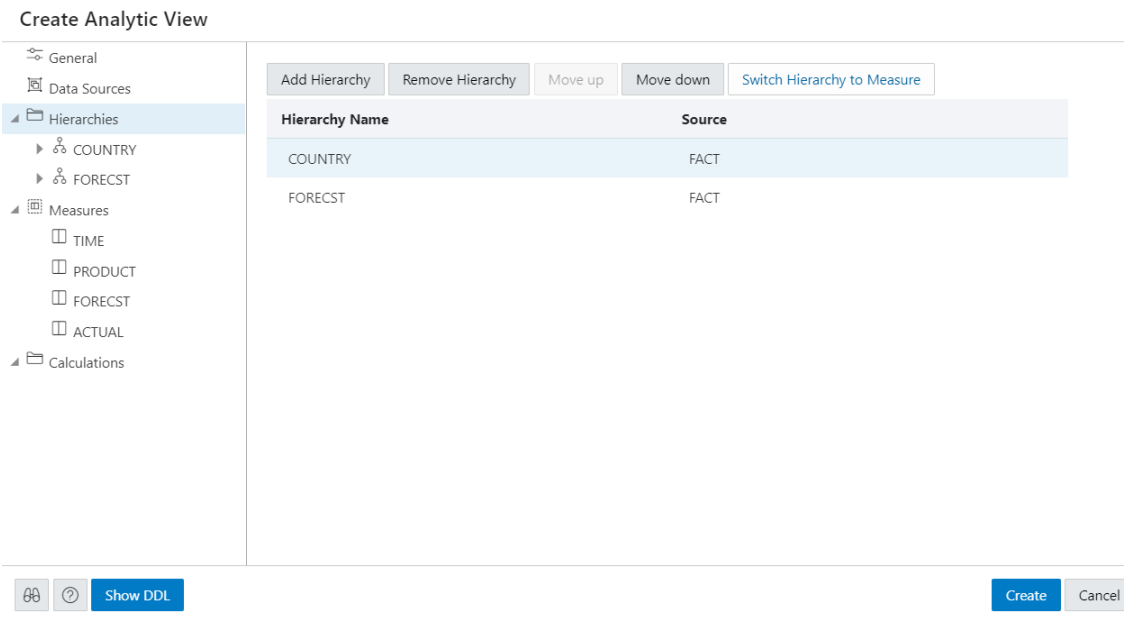
An expanded item displays the columns of the table. Pointing to a column displays the name, application, type, path, and schema of the column.



The lines that connect the dimension tables to the fact table indicate the join paths between them. Pointing to a line displays information about the join paths of the links between the tables. If the line connects a table that is collapsed, then the line is dotted. If the line connects two expanded tables, then the line is solid and connects the column in the dimension table to the column in the fact table.

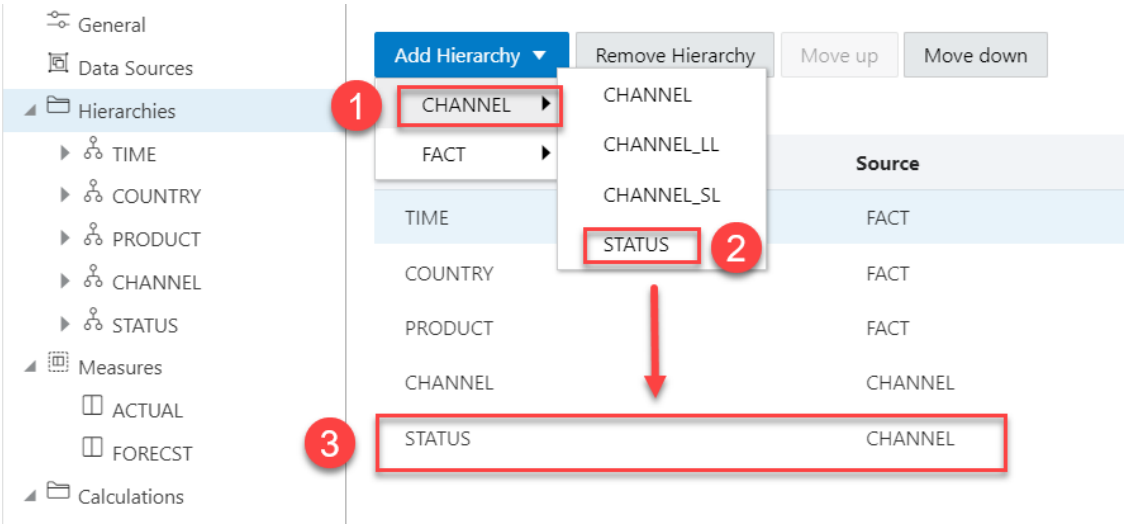
View and Manage Hierarchies

The Hierarchies tab displays the hierarchies generated by the Analytic View creation tool. The display includes the name of the hierarchy and the source table.



An analytic view must include at least one hierarchy.

To add a Hierarchy, click **Add Hierarchy**. This results in a display as a list of column in that table. Select a column that operates as the detailed level of the hierarchy and be the join-key to the fact table.



To remove the hierarchy, select the hierarchy you want to remove from the list and click **Remove Hierarchy**

Select **Move Up** or **Move Down** to position the order of the Hierarchy in the resulting view.

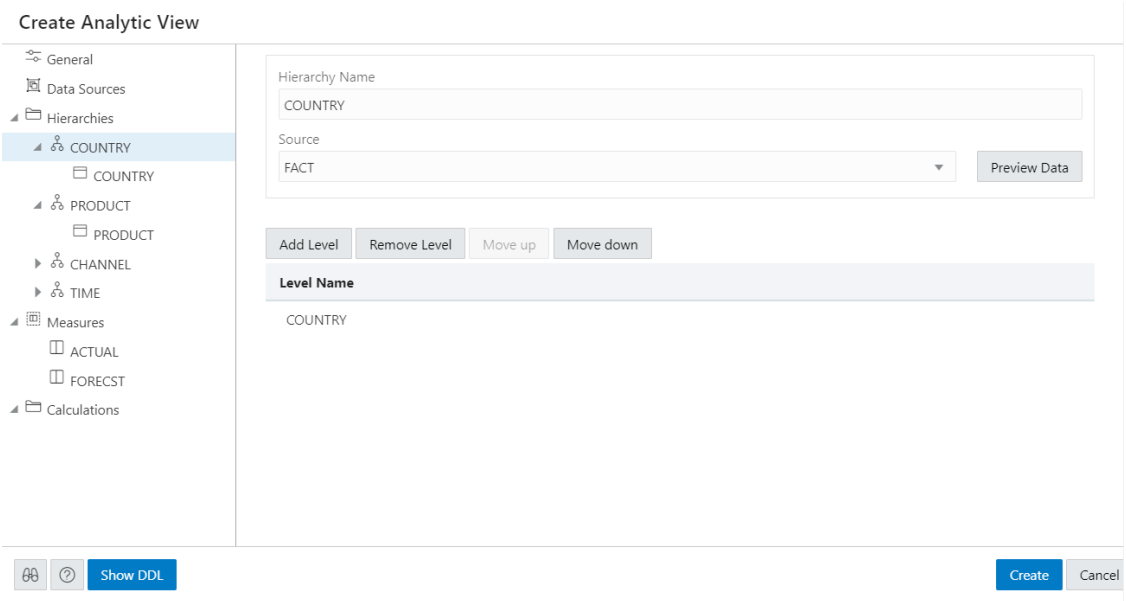
Click **Switch Hierarchy to Measure** to change the hierarchy you select to a measure in the Measures list.

You can also **Add Hierarchy** and **Add Hierarchy From Table** by right-clicking the Hierarchy tab.

If you click on a hierarchy name, a dialog box displays the Hierarchy Name and Source.

To change the source, select a different source from the drop-down list.

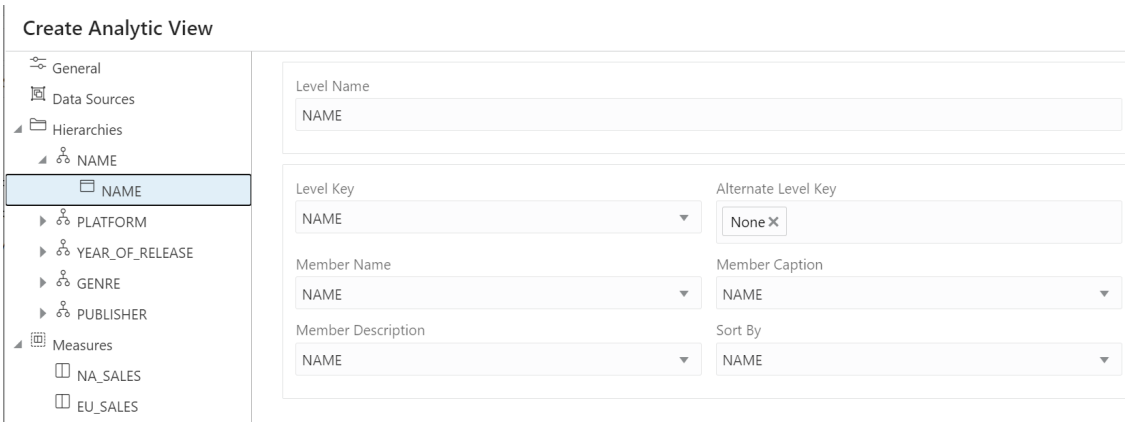
Select **Add Level** to add a level to the hierarchy. Click **Remove Level** to remove the selected level from the hierarchy.



To view the data in the fact table and statistics about the data, click the **Preview Data** button. In the Preview and Statistics pane, the Preview tab shows the columns of the table and the data in the columns. The Statistics tab shows the size of the table and the number of rows and columns.

If you click on a particular level in the Hierarchy tab, a dialog box displays it's respective Level Name, Level Key, Alternate Level Key, Member Name, Member Caption, Member Description, source, and Sort By drop-down. To change any of the field values, enter the value in the appropriate field.

> **Note:**
>
> You can enter multiple level keys Member Name, Member Caption, Member Description and Sort By.



Member Captions and Member Descriptions generally represent detailed labels for objects. These are typically end-user-friendly names. For example, you can caption a hierarchy representing geography areas named GEOGRAPHY_HIERARCHY as "Geography" and specify its description as "Geographic areas such as cities, states, and countries."

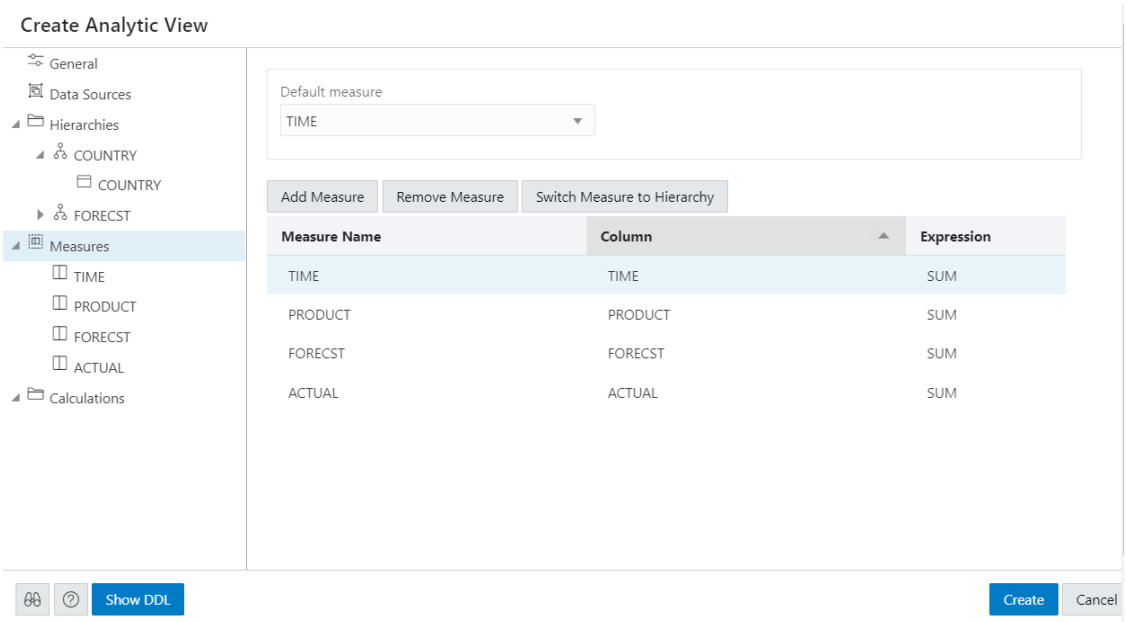
To see the measures for the Analytic View, click **Measures** tab. To immediately create the Analytic View, click **Create**. To cancel the creation, click **Cancel**.

View and Manage Measures

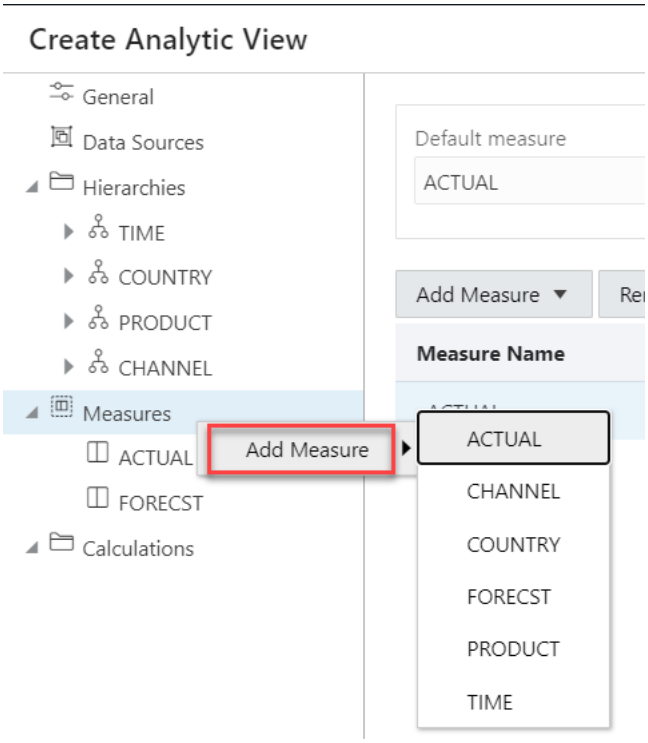
The Measures tab displays the measures suggested for the Analytic View. It displays the Measure Name, Column, and operator Expression for each measure.

The measures specify fact data and the calculations or other operations to perform on the data.

To add measures, click **Add Measure**. You can view a new measure at the bottom of the measures list. To remove the measure, select the measure you want to remove from the list and click **Remove Measure**.



To alternatively add a measure from the data source, right- click the Measures tab. This pops up a list of columns that can be used as measures. Select one measure from the list.



You can exclude a column from the measures on right-clicking the Measures tab and selecting Remove Measure.

Click **Switch Measure to Hierarchy** to change the measure you select to hierarchy in the Hierarchies list.

You must specify a measure as the default measure for the analytic view; otherwise, the first measure in the definition is the default. Select **Default Measure** from the drop-down.

To add a measure, right-click the Measures tab and select **Add Measure**. To remove a measure, select the particular measure you want to remove, right-click on it and select **Remove Measure**.

You can select a different column for a measure from the Column drop-down list. You can select a different operator from the Expression drop-down list.

In creating an analytic view, you must specify one or more hierarchies and a fact table that has at least one measure column and a column to join to each of the dimension tables outside of the fact table.

Create new calculated measures

You can add measure calculations to a query of an analytic view.

The measures and hierarchies associated with the analytic views enable us to create new calculated measures.

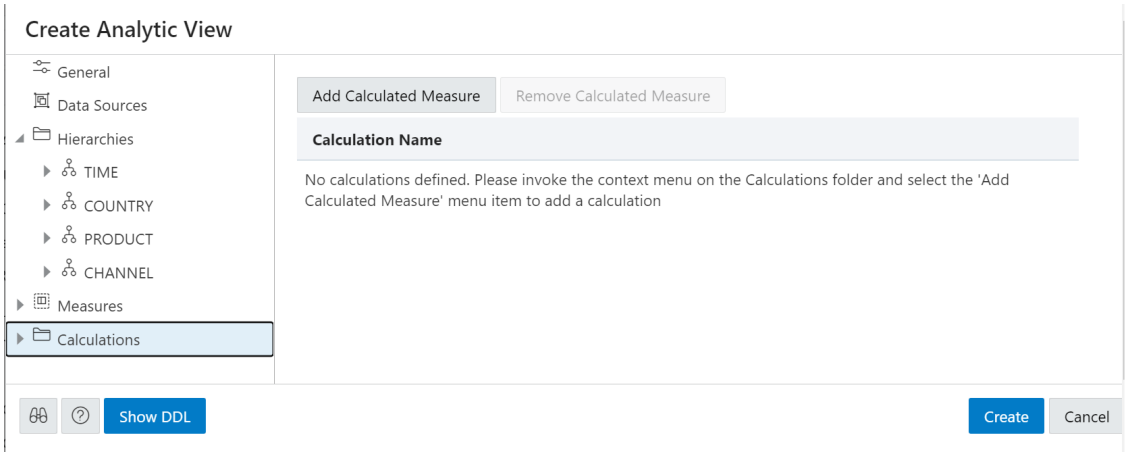
Calculated measures return values from data stored in one or more measures. You compute these measures at run time.

> **Note:**
>
> You can create the measures without increasing the size of the database since the calculated measures do not store the data. However, they may slow performance. You need to decide which measures to calculate on demand.

The Analytic Views provides easy-to-use templates for creating calculated measures.

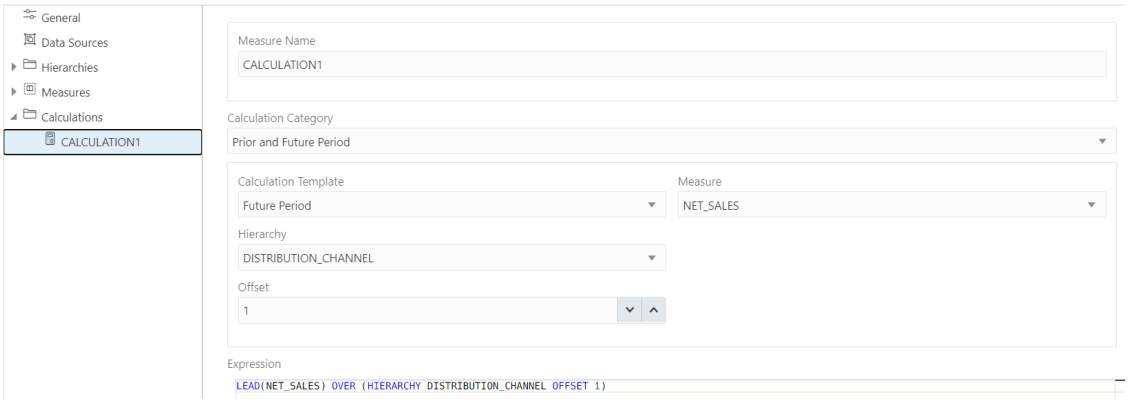
Once you create a calculated measure, it appears in the list of measures of the Analytic View .You can create a calculated measure at any time which is available for querying in SQL.

The Data Analysis tool provides easy-to-use templates for creating calculated measures.



Click **Add Calculated Measure** to add calculations to the measures. You can view the new calculation with system generated name in the **Calculations** tab.

Click the newly created calculated measure.



In the **Measure Name** field, enter the name of the calculated measure.

You can select preferred category of calculation from a list of options such as Prior and Future Period, Cumulative Aggregates, Period To Date, Parallel Period, Moving Aggregates, Share, Qualified Data Reference, and Ranking using the **Calculation Category** drop-down.

Your choice of category of calculation dynamically changes the **Calculation Template**.

For more details on how to use Calculation templates, see Using Calculation Templates.

Select the **Measure** and **Hierarchy** on which you want to base the calculated measures.

Select **Offset** value by clicking the up or the down arrow. The number specifies the number of members to move either forward or backward from the current member. The ordering of members within a level is dependent on the definition of the attribute dimension used by the hierarchy. The default value is 0 which represents POSITION FROM BEGINNING.

The Expression field lists the expressions which the calculated measure uses.

On the creation of the Analytic view, the calculated measure appears in the navigation tree in the Calculated Measures folder.

Click **Create**. A confirmation dialog box appears that asks for your confirmation. Select **Yes** to proceed with the creation of Analytic View.

After creating the Analytic View, you will view a success message informing you of its creation.

On editing the Analytic View you create, you can view the calculated measure in the navigation tree in the Calculations folder.

Click the **Tour** icon for a guided tour of the worksheet highlighting salient features and providing information if you are new to the interface.

Click the **help** icon to open the contextual or online help for the page you are viewing.

Click **Show DDL** to generate Data Definition Language statements for the analytic view.

Edit Analytic View

You might want to edit an Analytic View to make changes to the data sources, the hierarchies, or the measures.

To edit an Analytic View, click the **Action** icon on the Analytic View item, then click **Edit Analytic View**. On the Edit Analytic View screen, select a tab and make changes as desired.

When you have completed the changes, click **Update**.

Use Select AI for Natural Language Interaction with your Database

Select AI enables SQL access to generative AI using Large Language Models (LLMs) and embedding models. This includes support for natural language to SQL query generation and retrieval augmented generation, among other features.

- About Select AI
  Use natural language to interact with your database and LLMs through SQL to enhance user productivity and develop AI-based applications. Select AI simplifies and automates using generative AI, whether generating, running, and explaining SQL from a natural language prompt, using retrieval augmented generation with vector stores, generating synthetic data, or chatting with the LLM.
- Select AI Concepts
  Explores the concepts and terms related to Select AI.
- Select AI Use Cases
  Select AI enhances data interaction and enables developers to build AI-driven applications directly from SQL, transforming natural language prompts to SQL queries and text responses, supporting chat interaction with LLMs, enhancing response accuracy with current data using RAG, and generating synthetic data.
- Getting Started with Select AI
  To get started, review the prerequisites and the tasks that you need to perform to use Select AI.
- Manage AI Profiles
  You can create and manage your AI profiles through `DBMS_CLOUD_AI` package.
- Use AI Keyword to Enter Prompts
  Use `AI` as the keyword in a `SELECT` statement for interacting with the database using natural language prompts.
- Enable Conversations to Enhance User Interaction
  Conversations in Select AI refer to the interactive dialogue between the user and the system, where a sequence of user-provided natural language prompts are used to query or interact with the database.
- Select AI with Retrieval Augmented Generation (RAG)
  Select AI with RAG augments your natural language prompt by retrieving content from your specified vector store using semantic similarity search. This reduces hallucinations by using your specific and up-to-date content and provides more relevant natural language responses to your prompts.
- Synthetic Data Generation
  Generate synthetic data using random generators, algorithms, statistical models, and Large Language Models (LLMs) to simulate real data for developing and testing solutions effectively.
- Examples of Using Select AI
  Explore integrating Oracle's Select AI with various supported AI providers to generate, run, and explain SQL from natural language prompts or chat with the LLM.

Related Topics

- DBMS_CLOUD_AI Package
  The `DBMS_CLOUD_AI` package, with Select AI, facilitates and configures the translation of natural language prompts to generate, run, explain SQL statements. Also, enables retrieval

augmented generation and natural language-based interactions, including chatting with LLMs.

About Select AI

Use natural language to interact with your database and LLMs through SQL to enhance user productivity and develop AI-based applications. Select AI simplifies and automates using generative AI, whether generating, running, and explaining SQL from a natural language prompt, using retrieval augmented generation with vector stores, generating synthetic data, or chatting with the LLM.

When you use Select AI, Autonomous Database manages the process of converting natural language into SQL. This means you can provide a natural language prompt instead of SQL code to interact with your data. Select AI serves as a productivity tool for SQL users and developers and enables non-expert SQL users to derive useful insights from their data, without having to understand data structures or technical languages.

Select AI also automates the retrieval augmented generation (RAG) process from generating vector embeddings to retrieving relevant content based on your prompt through semantic similarity search using your vector store. Other features include synthetic data generation, supporting chat history for conversations, and other features, all from a SQL interface.

The `DBMS_CLOUD_AI` package enables integration with a user-specified LLM for generating SQL code using natural language prompts. For natural language to SQL generation, this package provides an augmented prompt to the LLM containing the relevant database schema metadata. This enables generating, running, and explaining SQL queries based on natural language prompts. It also facilitates retrieval augmented generation using vector stores, synthetic data generation, and allows for chatting with the LLM. The `DBMS_CLOUD_AI` package works with AI providers listed in Select your AI Provider and LLMs.

> **Note:**
>
> - You must have an account with the AI provider and provide the credentials through `DBMS_CLOUD_AI` objects that the Autonomous Database uses.
> - You can submit prompts in multiple languages. The quality of the result depends on the abilities of the specific LLM or the embedding model (transformer) being used. Check your LLM or embedding model documentation for multi-language support.

Topics

- Usage Guidelines
  Provides usage guidelines to assist in the use of Select AI for natural language to SQL generation..
- Supported Platforms
  Select AI is supported on Autonomous Database Serverless and Autonomous Database on Dedicated Exadata Infrastructure and Cloud at Customers.
- Select your AI Provider and LLMs
  Choose an AI provider and LLM that meets your security standards and aligns with your specific needs, like text or code generation.

Usage Guidelines

Provides usage guidelines to assist in the use of Select AI for natural language to SQL generation..

Intended Use

This feature generates, runs, and explains SQL queries from user-provided natural language prompts. It automates tasks that users would otherwise perform manually using their schema metadata and a large language model (LLM) of their choice. Additionally, it facilitates retrieval augmented generation with vector stores and enables chatting with the LLM.

Depending on the Select AI action you specify, you provide a prompt, whether for natural language to SQL generation, RAG, or pass-through chat, and Select AI automates the interaction with LLMs and your database using SQL and PL/SQL interfaces. Specifically, it generates SQL queries from natural language based on metadata from the specified schema and tables. Additionally, it facilitates chat-based generative AI, optionally enhanced with content from vector stores through retrieval augmented generation (RAG) for improved response quality. It also explains SQL queries based on natural language prompts and supports synthetic data generation for one or multiple schema tables. Select AI enables submitting general requests with the `chat` action.

Prompt Augmentation Data

For SQL query generation, the database augments the user-specified prompt with database metadata to mitigate hallucinations from the LLM. The augmented prompt is then sent to the user-specified LLM to produce the query. When using vector stores with retrieval augmented generation (RAG), content from the vector store is retrieved using semantic similarity search with the provided prompt. This content becomes part of the augmented prompt that is sent to the LLM.

The database augments the prompt with schema metadata only. This metadata may include schema definitions, table and column comments, and content available from the data dictionary. For the purposes of SQL generation, the database does not provide table or view contents (actual row or column values) when augmenting the prompt.

The `narrate` action, however, does provide to the LLM either:

- the result of a natural language to SQL query, which contains database data, or
- the result of semantic similarity search as retrieved from the vector store supporting retrieval augmented generation (RAG).

The LLM uses these results to generate a natural language text response.

> **WARNING:**
>
> Large language models (LLMs) have been trained on a broad set of text documentation and content, typically from the Internet. As a result, LLMs may have incorporated patterns from invalid or malicious content, including SQL injection. Thus, while LLMs are adept at generating useful and relevant content, they also can generate incorrect and false information including SQL queries that produce inaccurate results and/or compromise security of your data.
>
> The queries generated on your behalf by the user-specified LLM provider will be run in your database. Your use of this feature is solely at your own risk, and, notwithstanding any other terms and conditions related to the services provided by Oracle, constitutes your acceptance of that risk and express exclusion of Oracle's responsibility or liability for any damages resulting from that use.

Supported Platforms

Select AI is supported on Autonomous Database Serverless and Autonomous Database on Dedicated Exadata Infrastructure and Cloud at Customers.

- Autonomous Database Serverless
- Autonomous Database on Dedicated Exadata Infrastructure
- Autonomous Database on Dedicated Exadata Infrastructure Region
- Autonomous Database Cloud@Customer

Select your AI Provider and LLMs

Choose an AI provider and LLM that meets your security standards and aligns with your specific needs, like text or code generation.

Different LLMs excel at various tasks based on their training data and intended purpose. Some models are excellent for text generation but may not perform well in code generation, while others are specifically optimized for coding tasks. Choose an LLM that best suits your needs.

AI Provider	LLMs	Embedding Model for RAG	Purpose

Select AI Concepts

Explores the concepts and terms related to Select AI.

- Actions
- AI Profile
- AI Provider
- Conversations
- Database Credentials
- Hallucination in LLM
- IAM
- Large Language Model (LLM)
- Metadata
- Metadata Clone
- Natural Language Prompts
- Network Access Control List (ACL)
- Retrieval Augmented Generation (RAG)
- Semantic Similarity Search
- Vector Distance
- Vector Index
- Vector Store

Actions

An action in Select AI is a keyword that instructs Select AI to perform different behavior when acting on the prompt. By specifying an action, users can instruct Select AI to process their natural language prompt to generate SQL code, to respond to a chat prompt, narrate the output, display the SQL statement, or explain the SQL code, leveraging the LLMs to efficiently interact with the data within their database environment.

The following are the supported actions for Select AI:

- `runsql`: Generates the SQL statement for a natural language prompt and runs the underlying SQL query to return a rowset. This is the default action and does not require specifying this parameter.
- `showsql`: Displays the SQL statement for a natural language prompt.
- `narrate`: Sends the result of the SQL query run by the database back to the LLM to generate a natural language description of that result.

  When a vector index is specified in the AI profile to enable RAG, the system uses the specified transformer model to create a vector embedding from the prompt for semantic

similarity search against the vector store.. The system then adds the retrieved content from the vector store to the user prompt and sends it to the LLM to generate a response based on this information.

- `chat`: Passes the user prompt directly to the LLM to generate a response, which is provided to the user.
- `explainsql`: Explains the generated SQL from the prompt into natural language. This option sends the generated SQL to the AI provider, which then produces a natural language explanation.

For more details on how you can use these actions, see Examples of Using Select AI.

AI Profile

An AI profile is a specification that includes the AI provider to use and other details regarding metadata and database objects required for generating responses to natural language prompts. See CREATE_PROFILE Procedure and Profile Attributes.

AI Provider

An AI Provider in Select AI refers to the service provider that supplies the LLM or transformer or both for processing and generating responses to natural language prompts. These providers offer models that can interpret and convert natural language for the use cases highlighted under the LLM concept. See Select your AI Provider and LLMs for the supported providers.

Conversations

Conversations in Select AI represent an interactive exchange between the user and the system, enabling users to query or interact with the database through a series of natural language prompts. Select AI incorporates up to 10 previous prompts into the current request, creating an augmented prompt sent to the LLM. See Enable Conversations to Enhance User Interaction.

Database Credentials

Database credentials are authentication credentials used to access and interact with databases. They typically consist of a user name and a password, sometimes supplemented by additional authentication factors like security tokens. These credentials are used to establish a secure connection between an application or user and a database, such that only authorized individuals or systems can access and manipulate the data stored within the database.

Hallucination in LLM

Hallucination in the context of Large Language Models refers to a phenomenon where the model generates text that is incorrect, nonsensical, or unrelated to the input prompt. Despite being a result of the model's attempt to generate coherent text, these responses can contain information that is fabricated, misleading, or purely imaginative. Hallucination can occur due to biases in training data, lack of proper context understanding, or limitations in the model's training process.

IAM

Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who has access to your cloud resources. You can control what type of access a group of users have

and to which specific resources. To learn more, see Overview of Identity and Access Management.

Large Language Model (LLM)

A Large Language Model (LLM) refers to an advanced type of artificial intelligence model that is trained on massive amounts of text data to support a range of use cases depending on their training data. This includes understanding and generating human-like language as well as software code and database queries. These models are capable of performing a wide range of natural language processing tasks, including text generation, translation, summarization, question answering, sentiment analysis, and more. LLMs are typically based on sophisticated deep learning neural network models that learn patterns, context, and semantics from the input data, enabling them to generate coherent and contextually relevant text.

Metadata

Database metadata refers to the data that describes the structure, organization, and properties of the database tables and views.

Metadata Clone

A metadata clone or an Autonomous Database clone creates a copy of a metadata defining the database or schema, containing only the structure, not the actual data. This clone includes tables, indexes, views, statistics, procedures, and triggers without any data rows. Developers, testers, or those building database templates find this useful. To learn more, see Clone, Move, or Upgrade an Autonomous Database Instance.

Natural Language Prompts

Natural Language Prompts are human-readable instructions or requests provided to guide generative AI models, such as Large Language Models. Instead of using specific programming languages or commands, users can interact with these models by entering prompts in a more conversational or natural language form. The models then generate output based on the provided prompt.

Network Access Control List (ACL)

A Network Access Control List is a set of rules or permissions that define what network traffic is allowed to pass through a network device, such as a router, firewall, or gateway. ACLs are used to control and filter incoming and outgoing traffic based on various criteria such as IP addresses, port numbers, and protocols. They play a crucial role in network security by enabling administrators to manage and restrict network traffic to prevent unauthorized access, potential attacks, and data breaches.

Retrieval Augmented Generation (RAG)

Retrieval Augmented Generation (RAG) is a technique that involves retrieving relevant information for a user's query and supplying that information to a large language model (LLM) to improve responses and reduce hallucination.
Most commonly, RAG involves vector search, but more generally, includes augmenting a prompt of database content (either manually or automatically) such as schema metadata for SQL generation or database content explicitly queried. Other forms of augmentation can involve technologies such as graph analytics and traditional machine learning.

Semantic Similarity Search

Semantic similarity search identifies and retrieves data points that closely match a given query by comparing feature vectors in a vector store.

Vector Distance

Vector distance measure the similarity or dissimilarity between feature vectors by calculating the distance between them in a multidimensional space.

Vector Index

A vector index organizes and stores vectors to enable efficient similarity search and retrieval of related data.

Vector Store

A vector store includes systems that store, manage, and enable semantic similarity search involving vector embeddings. This includes standalone vector databases and Oracle Database 23ai AI Vector Search.

Select AI Use Cases

Select AI enhances data interaction and enables developers to build AI-driven applications directly from SQL, transforming natural language prompts to SQL queries and text responses, supporting chat interaction with LLMs, enhancing response accuracy with current data using RAG, and generating synthetic data.

Use cases include:

- Generate SQL from natural language prompts

  Developer productivity: Select AI significantly enhances developer productivity by providing "starter" SQL queries quickly. Developers can input natural language prompts, and Select AI generates SQL based on your database schema tables and views. This reduces the time and effort needed to write complex queries from scratch, allowing developers to focus on refining and optimizing the generated queries for their specific needs.

  Natural language queries for end-users: Select AI empowers end-users to interact with your application's underlying data tables and views using natural language queries. This functionality allows users without SQL expertise to ask questions and retrieve data directly, making data access more intuitive and user-friendly relative to the capabilities of LLM being used and the quality of the schema metadata available.

  Other capabilities for SQL generation: The following highlighted capabilities are also supported for natural language to SQL generation:

  – Specify schema or tables or views: Select AI enables you to specify an object list consisting of schema and optionally tables or views within that schema.
  – Automatically detect relevant table metadata: Select AI automatically detects relevant tables and send metadata only for those specific tables, relevant to the query, in Oracle Database 23ai.
  – Restrict table access: Select AI enables you to restrict table access by considering only the tables listed in the AI profile attributes for SQL generation.

  - Specify case sensitivity for columns: Select AI enables user to specify case sensitivity such that the LLM produces case-insensitive responses from the database and LLM.

- Conversations

  Enable chatbot-like features with Select AI, enabling users to have natural conversations for querying data and performing actions. These chats can keep track of context, giving follow-up answers that clarify or expand on original questions. This scenario boosts engagement and makes complicated queries easier through conversation.

- Customized media generation

  Select AI can be used to generate personalized media content such as emails tailored to individual customer details. For example, in your prompt you could instruct the LLM to create a friendly and upbeat email encouraging a customer to try a set of recommended products. These recommendations could be based on customer demographics or other specific information available in your database. This level of customization enhances customer engagement by delivering relevant and appealing content directly to the customer.

- Code generation

  With the Select AI `chat` action, you can use Select AI to ask your specified LLM to generate code from natural language prompts. This feature supports various programming languages such as SQL, Python, R, and Java. Examples include:

  - **Python Code**: "Write the Python code to compute a confusion matrix over a DataFrame with columns ACTUAL and PREDICTED."
  - **SQL DDL**: "Write the DDL for a SQL table with columns name, age, income, and country."
  - **SQL Query**: "Write the SQL query that will use the Oracle Machine Learning in-database model named CHURN_DT_MODEL to predict which customers will churn and with what probability."

- Retrieval Augmented Generation (RAG)

  Use vector store content for semantic similarity search to enhance prompt accuracy and relevance in LLM responses.

- Synthetic data generation

  Generate synthetic data using LLMs that conforms to your schema for solution testing, proofs of concept, and other uses. Synthetic data can support better testing of your applications in the absence of real data, leading to overall quality of your application.

  Synthetic data generation can also be used to populate an Autonomous Database clone or a metadata clone. Select AI supports generating synthetic data for such clones. Using synthetic data helps to protect sensitive data while enabling development, testing, and validating user experiences. It's also useful for AI and machine learning projects needing sample data for model training or test data for scoring.

Getting Started with Select AI

To get started, review the prerequisites and the tasks that you need to perform to use Select AI.

- Configure your system to use Select AI
- Create an AI profile and enable the AI profile
- Use AI keyword in SELECT statement and enter natural language prompts

- Example of using Select AI with OCI Generative AI
- Examples of Using Select AI
- Manage AI profile, configure vector index, or drop your AI profile by reviewing DBMS_CLOUD_AI package
- Customize your AI profiles by supplying the profile attributes
- Display AI profiles, AI profile attributes, and vector index details by querying DBMS_CLOUD_AI views
- See Autonomous Database Supplied Package Reference

Manage AI Profiles

You can create and manage your AI profiles through `DBMS_CLOUD_AI` package.

- Use DBMS_CLOUD_AI to Configure AI Profiles
  Autonomous Database uses AI profiles to facilitate and configure access to an LLM and to setup for generating, running, and explaining SQL based on natural language prompts. It also facilitates retrieval augmented generation using embedding models and vector indexes and allows for chatting with the LLM.
- Perform Prerequisites for Select AI
  Before you use Select AI, here are the steps to enable `DBMS_CLOUD_AI`.
- Create and Set an AI Profile
  Describes the steps to create and enable an AI profile.

> **See Also:**
>
> Use Select AI for Natural Language Interaction with your Database

Use DBMS_CLOUD_AI to Configure AI Profiles

Autonomous Database uses AI profiles to facilitate and configure access to an LLM and to setup for generating, running, and explaining SQL based on natural language prompts. It also facilitates retrieval augmented generation using embedding models and vector indexes and allows for chatting with the LLM.

AI profiles include database objects that are the target for natural language queries. Metadata used from these targets can include database table names, column names, column data types, and comments. You create and configure AI profiles using the `DBMS_CLOUD_AI.CREATE_PROFILE` and `DBMS_CLOUD_AI.SET_PROFILE` procedures.

In addition to specifying tables and views in the AI profile, you can also specify tables mapped with external tables, including those described in Query External Data with Data Catalog. This enables you to query data not just inside the database, but also data stored in a data lake's object store.

Perform Prerequisites for Select AI

Before you use Select AI, here are the steps to enable `DBMS_CLOUD_AI`.

The following are required to use `DBMS_CLOUD_AI`:

- Access to an Oracle Cloud Infrastructure cloud account and to an Autonomous Database instance.
- A paid API account of a supported AI provider, one of:

AI Provider	API Keys
OpenAI	See Use OpenAI to get your API keys.
Cohere	See Use Cohere to get your secret API keys.
Azure OpenAI Service	See Use Azure OpenAI Service for more information on how to configure Azure OpenAI Service.
OCI Generative AI	See Use OCI Generative AI.
Google	See Use Google to get your API keys.
Anthropic	See Use Anthropic to get your API keys.
Hugging Face	See Use Hugging Face to get your API keys.

- Network ACL privileges to access your external AI provider.

> **Note:**
>
> Network ACL privileges are not required for OCI Generative AI.

- A credential that provides access to the AI provider.

Enable `DBMS_CLOUD_AI`

To configure `DBMS_CLOUD_AI`:

1. Grant the `EXECUTE` privilege on the `DBMS_CLOUD_AI` package to the user who wants to use Select AI.

   By default, only the system administrator has `EXECUTE` privilege. The administrator can grant `EXECUTE` privilege to other users.

2. Grant `EXECUTE` privilege on `DBMS_CLOUD_PIPELINE` to the user who wants to use Select AI with RAG.

> **Note:**
>
> If the user already has the `DWROLE` role, this privilege is included and additional grant is not required.

3. Grant network ACL access to the user who wants to use Select AI and for the AI provider endpoint.

   The system administrator can grant network ACL access. See APPEND_HOST_ACE Procedure for more information.

4. Create a credential to enable access to your AI provider.
   See CREATE_CREDENTIAL Procedure for more information.

5. Grant quotas in tablespace to manage the amount of space in a specific tablespace to the user who wants to use Select AI with RAG.

Examples of Privileges to Run Select AI

The following example grants the `EXECUTE` privilege to `ADB_USER`:

```
GRANT execute on DBMS_CLOUD_AI to ADB_USER;
```

The following example grants `EXECUTE` privilege for the `DBMS_CLOUD_PIPELINE` package required for RAG:

```
GRANT EXECUTE on DBMS_CLOUD_PIPELINE to ADB_USER;
```

To check the privileges granted to a user for the `DBMS_CLOUD_AI` and `DBMS_CLOUD_PIPELINE` packages, an administrator can run the following:

```
SELECT table_name AS package_name, privilege
 FROM DBA_TAB_PRIVS
 WHERE grantee = '<username>'
 AND   (table_name = 'DBMS_CLOUD_PIPELINE'
        OR table_name = 'DBMS_CLOUD_AI');
```

The following example grants `ADB_USER` the privilege to use the *api.openai.com* endpoint.

> **Note:**
>
> This procedure is not applicable to OCI Generative AI.

```
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'api.openai.com',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
   );
END;
/
```

The parameters are:

- `host`: The host, which can be the name or the IP address of the host. You can use a wildcard to specify a domain or an IP subnet. The host or domain name is not case sensitive.

AI Provider	Host
OpenAI	*api.openai.com*
Cohere	*api.cohere.ai*
Azure OpenAI Service	*<azure_resource_name>.openai.azure.com* See Profile Attributes to know more about `azure_resource_name`.

AI Provider	Host
Google	*generativelanguage.googleapis.com*
Anthropic	*api.anthropic.com*
Hugging Face	*api-inference.huggingface.co*

- `ace`: The access control entries (ACE). The `XS$ACE_TYPE` type is provided to construct each ACE entry for the ACL. For more details, see Creating ACLs and ACEs.

The following example creates a credential to enable access to OpenAI.

```
EXEC
DBMS_CLOUD.CREATE_CREDENTIAL(
credential_name   => 'OPENAI_CRED',
username          =>  'OPENAI',
password          =>  '<your_api_token>');
```

The parameters are:

- `credential_name`: The name of the credential to be stored. The `credential_name` parameter must conform to Oracle object naming conventions.
- `username`: The `username` and `password` arguments together specify your AI provider credentials.

  The `username` is a user-specified user name.
- `password`: The `username` and `password` arguments together specify your AI provider credentials.

  The `password` is your AI provider secret API key, and depends on the provider:

AI Provider	API Keys
OpenAI	See Use OpenAI to get your API keys.
Cohere	See Use Cohere to get your API keys.
Azure OpenAI Service	See Use Azure OpenAI Service to get your API keys and to configure the service. **Note:** If you are using the Azure OpenAI Service principal to authenticate, you can skip the `DBMS_CLOUD.CREATE_CREDENTIAL` procedure. See Examples of Using Select AI for an example of authenticating using Azure OpenAI Service principal.
OCI Generative AI	See Use OCI Generative AI to generate API signing keys.

AI Provider	API Keys
Google	See Use Google to generate your API keys.
Anthropic	See Use Anthropic to generate your API keys.
Hugging Face	See Use Hugging Face to generate your API keys.

The following example grants quotas on tablespace to the `ADB_USER` to use Select AI with RAG:

```
ALTER USER ADB_USER QUOTA 1T ON <tablespace_name>;
```

To the check the tablespace quota granted to a user, run the following:

```
SELECT TABLESPACE_NAME, BYTES, MAX_BYTES
FROM DBA_TS_QUOTAS
WHERE USERNAME = '<username>' AND
      TABLESPACE_NAME LIKE 'DATA%';
```

The parameters are:

- `TABLESPACE_NAME`: The tablespace for which the quota is assigned. In Autonomous Database, tablespaces are managed automatically and have `DATA` as a prefix.
- `BYTES`: The amount of space currently used by the user in the tablespace.
- `MAX_BYTES`: The maximum quota assigned (in bytes). If `MAX_BYTES` is -1, it means the user has unlimited quota on the tablespace. The database user creating the vector index must have `MAX_BYTES` sufficiently larger than bytes to accommodate the vector index, or `MAX_BYTES` must be -1 for unlimited quota.

Topics

- Use OpenAI
  To enable OpenAI to generate SQL and text responses to your natural language prompts, obtain API keys from your OpenAI paid account.
- Use Cohere
  To enable Cohere to generate SQL and text responses to your natural language prompts, obtain API keys from your Cohere paid account.
- Use Azure OpenAI Service
  To enable Azure OpenAI Service to generate SQL and text responses to your natural language prompts, configure and provide access to the AI provider.
- Use OCI Generative AI
  To enable OCI Generative AI to generate SQL and text responses to your natural language prompts, generate an API signing key.
- Use Google
  To enable Google AI Studio to generate SQL and text responses to your natural language prompts, obtain API keys from your Google AI Studio paid account.
- Use Anthropic
  To enable Anthropic Developer Console to generate SQL and text responses to your natural language prompts, obtain API keys from your Anthropic Developer Console paid account.

- Use Hugging Face
  To enable Hugging Face as your AI provider to generate SQL and text responses to your natural language prompts, obtain API keys from your Hugging Face paid account.

Use OpenAI

To enable OpenAI to generate SQL and text responses to your natural language prompts, obtain API keys from your OpenAI paid account.

You can find your secret API key from your profile dashboard under API keys.

Use Cohere

To enable Cohere to generate SQL and text responses to your natural language prompts, obtain API keys from your Cohere paid account.

1. Login to Cohere's website with your credentials. Cohere Dashboard appears by default.
2. Alternately,click **Dashboard**.
3. Click **API Keys** on the left navigation. Copy the default API key or create another key. See API-Keys for more information.

Use Azure OpenAI Service

To enable Azure OpenAI Service to generate SQL and text responses to your natural language prompts, configure and provide access to the AI provider.

To use Azure OpenAI Service, perform the following steps:

1. Obtain your secret API keys. You can find your API keys in the Resource Management section of your Azure portal. On your Azure OpenAI Service Resource page, click **Keys and Endpoint**. You can copy either KEY1 or KEY2.
2. Create an Azure OpenAI Service resource and deploy a model: Create and deploy an Azure OpenAI Service resource.

   > **Tip:**
   >
   > - Make note of the resource name and deployment name as those parameters are used to provide network access permission and to create your Azure OpenAI Service profile using the `DBMS_CLOUD_AI.CREATE_PROFILE` procedure.
   > - To know about rate limits for token per minute on a model, see Azure OpenAI Service quotas and limits.

3. Allow access to Azure OpenAI Service:
   - You can use your secret API key to allow access to Azure OpenAI Service. To know more, see the example in Examples of Using Select AI.
   - Allow service principal to access Azure OpenAI Service and grant the required permissions to the service principal: Use Azure Service Principal to Access Azure Resources and Role-based access control for Azure OpenAI Service. To know more, see the example in Examples of Using Select AI.

Use OCI Generative AI

To enable OCI Generative AI to generate SQL and text responses to your natural language prompts, generate an API signing key.

Use the Console or command line to generate an API signing key for any Oracle Database instance. See How to Generate the API Signing Key.

Use Google

To enable Google AI Studio to generate SQL and text responses to your natural language prompts, obtain API keys from your Google AI Studio paid account.

1. Go to Google AI Studio.
2. Click Sign In to Google AI Studio.
3. Click Get API key on the prompt screen.
4. Select all the applicable options on the next page.
5. Click Create API key.
6. Click Create API key in new project.

   The screen displays the progress and generates an API key. Copy the key and save it.

Use Anthropic

To enable Anthropic Developer Console to generate SQL and text responses to your natural language prompts, obtain API keys from your Anthropic Developer Console paid account.

1. Go to Anthropic Developer Console.
2. Sign up for an account if you don't have one already.
3. Once logged in, navigate to the API section or the dashboard.
4. Look for an option to generate or view API keys.
5. Click to create a new API key.
6. Copy the generated API key and save it.

   The Claude API is a paid service. You'll need to add credits to your account before you can use the API key.

Use Hugging Face

To enable Hugging Face as your AI provider to generate SQL and text responses to your natural language prompts, obtain API keys from your Hugging Face paid account.

1. Go to Hugging Face.
2. Sign up for an account if you don't have one already.
3. Navigate to your account settings.
4. In the navigation menu locate the **Access Tokens**.
5. Click to create a new API key.
6. Copy the generated API key and save it.

Create and Set an AI Profile

Describes the steps to create and enable an AI profile.

Use `DBMS_CLOUD_AI.CREATE_PROFILE` to create an AI profile. Run `DBMS_CLOUD_AI.SET_PROFILE` to enable the AI profile so that you can use `SELECT AI` with a natural language prompt.

> **Note:**
>
> You must run `DBMS_CLOUD_AI.SET_PROFILE` in each new stateful database session (connection) before you use `SELECT AI`. If you are using a stateless connection, you must use the `DBMS_CLOUD_AI.GENERATE` function which enables you to specify the profile name in each invocation.

The following example with the OpenAI provider creates an `AI` profile called `OPENAI` and sets the `OPENAI` profile for the current user session.

```
-- Create AI profile
--BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
  profile_name   => 'OPENAI',
  attributes     =>'{"provider": "openai",
            "credential_name": "OPENAI_CRED",
            "object_list": [{"owner": "SH", "name": "customers"},
                      {"owner": "SH", "name": "sales"},
                      {"owner": "SH", "name": "products"},
                      {"owner": "SH", "name": "countries"}]
       }');
END;
/

PL/SQL procedure successfully completed.

--
-- Enable AI profile in current session
--
EXEC DBMS_CLOUD_AI.set_profile('OPENAI');

PL/SQL procedure successfully completed.
```

Use AI Keyword to Enter Prompts

Use `AI` as the keyword in a `SELECT` statement for interacting with the database using natural language prompts.

The `AI` keyword in a `SELECT` statement instructs the SQL execution engine to use the LLM identified in the active AI profile to process natural language and to generate SQL.

You can use the `AI` keyword in a query with Oracle clients such as SQL Developer, OML Notebooks, and third-party tools, to interact with database in natural language.

> **Note:**
>
> You cannot run PL/SQL statements, DDL statements, or DML statements using the `AI` keyword.

Syntax

The syntax for running AI prompt is:

```
SELECT AI action natural_language_prompt
```

Parameters

The following are the parameters available for the *action* parameter:

Parameter	Description
`runsql`	Runs the underlying SQL command for the natural language prompt. This is the default action and it is optional to specify this parameter.
`showsql`	Displays the SQL statement for a natural language prompt.
`explainsql`	Explains the generated SQL from the prompt in a natural language. This option sends the generated SQL to the AI provider to produce a natural language explanation.
`narrate`	Sends the result of the SQL query run by the database back to the LLM to generate a natural language description of that result. When a vector index is specified in the AI profile to enable RAG, the system uses the specified transformer (or default transformer) model to create a vector embedding from the prompt for semantic similarity search against the vector store. The system then adds the retrieved content from the vector store to the user prompt and sends it to the LLM to generate a response based on this information. If you do not want table data or vector search documents to be sent to an LLM, a user with administrator privileges can disable such access for all users of the given database. This, in effect, disables the `narrate` action.
`chat`	Passes the user prompt directly to the LLM to generate a response, which is provided to the user. If `conversation` in the `DBMS_CLOUD_AI.CREATE_PROFILE` function is set to `true`, this option includes content from prior interactions or prompts, potentially including schema metadata.

Usage Notes

- The `AI` keyword for Select AI is not supported in Database Actions or APEX Service. You can use only the `DBMS_CLOUD_AI.GENERATE` function.

  Do not use `DBMS_CLOUD_AI.SET_PROFILE` in Database Actions or APEX Service. Instead, set the AI profile in the `profile_name` argument of `DBMS_CLOUD_AI.GENERATE`.
- The `AI` keyword is supported only in a `SELECT` statement.
- You cannot run PL/SQL statements, DDL statements, or DML statements using the `AI` keyword.
- The sequence is `SELECT` followed by `AI`. These keywords are not case-sensitive. After setting your AI profile using `DBMS_CLOUD_AI.SET_PROFILE`, and optional action, the text

after `SELECT AI` is a natural language prompt. If an AI profile is not set, `SELECT AI` reports the following error when running a `SELECT AI` statement:

```
ORA-00923: FROM keyword not found where expected
00923. 00000 -  "FROM keyword not found where expected"
```

- Special character usage rules apply according to Oracle guidelines. For example, use single quotes twice if you are using an apostrophe in a sentence.

```
select ai how many customers in SF don''t own their own home
```

- LLMs are subject to *hallucinations* and results are not always correct:
  - It is possible that `SELECT AI` may not be able to run the generated SQL query for a specific natural language prompt.
  - It is possible that `SELECT AI` may not be able to generate a SQL query for a specific natural language prompt.
  - It is possible that the LLM may not generate a SQL query that produces a correct result given your natural language prompt.

  In such a scenario, `SELECT AI` may respond with information to assist you in generating valid SQL.
- For better results with natural language to SQL generation, use database views or tables with contextual column names or consider adding column comments explaining values stored in the columns.
- Use the `explainsql` action, as in `SELECT AI explainsql`, to get a more detailed explanation of the SQL statement, as compared to `SELECT AI showsql`.
- To access DBA or USER views, see DBMS_CLOUD_AI Views.

Enable Conversations to Enhance User Interaction

Conversations in Select AI refer to the interactive dialogue between the user and the system, where a sequence of user-provided natural language prompts are used to query or interact with the database.

Select AI includes past prompts (up to 10) in the current call as part of the augmented prompt sent to the LLM. Conversations enable a more intuitive and accessible way to work with your data, making it easier for users to extract insights and perform tasks without needing deep technical knowledge of SQL.

For example, conversations provide an intuitive way to analyze data:

- Ask a question such as "What are the total number of customers"
- Follow up with context aware questions like:
  - "break out count of customers by country"
  - "What age group is most common"
  - "keep the top 5 customers and their country by their purchases and include a rank in the result"

To enable conversations, set the `conversation` attribute to `true` in your AI profile, see Profile Attributes. See Example: Enable Conversations in Select AI for a complete example.

Select AI with Retrieval Augmented Generation (RAG)

Select AI with RAG augments your natural language prompt by retrieving content from your specified vector store using semantic similarity search. This reduces hallucinations by using your specific and up-to-date content and provides more relevant natural language responses to your prompts.

Select AI automates the Retrieval Augmented Generation (RAG) process. This technique retrieves data from enterprise sources using AI vector search and augments user prompts for your specified large language model (LLM). By leveraging information from enterprise data stores, RAG reduces hallucinations and generates grounded responses.

RAG uses AI vector search on a vector index to find semantically similar data for the specified question. Vector store processes vector embeddings, which are mathematical representations of various data points like text, images, and audio. These embeddings capture the meaning of the data, enabling efficient processing and analysis. For more details on vector embeddings and AI vector search, see Overview of AI Vector Search.

Select AI integrates with AI vector search available in Oracle Autonomous Database 23ai for similarity search using vector embeddings.

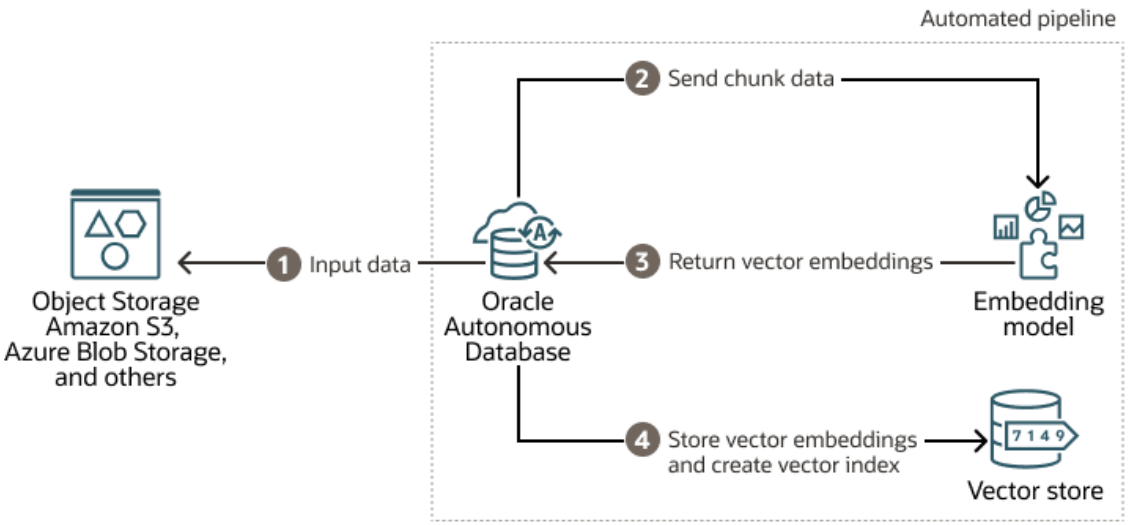
Topics

- Build your Vector Store
- Use DBMS_CLOUD_AI to Create and Manage Vector Indexes
  Use the `DBMS_CLOUD_AI` package to create and manage vector indexes and configure vector database JSON parameters.
- Use In-database Transformer Models
  Select AI RAG enables you to use pretrained ONNX transformer models that are imported into your database in Oracle Database 23ai instance for generating embedding vectors from document chunks and user prompts.
- Benefits of Select AI RAG
  Simplify querying, enhance response accuracy with current data, and gain transparency by reviewing sources used by the LLM.

Build your Vector Store

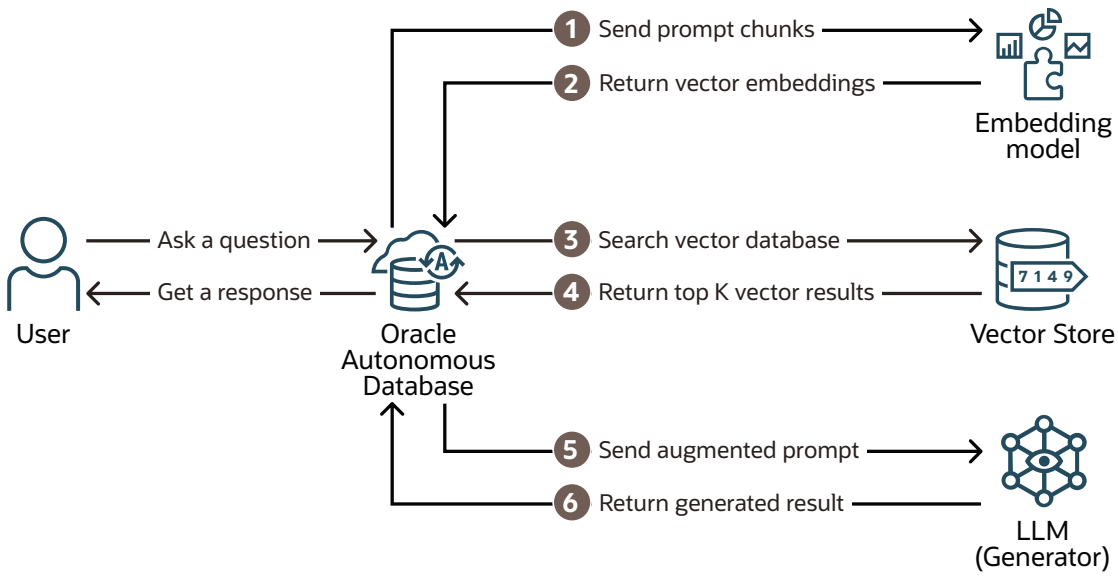
Select AI automates the creation and population of vector store by converting input documents (for example, PDF, DOC, JSON, XML, or HTML) from your object store to plain text. Oracle Text supports around 150 file types. For a complete list of all the supported document formats, see Supported Document Formats.
Select AI automatically processes documents to chunks, generates embeddings, stores them in the specified vector store, and updates the vector index as new data arrives.

Here is how the input from Object Storage is used with Select AI RAG:



1. Input: Data is initially stored in an Object Storage.
2. Oracle Autonomous Database retrieves the input data or the document, chunks it and sends the chunks to an embedding model.
3. The embedding model processes the chunk data and returns vector embeddings.
4. The vector embeddings are then stored in a vector store for use with RAG. As content is added, the vector index is automatically updated.

RAG retrieves relevant pieces of information from the enterprise database to answer a user's question. This information is provided to the specified large language model along with the user prompt. Select AI uses this additional enterprise information to enhance the prompt, improving the LLM's response. RAG can enhance response quality with update-to-date enterprise information from the vector store.



Select AI implements RAG as follows:

1. Input: User asks a question (specifies a prompt) using Select AI `narrate` action.

2. Select AI generates vector embeddings of the prompt using the embedding model specified in the AI profile.
3. The vector search index uses the vector embedding of the question to find matching content from the customer's enterprise data (searching the vector store) which has been indexed.
4. The vector search returns top K texts similar to the input to your Autonomous Database instance.
5. Autonomous Database then sends these top K query results with user question to the LLM.
6. The LLM returns its response to your Autonomous Database instance.
7. Autonomous Database Select AI provides the response to the user.

Use DBMS_CLOUD_AI to Create and Manage Vector Indexes

Use the `DBMS_CLOUD_AI` package to create and manage vector indexes and configure vector database JSON parameters.

After you create credentials and provide network access to the vector database and the AI provider, your Autonomous Database instance uses AI profiles to configure access to LLMs. See Example: Set Up and Use Select AI with RAG for a complete example on setting it up and using it in Select AI statements.

> **Note:**
>
> If you do not want table data or vector search documents to be sent to an LLM, a user with administrator privileges can disable such access for all users of the given database. This, in effect, disables the `narrate` action for RAG.

You can configure AI profiles for providers listed in Select your AI Provider and LLMs through the `DBMS_CLOUD_AI` package.

> **See Also:**
>
> - Create a vector index: CREATE_VECTOR_INDEX Procedure.
> - Manage vector index profiles and other AI profiles: Summary of DBMS_CLOUD_AI Subprograms
> - Query vector index views: DBMS_CLOUD_AI Views.

Use In-database Transformer Models

Select AI RAG enables you to use pretrained ONNX transformer models that are imported into your database in Oracle Database 23ai instance for generating embedding vectors from document chunks and user prompts.

To learn more about importing a pretrained ONNX model into your Oracle Database 23ai instance, see

- Import Pretrained Models in ONNX Format for Vector Generation Within the Database
- Alternate Method to Import ONNX Models
- Pre-built Embedding Generation model for Oracle Database 23ai

> **Note:**
>
> You must import a pretrained ONNX-format transformer model into Oracle Database 23ai instance to use Select AI RAG with imported in-database transformer model. You can also use other transformer models from supported AI providers.

See Example: Select AI with In-database Transformer Models to explore the feature.

Benefits of Select AI RAG

Simplify querying, enhance response accuracy with current data, and gain transparency by reviewing sources used by the LLM.

Select AI RAG offers the following benefits:

- Simplify data querying and increase response accuracy: Enable users to query enterprise data using natural language and provide LLMs with detailed context from enterprise data to generate more accurate and relevant responses, reducing instances of LLM hallucinations.
- Up-to-date information: Provide LLMs access to current enterprise information using vector stores, eliminating the need for costly, time-consuming fine-tuning of LLMs trained on static data sets.
- Seamless integration: Integrate with Oracle AI Vector Search for streamlined data handling and enhanced performance.
- Automated data orchestration: Automate orchestration steps with a fully managed Vector Index pipeline, ensuring efficient processing of new data.
- Understandable contextual results: Has access and retrieves the sources used by the LLM from vector stores, ensuring transparency and confidence in results. Views and extracts data in natural language text or JSON format for easier integration and application development.

Synthetic Data Generation

Generate synthetic data using random generators, algorithms, statistical models, and Large Language Models (LLMs) to simulate real data for developing and testing solutions effectively.

Synthetic data can be a powerful tool when developing and testing solutions, especially when actual data doesn't yet exist or isn't allowed to be used. Synthetic, or artificially generated, data can have many of the characteristics of real data. Synthetic data is typically created using random generators, algorithms, or statistical models to simulate the characteristics and distributions of real data. However, this can be complex to produce or rely on tools with features of varying sophistication. With the availability of Large Language Models (LLMs), more relevant and schema-specific data may be generated that considers characteristics expressed in natural language.

Topics

- Benefits of Synthetic Data Generation
  Synthetic data generation enables populating database metadata clones, supporting development, testing, and machine learning projects without using sensitive data from original tables.
- Generate Synthetic Data
  Use `DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA` function to generate synthetic data and query the data using Select AI actions.
- Monitor and Troubleshoot Synthetic Data Generation
  When generating large amounts of data across many tables, Select AI splits synthetic data generation tasks into smaller chunks and runs tasks in parallel. The status of each chunk is tracked in the `SYNTHETIC_DATA$<operation_id>_STATUS` table.

Benefits of Synthetic Data Generation

Synthetic data generation enables populating database metadata clones, supporting development, testing, and machine learning projects without using sensitive data from original tables.

Synthetic Data Generation offers the following benefits:

- **Populating metadata clones with synthetic data**: A metadata clone replicates the structure of a database or schema without including actual data. Select AI allows synthetic data generation to populate these clones, protecting sensitive data while enabling development, testing, and creating templates. This approach supports performance and scalability testing.
- **Starting new projects**: When starting a new project, actual data may not be available. Synthetic data provides realistic samples to help demonstrate concepts and gain support for project proposals.
- **Validating user experience**: Synthetic data aids in testing user interfaces by providing diverse data sets to uncover design flaws, performance, and scalability issues.
- **Supporting AI and machine learning projects**: Synthetic data is useful for training AI and machine learning models when real data is unavailable or restricted. LLMs can generate data with specific patterns to facilitate model training and scoring.

Generate Synthetic Data

Use `DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA` function to generate synthetic data and query the data using Select AI actions.

To learn more, see GENERATE_SYNTHETIC_DATA Function and Example: Generate Synthetic Data.

Monitor and Troubleshoot Synthetic Data Generation

When generating large amounts of data across many tables, Select AI splits synthetic data generation tasks into smaller chunks and runs tasks in parallel. The status of each chunk is tracked in the `SYNTHETIC_DATA$<operation_id>_STATUS` table.

Synthetic data generation operations are logged in the tables `DBA_LOAD_OPERATIONS` and `USER_LOAD_OPERATIONS`. Use these tables to monitor the

`DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA` operation. See Track DBMS_CLOUD Load Operations for more details.

After running synthetic data generation in a given session, you can get the latest <*operation_id*> from `USER_LOAD_OPERATION` using the following:

```
SELECT max(id) FROM user_load_operations;
```

To view the synthetic data operations running in a different session, use the `DBA_LOAD_OPERATIONS` view.

View Status of Synthetic Data Generation

The status table of synthetic data generation operation shows the progress of each table and its corresponding chunk. The `STATUS_TABLE` column in `USER_LOAD_OPERATIONS` or `DBA_LOAD_OPERATIONS` shows the status table name. The table name is `SYNTHETIC_DATA$<operation_id>_STATUS` and it has following columns:

Name	Datatype	Description
`ID`	`NUMBER`	Unique identifier of the record.
`NAME`	`VARCHAR2`	Qualified name of the table, such as `"ADB_USER"."EMPLOYEES"`
`BYTES`	`NUMBER`	Desired number of records for this data generation task
`ROWS_LOADED`	`NUMBER`	Actual number of records generated.
`CHECKSUM`	`VARCHAR2`	Starting value for the primary key during this data generation task.
`LAST_MODIFIED`	`TIMESTAMP WITH TIME ZONE`	Timestamp indicating when the record was last modified.
`STATUS`	`VARCHAR2`	Status of the data generation task. The valid values are: • `COMPLETED` • `FAILED` • `PENDING` • `SKIPPED`
`ERROR_CODE`	`NUMBER`	Error code, if the data generation task fails.
`ERROR_MESSAGE`	`VARCHAR2`	Error message provided if the task fails.
`END_TIME`	`TIMESTAMP WITH TIME ZONE`	Timestamp marking the end of the data generation task.

Example: Check the Number of Records Generated for Each Table
To check the number of records generated for each table, issue the following:

```
SELECT name, SUM(rows_loaded) FROM synthetic_data$<operation_id>_status group
by name;
```

Query `ROWS_LOADED` to confirm how many number of rows are loaded for each chunk, and `SUM(ROWS_LOADED)` for rows for each table.

```
BEGIN
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name => 'GENAI',
        object_list => '[{"owner": "ADB_USER", "name":
"DIRECTOR","record_count":150},
                        {"owner": "ADB_USER", "name":
"MOVIE_ACTOR","record_count":300},
                        {"owner": "ADB_USER", "name": "CLASSES",
"user_prompt":"all in fall semester","record_count":5},
                        {"owner": "ADB_USER", "name":
"ACTOR","record_count":220},
                        {"owner": "ADB_USER", "name":
"MOVIE","record_count":50}]'
    );
END;
/

-- Check loaded rows for each chunk
SQL> SELECT name, rows_loaded FROM synthetic_data$141_status order by name;
NAME                           ROWS_LOADED
----------------------------------------
"ADB_USER"."ACTOR"                      188
"ADB_USER"."ACTOR"                       32
"ADB_USER"."CLASSES"                      5
"ADB_USER"."DIRECTOR"                   150
"ADB_USER"."MOVIE"                       50
"ADB_USER"."MOVIE_ACTOR"                 38
"ADB_USER"."MOVIE_ACTOR"                114
"ADB_USER"."MOVIE_ACTOR"                148

-- Check loaded rows for each table
SQL> SELECT name, SUM(rows_loaded) FROM synthetic_data$141_status group by
name;

NAME                       SUM(ROWS_LOADED)
----------------------------------------
"ADB_USER"."DIRECTOR"                   150
"ADB_USER"."MOVIE_ACTOR"                300
"ADB_USER"."CLASSES"                      5
"ADB_USER"."ACTOR"                      220
"ADB_USER"."MOVIE"                       50
```

Examples of Using Select AI

Explore integrating Oracle's Select AI with various supported AI providers to generate, run, and explain SQL from natural language prompts or chat with the LLM.

- Example: Select AI Actions
  These examples illustrate common Select AI actions.

- Example: Select AI with OCI Generative AI
  These examples show how you can access OCI Generative AI using your OCI API key or Resource Principal, create an AI profile, and generate, run, and explain SQL from natural language prompts or chat using the OCI Generative AI LLMs.
- Example: Select AI with OpenAI
  This example shows how you can use OpenAI to generate SQL statements from natural language prompts.
- Example: Select AI with Cohere
  This example shows how you can use Cohere to generate SQL statements from natural language prompts.
- Example: Select AI with Azure OpenAI Service
  The following examples shows how you can enable access to Azure OpenAI Service using your API key or use Azure OpenAI Service Principal, create an AI profile, and generate SQL from natural language prompts.
- Example: Select AI with Google
- Example: Select AI with Anthropic
- Example: Select AI with Hugging Face
- Example: Enable Conversations in Select AI
  This example illustrates enabling conversations in Select AI.
- Example: Set Up and Use Select AI with RAG
  This example guides you through setting up credentials, configuring network access, and creating a vector index for integrating OCI Generative AI vector store cloud services with OpenAI using Oracle Autonomous Database.
- Example: Select AI with In-database Transformer Models
  This example demonstrates how you can import a pretrained transformer model that is stored in Oracle object storage into your Oracle Database 23ai instance and then use the imported in-database model in Select AI profile to generate vector embeddings for document chunks and user prompts.
- Example: Improve SQL Query Generation
  These examples demonstrate how comments, annotations, foreign key, and referential integrity constraints in database tables and columns can improve the generation of SQL queries from natural language prompts.
- Example: Generate Synthetic Data
- Example: Enable or Disable Data Access
  This example illustrates how administrators can control data access and prevent Select AI from sending actual schema tables to the LLM.
- Example: Restrict Table Access in AI Profile
  This example demonstrates how to restrict table access and instruct the LLM to use only the tables specified in the `object_list` of the AI profile.
- Example: Specify Case Sensitivity for Columns
  This example shows how you can set case sensitivity for columns in AI profile.

Example: Select AI Actions

These examples illustrate common Select AI actions.

The following example illustrates actions such as `runsql` (the default), `showsql`, `narrate`, `chat`, and `explainsql` that you can perform with `SELECT AI`. These examples use the `sh` schema with AI provider and profile attributes set in the `DBMS_CLOUD_AI.CREATE_PROFILE` function.

```
SQL> select ai how many customers exist;

CUSTOMER_COUNT
--------------
         55500

SQL> select ai showsql how many customers exist;

RESPONSE
--------------------------------------------------
SELECT COUNT(*) AS total_customers
FROM SH.CUSTOMERS

SQL> select ai narrate how many customers exist;

RESPONSE
--------------------------------------------------
There are a total of 55,500 customers in the database.

SQL> select ai chat how many customers exist;

RESPONSE
--------------------------------------------------------------------------------
--
It is impossible to determine the exact number of customers that exist as it
con
stantly changes due to various factors such as population growth, new
businesses
, and customer turnover. Additionally, the term "customer" can refer to
individu
als, businesses, or organizations, making it difficult to provide a specific
num
ber.

SQL> select ai explainsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS customer_count
FROM SH.CUSTOMERS AS c
WHERE c.CUST_STATE_PROVINCE = 'San Francisco' AND c.CUST_MARITAL_STATUS =
'Married';

Explanation:
```

```
- We use the 'SH' table alias for the 'CUSTOMERS' table for better
readability.
- The query uses the 'COUNT(*)' function to count the number of rows that
match the given conditions.
- The 'WHERE' clause is used to filter the results:
  - 'c.CUST_STATE_PROVINCE = 'San Francisco'' filters customers who have 'San
Francisco' as their state or province.
  - 'c.CUST_MARITAL_STATUS = 'Married'' filters customers who have 'Married'
as their marital status.
The result of this query will give you the count of customers in San
Francisco who are married, using the column alias 'customer_count' for the
result.

Remember to adjust the table and column names based on your actual schema if
they differ from the example.

Feel free to ask if you have more questions related to SQL or database in
general.
```

Example: Select AI with OCI Generative AI

These examples show how you can access OCI Generative AI using your OCI API key or Resource Principal, create an AI profile, and generate, run, and explain SQL from natural language prompts or chat using the OCI Generative AI LLMs.

> **Note:**
>
> If you do not specify the `model_name` parameter, OCI Generative AI uses the default model as per the table in Select your AI Provider and LLMs. To learn more about the parameters, see Profile Attributes.

```
-- Create Credential with OCI API key
--
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'GENAI_CRED',
    user_ocid       => 'ocid1.user.oc1..aaaa...',
    tenancy_ocid    => 'ocid1.tenancy.oc1..aaaa...',
    private_key     => '<your_api_key>',
    fingerprint     => '<your_fingerprint>'
  );
END;

SQL> select ai how many customers exist;
Number of Customers
-------------------
              55500

SQL> select ai how many customers in San Francisco are married;
COUNT(DISTINCTC."CUST_ID")
--------------------------
                        28

SQL> select ai showsql how many customers in San Francisco are married;
RESPONSE

--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
----------------------------------------
SELECT COUNT(DISTINCT c."CUST_ID")
FROM "SH"."CUSTOMERS" c
```

```
JOIN "SH"."COUNTRIES" co ON c."COUNTRY_ID" = co."COUNTRY_ID"
WHERE c."CUST_CITY" = 'San Francisco' AND c."CUST_MARITAL_STATUS" = 'married'

SQL> select ai explainsql how many customers in San Francisco are married;
RESPONSE

Here is the Oracle SQL query to find the number of customers in San Francisco
who are married:
```
SELECT COUNT(*)
FROM "SH"."CUSTOMERS" c
WHERE c."CUST_CITY" = 'San Francisco'
AND c."CUST_MARITAL_STATUS" = 'Married';
```
Explanation:
* We use the `COUNT(*)` aggregate function to count the number of rows that
match the conditions.
* We specify the table alias `c` for the `"SH"."CUSTOMERS"` table to make the
query more readable.
* We use the `WHERE` clause to filter the rows based on two conditions:
    + `c."CUST_CITY" = 'San Francisco'`: We filter the rows where the
customer's city is San Francisco.
    + `c."CUST_MARITAL_STATUS" = 'Married'`: We filter the rows where the
customer's marital status is Married.
* The double quotes around the table and column names are used to make the
query case-sensitive, as required in Oracle SQL.
Note: The column names and table names are assumed to be case-sensitive, so
we enclose them in double quotes. If the column names and table names are not
case-sensitive, you can remove the double quotes.

SQL> select ai narrate how many customers in San Francisco are married;

RESPONSE
-----------------------------------------------------------
There are 28 customers in San Francisco who are married.

SQL> select ai chat what is Autonomous Database;

RESPONSE

An Autonomous Database is a type of database that uses artificial
intelligence (AI) and machine learning (ML) to automate many of the
administrative and maintenance tasks typically performed by a database
administrator (DBA). This allows the database to manage itself, without human
intervention, to a large extent.
Autonomous databases are designed to be self-driving, self-securing, and self-
repairing, which means they can:
1. **Automate administrative tasks**: Such as provisioning, patching,
upgrading, and tuning, which frees up DBAs to focus on higher-level tasks.
2. **Optimize performance**: By automatically adjusting parameters, indexing,
```

```
and caching to ensure optimal performance and efficiency.
3. **Detect and respond to security threats**: By using AI-powered security
tools to identify and respond to potential security threats in real-time.
4. **Heal itself**: By automatically detecting and repairing errors,
corruption, or other issues that may arise.
5. **Scale up or down**: To match changing workload demands, without the need
for manual intervention.
The benefits of Autonomous Databases include:
1. **Increased efficiency**: By automating routine tasks, DBAs can focus on
more strategic activities.
2. **Improved performance**: Autonomous databases can optimize performance in
real-time, leading to faster query response times and better overall system
performance.
3. **Enhanced security**: AI-powered security tools can detect and respond to
threats more quickly and effectively than human administrators.
4. **Reduced costs**: By minimizing the need for manual intervention,
Autonomous Databases can help reduce labor costs and improve resource
utilization.
5. **Improved reliability**: Autonomous Databases can detect and repair
errors more quickly, reducing downtime and improving overall system
reliability.
Oracle Autonomous Database is a popular example of an Autonomous Database,
which was introduced in 2018. Other vendors, such as Amazon, Microsoft, and
Google, also offer Autonomous Database services as part of their cloud
offerings.
In summary, Autonomous Databases are designed to be self-managing, self-
optimizing, and self-healing, which can lead to improved performance,
security, and efficiency, while reducing costs and administrative burdens.

```

Example: Select AI with OCI Generative AI Resource Principal

To use resource principal with OCI Generative AI, Oracle Cloud Infrastructure tenancy administrator must grant access for Generative AI resources to a dynamic group. See Perform Prerequisites to Use Resource Principal with Autonomous Database to provide access to a dynamic group.

Set the required policies to obtain access to all Generative AI resources. See Getting Access to Generative AI to know more about Generative AI policies.

- To get access to all Generative AI resources in the entire tenancy, use the following policy:

  ```
  allow group <your-group-name> to manage generative-ai-family in tenancy
  ```

- To get access to all Generative AI resources in your compartment, use the following policy:

  ```
  allow group <your-group-name> to manage generative-ai-family in
  compartment <your-compartment-name>
  ```

Connect as an administrator and enable OCI resource principal. See ENABLE_PRINCIPAL_AUTH Procedure to configure the parameters.

> **Note:**
>
> OCI Generative AI uses `meta.llama-3-70b-instruct` as the default model if you do not specify the `model`. To learn more about the parameters, see Profile Attributes.

EXEC DBMS_CLOUD_AI.SET_PROFILE('GENAI');

    PL/SQL procedure successfully completed.

SQL> set linesize
150
SQL> SELECT AI chat what is the sentiment of this comment I am not going to
waste my time filling up this three page form. Lousy idea;
SQL>
    RESPONSE

--------------------------------------------------------------------------------
--------------------------------------------------------------------------------

    The sentiment of this comment is strongly negative. The user is
expressing frustration and annoyance with the idea of filling out a three-
page form, an
       d is explicitly stating that they consider it a "lousy idea". The use
of the phrase "waste my time" also implies that they feel the task is
unnecessary
       and unproductive. The tone is dismissive and critical.

SQL> SELECT AI chat Write an enthusiastic introductory paragraph on how to
get started with rock climbing with Athletes as the target audience;
    RESPONSE
```

```
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
    Rock climbing is an exhilarating and challenging sport that's perfect for
athletes looking to push their limits and test their strength, endurance,
       and mental toughness. Whether you're a seasoned athlete or just
starting out, rock climbing offers a unique and rewarding experience that
will have
       you hooked from the very first climb. With its combination of physical
and mental challenges, rock climbing is a great way to build strength, improve
       flexibility, and develop problem-solving skills. Plus, with the
supportive community of climbers and the breathtaking views from the top of
the climb,
       you'll be hooked from the very first climb. So, if you're ready to
take on a new challenge and experience the thrill of adventure, then it's
time to
       get started with rock climbing!
```

Using OCI Generative AI with the Default Model

The following example uses the default OCI Generative AI Chat Model. If you do not specify the `model_name` parameter, OCI Generative AI uses the default model as per the table in Select your AI Provider and LLMs.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
      profile_name => 'OCI_DEFAULT',
      attributes   => '{"provider": "oci",
                        "credential_name": "OCI_CRED",
                        "object_list": [{"owner": "ADB_USER"}]
                        }');
END;
/
```

Using OCI Generative AI with Chat Model

The following example uses `cohere.command-r-plus-08-2024` as the OCI Generative AI Chat Model.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
      profile_name => 'OCI_COHERE_COMMAND_R_PLUS',
      attributes   => '{"provider": "oci",
                        "credential_name": "OCI_CRED",
                        "object_list": [{"owner": "ADB_USER"}],
                        "model": "cohere.command-r-plus-08-2024"
                       }');
END;
/
```

Using OCI Generative AI with Chat Model Endpoint ID

The following example demonstrates how to specify the OCI Generative AI Chat Model endpoint ID instead of `model`. If you are using Meta Llama Chat Model endpoint ID, then specify `oci_apiformat` as `GENERIC`.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
```

```
      profile_name => 'OCI_CHAT_ENDPOINT',
      attributes => '{"provider": "oci",
                      "credential_name": "OCI_CRED",
                      "object_list": [{"owner": "ADB_USER"}],
                      "oci_endpoint_id": "<endpoint_id>",
                      "oci_apiformat": "GENERIC"
                     }');
END;
/
```

Using OCI Generative AI with Chat Model OCID
This example demonstrates how to specify the OCI Generative AI Cohere Chat Model endpoint ID instead of `model`. If you are using Meta Llama Chat Model endpoint ID, then specify `oci_apiformat` as `GENERIC`.

```
BEGIN

  DBMS_CLOUD_AI.CREATE_PROFILE(
      profile_name => 'OCI_CHAT_OCID',
      attributes   => '{"provider": "oci",
                        "credential_name": "OCI_CRED",
                        "object_list": [{"owner": "ADB_USER"}],
                        "model": "<model_ocid>",
                        "oci_apiformat": "COHERE"
                       }');
END;
/
```

Example: Select AI with OpenAI

This example shows how you can use OpenAI to generate SQL statements from natural language prompts.

> **Note:**
>
> Only a DBA can run `EXECUTE` privileges and network ACL procedure.

```
--Grants EXECUTE privilege to ADB_USER
--
SQL> grant execute on DBMS_CLOUD_AI to ADB_USER;

-- Grant Network ACL for OpenAI endpoint
--
SQL> BEGIN
     DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'api.openai.com',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
     );
    END;
```

```
    /

```

```
--
SQL> select ai how many customers exist;

CUSTOMER_COUNT
--------------
         55500

SQL> select ai how many customers in San Francisco are married;

MARRIED_CUSTOMERS
-----------------
               18

SQL> select ai showsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS married_customers_count
FROM SH.CUSTOMERS c
WHERE c.CUST_CITY = 'San Francisco'
  AND c.CUST_MARITAL_STATUS = 'Married'

SQL> select ai explainsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS customer_count
FROM SH.CUSTOMERS AS c
WHERE c.CUST_STATE_PROVINCE = 'San Francisco' AND c.CUST_MARITAL_STATUS =
'Married';

Explanation:
- We use the 'SH' table alias for the 'CUSTOMERS' table for better
readability.
- The query uses the 'COUNT(*)' function to count the number of rows that
match the given conditions.
- The 'WHERE' clause is used to filter the results:
  - 'c.CUST_STATE_PROVINCE = 'San Francisco'' filters customers who have 'San
Francisco' as their state or province.
  - 'c.CUST_MARITAL_STATUS = 'Married'' filters customers who have 'Married'
as their marital status.
The result of this query will give you the count of customers in San
Francisco who are married, using the column alias 'customer_count' for the
result.

Remember to adjust the table and column names based on your actual schema if
they differ from the example.

Feel free to ask if you have more questions related to SQL or database in
general.

SQL> select ai narrate what are the top 3 customers in San Francisco;
```

```
RESPONSE
--------------------------------------------------------------------------------
--
The top 3 customers in San Francisco are:

1. Hector Colven - Total amount sold: $52,025.99
2. Milburn Klemm - Total amount sold: $50,842.28
3. Gavin Xie - Total amount sold: $48,677.18

SQL> select ai chat what is Autonomous Database;

RESPONSE
--------------------------------------------------------------------------------
--
Autonomous Database is a cloud-based database service provided by Oracle. It
is designed to automate many of the routine tasks involved in managing a
database,
such as patching, tuning, and backups. Autonomous Database uses machine
learning and automation to optimize performance, security, and availability,
allowing
users to focus on their applications and data rather than database
administration tasks. It offers both Autonomous Transaction Processing (ATP)
for
transactional workloads and Autonomous Data Warehouse (ADW) for analytical
workloads. Autonomous Database provides high performance, scalability, and
reliability, making it an ideal choice for modern cloud-based applications.

SQL> EXEC DBMS_CLOUD_AI.DROP_PROFILE('OPENAI');

PL/SQL procedure successfully completed.
```

The following example shows specifying a different model in your AI profile:

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
  profile_name   => 'OPENAI',
  attributes     =>'{"provider":
"openai",
        "credential_name": "OPENAI_CRED",
        "model": "gpt-3.5-turbo",
     "object_list": [{"owner": "SH", "name": "customers"},
                     {"owner": "SH", "name": "countries"},
                     {"owner": "SH", "name": "supplementary_demographics"},
                     {"owner": "SH", "name": "profits"},
                     {"owner": "SH", "name": "promotions"},
                     {"owner": "SH", "name": "products"}],
        "conversation": "true"
       }');
END;
/
```

Example: Select AI with Cohere

This example shows how you can use Cohere to generate SQL statements from natural language prompts.

> **Note:**
>
> Only a DBA can run `EXECUTE` privileges and network ACL procedure.

```
--Grants EXECUTE privilege to ADB_USER
--
SQL>GRANT execute on DBMS_CLOUD_AI to ADB_USER;
--
-- Create Credential for AI provider
--
EXEC
DBMS_CLOUD.CREATE_CREDENTIAL(
CREDENTIAL_NAME   => 'COHERE_CRED',
username          =>  'COHERE',
password          =>  'your_api_token');

PL/SQL procedure successfully completed.

--
-- Grant Network ACL for Cohere endpoint
--
SQL> BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'api.cohere.ai',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
    );
     END;
     /
    /

PL/SQL procedure successfully completed.

--
-- Create AI profile
--
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
  profile_name   => 'COHERE',
  attributes     =>'{"provider": "cohere",
     "credential_name": "COHERE_CRED",
        "object_list": [{"owner": "SH", "name": "customers"},
                        {"owner": "SH", "name": "sales"},
                        {"owner": "SH", "name": "products"},
                        {"owner": "SH", "name": "countries"}]
```

```
       }');
END;
/

PL/SQL procedure successfully completed.

--
-- Enable AI profile in current session
--
SQL> EXEC DBMS_CLOUD_AI.SET_PROFILE('COHERE');

PL/SQL procedure successfully completed.

--
-- Get Profile in current session
--
SQL> SELECT DBMS_CLOUD_AI.get_profile() from dual;

DBMS_CLOUD_AI.GET_PROFILE()
--------------------------------------------------------------------------------
--
"COHERE"

--
-- Use AI
--
SQL> select ai how many customers exist;

CUSTOMER_COUNT
--------------
         55500

SQL> EXEC DBMS_CLOUD_AI.DROP_PROFILE('COHERE');

PL/SQL procedure successfully completed.
```

The following example shows specifying a different model and custom attributes in your AI profile:

```
BEGIN
DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name => 'COHERE',
     attributes =>
      '{"provider": "cohere",
        "credential_name": "COHERE_CRED",
    "model": "cohere.command-a-03-2025",
        "object_list": [{"owner": "ADB_USER"}],
        "max_tokens":512,
        "stop_tokens": [";"],
        "temperature": 0.5,
        "comments": true
       }');
END;
/
```

Example: Select AI with Azure OpenAI Service

The following examples shows how you can enable access to Azure OpenAI Service using your API key or use Azure OpenAI Service Principal, create an AI profile, and generate SQL from natural language prompts.

```
-- Create Credential for AI integration
--
EXEC
DBMS_CLOUD.CREATE_CREDENTIAL(
CREDENTIAL_NAME   => 'AZURE_CRED',
username          =>  'AZUREAI',
password          =>  'your_api_token');

PL/SQL procedure successfully completed.

--
-- Grant Network ACL for OpenAI endpoint
--
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => '<azure_resource_name>.openai.azure.com',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
       );
END;
/

PL/SQL procedure successfully completed.

--
-- Create AI profile
--
BEGIN

DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name=>
'AZUREAI',
     attributes=> '{"provider": "azure",
        "azure_resource_name": "<azure_resource_name>",
        "azure_deployment_name":
"<azure_deployment_name>"

        "credential_name": "AZURE_CRED",
        "object_list": [{"owner": "SH", "name": "customers"},
                        {"owner": "SH", "name": "countries"},
                        {"owner": "SH", "name": "supplementary_demographics"},
                        {"owner": "SH", "name": "profits"},
                        {"owner": "SH", "name": "promotions"},
                        {"owner": "SH", "name": "products"}],
        "conversation": "true"
       }');
END;
/
```

```
PL/SQL procedure successfully completed.

--
-- Enable AI profile in current session
--
EXEC DBMS_CLOUD_AI.SET_PROFILE('AZUREAI');

PL/SQL procedure successfully completed.

--
-- Get Profile in current session
--
SELECT DBMS_CLOUD_AI.get_profile() from dual;

DBMS_CLOUD_AI.GET_PROFILE()
--------------------------------------------------------------------------------
--
"AZUREAI"

--
-- Use AI
--
select ai how many customers exist;

CUSTOMER_COUNT
--------------
         55500

select ai how many customers in San Francisco are married;

MARRIED_CUSTOMERS
-----------------
               18

select ai showsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS married_customers_count
FROM SH.CUSTOMERS c
WHERE c.CUST_CITY = 'San Francisco'
  AND c.CUST_MARITAL_STATUS = 'Married'

select ai explainsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS customer_count
FROM SH.CUSTOMERS AS c
WHERE c.CUST_STATE_PROVINCE = 'San Francisco' AND c.CUST_MARITAL_STATUS =
```

```
'Married';

Explanation:
- We use the 'SH' table alias for the 'CUSTOMERS' table for better
readability.
- The query uses the 'COUNT(*)' function to count the number of rows that
match the given conditions.
- The 'WHERE' clause is used to filter the results:
  - 'c.CUST_STATE_PROVINCE = 'San Francisco'' filters customers who have 'San
Francisco' as their state or province.
  - 'c.CUST_MARITAL_STATUS = 'Married'' filters customers who have 'Married'
as their marital status.
The result of this query will give you the count of customers in San
Francisco who are married, using the column alias 'customer_count' for the
result.

Remember to adjust the table and column names based on your actual schema if
they differ from the example.

Feel free to ask if you have more questions related to SQL or database in
general.

select ai narrate what are the top 3 customers in San Francisco;

RESPONSE
--------------------------------------------------------------------------------
--
The top 3 customers in San Francisco are:

1. Hector Colven - Total amount sold: $52,025.99
2. Milburn Klemm - Total amount sold: $50,842.28
3. Gavin Xie - Total amount sold: $48,677.18

select ai chat what is Autonomous Database;

RESPONSE
--------------------------------------------------------------------------------
--
Autonomous Database is a cloud-based database service provided by Oracle. It
is designed to automate many of the routine tasks involved in managing a
database,
such as patching, tuning, and backups. Autonomous Database uses machine
learning and automation to optimize performance, security, and availability,
allowing
users to focus on their applications and data rather than database
administration tasks. It offers both Autonomous Transaction Processing (ATP)
for transactional
workloads and Autonomous Data Warehouse (ADW) for analytical workloads.
Autonomous Database provides high performance, scalability, and reliability,
making it
an ideal choice for modern cloud-based applications.

EXEC DBMS_CLOUD_AI.DROP_PROFILE('AZUREAI');
```

```
PL/SQL procedure successfully completed.
```

The following example shows specifying a different model in your AI profile:

```
BEGIN

DBMS_CLOUD_AI.CREATE_PROFILE(

profile_name=>'AZUREAI',

      attributes=>'{"provider":
"azure",
        "credential_name": "AZURE$PA",
        "model": "gpt-3.5-turbo",
        "object_list": [{"owner": "SH", "name": "customers"},
                        {"owner": "SH", "name": "countries"},
                        {"owner": "SH", "name": "supplementary_demographics"},
                        {"owner": "SH", "name": "profits"},
                        {"owner": "SH", "name": "promotions"},
                        {"owner": "SH", "name": "products"}],
    "azure_resource_name":
"<azure_resource_name>",
        "azure_deployment_name": "<azure_deployment_name>"
       }');
END;
/
```

Example: Select AI with Azure OpenAI Service Principal
Connect as a database administrator to provide access to Azure service principal authentication and then grant the network ACL permissions to the user (`ADB_USER`) who wants to use Select AI. To provide access to Azure resources, see Use Azure Service Principal to Access Azure Resources.

> **Note:**
>
> Only a DBA user can run `EXECUTE` privileges and network ACL procedure.

```
-- Connect as ADMIN user and enable Azure service principal authentication.
BEGIN
  DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(provider  => 'AZURE',
                                         params    =>
JSON_OBJECT('azure_tenantid' value 'azure_tenantid'));
END;
/

-- Copy the consent url from cloud_integrations view and consents the ADB-S
application.
SQL> select param_value from CLOUD_INTEGRATIONS where param_name =
'azure_consent_url';
PARAM_VALUE
--------------------------------------------------------------------------------
```

```
--
https://login.microsoftonline.com/<tenant_id>/oauth2/v2.0/authorize?
client_id=<client_id>&response_type=code&scope=User.read

-- On the Azure OpenAI IAM console, search for the Azure application name and
assign the permission to the application.
-- You can get the application name in the cloud_integrations view.
SQL> select param_value from CLOUD_INTEGRATIONS where param_name =
'azure_app_name';
PARAM_VALUE
--------------------------------------------------------------------------------
--
ADBS_APP_DATABASE_OCID

--
-- Grant Network ACL for Azure OpenAI endpoint
--SQL> BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'azure_resource_name.openai.azure.com',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
       );
       END;

select ai explainsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS customer_count
FROM SH.CUSTOMERS AS c
WHERE c.CUST_STATE_PROVINCE = 'San Francisco' AND c.CUST_MARITAL_STATUS =
'Married';

Explanation:
- We use the 'SH' table alias for the 'CUSTOMERS' table for better
readability.
```

```
- The query uses the 'COUNT(*)' function to count the number of rows that
match the given conditions.
- The 'WHERE' clause is used to filter the results:
  - 'c.CUST_STATE_PROVINCE = 'San Francisco'' filters customers who have 'San
Francisco' as their state or province.
  - 'c.CUST_MARITAL_STATUS = 'Married'' filters customers who have 'Married'
as their marital status.
The result of this query will give you the count of customers in San
Francisco who are married, using the column alias 'customer_count' for the
result.

Remember to adjust the table and column names based on your actual schema if
they differ from the example.

Feel free to ask if you have more questions related to SQL or database in
general.

FROM SH.CUSTOMERS c
WHERE c.CUST_CITY = 'San Francisco'
  AND c.CUST_MARITAL_STATUS = 'Married'

SQL> select ai explainsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--
SELECT COUNT(*) AS customer_count
FROM SH.CUSTOMERS AS c
WHERE c.CUST_STATE_PROVINCE = 'San Francisco' AND c.CUST_MARITAL_STATUS =
'Married';

Explanation:
- We use the 'SH' table alias for the 'CUSTOMERS' table for better
readability.
- The query uses the 'COUNT(*)' function to count the number of rows that
match the given conditions.
- The 'WHERE' clause is used to filter the results:
  - 'c.CUST_STATE_PROVINCE = 'San Francisco'' filters customers who have 'San
Francisco' as their state or province.
  - 'c.CUST_MARITAL_STATUS = 'Married'' filters customers who have 'Married'
as their marital status.
The result of this query will give you the count of customers in San
Francisco who are married, using the column alias 'customer_count' for the
result.

Remember to adjust the table and column names based on your actual schema if
they differ from the example.

Feel free to ask if you have more questions related to SQL or database in
general.

SQL> select ai narrate what are the top 3 customers in San Francisco;

RESPONSE
--------------------------------------------------------------------------------
--
The top 3 customers in San Francisco are:

1. Hector Colven - Total amount sold: $52,025.99
2. Milburn Klemm - Total amount sold: $50,842.28
3. Gavin Xie - Total amount sold: $48,677.18

SQL> select ai chat what is Autonomous Database;
```

```
RESPONSE
--------------------------------------------------------------------------------
--
Autonomous Database is a cloud-based database service provided by Oracle. It
is designed to automate many of the routine tasks involved in managing a
database,
such as patching, tuning, and backups. Autonomous Database uses machine
learning and automation to optimize performance, security, and availability,
allowing
users to focus on their applications and data rather than database
administration tasks. It offers both Autonomous Transaction Processing (ATP)
for transactional
workloads and Autonomous Data Warehouse (ADW) for analytical workloads.
Autonomous Database provides high performance, scalability, and reliability,
making it
an ideal choice for modern cloud-based applications.

--
--Drop the profile
--
EXEC DBMS_CLOUD_AI.DROP_PROFILE('ANTHROPIC');

PL/SQL procedure successfully completed.
```

The following example shows specifying a different model in your AI profile:

```
BEGIN
      DBMS_CLOUD_AI.CREATE_PROFILE(
        profile_name =>'ANTHROPIC',
        attributes   =>'{"provider": "anthropic",
          "credential_name": "ANTHROPIC_CRED",
          "model": "claude-3-opus-20240229",
          "object_list": [{"owner": "SH", "name":
"customers"},
                          {"owner": "SH", "name": "countries"},
                          {"owner": "SH", "name": "supplementary_demographics"},
                          {"owner": "SH", "name": "profits"},
                          {"owner": "SH", "name": "promotions"},
                          {"owner": "SH", "name": "products"}]
         }');
END;
/
```

Example: Select AI with Hugging Face

This example shows how you can use Hugging Face to generate, run, and explain SQL from natural language prompts or chat using the Hugging Face LLM.

The following example demonstrates using Hugging Face as your AI provider. The example demonstrates using your Hugging Face API signing key to provide network access, creating an

AI profile, and using Select AI actions to generate SQL queries from natural language prompts and chat using the Hugging Face LLM.

```
--Grant EXECUTE privilege to ADB_USER

SQL>GRANT EXECUTE on DBMS_CLOUD_AI to ADB_USER;

--
-- Create Credential for AI provider
--
SQL>BEGIN
      DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'HF_CRED',
        username    => 'HF',
        password    => '<your_api_key>'
      );
    END;
     /

PL/SQL procedure successfully completed.

--
-- Grant Network ACL for Hugging Face endpoint
--
SQL>BEGIN
      DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host => 'api-inference.huggingface.co',
        ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                    principal_name => 'ADB_USER',
                    principal_type => xs_acl.ptype_db)
       );
    END;
     /

PL/SQL procedure successfully completed.

--
-- Create AI profile
--
SQL>BEGIN
      DBMS_CLOUD_AI.CREATE_PROFILE(
        profile_name =>'HF',
        attributes   =>'{"provider": "huggingface",
          "credential_name": "HF_CRED",
          "object_list": [{"owner": "SH", "name":
"customers"},
                          {"owner": "SH", "name": "countries"},
                          {"owner": "SH", "name": "supplementary_demographics"},
                          {"owner": "SH", "name": "profits"},
                          {"owner": "SH", "name": "promotions"},
                          {"owner": "SH", "name": "products"}],
           "model" : "Qwen/Qwen2.5-72B-Instruct"
         }');
    END;
```

-- Use AI
--SQL> select ai how many customers exist;

Customer_Count
--------------
         55500

SQL> select ai how many customers in San Francisco are married;

Married_Customers
-----------------
               46

SQL> select ai showsql how many customers in San Francisco are married;

RESPONSE
------------------------------------------------------------
SELECT COUNT("CUST_ID") AS "Married_Customers"
FROM "SH"."CUSTOMERS" "C"
WHERE "CUST_CITY" = 'San Francisco' AND "CUST_MARITAL_STATUS
" = 'Married'

SQL> select ai explainsql how many customers in San Francisco are married;

RESPONSE
------------------------------------------------------------
To answer the question "How many customers in San Francisco are married?", we
need to query the "SH"."CUSTOMERS" table and filter the results based on the
city and marital status.
We will use table aliases to make the query more readable and ensure that the
string comparisons follow the specified rules.

Here is the Oracle SQL query:

```sql
SELECT COUNT("CUST_ID") AS "Married_Customers_in_San_Francisco"
FROM "SH"."CUSTOMERS" c
WHERE c."CUST_CITY" = 'San Francisco' -- Case insensitive comparison
  AND UPPER(c."CUST_MARITAL_STATUS") = UPPER('Married'); --
Case insensitive comparison
```
```

```
### Explanation:

1. **Table Alias**:

RESPONSE
------------------------------------------------------------
   - We use the alias `c` for the "SH"."CUSTOMERS" table to make the query
more readable.

2. **Column Selection**:
   - We select the count of "CUST_ID" to get the number of customers who meet
the criteria. We alias this count as "Married_Customers_in_San_Francisco" for
clarity.

3. **WHERE Clause**:
   - **City Filter**: `c."CUST_CITY" = 'San Francisco'`
     - Since 'San Francisco' is not in double quotes, we use a case-
insensitive comparison.
   - **Marital Status Filter**: `UPPER(c."CUST_MARITAL_STATUS") =
UPPER('Married')`
     - Since 'Married' is not in double quotes, we use a case-insensitive
comparison by applying the `UPPER` function to both sides of the comparison.

This query will return the number of customers in San Francisco who are
married.

SQL> select ai narrate what are the top 3 customers in San Francisco;

RESPONSE
------------------------------------------------------------
The top 3 customers in San Francisco are:

- Hector Colven, with a customer ID of 8866.
- Milburn Klemm, with a customer ID of 1944.
- Gavin Xie, with a customer ID of 2579.

These customers have the highest total sales among all customers in San
Francisco.

SQL> select ai chat what is Autonomous Database;

RESPONSE
------------------------------------------------------------
An Autonomous Database is a type of database management system that uses
artificial intelligence (AI) and machine learning (ML) to automate many of
the routine tasks typically performed by database administrators (DBAs).
These tasks include provisioning, patching, backups, tuning, and security.
The goal of an autonomous database is to reduce the need for human
intervention, minimize errors, and optimize performance,thereby allowing
organizations to focus on more strategic activities.

### Key Features of Autonomous Databases:
```

```
RESPONSE
------------------------------------------------------------
1. **Automated Provisioning**: The database can be set up and configured
automatically, reducing the time and effort required to get it up and running.
2. **Self-Patching and Updates**: The database automatically applies security
patches and updates without downtime, ensuring that the system remains secure
and up-to-date.
3. **Self-Tuning**: The database continuously monitors its performance and
adjusts settings to optimize query execution and resource utilization.
4. **Self-Backup and Recovery**: Automated backup and recovery processes
ensure that data is protected and can be restored quickly in the event of a
failure.
5. **Security**: Advanced security features, including threat detection and
response, are built into the database to protect against cyber threats.
6. **Scalability**: The database can automatically scale resources up or down
based on demand, ensuring optimal performance and cost efficiency.
7. **Monitoring and Diagnostics**: Real-time monitoring and diagnostics help
identify and resolve issues before they impact performance.

RESPONSE
------------------------------------------------------------
### Benefits of Autonomous Databases:
- **Reduced Operational Costs**: By automating routine tasks, the need for
dedicated DBAs is reduced, lowering operational costs.
- **Improved Reliability**: Automated processes reduce the risk of human
error, leading to more reliable and consistent performance.
- **Enhanced Security**: Continuous monitoring and automated security
measures help protect against threats.
- **Faster Time to Market**: Automated provisioning and tuning allow
applications to be deployed more quickly.

RESPONSE
------------------------------------------------------------
- **Scalability and Flexibility**: The ability to scale resources
automatically ensures that the database can handle varying workloads
efficiently.

### Use Cases:
- **Cloud Applications**: Autonomous databases are particularly useful in
cloud environments where scalability and reliability are critical.
- **Data Warehousing**: They can handle large volumes of data and complex
queries, making them ideal for data warehousing and analytics.

RESPONSE
------------------------------------------------------------
- **IoT and Real-Time Data Processing**: They can process and analyze real-
time data from IoT devices efficiently.
- **E-commerce**: They can handle high transaction volumes and ensure fast
response times for online shopping platforms.

### Examples of Autonomous Databases:
- **Oracle Autonomous Database**: One of the first and most well-known
autonomous databases, offering both transactional
 and data warehousing capabilities.
```

```
- **Amazon Aurora**: A managed relational database service that includes
automated scaling, patching, and backups.
- **Microsoft Azure SQL Database Managed Instance**: Provides a high level of
automation and management for SQL Server databases in the cloud.
- **Google Cloud Spanner**: A globally distributed, horizontally scalable
relational database that is highly available and consistent.

Autonomous databases represent a significant advancement in database
technology, offering organizations a more efficient, secure, and cost-
effective way to manage their data.

SQL> EXEC DBMS_CLOUD_AI.DROP_PROFILE('HF');

PL/SQL procedure successfully completed.
```

Example: Enable Conversations in Select AI

This example illustrates enabling conversations in Select AI.

> **Note:**
>
> Only a DBA can run `EXECUTE` privileges and network ACL procedure.

Create your AI profile. Set the `conversation` attribute to `true` in the profile, this action includes content from prior interactions or prompts, potentially including schema metadata, and set your profile. Once the profile is enabled, you can begin having conversations with your data. Use natural language to ask questions and follow up as needed.

```
--Grants EXECUTE privilege to ADB_USER
--
SQL> grant execute on DBMS_CLOUD_AI to ADB_USER;

-- Grant Network ACL for OpenAI endpoint
--
SQL> BEGIN
     DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'api.openai.com',
         ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'ADB_USER',
                             principal_type => xs_acl.ptype_db)
     );
    END;
    /

PL/SQL procedure successfully completed.
```

Example: Set Up and Use Select AI with RAG

This example guides you through setting up credentials, configuring network access, and creating a vector index for integrating OCI Generative AI vector store cloud services with OpenAI using Oracle Autonomous Database.

The setup concludes with creating an AI profile that uses the vector index to enhance LLM responses. Finally, this example uses the Select AI `narrate` action, which returns a response that has been enhanced using information from the specified vector database.

The following example demonstrates building and querying vector index in Oracle 23ai.

```
--Grants EXECUTE privilege to ADB_USER
GRANT EXECUTE on DBMS_CLOUD_AI to ADB_USER;

--Grants EXECUTE privilege DBMS_CLOUD_PIPELINE to ADB_USER
GRANT EXECUTE on DBMS_CLOUD_PIPELINE to ADB_USER;

-- Create the OpenAI credential
BEGIN
      DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'OPENAI_CRED',
        username => 'OPENAI_CRED',
        password => '<your_api_key>'
      );
END;
/

PL/SQL procedure successfully completed.

 -- Append the OpenAI endpoint
BEGIN
        DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
             host => 'api.openai.com',
             ace  => xs$ace_type(privilege_list => xs$name_list('http'),
                     principal_name => 'ADB_USER',
                     principal_type => xs_acl.ptype_db)
       );
END;
/

PL/SQL procedure successfully completed.

-- Create the object store credential
BEGIN
      DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'OCI_CRED',
        username => '<your_username>',
        password => '<OCI_profile_password>'
      );
END;
/

PL/SQL procedure successfully completed.
```

```
 -- Create the profile with the vector index.

BEGIN
      DBMS_CLOUD_AI.CREATE_PROFILE(
          profile_name =>'OPENAI_ORACLE',
          attributes   =>'{"provider": "openai",
            "credential_name": "OPENAI_CRED",
            "vector_index_name": "MY_INDEX",
            "temperature": 0.2,
            "max_tokens": 4096,
            "model": "gpt-3.5-turbo-1106"
          }');

SELECT AI narrate how can I deploy an oracle machine learning model;
RESPONSE
To deploy an Oracle Machine Learning model, you would first build your model
within the Oracle database. Once your in-database models are built, they
become immediately available for use, for instance, through a SQL query using
the prediction operators built into the SQL language.

The model scoring, like model building, occurs directly in the database,
eliminating the need for a separate engine or environment within which the
model and corresponding algorithm code operate. You can also use models from
a different schema (user account) if the appropriate permissions are in place.

Database.txt)
  - Develop-and-deploy-machine-learning-models-using-Oracle-Autonomous-
Database-Machine-Learning-and-APEX.txt (https://objectstorage.../v1/
my_namespace/my_bucket/my_data_folder/Develop-and-deploy-machine-learning-
models-using-Oracle-Autonomous-Database-Machine-Learning-and-APEX.txt)
```

Example: Select AI with In-database Transformer Models

This example demonstrates how you can import a pretrained transformer model that is stored in Oracle object storage into your Oracle Database 23ai instance and then use the imported in-database model in Select AI profile to generate vector embeddings for document chunks and user prompts.

To use in-database transformer models in your Select AI profile, be sure you have:

- your pretrained model imported in your Oracle Database 23ai instance.
- optionally, access to Oracle object storage.

Import a Pretrained Transformer Model into your Oracle Database 23ai From Oracle Object Storage
Review the steps in Import Pretrained Models in ONNX Format for Vector Generation Within the Database and the blog Pre-built Embedding Generation model for Oracle Database 23ai to import a pretrained transformer model into your database.

The following example shows how to import a pretained transformer model from Oracle object storage into your database and then view the imported model.

```
- Create a Directory object, or use an existing directory object
CREATE OR REPLACE DIRECTORY ONNX_DIR AS 'onnx_model';

-- Object storage bucket
VAR location_uri VARCHAR2(4000);
EXEC :location_uri := 'https://adwc4pm.objectstorage.us-
ashburn-1.oci.customer-oci.com/p/
eLddQappgBJ7jNi6Guz9m9LOtYe2u8LWY19GfgU8flFK4N9YgP4kTlrE9Px3pE12/n/adwc4pm/b/
OML-Resources/o/';
```

```
-- Model file name
VAR file_name VARCHAR2(512);
EXEC :file_name := 'all_MiniLM_L12_v2.onnx';

-- Download ONNX model from object storage into the directory object
BEGIN
  DBMS_CLOUD.GET_OBJECT(
        credential_name => NULL,
        directory_name  => 'ONNX_DIR',
        object_uri      => :location_uri || :file_name);
END;
/

-- Load the ONNX model into the database
BEGIN
  DBMS_VECTOR.LOAD_ONNX_MODEL(
        directory  => 'ONNX_DIR',
        file_name  => :file_name,
        model_name => 'MY_ONNX_MODEL');
END;
/

-- Verify
SELECT model_name, algorithm, mining_function
FROM user_mining_models
WHERE  model_name='MY_ONNX_MODEL';
```

Use In-database Transformer Models in Select AI Profiles

These examples illustrate how to use in-database transformer models within a Select AI profile. One profile is configured only for generating vector embeddings, while the other supports both Select AI actions and vector index creation.

Review Examples of Privileges to Run Select AI to complete the prerequisites.

The following is an example for generating vector embeddings only:

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name => 'EMBEDDING_PROFILE',
     attributes   => '{"provider" : "database",
                       "embedding_model": "MY_ONNX_MODEL"}'
  );
END;
/
```

The following is an example for general Select AI actions and vector index generation where you can specify a supported AI provider. This example uses OCI Gen AI profile and credentials. See Select your AI Provider and LLMs for list of supported providers. However, if you want to use in-database transformer model for generating vector embeddings, then use `"database: <MY_ONNX_MODEL>"` in `embedding_model` attribute:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'GENAI_CRED',
```

```
    user_ocid       => 'ocid1.user.oc1..aaaa...',
    tenancy_ocid    => 'ocid1.tenancy.oc1..aaaa...',
    private_key     => '<your_api_key>',
    fingerprint     => '<your_fingerprint>'
  );
END;
/

BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name => 'OCI_GENAI',
     attributes   => '{"provider": "oci",
                       "model": "meta.llama-3.3-70b-instruct",
                       "credential_name": "GENAI_CRED",
                       "vector_index_name": "MY_INDEX",
                       "embedding_model": "database: MY_ONNX_MODEL"}'
  );
END;
/
```

Use Select AI with an In-database Transformer Model from Another Schema
This example demonstrates how to use Select AI with an in-database transformer model if another schema owner owns the model. Specify `schema_name.object_name` as the fully qualified name of the model in `embedding_model` attribute. If the current user is the schema owner or owns the model, you can omit the schema name.

Be sure to have the following privileges if a different schema owner owns the model:

- `CREATE ANY MINING MODEL` system privilege
- `SELECT ANY MINING MODEL` system privilege
- `SELECT MINING MODEL` object privilege on the specific model

To grant a system privilege, you must either have been granted the system privilege with the `ADMIN OPTION` or have been granted the `GRANT ANY PRIVILEGE` system privilege.

See System Privileges for Oracle Machine Learning for SQL to review the privileges.

The following statements allow `ADB_USER1` to score data and view model details in any schema as long as `SELECT` access has been granted to the data. However, `ADB_USER1` can only create models in the `ADB_USER1` schema.

```
GRANT CREATE MINING MODEL TO ADB_USER1;
GRANT SELECT ANY MINING MODEL TO ADB_USER1;

BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name => 'OCI_GENAI',
     attributes   => '{"provider": "oci",
                       "credential_name": "GENAI_CRED",
                       "vector_index_name": "MY_INDEX",
                       "embedding_model": "database:
ADB_USER1.MY_ONNX_MODEL"}'
  );
```

```
END;
/
```

The following example shows how you can specify case sensitive model object name:

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
     profile_name => 'OCI_GENAI',
     attributes   => '{"provider": "oci",
                       "credential_name": "GENAI_CRED",
                       "model": "meta.llama-3.3-70b-instruct",
                       "vector_index_name": "MY_INDEX",
                       "embedding_model": "database:
\"adb_user1\".\"my_model\""}'
  );
END;
/
```

End-to-end Examples with Different AI Providers

These examples demonstrate end-to-end steps for using in-database transformer model with Select AI RAG. One profile uses *database* as the `provider` exclusively created for generating embedding vectors while the other profile uses *oci* as the `provider` created for Select AI actions as well as vector index.

Review Perform Prerequisites for Select AI to provide the necessary privileges.

```
--Grant create any directory privilege to the user
GRANT CREATE ANY DIRECTORY to ADB_USER;

- Create a Directory object, or use an existing directory object
CREATE OR REPLACE DIRECTORY ONNX_DIR AS 'onnx_model';

-- Object storage bucket
VAR location_uri VARCHAR2(4000);
EXEC :location_uri := 'https://adwc4pm.objectstorage.us-

SELECT AI narrate how can I deploy an oracle machine learning model;
RESPONSE
To deploy an Oracle Machine Learning model, you would first build your model
within the Oracle database. Once your in-database models are
built, they become immediately available for use, for instance, through a SQL
query using the prediction operators built into the SQL
language.

The model scoring, like model building, occurs directly in the database,
eliminating the need for a separate engine or environment within
which the model and corresponding algorithm code operate. You can also use
models from a different schema (user account) if the appropriate
permissions are in place.

Example: Improve SQL Query Generation

These examples demonstrate how comments, annotations, foreign key, and referential integrity constraints in database tables and columns can improve the generation of SQL queries from natural language prompts.

Example: Improve SQL Generation with Table and Column Comments
If you have table and column comments in your database tables, enable `"comments":"true"` parameter in `DBMS_CLOUD_AI.CREATE_PROFILE` function to retrieve table level and column level comments. The comments are added to the metadata of the LLM for a better SQL generation.

```
-- Adding comments to table 1, table 2, and table 3. Table 1 has 3 columns,
table 2 has 7 columns, table 3 has 2 columns.

-- TABLE1
COMMENT ON TABLE table1 IS 'Contains movies, movie titles and the year it was
released';
COMMENT ON COLUMN table1.c1 IS 'movie ids. Use this column to join to other
tables';
COMMENT ON COLUMN table1.c2 IS 'movie titles';
COMMENT ON COLUMN table1.c3 IS 'year the movie was released';
-- TABLE2
COMMENT ON TABLE table2 IS 'transactions for movie views - also known as
streams';
COMMENT ON COLUMN table2.c1 IS 'day the movie was streamed';
COMMENT ON COLUMN table2.c2 IS 'genre ids. Use this column to join to other
tables';
COMMENT ON COLUMN table2.c3 IS 'movie ids. Use this column to join to other
```

```
tables';
COMMENT ON COLUMN table2.c4 IS 'customer ids. Use this column to join to
other tables';
COMMENT ON COLUMN table2.c5 IS 'device used to stream, watch or view the
movie';
COMMENT ON COLUMN table2.c6 IS 'sales from the movie';
COMMENT ON COLUMN table2.c7 IS 'number of views, watched, streamed';

-- TABLE3
COMMENT ON TABLE table3 IS 'Contains the genres';
COMMENT ON COLUMN table3.c1 IS 'genre id. use this column to join to other
tables';
COMMENT ON COLUMN table3.c2 IS 'name of the genre';

BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
    profile_name => 'myprofile',
    attributes =>
        '{"provider": "azure",
          "azure_resource_name": "my_resource",
          "azure_deployment_name": "my_deployment",
          "credential_name": "my_credential",
          "comments":"true",
          "object_list": [
            {"owner": "moviestream", "name": "table1"},
            {"owner": "moviestream", "name": "table2"},
            {"owner": " moviestream", "name": "table3"}
          ]
          }'
    );

    DBMS_CLOUD_AI.SET_PROFILE(
        profile_name => 'myprofile'
    );

END;

Example: Improve SQL Query Generation with Table and Column Annotations
This example demonstrates the integration of annotations in Select AI, applicable in Oracle Database 23ai. The annotations are added to the metadata that is sent to the LLM.

If you have a table with annotations in your schema, enable `"annotations":"true"` in the `DBMS_CLOUD_AI.CREATE_PROFILE` function to instruct Select AI to add annotations to the metadata.

```
--
-- Annotations
--

CREATE TABLE emp2 (
    empno NUMBER,
    ename VARCHAR2(50) ANNOTATIONS (display 'lastname'),
    salary NUMBER ANNOTATIONS ("person_salary", "column_hidden"),
    deptno NUMBER ANNOTATIONS (display 'department')
)ANNOTATIONS (requires_audit 'yes', version '1.0', ówner 'HR Organization');

Table created.

 BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
   profile_name => 'GOOGLE_ANNOTATIONS',
   attributes   => '{"provider": "google",
      "credential_name": "GOOGLE_CRED",
      "object_list": [{"owner": "ADB_USER", "name": "emp2"}],
      "annotations" : "true"
      }');
END;
/

PL/SQL procedure successfully completed.
```

```
EXEC DBMS_CLOUD_AI.SET_PROFILE('GOOGLE_ANNOTATIONS');

PL/SQL procedure successfully completed.
```

Example: Improve SQL Query Generation with Foreign Key and Referential Key Constraints

This example demonstrates the ability of the LLM to generate accurate `JOIN` conditions by retrieving the foreign key and referential key constraints into the metadata of the LLM. The foreign key and referential key constraints provide structured relationship data between the tables to the LLM.

Enable `"constraints":"true"` in the `DBMS_CLOUD_AI.CREATE_PROFILE` function for Select AI to retrieve foreign key and referential key.

```
--
-- Referential Constraints
--
CREATE TABLE dept_test (
    deptno NUMBER PRIMARY KEY,
    dname VARCHAR2(50)
);

Table created.

CREATE TABLE emp3 (
    empno NUMBER PRIMARY KEY,
    ename VARCHAR2(50),
    salary NUMBER,
    deptno NUMBER,
    CONSTRAINT emp_dept_fk FOREIGN KEY (deptno) REFERENCES dept_test(deptno)
);

Table created.

BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
    profile_name=>'GOOGLE_CONSTRAINTS',
    attribues   =>'{"provider": "google",
      "credential_name": "GOOGLE_CRED",
      "object_list": [{"owner": "ADB_USER", "name": "dept_test"},
                      {"owner": "ADB_USER", "name": "emp3"}],
      "constraints" : "true"
      }');
END;
/

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.SET_PROFILE('GOOGLE_CONSTRAINTS');

PL/SQL procedure successfully completed.
```

Example: Automatically Detect Relevant Table Metadata

These examples shows how Select AI automatically detects relevant tables and sends metadata only for those specific tables relevant to the query in Oracle Database 23ai. To enable this feature, set `object_list_mode` to *automated*. This automatically creates a vector index named `<profile_name>_OBJECT_LIST_VECINDEX`. The vector index is initialized with default attributes and values such as `refresh_rate`, `similarity_threshold`, and `match_limit`. You can modify some of the attributes through `DBMS_CLOUD_AI.UPDATE_VECTOR_INDEX`. See UPDATE_VECTOR_INDEX Procedure for more information.

One profile is configured to use `object_list` to specify the schema or the objects in the schema while the other does not specify `object_list`. However, the same SQL construct is expected.

Review Perform Prerequisites for Select AI to provide access to the `DBMS_CLOUD_AI` package and provide network access to the AI provider.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
    profile_name=>'OCI_AUTO',
    attributes=>'{"provider":
"oci",
      "credential_name": "GENAI_CRED",
      "object_list": [{"owner": "SH"}],
      "oci_compartment_id": "ocid1.compartment.oc1..aaaa...",
      "model" : "meta.llama-3.3-70b-instruct"
      }');
END;
/

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.SET_PROFILE('OCI_AUTO');

PL/SQL procedure successfully completed.

select ai showsql how many customers in San Francisco are married;

RESPONSE
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
-----------------------------------
SELECT COUNT(DISTINCT c."CUST_ID") AS "NUMBER_OF_CUSTOMERS"
FROM "SH"."CUSTOMERS" c
WHERE UPPER(c."CUST_CITY") = UPPER('San Francisco')
AND UPPER(c."CUST_MARITAL_STATUS") = UPPER('married')
```

The following example compares the same scenario without using `object_list`. When you don't specify `object_list`, Select AI automatically chooses all objects available to the current schema.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
    profile_name=>'OCI_AUTO1',
    attributes=>'{"provider":
"oci",
      "credential_name": "GENAI_CRED",
```

```
      "oci_compartment_id": "ocid1.compartment.oc1..aaaa...",
      "object_list_mode": "automated",
      "model" : "meta.llama-3.3-70b-instruct"
      }');
END;
/
PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.SET_PROFILE('OCI_AUTO1');

PL/SQL procedure successfully completed.

select ai showsql how many customers in San Francisco are married?;

RESPONSE
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
----------
SELECT COUNT(c."CUST_ID") AS "Number_of_Customers"
FROM "SH"."CUSTOMERS" c
WHERE UPPER(c."CUST_CITY") = UPPER('San Francisco')
AND UPPER(c."CUST_MARITAL_STATUS") = UPPER('Married')
```

Example: Generate Synthetic Data

This example explores how you can generate synthetic data mimicking the characteristics and distribution of real data.

The following example shows how to create a few tables in your schema, use OCI Generative AI as your AI provider to create an AI profile, synthesize data into those tables using the `DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA` function, and query or generate responses to natural language prompts with Select AI.

```
--Create tables or use cloned tables

CREATE TABLE ADB_USER.Director (
    director_id     INT PRIMARY KEY,
    name            VARCHAR(100)
);
CREATE TABLE ADB_USER.Movie (
    movie_id        INT PRIMARY KEY,
    title           VARCHAR(100),
    release_date    DATE,
    genre           VARCHAR(50),
    director_id     INT,
    FOREIGN KEY (director_id) REFERENCES ADB_USER.Director(director_id)
);
CREATE TABLE ADB_USER.Actor (
    actor_id        INT PRIMARY KEY,
    name            VARCHAR(100)
);
CREATE TABLE ADB_USER.Movie_Actor (
    movie_id        INT,
    actor_id        INT,
    PRIMARY KEY (movie_id, actor_id),
    FOREIGN KEY (movie_id) REFERENCES ADB_USER.Movie(movie_id),
```

```
    FOREIGN KEY (actor_id) REFERENCES ADB_USER.Actor(actor_id)
);

-- Create the GenAI credential
BEGIN
  DBMS_CLOUD.create_credential(
    credential_name => 'GENAI_CRED',
    user_ocid       => 'ocid1.user.oc1....',
    tenancy_ocid    => 'ocid1.tenancy.oc1....',
    private_key     => 'vZ6cO...',
    fingerprint     => '86:7d:...'
  );
END;
/

-- Create a profile
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
      profile_name
=>'GENAI',
      attributes  =>'{"provider":
"oci",
        "credential_name": "GENAI_CRED",
        "object_list": [{"owner": "ADB_USER",
        "oci_compartment_id": "ocid1.compartment.oc1...."}]
       }');
END;
/

EXEC DBMS_CLOUD_AI.set_profile('GENAI');

-- Run the API for single table
BEGIN
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name => 'GENAI',
        object_name  => 'Director',
        owner_name   => 'ADB_USER',
        record_count => 5
    );
END;
/
PL/SQL procedure successfully completed.

-- Query the table to see results
SQL> SELECT * FROM ADB_USER.Director;

DIRECTOR_ID NAME
-----------
--------------------------------------------------------------------------------
----------------------
          1 John Smith
          2 Emily Chen
          3 Michael Brown
          4 Sarah Taylor
```

```
         5 David Lee

-- Or ask select ai to show the results
SQL> select ai how many directors are there;

NUMBER_OF_DIRECTORS
-------------------
                  5
```

Example: Generate Synthetic Data for Multiple Tables

After you create and set your AI provider profile, use the `DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA` to generate data for multiple tables. You can query or use Select AI to respond to the natural language prompts.

```
BEGIN
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name => 'GENAI',
        object_list => '[{"owner": "ADB_USER", "name":
"Director","record_count":5},
                        {"owner": "ADB_USER", "name":
"Movie_Actor","record_count":5},
                        {"owner": "ADB_USER", "name":
"Actor","record_count":10},
                        {"owner": "ADB_USER", "name":
"Movie","record_count":5,"user_prompt":"all movies released in 2009"}]'
    );
END;
/
PL/SQL procedure successfully completed.

-- Query the table to see results
SQL> select * from ADB_USER.Movie;

 MOVIE_ID
TITLE                                                    RELEASE_D
                 GENRE                                  DIRECTOR_ID
---------- ---------------------------------------------------------- ---------
------------------------------------------------------------------
-----------
         1 The Dark Knight                                        15-
JUL-09                           Action                             8
         2 Inglourious Basterds                                   21-

AUG-09                           Science Fiction                   10

-- Or ask select ai to show the results
```

```
SQL> select ai how many actors are there;

Number of Actors
----------------
              10
```

Example: Guide Synthetic Data Generation with Sample Rows
To guide AI service in generating synthetic data, you can randomly select existing records from a table. For instance, by adding `{"sample_rows": 5}` to the `params` argument, you can send 5 sample rows from a table to the AI provider. This example generates 10 additional rows based on the sample rows from the `Transactions` table.

```
BEGIN
  DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
    profile_name => 'GENAI',
    object_name  => 'Transactions',
    owner_name   => 'ADB_USER',
    record_count => 10,
    params       => '{"sample_rows":5}'
  );
END;
/
```

Example: Customize Synthetic Data Generation with User Prompts
The `user_prompt` argument enables you to specify additional rules or requirements for data generation. This can be applied to a single table or as part of the `object_list` argument for multiple tables. For example, in the following calls to `DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA`, the prompt instructs the AI to generate synthetic data on movies released in 2009.

```
-- Definition for the Movie table CREATE TABLE Movie

CREATE TABLE Movie (
    movie_id        INT PRIMARY KEY,
    title           VARCHAR(100),
    release_date    DATE,
    genre           VARCHAR(50),
    director_id     INT,
    FOREIGN KEY (director_id) REFERENCES Director(director_id)
);

BEGIN
  DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
    profile_name      => 'GENAI',
    object_name       => 'Movie',
    owner_name        => 'ADB_USER',
    record_count      => 10,
    user_prompt       => 'all movies are released in 2009',
    params            => '{"sample_rows":5}'
  );
END;
/
```

```
BEGIN
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name => 'GENAI',
        object_list => '[{"owner": "ADB_USER", "name":
"Director","record_count":5},
                        {"owner": "ADB_USER", "name":
"Movie_Actor","record_count":5},
                        {"owner": "ADB_USER", "name":
"Actor","record_count":10},
                        {"owner": "ADB_USER", "name":
"Movie","record_count":5,"user_prompt":"all movies are released in 2009"}]'
    );
END;
/
```

Example: Improve Synthetic Data Quality by Using Table Statistics
If a table has column statistics or is cloned from a database that includes metadata, Select AI can use these statistics to generate data that closely resembles or is consistent with the original data.

For `NUMBER` columns, the high and low values from the statistics guide the value range. For instance, if the `SALARY` column in the original `EMPLOYEES` table ranges from 1000 to 10000, the synthetic data for this column will also fall within this range.

For columns with distinct values, such as a `STATE` column with values *CA*, *WA*, and *TX*, the synthetic data will use these specific values. You can manage this feature using the `{"table_statistics": true/false}` parameter. By default, the table statistics are enabled.

```
BEGIN
  DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
    profile_name      => 'GENAI',
    object_name       => 'Movie',
    owner_name        => 'ADB_USER',
    record_count      => 10,
    user_prompt => 'all movies released in 2009',
    params            => '{"sample_rows":5,"table_statistics":true}'
  );
END;
/
```

Example: Use Column Comments to Guide Data Generation
If column comments exist, Select AI automatically includes them to provide additional information for the LLM during data generation. For example, a comment on the `Status` column in a Transaction table might list allowed values such as *successful*, *failed*, *pending*, *canceled*, and *need manual check*. You can also add comments to further explain the column, giving AI services more precise instructions or hints for generating accurate data. By default, comments are disabled. See Optional Parameters for more details.

```
-- Use comment on column
COMMENT ON COLUMN Transaction.status IS 'the value for state should either be
''successful'', ''failed'', ''pending'' or ''canceled''';
/

BEGIN
```

```
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name  => 'GENAI',
        object_name   => 'employees',
        owner_name    => 'ADB_USER',
        record_count  => 10
        params        => '{"comments":true}'

    );
END;
/
```

Example: Set Unique Values in Synthetic Data Generation
When generating large amounts of synthetic data with LLMs, duplicate values are likely to occur. To prevent this, set up a unique constraint on the relevant column. This ensures that Select AI ignores rows with duplicate values in the LLM response. Additionally, to restrict values for certain columns, you can use the `user_prompt` or add comments to specify the allowed values, such as limiting a `STATE` column to *CA*, *WA*, and *TX*.

```
-- Use 'user_prompt'
BEGIN
    DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
        profile_name  => 'GENAI',
        object_name   => 'employees',
        owner_name    => 'ADB_USER',
        user_prompt   => 'the value for state should either be CA, WA, or TX',
        record_count  => 10
    );
END;
/

-- Use comment on column
COMMENT ON COLUMN EMPLOYEES.state IS 'the value for state should either be
CA, WA, or TX'
/
```

Example: Enhance Synthetic Data Generation by Parallel Processing
To reduce runtime, Select AI splits synthetic data generation tasks into smaller chunks for tables without primary keys or with numeric primary keys. These tasks run in parallel, interacting with the AI provider to generate data more efficiently. The Degree of Parallelism (DOP) in your database, influenced by your Autonomous Database service level and ECPU or OCPU settings, determines the number of records each chunk processes. Running tasks in parallel generally improves performance, especially when generating large amounts of data across many tables. To manage the parallel processing of synthetic data generation, set `priority` as an optional parameter. See Optional Parameters.

Example: Enable or Disable Data Access

This example illustrates how administrators can control data access and prevent Select AI from sending actual schema tables to the LLM.

Disabling Data Access

To restrict access to schema tables, log in as an administrator and run the following procedure.

```
EXEC DBMS_CLOUD_AI.DISABLE_DATA_ACCESS;

PL/SQL procedure successfully completed.
```

Disabling data access limits Select AI's `narrate` action and Synthetic Data Generation. The `narrate` action and synthetic data generation raise an error.

Log in as database user, create and configure your AI profile. Review Perform Prerequisites for Select AI to configure your AI profile.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
          profile_name =>'DATA_ACCESS',
          attributes   =>'{"provider": "openai",
            "credential_name": "OPENAI_CRED",
            "object_list": [{"owner":"SH"}]
          }');
END;
/

EXEC DBMS_CLOUD_AI.SET_PROFILE('DATA_ACCESS');

select ai how many customers;

NUM_CUSTOMERS
55500

select ai narrate what are the top 3 customers in San Francisco;

ORA-20000: Data access is disabled for SELECT AI.
ORA-06512: at "C##CLOUD$SERVICE.DBMS_CLOUD", line 2228
ORA-06512: at "C##CLOUD$SERVICE.DBMS_CLOUD_AI", line 13157
ORA-06512: at line 1 https://docs.oracle.com/error-help/db/ora-20000/
The stored procedure 'raise_application_error' was called which causes this
error to be generated
Error at Line: 1 Column: 6
```

The following example shows the errors that are triggered when you try to generate synthetic data.

```
BEGIN
DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
profile_name => 'DATA_ACCESS_SDG',
object_name => 'CUSTOMERS_NEW',
owner_name => 'ADB_USER,
record_count => 5
);
END;
/

ERROR at line 1:
```

```

ORA-06512: at line 2
```

Enabling Data Access

The following example shows enabling data access. Log in as an administrator and run the following procedure:

```
EXEC DBMS_CLOUD_AI.ENABLE_DATA_ACCESS;

PL/SQL procedure successfully completed.
```

Log in as database user, create and configure your AI profile. Review Perform Prerequisites for Select AI to configure your AI profile. Run `narrate` action and separately generate synthetic data.

```
BEGIN
  DBMS_CLOUD_AI.CREATE_PROFILE(
          profile_name =>'DATA_ACCESS_NEW',
          attributes   =>'{"provider": "openai",
            "credential_name": "OPENAI_CRED",
            "object_list": [{"owner":"SH"}]
          }');
   END;
   /

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.SET_PROFILE('DATA_ACCESS_NEW');

PL/SQL procedure successfully completed.

select ai how many customers;

NUM_CUSTOMERS
55500

select ai narrate what are the top 3 customers in San Francisco;

"RESPONSE"
"The top 3 customers in San Francisco are Cody Seto, Lauren Yaskovich, and
Ian Mc"
```

The following example shows successful synthetic data generation after enabling data access.

```
BEGIN
DBMS_CLOUD_AI.GENERATE_SYNTHETIC_DATA(
profile_name => 'DATA_ACCESS_SDG',
object_name => 'CUSTOMERS_NEW',
owner_name => 'ADB_USER',
record_count => 5
```

```
);
END;
/

PL/SQL procedure successfully completed.
```

Example: Restrict Table Access in AI Profile

This example demonstrates how to restrict table access and instruct the LLM to use only the tables specified in the `object_list` of the AI profile.

Set `enforce_object_list` to *true* to restrict table access to the LLM.

As a database user, create and configure your AI profile. Review Perform Prerequisites for Select AI to configure your AI profile.

```
BEGIN
      DBMS_CLOUD_AI.CREATE_PROFILE(
        profile_name =>'GOOGLE_ENFORCED',
        attributes   =>'{"provider": "google",
          "credential_name": "GOOGLE_CRED",
          "object_list": [{"owner": "ADB_USER", "name": "GENRE"},
                  {"owner": "ADB_USER", "name": "CUSTOMER"},
                  {"owner": "ADB_USER", "name": "PIZZA_SHOP"},
                  {"owner": "ADB_USER", "name": "STREAMS"},
                  {"owner": "ADB_USER", "name": "MOVIES"},
                  {"owner": "ADB_USER", "name": "ACTIONS"}],
          "enforce_object_list" : "true"
          }');
END;
/

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.set_profile('GOOGLE_ENFORCED');

PL/SQL procedure successfully completed.

select ai showsql please list the user tables;

RESPONSE
--------------------------------------------------------------------------------
--------------
SELECT 'ADB_USER.GENRE' AS TABLE_NAME FROM DUAL UNION ALL SELECT
'ADB_USER.CUSTOMER' AS
TABLE_NAME FROM DUAL UNION ALL SELECT 'ADB_USER.PIZZA_SHOP' AS TABLE_NAME
FROM DUAL UNION
 ALL SELECT 'ADB_USER.STREAMS' AS TABLE_NAME FROM DUAL UNION ALL SELECT
'ADB_USER.MOVIES'
AS TABLE_NAME FROM DUAL
--
```

Setting `enforce_object_list` to *false* instructs the LLM to use other tables and views based on its prior knowledge.

```
BEGIN
      DBMS_CLOUD_AI.CREATE_PROFILE(
        profile_name =>'GOOGLE_ENFORCED1',
        attributes   =>'{"provider": "google",
          "credential_name": "GOOGLE_CRED",
          "object_list": [{"owner": "ADB_USER", "name": "GENRE"},
                  {"owner": "ADB_USER", "name": "CUSTOMER"},
                  {"owner": "ADB_USER", "name": "PIZZA_SHOP"},
                  {"owner": "ADB_USER", "name": "STREAMS"},
                  {"owner": "ADB_USER", "name": "MOVIES"},
                  {"owner": "ADB_USER", "name": "ACTIONS"}],
          "enforce_object_list" : "false"
          }');
END;
/

PL/SQL procedure successfully completed.

EXEC DBMS_CLOUD_AI.set_profile('GOOGLE_ENFORCED1');

PL/SQL procedure successfully completed.

select ai showsql please list the user tables;
RESPONSE
----------------------------------
SELECT TABLE_NAME FROM USER_TABLES
```

Example: Specify Case Sensitivity for Columns

This example shows how you can set case sensitivity for columns in AI profile.

Set `case_sensitive_values` to *false* to retrieve queries that are not case sensitive.

As a database user, create and configure your AI profile. Review Perform Prerequisites for Select AI to configure your AI profile.

```
BEGIN
      DBMS_CLOUD_AI.create_profile(
        profile_name   =>'GOOGLE',
        attributes     =>'{"provider": "google",
          "credential_name": "GOOGLE_CRED",
          "object_list": [{"owner": "ADB_USER", "name": "GENRE"},
                  {"owner": "ADB_USER", "name": "CUSTOMER"},
                  {"owner": "ADB_USER", "name": "PIZZA_SHOP"},
                  {"owner": "ADB_USER", "name": "STREAMS"},
                 {"owner": "ADB_USER", "name": "MOVIES"},
                 {"owner": "ADB_USER", "name": "ACTIONS"}],
         "case_sensitive_values" : "false"
         }');
 END;
 /
```

```
PL/SQL procedure successfully completed.

-- With "case_sensitive_values" set to "false", LLM will give back case
insensitive query.

select ai showsql how many people watch Inception;

RESPONSE
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
------------------------------------------------------------
SELECT COUNT(DISTINCT c.CUSTOMER_ID) AS "COUNT"
FROM "ADB_USER"."CUSTOMER" c
JOIN "ADB_USER"."STREAMS" s ON c.CUSTOMER_ID = s.CUSTOMER_ID
JOIN "ADB_USER"."MOVIES" m ON s.MOVIE_ID = m.MOVIE_ID
WHERE UPPER(m.TITLE) = UPPER('Inception')
```

You can specify case sensitive query using double quotes even though the `case_sensitive_values` is set to *false*.

```
select ai showsql how many people watch "Inception";

RESPONSE
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
------------------------------------------------------
SELECT COUNT(DISTINCT c.CUSTOMER_ID) AS "COUNT"
FROM "ADB_USER"."CUSTOMER" c JOIN "ADB_USER"."STREAMS" s ON
c.CUSTOMER_ID = s.CUSTOMER_ID JOIN "ADB_USER"."MOVIES" m ON
s.MOVIE_ID = m.MOVIE_ID WHERE m.TITLE = 'Inception'
```

JSON Document Stores

Autonomous Database has full support for data represented as JSON documents. In Autonomous Databases, JSON documents can coexist with relational data.

For more details on JSON Documents, see JSON Developer's Guide.

Cache Messages with Singleton Pipes and Using Pipes for Persistent Messaging

On Autonomous Database the `DBMS_PIPE` package includes support for Singleton Pipes and Persistent Messaging Pipes.

- **Singleton Pipes** allow you to cache and retrieve a custom message and share the message across multiple database sessions with concurrent reads.
- **Persistent Messaging Pipes** allow you to store messages in Cloud Object Storage. Using persistent messages you can send and receive messages within a single database or between multiple databases in the same or in different regions, without message size limitations.

- Cache Messages with Singleton Pipes
  Singleton Pipe is an addition to the `DBMS_PIPE` package that allows you to cache and retrieve a custom message and share the message across multiple database sessions with concurrent reads.
- Use Persistent Messaging with Messages Stored in Cloud Object Store
  The `DBMS_PIPE` package has extended functionality on Autonomous Database to support persistent messaging, where messages are stored in Cloud Object Store.

Cache Messages with Singleton Pipes

Singleton Pipe is an addition to the `DBMS_PIPE` package that allows you to cache and retrieve a custom message and share the message across multiple database sessions with concurrent reads.

- About Caching Messages with Singleton Pipes
  The `DBMS_PIPE` package has extended functionality on Autonomous Database to support Singleton Pipes.
- Automatic Refresh of Cached Message with a Cache Function
  The `DBMS_PIPE` package allows you to automatically populate a Singleton Pipe message using a user-defined cache function.
- Create an Explicit Singleton Pipe
  Describes the steps to create a Singleton Pipe with a specified pipe name (an Explicit Singleton Pipe).
- Create an Explicit Singleton Pipe with a Cache Function
  Describes the steps to create a Singleton Pipe with a specified pipe name, an Explicit Singleton Pipe, and provide a cache function. A cache function allows you to automatically populate the message in a singleton pipe.

About Caching Messages with Singleton Pipes

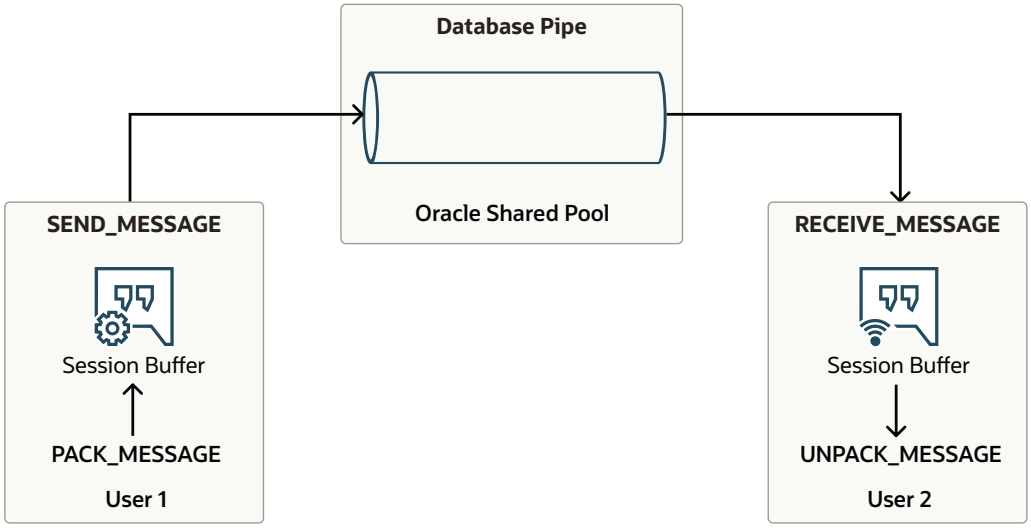
The `DBMS_PIPE` package has extended functionality on Autonomous Database to support Singleton Pipes.

A Singleton Pipe in `DBMS_PIPE`:

- Provides in-memory caching of custom data using Singleton Pipe messages.
- Supports the ability to cache and retrieve a custom message of up to 32,767 bytes.
- Supports sharing a cached message across multiple database sessions with concurrent reads. This provides high throughput and supports concurrent reads of messages across database sessions.
- Supports Read-Only and Read-Write databases.
- Supports several cache invalidation methods:
  - Explicit cache invalidation controlled by user.
  - Cache invalidation after a user specified time interval (in seconds). This invalidation method is controlled by the message sender, using the `shelflife` parameter, instead of by message readers. This avoids the common pitfalls due to incorrect use of cache by readers.

About Standard Pipes and Singleton Pipes

The DBMS_PIPE Package allows two or more database sessions to communicate using in-memory messages. Pipe functionality has several applications such as external service interface, debugging, independent transactions, and alerts.

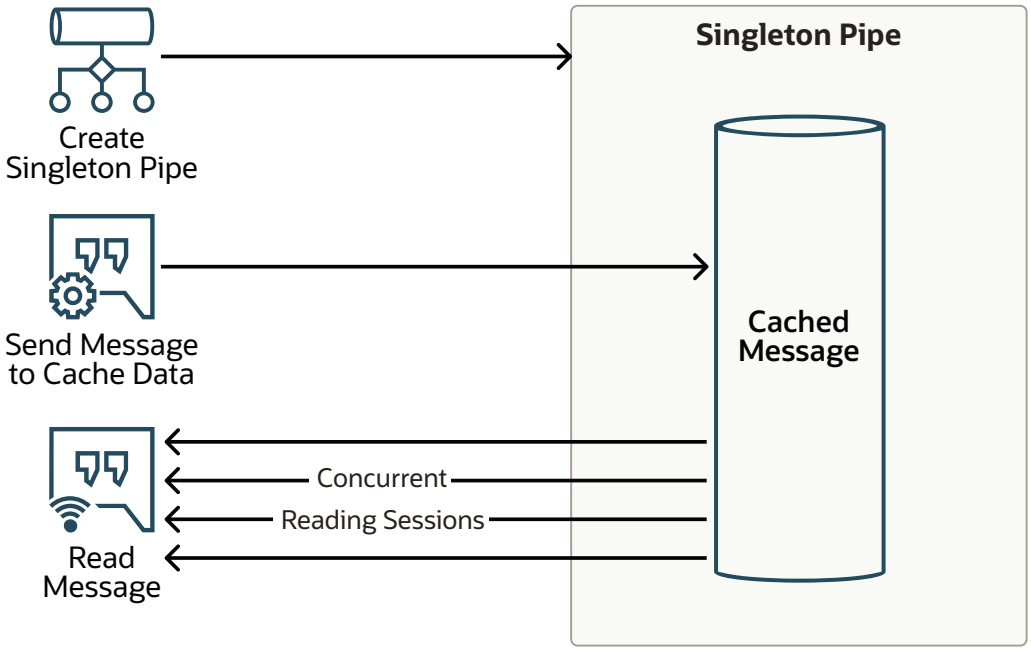


A Singleton Pipe can be any one of the supported `DBMS_PIPE` types:

- **Implicit Pipe:** Automatically created when a message is sent with an unknown pipe name using the `DBMS_PIPE.SEND_MESSAGE` function.
- **Explicit Pipe:** Created using the `DBMS_PIPE.CREATE_PIPE` function with a user specified pipe name.
- **Public Pipe:** Accessible by any user with `EXECUTE` permission on `DBMS_PIPE` package.
- **Private Pipe:** Accessible by sessions with the same user as the pipe creator.

Singleton Pipes provide the ability to cache a single message in the memory of the Autonomous Database instance.

The following shows the general workflow for using singleton pipes.



Singleton Pipe Overview and Features

- **Singleton Messages**
  - A Singleton Pipe can cache one message in the pipe, hence the name "singleton".
  - The message in a Singleton Pipe can be comprised of multiple fields, up to a total message size of 32,767 bytes.
  - `DBMS_PIPE` supports the ability to pack multiple attributes in a message using `DBMS_PIPE.PACK_MESSAGE` procedure.
  - For a Public Singleton Pipe, the message can be received by any database session with execute privilege on `DBMS_PIPE` package.
  - For Private Singleton Pipe, the message can be received by sessions with the same user as the creator of the Singleton Pipe.
- **High Message Throughput for Reads**
  - Singleton Pipes cache the message in the pipe until it is invalidated or purged. Database sessions can concurrently read a message from the Singleton Pipe.
  - Receiving a message from a Singleton Pipe is a non-blocking operation.
- **Message Caching**
  - A message is cached in a Singleton Pipe using `DBMS_PIPE.SEND_MESSAGE`.
  - If there is an existing cached message in the Singleton Pipe, then `DBMS_PIPE.SEND_MESSAGE` overwrites the previous message to maintain only one message in the Singleton Pipe.
- **Message Invalidation**
  - **Explicit Invalidation**: purges the pipe with the procedure `DBMS_PIPE.PURGE` or by overwriting the message using `DBMS_PIPE.SEND_MESSAGE`.
  - **Automatic Invalidation**: a message can be invalidated automatically after the specified `shelflife` time has elapsed.
- **No Eviction from Database Memory**

- Singleton Pipes do not get evicted from Oracle Database memory.
- An Explicit Singleton Pipe continues to reside in database memory until it is removed using `DBMS_PIPE.REMOVE_PIPE` or until the database restarts.
- An Implicit Singleton Pipe stays in database memory until there is one cached message in the pipe.

Singleton Pipe Operations

Operation	DBMS_PIPE Function or Procedure
Create an Explicit Singleton Pipe	CREATE_PIPE Function
Cache a message in Singleton Pipe	PACK_MESSAGE Procedures, SEND_MESSAGE Function
Read a cached message from Singleton Pipe	RECEIVE_MESSAGE Function, UNPACK_MESSAGE Procedures
Delete a message in Singleton Pipe	PURGE Procedure
Remove an Explicit Singleton Pipe	REMOVE_PIPE Function

Automatic Refresh of Cached Message with a Cache Function

The `DBMS_PIPE` package allows you to automatically populate a Singleton Pipe message using a user-defined cache function.

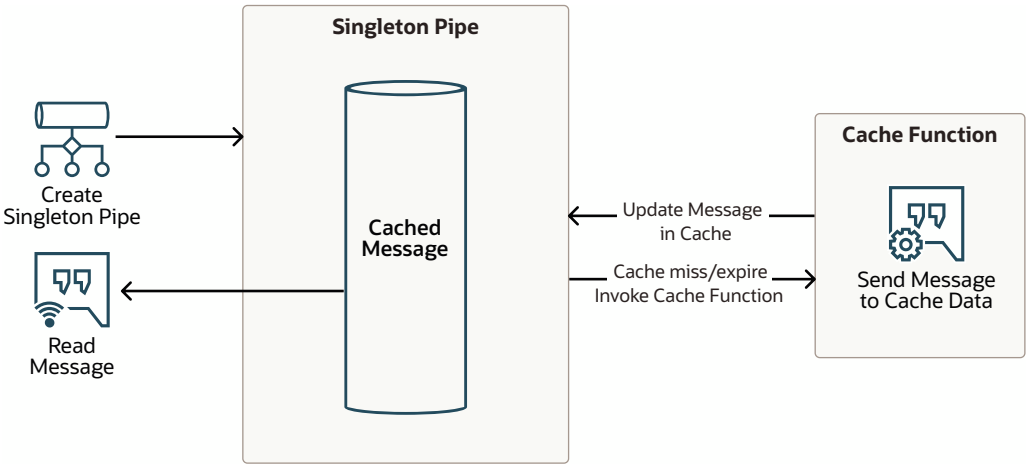
By default, after a message is invalidated with either Singleton Pipe explicit or implicit invalidation, a subsequent `DBMS_PIPE.RECEIVE_MESSAGE` results in no message being received. To add a new message to the pipe, the message must be explicitly cached by calling `DBMS_PIPE.SEND_MESSAGE`. To avoid this case, where no message is available when you read from a Singleton Pipe, you can define a cache function. With a cache function defined, the cache function is automatically invoked when you receive a message in following scenarios:

- When the Singleton Pipe is empty.
- When the message in a Singleton Pipe is invalid due to the `shelflife` time elapsed.

To use a cache function define the cache function and include the `cache_func` parameter with `DBMS_PIPE.RECEIVE_MESSAGE`. A user-defined cache function provides the following:

- The cache function can be specified when reading a message from a Singleton Pipe using `DBMS_PIPE.RECEIVE_MESSAGE`.
- When there is no message in the Singleton Pipe, `DBMS_PIPE.RECEIVE_MESSAGE` calls the cache function.
- When the message `shelflife` time has elapsed, the database automatically populates a new message in the Singleton Pipe.

Using a cache function simplifies working with Singleton Pipes. You do not need to handle failure cases for receiving a message from an empty pipe. In addition, a cache function ensures there is no cache-miss when you read messages from a Singleton Pipe, providing maximum use of the cached message.



When you define a cache function, the function name must be fully qualified with the owner schema:

- *OWNER.FUNCTION_NAME*
- *OWNER.PACKAGE.FUNCTION_NAME*

Define a cache function with the following signature:

```
CREATE OR REPLACE FUNCTION cache_function_name(
       pipename  IN VARCHAR2
) RETURN INTEGER;
```

The typical operations within a cache function are:

- Create a Singleton Pipe, for an Explicit Pipe, using `DBMS_PIPE.CREATE_PIPE`.
- Create a message to cache in the Singleton Pipe.
- Send the message to the pipe specified in the cache function, optionally specifying a `shelflife` for the implicit message.

To use a cache function, the current session user that invokes `DBMS_PIPE.RECEIVE_MESSAGE` must have required privileges to execute the cache function.

See RECEIVE_MESSAGE Function more information on defining a cache function.

Create an Explicit Singleton Pipe

Describes the steps to create a Singleton Pipe with a specified pipe name (an Explicit Singleton Pipe).

First, for this example create the `receive_message` helper function to repeatedly call `DBMS_PIPE.RECEIVE_MESSAGE`. This allows you to test singleton pipe functionality.

```
CREATE OR REPLACE FUNCTION msg_types AS
       TYPE t_rcv_row IS RECORD (c1 VARCHAR2(32767), c2 NUMBER);
       TYPE t_rcv_tab IS TABLE OF t_rcv_row;
END;

CREATE OR REPLACE FUNCTION receive_message(
      pipename    IN VARCHAR2,
      rcv_count   IN NUMBER DEFAULT 1,
```

```
     cache_func  IN VARCHAR2 DEFAULT NULL)
  RETURN msg_types.t_rcv_tab pipelined
   AS
      l_msg    VARCHAR2(32767);
      l_status NUMBER;
BEGIN
     FOR i IN 1..rcv_count LOOP
          l_status := DBMS_PIPE.RECEIVE_MESSAGE(
           pipename   => pipename,
           cache_func => cache_func,
           timeout    => 1);
        IF l_status != 0 THEN
             raise_application_error(-20000,
            'Message not received for attempt: ' || to_char(i) || ' status:
' ||
           l_status);
        END IF;

        DBMS_PIPE.UNPACK_MESSAGE(l_msg);
            pipe row(msg_types.t_rcv_row(l_msg));
    END LOOP;
RETURN;
END;
```

1. Create an explicit singleton pipe named `PIPE_TEST` with `shelflife` parameter set to 3600 (seconds).

   ```
   DECLARE
     l_status INTEGER;
   BEGIN
     l_status := DBMS_PIPE.CREATE_PIPE(
                   pipename => 'MY_PIPE1',
                   private => TRUE,
                   singleton => TRUE,
                   shelflife => 3600);
   END;
   /
   ```

   See CREATE_PIPE Function for more information.

2. Verify the singleton pipe is created.

   ```
   SELECT name, singleton, type
        FROM v$db_pipes WHERE name= '&pipename' ORDER BY 1;

   NAME                 SINGLETON  TYPE
   -------------------- ---------- -------
   PIPE_TEST            YES        PRIVATE
   ```

3. Pack and send a message on the singleton pipe.

   ```
   EXEC DBMS_PIPE.PACK_MESSAGE('This is a real message that you can get
   multiple times');
   ```

```
SELECT DBMS_PIPE.SEND_MESSAGE(pipename => '&pipename') status FROM DUAL;

STATUS
----------
0
```

See PACK_MESSAGE Procedures and SEND_MESSAGE Function for more information.

4. Receive a message from a singleton pipe.

```
SELECT * FROM receive_message(
    pipename => '&pipename',
    rcv_count => 2);

MESSAGE
--------------------------------------------------------------------------------
-----
This is a real message that you can get multiple times
This is a real message that you can get multiple times
```

The `receive_message` function is a helper function that calls `DBMS_PIPE.RECEIVE_MESSAGE`.

5. Purge the message and remove the pipe.

```
EXEC DBMS_PIPE.PURGE('&pipename');
SELECT DBMS_PIPE.REMOVE_PIPE('&pipename') status FROM DUAL;
```

Create an Explicit Singleton Pipe with a Cache Function

Describes the steps to create a Singleton Pipe with a specified pipe name, an Explicit Singleton Pipe, and provide a cache function. A cache function allows you to automatically populate the message in a singleton pipe.

1. Create a cache function, `test_cache_message` for a singleton pipe.

```
CREATE OR REPLACE FUNCTION test_cache_message(
     pipename IN VARCHAR2) return NUMBER
AS
   l_status NUMBER;
   l_data VARCHAR2(4000);
BEGIN
   l_status := DBMS_PIPE.CREATE_PIPE(
          pipename => pipename,
          private => TRUE,
          singleton => true,
          shelflife => 600);
   IF l_status != 0 THEN RETURN l_status;
   END IF;

   DBMS_PIPE.PACK_MESSAGE('This is a placeholder cache message for an
empty pipe');
   l_status := DBMS_PIPE.SEND_MESSAGE(pipename => pipename);
   RETURN l_status;
 END;
/
```

> **Note:**
>
> The current session user invoking `DBMS_PIPE.RECEIVE_MESSAGE` must have required privilege to execute the cache function.

2. Receive with a cache function and confirm the message populates in pipe. The pipe must exist as a private pipe created in the cache function.

```
SELECT * FROM receive_message(
     pipename => '&pipename',
     rcv_count => 1,
     cache_func => 'TEST_CACHE_MESSAGE');

MESSAGE
---------------
This is a placeholder cache message for an empty pipe
```

   The `receive_message` function is a helper function that calls `DBMS_PIPE.RECEIVE_MESSAGE`. See Create an Explicit Singleton Pipe for the `receive_message` definition.

   See CREATE_PIPE Function for more information.

3. Receive without the cache function to confirm the message persists in the pipe.

```
SELECT * FROM receive_message(
     pipename => '&pipename',
     rcv_count => 2);

MESSAGE
---------------
This is a placeholder cache message for an empty pipe
This is a placeholder cache message for an empty pipe
```

   The `receive_message` function is a helper function that calls `DBMS_PIPE.RECEIVE_MESSAGE`. See Create an Explicit Singleton Pipe for the `receive_message` definition.

   See CREATE_PIPE Function for more information.

Use Persistent Messaging with Messages Stored in Cloud Object Store

The `DBMS_PIPE` package has extended functionality on Autonomous Database to support persistent messaging, where messages are stored in Cloud Object Store.

- About Persistent Messaging with DBMS_PIPE
- Create an Explicit Persistent Pipe and Send a Message
  Describes the steps to create a persistent pipe with a specified pipe name (Explicit Pipe).
- Retrieve a Persistent Message on Same Database
  Describes the steps to retrieve a persistent message from an explicit pipe on the same Autonomous Database instance (the instance where the message was sent).
- Retrieve a Persistent Message by Creating a Pipe on a Different Database
  Describes the steps to retrieve a persistent message stored in Cloud Object Store with an explicit pipe on an Autonomous Database instance that is different than the instance that sent the message.

- Remove a Persistent Pipe
  Describes the steps to remove a persistent pipe.

About Persistent Messaging with DBMS_PIPE

Persistent messaging with `DBMS_PIPE` allows one or more database sessions to communicate in the same region or across regions with messages that are stored in Cloud Object Store. Persistent messages in `DBMS_PIPE`:

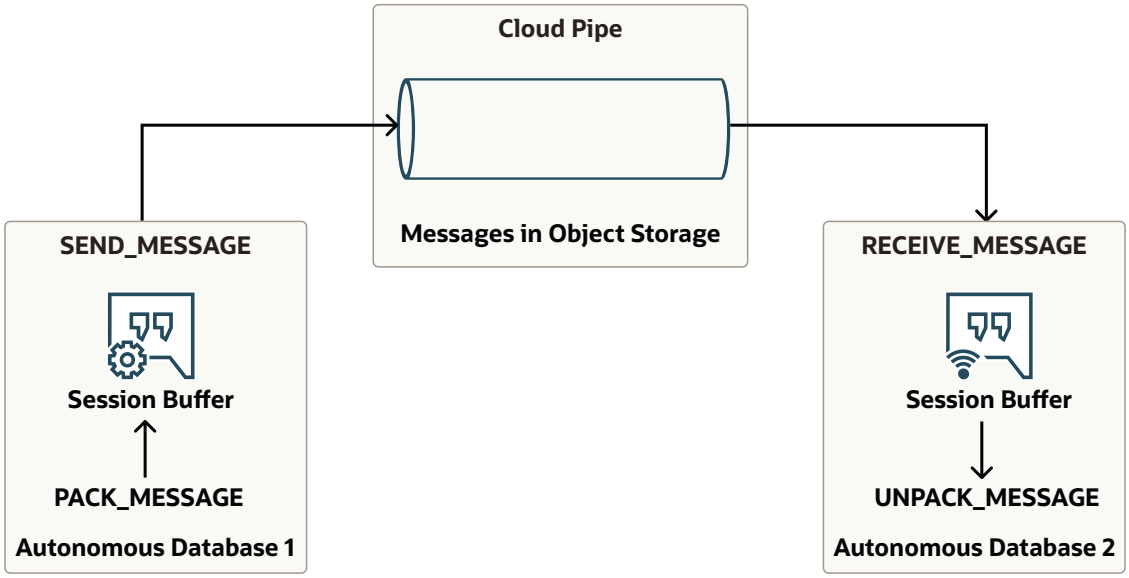
- Allow you to send and retrieve very large messages.
- Support a sending a large number of pipe messages.
- Support sending and receiving messages within a single database, across multiple databases and across databases in different regions.
- Support multiple pipes using the same Cloud Object Store location URI.

Persistent messaging pipes can be created in any of the supported `DBMS_PIPE` types:

- **Implicit Pipe:** Automatically created when a message is sent with an unknown pipe name using the `DBMS_PIPE.SEND_MESSAGE` function.
- **Explicit Pipe:** Created using the `DBMS_PIPE.CREATE_PIPE` function with a user specified pipe name.
- **Public Pipe:** Accessible by any user with `EXECUTE` permission on `DBMS_PIPE` package.
- **Private Pipe:** Accessible by sessions with the same user as the pipe creator.

> **Note:**
>
> Oracle recommends creating an explicit pipe before you send or receive messages with persistent messaging. Creating an explicit pipe with `DBMS_PIPE.CREATE_PIPE` ensures that the pipe is created with the access permissions you want, either public or private (by setting the `private` parameter).

The following shows the general workflow for `DBMS_PIPE` with persistent messaging:



Existing applications using DBMS_PIPE can continue to operate with minimal changes. You can configure existing applications that use DBMS_PIPE with a credential object and location URI using a logon trigger or using some other initialization routine. After setting the DBMS_PIPE credential and location URI, no other changes are needed to use persistent messaging. All subsequent use of the pipe stores the messages in Cloud Object Store instead of in database memory. This allows you to change the storage method for messages from in-memory to persistent Cloud Object Storage, with minimal changes.

Persistent Messaging Overview and Features

Features of DBMS_PIPE using persistent messaging:

- Messages can be sent and retrieved across multiple Autonomous Database instances in the same region or across regions.
- Persistent messages are guaranteed to either be written or read by exactly one process. This prevents message content inconsistency due to concurrent writes and reads. Using a persistent messaging pipe, DBMS_PIPE allows only one operation, sending a message or a receiving message to be active at a given time. However, if an operation is not possible due to an ongoing operation, the process retries periodically until the timeout value is reached.
- DBMS_PIPE uses DBMS_CLOUD to access Cloud Object Store. Messages can be stored in any of the supported Cloud Object Stores. See DBMS_CLOUD URI Formats for more information.
- DBMS_PIPE uses DBMS_CLOUD to access Cloud Object Store and all supported credential types are available:
  - DBMS_CLOUD.CREATE_CREDENTIAL: See CREATE_CREDENTIAL Procedure for more information.

DBMS_PIPE Privileges Authorization and Security

The DBMS_PIPE procedures run with invoker's rights. Private pipes are owned by the current user and a private pipe that is created by a user can only be used by the same user. This applies to both in-memory pipes and persistent messaging pipes where messages are stored to Cloud Object Store. Sending and receiving messages run in the invoker's schema.

Using private pipes, where messages are stored to Cloud Object Store, a credential object is required for authentication with the Cloud Object store identified by the location_uri parameter. The invoking user must have EXECUTE privilege on the credential object specified with the credential_name parameter that is used to access the Object Store.

To use a public pipe, the user, database session, must have execute privilege on DBMS_PIPE. For a public pipe using persistent messaging and storing messages to Cloud Object Store, the user, database session, must have execute privilege on DBMS_CLOUD and execute privilege on the credential object (or you can create a credential object that is allowed to access the location URI that contains the message.

DBMS_PIPE Limitation

The DBMS_PIPE package does not support sending messages between databases that use different character sets. For example, if you have one Autonomous Database instances that uses AL32UTF8 and another instance that uses WE8MSWIN1252, you cannot send messages with DBMS_PIPE between these two databases. In this case, you the system will raise the error ORA-12704 if you attempt to send messages with DBMS_PIPE between these two databases.

See Choose a Character Set for Autonomous Database for more information.

Create an Explicit Persistent Pipe and Send a Message

Describes the steps to create a persistent pipe with a specified pipe name (Explicit Pipe).

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'my_persistent_pipe_cred',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. After you store the credentials you can then use the same credential name to access Cloud Object Store to send and receive messages with `DBMS_PIPE`.

   For detailed information about the parameters, see CREATE_CREDENTIAL Procedure. For Oracle Cloud Infrastructure Object Storage, it is required that the credential uses native Oracle Cloud Infrastructure authentication.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   > **Note:**
   >
   > Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character and get the credential created properly.

2. Create an explicit pipe to send and retrieve messages. For example, create a pipe named `ORDER_PIPE`.

```
DECLARE
  r_status INTEGER;
BEGIN
    r_status := DBMS_PIPE.CREATE_PIPE(pipename => 'ORDER_PIPE');
END;
/
```

   See CREATE_PIPE Function for more information.

3. Verify that the pipe is created.

```
SELECT ownerid, name, type FROM v$db_pipes
       WHERE name = 'ORDER_PIPE';
```

```
OWNERID NAME       TYPE
------- ---------- -------
     80 ORDER_PIPE PRIVATE
```

4. Use `DBMS_PIPE` procedures to set the default access credential and location URI to store persistent messages to Cloud Object Store.

```
BEGIN
    DBMS_PIPE.SET_CREDENTIAL_NAME('my_persistent_pipe_cred');
    DBMS_PIPE.SET_LOCATION_URI('https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/');
END;
/
```

These procedures set the default credential name and the default location URI for use with `DBMS_PIPE` procedures.

If you use Oracle Cloud Infrastructure Object Storage to store messages, you can use Oracle Cloud Infrastructure Native URIs or Swift URIs. However, the location URI and the credential must match in type as follows:

- If you use a native URI format to access Oracle Cloud Infrastructure Object Storage, you must use Native Oracle Cloud Infrastructure Signing Keys authentication in the credential object.
- If you use Swift URI format to access Oracle Cloud Infrastructure Object Storage, you must use an auth token authentication in the credential object.

See SET_CREDENTIAL_NAME Procedure and SET_LOCATION_URI Procedure for more information.

5. Pack and send a message on the pipe.

```
DECLARE
  l_result INTEGER;
  l_date   DATE;
BEGIN
    l_date := sysdate;
    DBMS_PIPE.PACK_MESSAGE(l_date);         -- date of order
    DBMS_PIPE.PACK_MESSAGE('C123');         -- order number
    DBMS_PIPE.PACK_MESSAGE(5);              -- number of items in order
    DBMS_PIPE.PACK_MESSAGE('Printers');     -- type of item in order

    l_result := DBMS_PIPE.SEND_MESSAGE(
                    pipename => 'ORDER_PIPE',
                    credential_name => DBMS_PIPE.GET_CREDENTIAL_NAME,
                    location_uri => DBMS_PIPE.GET_LOCATION_URI);

    IF l_result = 0 THEN
        DBMS_OUTPUT.put_line('DBMS_PIPE sent order successfully');
    END IF;

END;
/
```

See PACK_MESSAGE Procedures and SEND_MESSAGE Function for more information.

Retrieve a Persistent Message on Same Database

Describes the steps to retrieve a persistent message from an explicit pipe on the same Autonomous Database instance (the instance where the message was sent).

On an Autonomous Database instance you can receive messages sent to a pipe from a different session. The `DBMS_PIPE` procedures are invoker's rights procedures and run as the current invoked user.

Private pipes are owned by the current user that creates the pipe. Private pipes can only be accessed by the same user that created the pipe. This applies to pipes using in-memory messages and to pipes using persistent messaging with messages stored in Cloud Object Store.

Public pipes can be accessed by any database session having execute privilege on `DBMS_PIPE`. This applies to pipes using in-memory messages and to pipes using persistent messaging with messages stored in Cloud Object Store.

1. Verify that the pipe is created.

```
SELECT ownerid, name, type FROM v$db_pipes
       WHERE name = 'ORDER_PIPE';

OWNERID NAME       TYPE
------- ---------- -------
     80 ORDER_PIPE PRIVATE
```

   When you are on the same Autonomous Database instance and the pipe exists, you do not need to run `DBMS_PIPE.CREATE_PIPE` before you receive a message. This applies when the pipe was created on the same instance, as shown in Create an Explicit Persistent Pipe and Send a Message.

2. Receive a message from the pipe.

```
DECLARE
    message1  DATE;
    message2  VARCHAR2(100);
    message3  INTEGER;
    message4  VARCHAR2(100);
    l_result  INTEGER;

BEGIN

    DBMS_PIPE.SET_CREDENTIAL_NAME('my_persistent_pipe_cred');
    DBMS_PIPE.SET_LOCATION_URI('https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/');
    l_result := DBMS_PIPE.RECEIVE_MESSAGE (
                  pipename => 'ORDER_PIPE',
                  timeout  => DBMS_PIPE.MAXWAIT,
                  credential_name => DBMS_PIPE.GET_CREDENTIAL_NAME,
                  location_uri => DBMS_PIPE.GET_LOCATION_URI);

    IF l_result = 0 THEN
        DBMS_PIPE.unpack_message(message1);
        DBMS_PIPE.unpack_message(message2);
```

```
        DBMS_PIPE.unpack_message(message3);
        DBMS_PIPE.unpack_message(message4);

        DBMS_OUTPUT.put_line('Order Received Successfully On: ' ||
TO_CHAR(sysdate, 'dd-mm-yyyy hh24:mi:ss'));
        DBMS_OUTPUT.put_line('Date of Order: ' || message1);
        DBMS_OUTPUT.put_line('Order Number: ' || message2);
        DBMS_OUTPUT.put_line('Number of Items In Order: ' || message3);
        DBMS_OUTPUT.put_line('Item Type in Order: ' || message4);
    END IF;

END;
/
```

When you are on the same Autonomous Database instance, the credential already exists and you do not need to run `DBMS_CLOUD.CREATE_CREDENTIAL` to receive a message. This applies when the pipe was created on the same instance, as shown in Create an Explicit Persistent Pipe and Send a Message.

See SET_CREDENTIAL_NAME Procedure and SET_LOCATION_URI Procedure for more information.

See RECEIVE_MESSAGE Function for more information.

Retrieve a Persistent Message by Creating a Pipe on a Different Database

Describes the steps to retrieve a persistent message stored in Cloud Object Store with an explicit pipe on an Autonomous Database instance that is different than the instance that sent the message.

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'my_persistent_pipe_cred',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name to access the Cloud Object Store to send and receive messages with `DBMS_PIPE`.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (&) as a special character. If you have the ampersand character in your password use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character and get the credential created properly.

2. Create an explicit pipe with the same name as the pipe that sent the message. For example, create a pipe named `ORDER_PIPE`.

```
DECLARE
  r_status INTEGER;
BEGIN
    r_status := DBMS_PIPE.CREATE_PIPE(pipename => 'ORDER_PIPE');
END;
/
```

See CREATE_PIPE Function.

3. Verify that the pipe is created.

```
SELECT ownerid, name, type FROM v$db_pipes
       WHERE name = 'ORDER_PIPE';

OWNERID NAME       TYPE
------- ---------- -------
     80 ORDER_PIPE PRIVATE
```

4. Use `DBMS_PIPE` procedures to set the default access credential and location URI for Object Store so that `DBMS_PIPE` can access the persistent message.

```
BEGIN
    DBMS_PIPE.SET_CREDENTIAL_NAME('my_persistent_pipe_cred');
    DBMS_PIPE.SET_LOCATION_URI('https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/');
END;
/
```

These procedures set the default credential name and the default location URI for use with `DBMS_PIPE` procedures.

If you use Oracle Cloud Infrastructure Object Storage to store messages, you can use Oracle Cloud Infrastructure Native URIs or Swift URIs. However, the location URI and the credential must match in type as follows:

- If you use a native URI format to access Oracle Cloud Infrastructure Object Storage, you must use Native Oracle Cloud Infrastructure Signing Keys authentication in the credential object.
- If you use Swift URI format to access Oracle Cloud Infrastructure Object Storage, you must use an auth token authentication in the credential object.

See SET_CREDENTIAL_NAME Procedure and SET_LOCATION_URI Procedure for more information.

5. Receive a message from the persistent pipe.

```
DECLARE
    message1  DATE;
    message2  VARCHAR2(100);
    message3  INTEGER;
    message4  VARCHAR2(100);
    l_result  INTEGER;

BEGIN

    DBMS_PIPE.SET_CREDENTIAL_NAME('my_persistent_pipe_cred');
    DBMS_PIPE.SET_LOCATION_URI('https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/');
    l_result := DBMS_PIPE.RECEIVE_MESSAGE (
                  pipename => 'ORDER_PIPE',
                  timeout  => DBMS_PIPE.MAXWAIT,
                  credential_name => DBMS_PIPE.GET_CREDENTIAL_NAME,
                  location_uri => DBMS_PIPE.GET_LOCATION_URI);

    IF l_result = 0 THEN
        DBMS_PIPE.unpack_message(message1);
        DBMS_PIPE.unpack_message(message2);
        DBMS_PIPE.unpack_message(message3);
        DBMS_PIPE.unpack_message(message4);

        DBMS_OUTPUT.put_line('Order Received Successfully On: ' ||
TO_CHAR(sysdate, 'dd-mm-yyyy hh24:mi:ss'));
        DBMS_OUTPUT.put_line('Date of Order: ' || message1);
        DBMS_OUTPUT.put_line('Order Number: ' || message2);
        DBMS_OUTPUT.put_line('Number of Items In Order: ' || message3);
        DBMS_OUTPUT.put_line('Item Type in Order: ' || message4);
    END IF;

END;
/
```

See RECEIVE_MESSAGE Function for more information.

Remove a Persistent Pipe

Describes the steps to remove a persistent pipe.

Persistent pipes send and receive messages by storing messages in Cloud Object Store. Use `DBMS_PIPE.REMOVE_PIPE` to remove a persistent pipe on an Autonomous Database instance.

1. Call the `DBMS_PIPE.REMOVE_PIPE` function to remove a pipe.

```
DECLARE
   l_result  INTEGER;
BEGIN
     l_result := DBMS_PIPE.REMOVE_PIPE('ORDER_PIPE');
END;
/
```

The `REMOVE_PIPE` function removes the pipe from the Autonomous Database instance where it runs, however `REMOVE_PIPE` does not affect other Autonomous Database instances with a pipe with the same name that uses the same location URI.

2. On the Autonomous Database instance were you run `DBMS_PIPE.REMOVE_PIPE`, verify that the pipe is removed.

```
SELECT ownerid, name, type FROM v$db_pipes
       WHERE name = 'ORDER_PIPE';

No rows selected
```

Full-Text Search Queries

The PL/SQL package `DBMS_CLOUD` enables you to build a text index on the object store files, which allows you to search the text and use wildcards with your search. You can use `JSON_TEXTCONTAINS` to do full-text JSON search on files stored in Object Storage.

- Use Full-Text Search on Files in Object Storage
  The PL/SQL package DBMS_CLOUD enables you to build a text index on the object store files, which allows you to search the text and use wildcards with your search.
- Use JSON Search on Documents in Object Storage
  You can build a JSON search index on documents residing in files stored in Object Storage, which allows you to search fields in your JSON documents using `JSON_TEXTCONTAINS`, for example, searching with wildcards.

Use Full-Text Search on Files in Object Storage

The PL/SQL package DBMS_CLOUD enables you to build a text index on the object store files, which allows you to search the text and use wildcards with your search.

- About Full-Text Search on Files in Object Storage
- Create a Text Index on Object Storage Files
  Use `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` to create a text index on files in object storage.
- Drop an Index on the Cloud Storage Files
  Use the `DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX` procedure to drop a text index on object storage files.
- Text Index Reference Table
  A local table is created within your database with a standard suffix *`INDEX_NAME`*`$TXTIDX`. This table is created internally when you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX`.
- Monitor Text Index Creation
  When you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` the text index creation operation is logged in the `ALL_SCHEDULER_JOB_RUN_DETAILS` view.

About Full-Text Search on Files in Object Storage

You can create a text index on files in object storage. A text index allows you to perform a word-based search across very large data sets in object store.

DBMS_CLOUD provides fast and efficient ways to manage data in object store. The DBMS_CLOUD APIs let you create, copy, download, delete, and traverse files present in object store. When you define external tables you can run SQL queries on data stored in your object store (or with hybrid partitioned external tables, across data in your database and in object store). When you use DBMS_CLOUD to define a text index, this allows you to search your data for text and use wildcards.

Autonomous Database support for word-based search works for commonly used data formats, for example CSV or JSON and with formatted documents (binary), for example PDF and DOC (MS Word) formats. You can configure a refresh rate that indicates the frequency in minutes at which the index is refreshed for any new uploads or deletes.

A local table with the standard suffix *INDEX_NAME*$TXTIDX is created when you create an index on the object storage, and you can utilize the table to perform a search using the CONTAINS keyword.

See Indexing with Oracle Text for more information.

Create a Text Index on Object Storage Files

Use DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX to create a text index on files in object storage.

Formatted documents (binary) are supported when you specify the binary_files format option with DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX.

You can include a stop word list when you specify the stop_words format option with DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX.

See Indexing with Oracle Text for more information on Oracle Text stop words and working with binary files.

1. Create a credential object to access the source location.

   See CREATE_CREDENTIAL Procedure for more information.

2. Run the DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX procedure to create a text index on the object storage files.

```
BEGIN
DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX (
        credential_name => 'DEFAULT_CREDENTIAL',
        location_uri    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/ts_data/'
        index_name      => 'EMP',
        format          => JSON_OBJECT ('refresh_rate' value 10)
);
END;
/
```

   This example creates a text index EMP on the object storage files located at the URI specified in the location_uri parameter. The refresh_rate option in the format parameter specifies that the index EMP is refreshed at an interval of 10 minutes.

   This creates a local table *INDEX_NAME*$TXTIDX. You can utilize the table *INDEX_NAME*$TXTIDX to perform a search using CONTAINS.

For example:

```
SELECT object_name FROM EMP$TXTIDX
     WHERE CONTAINS(object_name,'king') > 0;
```

This query returns the object or file names that contain the string `king`.

See Text Index Reference Table for more information.

You can query an external table using the `EXTERNAL MODIFY` clause to retrieve the actual records.

```
SELECT * FROM EMPEXTTAB EXTERNAL MODIFY ((location_url object_name));
```

> **Note:**
>
> The external table `EMPEXTTAB` is a sample external table that is created on the same `location_url`.

See Query External Data with Autonomous Database for more information.

See CREATE_EXTERNAL_TEXT_INDEX Procedure for more information.

See Configure Policies and Roles to Access Resources for more information.

Drop an Index on the Cloud Storage Files

Use the `DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX` procedure to drop a text index on object storage files.

Run the `DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX` procedure to drop a text index on files in object storage.

```
BEGIN
DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX (
        index_name => 'EMP',
);
END;
/
```

This example drops the `EMP` text index.

See DROP_EXTERNAL_TEXT_INDEX Procedure for more information.

Text Index Reference Table

A local table is created within your database with a standard suffix *`INDEX_NAME`*`$TXTIDX`. This table is created internally when you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX`.

You can query the *`INDEX_NAME`*`$TXTIDX` table to search for a string using the `CONTAINS` keyword. For example, when you call `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` procedure the *`INDEX_NAME`* value as `EMP`, this creates the `EMP$TXTIDX` the text reference table.

The text reference table has the following columns:

- `object_name`: is the file name on the object storage that contains the searched text string.
- `object_path`: is the object storage bucket or folder URI that contains the object storage file.
- `mtime`: is the last modified timestamp of the object storage file. This is the time when the file was last accessed by `DBMS_CLOUD`.

For example:

```
SELECT object_path, object_name FROM EMP$TXTIDX WHERE CONTAINS(OBJECT_NAME, 'king') > 0;

OBJECT_PATH
    OBJECT_NAME
--------------------------------------------------------------------------------
   ----------------------------------
https://objectstorage.us-phoenix-1.oraclecloud.com/n/example1/b/adbs_data_share/o/
ts_data/       data_2_20221026T195313585601Z.json
```

This query returns the file names and location URI on the object storage which contains the text string `king`, in either upper or lowercase.

```
SELECT object_name, mtime FROM EMP$TXTIDX;

OBJECT_NAME                    MTIME
------------------------------ -----------------------------------
data_1_20220531T165402Z.json    31-MAY-22 04.54.02.979000 PM +00:00
data_1_20220531T165427Z.json    31-MAY-22 04.54.27.997000 PM +00:00
```

This query returns file name and last modified timestamp of the object files on which the index `EMP` is created.

Monitor Text Index Creation

When you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` the text index creation operation is logged in the `ALL_SCHEDULER_JOB_RUN_DETAILS` view.

You can query the `ALL_SCHEDULER_JOB_RUN_DETAILS` view to obtain the status and any error reported by the index creation job.

The name of the `DBMS_SCHEDULER` job is derived from the `INDEX_NAME` parameter specified when you call `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX`.

To query the `ALL_SCHEDULER_JOB_RUN_DETAILS` view, you must be logged in as the `ADMIN` user or have `READ` privilege on the `ALL_SCHEDULER_JOB_RUN_DETAILS` view.

For example, the following `SELECT` statement with a `WHERE` clause on `job_name` shows the run details for the job:

```
SELECT status, additional_info
   FROM all_scheduler_job_run_details WHERE LOWER(job_name) = LOWER('index_name$JOB');
```

You can also query for the existence of an index creation scheduler job.

For example:

```
SELECT status
    FROM all_scheduler_jobs where LOWER(job_name) = LOWER('index_name$JOB');
```

See CREATE_EXTERNAL_TEXT_INDEX Procedure for more information.

Use JSON Search on Documents in Object Storage

You can build a JSON search index on documents residing in files stored in Object Storage, which allows you to search fields in your JSON documents using `JSON_TEXTCONTAINS`, for example, searching with wildcards.

- Use JSON Search on Documents in Object Storage
- Create a JSON Search Index on JSON Documents in Files
  Use `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` to create a JSON search index on the JSON files stored in Object Storage.
- Drop a JSON Search Index
  Use the `DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX` procedure to drop a JSON search index on the JSON files stored in Object Storage.
- Monitor JSON Search Index Creation
  When you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` the JSON search index creation operation is logged in the `ALL_SCHEDULER_JOB_RUN_DETAILS` view.
- JSON Search Index Reference Table
  A local table is created within your database with a standard suffix *`INDEX_NAME`*`$TXTIDX`. This table is created internally when you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX`.
- JSON Search Index Reference View
  A view with the name *`INDEX_NAME`* is created when you run `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` to create a JSON index.
- Error Log Table

Use JSON Search on Documents in Object Storage

You can create a JSON search index on documents in files stored in Object Storage. A JSON search index is specifically designed for JSON documents and enables you to do regular as well as full text search on your documents or fragments of your documents using `JSON_TEXTCONTAINS`.

See JSON_TEXTCONTAINS Condition for more information.

You use `DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX` to create a JSON search index on files in Object Storage. You can configure a refresh rate that indicates the frequency in minutes at which the index is refreshed for any new uploads or deletes. See Create a JSON Search Index on JSON Documents in Files for more information.

The following objects are created when you create a JSON search index:

- A JSON search index *`index_name`* on the Object Storage JSON files.
- A local table *`INDEX_NAME`*`$TXTIDX`. This table is the mapping table between your documents in the files in Object Storage and the JSON search index that is created in the database. See JSON Search Index Reference Table for more information.

- A view with the standard name *INDEX_NAME*. You can utilize the view to perform a search using JSON_TEXTCONTAINS. This view is created on top of the *INDEX_NAME*$TXTIDX table. See JSON Search Index Reference View for more information.
- An error log table with the standard suffix *index_name*$txtidx_err. See Error Log Table for more information.

The JSON search index creation operation is logged in the ALL_SCHEDULER_JOB_RUN_DETAILS view. See Monitor Text Index Creation for more information.

Autonomous Database supports JSON search index creation for a variety of text files containing JSON documents. For example, you can index JSON files in both compressed and uncompressed format, or choose a different JSON document delimiter. See DBMS_CLOUD Package for more information about the file handling options.

See Indexing with Oracle Text for more information.

Create a JSON Search Index on JSON Documents in Files

Use DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX to create a JSON search index on the JSON files stored in Object Storage.

See Indexing with Oracle Text for more information on Oracle Text stop words.

1. Create a credential object to access the source location.

   See CREATE_CREDENTIAL Procedure for more information.

2. Run the DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX procedure to create a JSON search index on the object storage files.

```
BEGIN
 DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX (
        credential_name => 'OBJ_STORE_CRED',
        location_uri    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/vcnlogs/',
        index_name      => 'VNCLOGS',
        format          =>  JSON_OBJECT ('json_index' value 'true',
'json_index_doc_len' value 12000, 'file_compression' value 'gzip')
);
END;
/
```

   This example creates the following:

   - A JSON search index VNCLOGS on the Object Storage files located at the URI specified in the location_uri parameter.
   - A local table VNCLOGS$TXTIDX. See JSON Search Index Reference Table for more information.
   - A view with the name VNCLOGS. This view is created on top of the VNCLOGS$TXTIDX table. You can utilize the view to perform a search using JSON_TEXTCONTAINS. See JSON Search Index Reference View for more information.
   - An error log table with the name VNC$TXTIDX_ERR. The table contains a list of invalid JSON documents in your files. See Error Log Table for more information.

After creating the JSON search index, you can query the VNCLOGS view. For example:

```
SELECT JSON_QUERY (data, '$' returning CLOB pretty) AS RECORD
 FROM vnclogs WHERE JSON_TEXTCONTAINS(file_line_json, '$.tuples',
'{XXX.XXX.0.1.10.10.10.10.null.XXX_345}');
```

This query returns the log details for the specified IP addresses in the JSON_TEXTCONTAINS condition. Note that the JSON Search index criteria is specified on the file_line_json column, the indexed column in your JSON search index table in the database, while the JSON documents are streamed directly from Object Storage, represented through the data column. The data column contains the content of the Object Storage file.

See CREATE_EXTERNAL_TEXT_INDEX Procedure for more information.

Drop a JSON Search Index

Use the DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX procedure to drop a JSON search index on the JSON files stored in Object Storage.

For example:

```
BEGIN
 DBMS_CLOUD.DROP_EXTERNAL_TEXT_INDEX (
  index_name => 'VCNLOGS',
);
END;
/
```

This example drops the VCNLOGS JSON search index.

See DROP_EXTERNAL_TEXT_INDEX Procedure for more information.

Monitor JSON Search Index Creation

When you run DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX the JSON search index creation operation is logged in the ALL_SCHEDULER_JOB_RUN_DETAILS view.

You can query the ALL_SCHEDULER_JOB_RUN_DETAILS view to obtain the status and any error reported by the index creation job.

The name of the DBMS_SCHEDULER job is derived from the INDEX_NAME parameter specified when you call DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX.

To query the ALL_SCHEDULER_JOB_RUN_DETAILS view, you must be logged in as the ADMIN user or have READ privilege on the ALL_SCHEDULER_JOB_RUN_DETAILS view.

For example, the following SELECT statement with a WHERE clause on job_name shows the run details for the job:

```
SELECT status, additional_info
   FROM all_scheduler_job_run_details WHERE LOWER(job_name) = LOWER('index_name$JOB');
```

You can also query for the existence of an index creation scheduler job.

For example:

```
SELECT status
    FROM all_scheduler_jobs where LOWER(job_name) = LOWER('index_name$JOB');
```

See CREATE_EXTERNAL_TEXT_INDEX Procedure for more information.

JSON Search Index Reference Table

A local table is created within your database with a standard suffix *INDEX_NAME*$TXTIDX. This table is created internally when you run DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX.

You can query the *INDEX_NAME*$TXTIDX table to search for a string using the JSON_TEXTCONTAINS keyword. For example, when you call DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX procedure the *INDEX_NAME* value as VNCLOGS, this creates the VNCLOGS$TXTIDX JSON search index reference table.

The JSON search index reference table has the following columns:

- object_name: is the file name on the Object Storage that contains the searched text string.
- object_path: is the Object Storage bucket or folder URI that contains the object storage file.
- length: is the length of the JSON document.
- offset: is the byte offset of the beginning of the file.
- mtime: is the last modified timestamp of the object storage file. This is the time when the file was last accessed by DBMS_CLOUD.

Run the following query to retrieve the object name, object path, offset and length from the JSON search index reference table:

```
SELECT * FROM (SELECT object_name, object_path, length, offset
 FROM vnclogs$txtidx
 WHERE JSON_TEXTCONTAINS (file_line_json, '$.tuples',
'{XXX.XXX.0.1.10.10.10.10.null.XXX_345}')
 ORDER BY mtime DESC)
 WHERE rownum < 3;
```

This query provides internal information about where in your files in Object Storage the relevant documents are located. The query does not provide the actual documents.

To retrieve the documents directly, use the following query:

```
SELECT * FROM (SELECT object_name, object_path, data
 FROM vnclogs
 WHERE JSON_TEXTCONTAINS (file_line_json, '$.tuples',
'{XXX.XXX.0.1.10.10.10.10.null.XXX_345}')
 ORDER BY mtime DESC)
 WHERE rownum < 3;
```

JSON Search Index Reference View

A view with the name *INDEX_NAME* is created when you run DBMS_CLOUD.CREATE_EXTERNAL_TEXT_INDEX to create a JSON index.

The view itself contains no data. The data is fetched in the view when you query the *INDEX_NAME* view using SQL condition JSON_TEXTCONTAINS.

Column	Description
OBJECT_NAME	The file name on the Object Storage that contains the searched text string.
OBJECT_PATH	The Object Storage bucket or folder URI that contains the object storage file.
LENGTH	The length of the JSON document.
OFFSET	The byte offset of the beginning of the file.
DATA	The content of the Object Storage file.
FILE_LINE_JSON	The column on which the JSON_TEXTCONTAINS is performed.
MTIME	The last modified timestamp of the object storage file. This is the time when the file was last accessed by DBMS_CLOUD.

Error Log Table

An error log table *index_name*$txtidx_err is created when you create a JSON search index on the JSON files stored in Object Storage.

The table contains a list of the invalid JSON documents in your files. A JSON document is marked as invalid if the length of the source file that is indexed exceeds the default value or the specified value. The default value is 32767 bytes, and the maximum value you can specify using the json_index_doc_len format option is 200000 bytes. See Create a JSON Search Index on JSON Documents in Files for more information.

You can query the *index_name*$txtidx_err to get the list of invalid JSON files reported during the index creation.

Column	Description
OBJECT_NAME	The file name on the Object Storage that contains the searched text string.
OBJECT_PATH	The Object Storage bucket or folder URI that contains the object storage file.
OFFSET	Byte offset of beginning of the line.
LENGTH	Length of the JSON document.
LINE_NUMBER	Line number in the file at object store.

Use Oracle Workspace Manager on Autonomous Database

Workspace Manager provides an infrastructure that enables applications to create workspaces and group different versions of table row values in different workspaces.

- About Using Oracle Workspace Manager on Autonomous Database
  Use Oracle Workspace Manager to version-enable one or more user tables in the database. When a table is version-enabled, all rows in the table can support multiple versions of the data.
- Enable Oracle Workspace Manager on Autonomous Database
  Oracle Workspace Manager must be enabled to be used on Autonomous Database. You can migrate existing data that has enabled Oracle Workspace Manager.
- Disable Oracle Workspace Manager on Autonomous Database
  Use the following steps to disable Oracle Workspace Manager on Autonomous Database.

About Using Oracle Workspace Manager on Autonomous Database

Use Oracle Workspace Manager to version-enable one or more user tables in the database. When a table is version-enabled, all rows in the table can support multiple versions of the data.

Applications that can benefit from Workspace Manager typically do one or more of the following operations:

- Manage a collection of updates and insertions as a unit before incorporating them into production data
- Support a collaborative development effort
- Use a common data set to create multiple scenarios for what-if analyses or multiple editions of data for publication
- Keep a history of changes to data

Introduction to Workspace Manager provides relevant usage and reference information.

Workspace manager is enabled using the procedure `DBMS_CLOUD_ADMIN.ENABLE_FEATURE`.

Enable Oracle Workspace Manager on Autonomous Database

Oracle Workspace Manager must be enabled to be used on Autonomous Database. You can migrate existing data that has enabled Oracle Workspace Manager.

As the `ADMIN` user, run `DBMS_CLOUD_ADMIN.ENABLE_FEATURE` to enable Oracle Workspace Manager.

1. Enable Oracle Workspace Manager.

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_FEATURE(
        feature_name => 'OWM');
END;
/
```

2. Restart the Autonomous Database instance.

   See Restart Autonomous Database for more information.

3. Query `dba_cloud_config` to verify that Oracle Workspace Manager is enabled.

```
SELECT param_name, param_value FROM dba_cloud_config WHERE
       UPPER(param_name) = 'OWM';

PARAM_NAME PARAM_VALUE
```

```
---------- -----------
owm        enabled
```

4. (Optional) If you have existing data using Oracle Workspace Manager on another database that you want to migrate to Autonomous Database, Oracle Workspace Manager provides import and export procedures that enable you to migrate the data. See Export_Schemas and Import_Schemas for additional information.
5. Continue with the imported schemas or the new schemas.

See ENABLE_FEATURE Procedure for more information.

Disable Oracle Workspace Manager on Autonomous Database

Use the following steps to disable Oracle Workspace Manager on Autonomous Database.

As the `ADMIN` user, run `DBMS_CLOUD_ADMIN.DISABLE_FEATURE` to disable Oracle Workspace Manager.

1. Disable Oracle Workspace Manager.

```
BEGIN
   DBMS_CLOUD_ADMIN.DISABLE_FEATURE(
        feature_name => 'OWM');
END;
/
```

2. Query `dba_cloud_config` to verify that Oracle Workspace Manager is disabled.

```
SELECT param_name, param_value FROM dba_cloud_config
     WHERE UPPER(param_name) = 'OWM';

0 rows selected.
```

See DISABLE_FEATURE Procedure for more information.

Use and Manage Elastic Pools on Autonomous Database

Use an elastic pool to consolidate your Autonomous Database instances, in terms of their allocation of compute resources, and to provide up to 87% cost savings.

> **Note:**
>
> Elastic pools are only available for Autonomous Database instances that use the ECPU compute model.

- About Elastic Pools
  Elastic pools help you improve operating efficiency and reduce costs by bringing all of your databases to the Cloud. This also supports consolidating resources and simplifying administration and operations by using Autonomous Database.
- About Elastic Pool Billing

- About Elastic Pool Billing with Autonomous Data Guard Enabled
  An Autonomous Data Guard primary database can use a local or a cross-region standby that is part of an elastic pool, either as a leader or a member.
- Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies
  Provides information on required policies for working with elastic pools with a pool member in a child tenancy and the pool leader in the parent tenancy.
- Create, Join or Manage an Elastic Pool
  Shows the steps to create, join, or manage an elastic pool.
- List Elastic Pool Members
  Shows the steps for the pool leader to list elastic pool members.
- Offload Queries to Member Refreshable Clones
  When you have heavy read workloads, where a relatively small amount of data is scanned by multiple queries, you can offload queries (reads) either from an elastic pool leader or from an elastic pool member to Refreshable Clones.
- Remove Pool Members from an Elastic Pool
  As an elastic pool member you can remove yourself from an elastic pool. As an elastic pool leader you can remove pool members from an elastic pool.
- Terminate an Elastic Pool
  Shows the steps to terminate an elastic pool. Only the pool leader can terminate an elastic pool.
- Elastic Pool Notes
  Provides information about elastic pool usage.

About Elastic Pools

Elastic pools help you improve operating efficiency and reduce costs by bringing all of your databases to the Cloud. This also supports consolidating resources and simplifying administration and operations by using Autonomous Database.

Elastic pools are only available for Autonomous Database instances that use the ECPU compute model.

When you need a large number of databases that can scale up and down elastically without downtime, you can benefit by creating and using elastic pools. Elastic pools have the following advantages:

- Enable operating with a fixed budget for a group of databases, while delivering performance elasticity for each individual database.
- Allow for easy migration from on-prem Oracle environments that include oversubscription, to provide a cost effective way to move to Autonomous Database.
- Support SaaS vendors with a large number of individual customer databases.
- Provide resources for using a microservices architecture, where the ability to supply of large number of databases is required.
- The pool members in an elastic pool are not billed individually (the pool leader is billed based on the pool shape). You can allocate additional ECPUs per instance for pool members, without worrying about the cost associated with the ECPU usage for the individual members. Autonomous Database IO capacity and memory allocation is directly correlated with the **ECPU count**, so by selecting a greater number of ECPUs for an instance, this allows you to run with greater IO capacity and more memory without having to pay for the additional resources. This means, using a larger number of ECPUs per

instance allows you to use more IO capacity and more memory per instance, where the cost is based on the pool shape and is not based on an individual instance's **ECPU count**.

When you create an elastic pool you select a pool size from a predefined set of pool sizes. Pool size determines how much you pay for compute as well as how many ECPUs you can provision in a given pool.

There are several terms to use when you work with elastic pools:

- **Pool Leader**: Is the Autonomous Database instance that creates an elastic pool.
- **Pool Member**: Is an Autonomous Database instance that is added to an elastic pool.
- **Pool Size**: Is a value that you set when you create an elastic pool. The pool size must be one of the available elastic pool shapes.
- **Pool Capacity**: The pool capacity is the maximum number of ECPUs that an elastic pool can use, and is four times (x4) the pool size.
- **Pool Shape**: A pool shape is one of the valid pool sizes that you select when you create an elastic pool. The pool shape must be one of: 128, 256, 512, 1024, 2048, or 4096 ECPUs.

> **Note:**
>
> By default each instance in an elastic pool is automatically assigned a maintenance window. By selecting a pool shape that is 1024 ECPUs or greater, you have the option of assigning a custom 2-hour maintenance window during which the leader and all elastic pool members are patched together. To select a custom maintenance window for your elastic pool, file a Service Request at Oracle Cloud Support.

Requirements to Create an Elastic Pool

The following are the requirements for an Autonomous Database instance to create an elastic pool and become a pool leader:

- The instance must use the ECPU compute model.
- Auto scaling must be disabled.
- The instance must not be a member of an existing elastic pool.
- The maximum allowed individual **ECPU count** for an Autonomous Database instance that creates an elastic pool is 4 times the pool size specified when you create the pool.
- The instance that creates an elastic pool is subject to tenancy limits. To create an elastic pool you must have a sufficient number of ECPUs available, below the tenancy limit, to accommodate the size of the elastic pool.

> **Note:**
>
> An elastic pool leader can be of any workload type. Elastic pool billing for compute usage is always billed to the pool leader at the **Transaction Processing** compute usage rate. This includes when the elastic pool leader has the **Transaction Processing**, **Data Warehouse**, **JSON Database**, or **APEX** workload type. See About Elastic Pool Billing and ECPU Compute Model Billing Information for more information.

Requirements to Join an Elastic Pool

The following are the requirements for an Autonomous Database instance to join an elastic pool:

- The instance must use the ECPU compute model.
- An elastic pool can contain Autonomous Database instances with **Transaction Processing**, **Data Warehouse**, **JSON Database**, or **APEX** workload types.
- Auto scaling must be disabled.
- The instance must not be a member of an elastic pool.
- The maximum allowed individual **ECPU count** for an Autonomous Database instance is the available pool capacity. When an instance has an ECPU count greater than the available pool capacity, it is not allowed to join that elastic pool.

Pool Leader and Member Minimum ECPU Allocation

When an Autonomous Database instance is part of an elastic pool, the minimum allowed individual ECPU allocation is 1 ECPU.

When an Autonomous Database instance is part of an elastic pool, increments of 1 ECPU are allowed for individual Autonomous Database instance ECPU allocation.

Pool Capacity for an Elastic Pool

An elastic pool has a pool capacity of 4 times the pool size. For example, a pool with pool size of 128 ECPUs can hold up to 512 ECPUs for its leader and the members.

> **Note:**
>
> In these examples Autonomous Data Guard is not enabled. See About Elastic Pool Billing with Autonomous Data Guard Enabled for information on using elastic pools with Autonomous Data Guard.

The following are examples of Autonomous Database instances that could be in an elastic pool with a pool size of 128 and a pool capacity of 512:

- Each of these are valid for pool members in an elastic pool with a pool size of 128:
  - 1 instance with 512 ECPUs, for a total of 512 ECPUs
  - 128 instances with 4 ECPUs, for a total of 512 ECPUs
  - 256 instances with 2 ECPUs, for a total of 512 ECPUs
  - 50 instances with 10 ECPUs and 3 instances with 4 ECPUs, for a total of 512 ECPUs
- Similarly, each of the following are valid for pool members in an elastic pool with a pool size of 128:
  - 1 instance with 128 ECPUs, 2 instances with 64 ECPUs, 32 instances with 4 ECPUs, and 64 instances with 2 ECPUs, for a total of 512 ECPUs
  - 256 instances with 1 ECPU, 64 instances with 2 ECPUs, for a total of 384 ECPUs, which is less than the pool capacity of 512 ECPUs.
  - 100 instances with 4 ECPUs and 50 instances with 2 ECPUs, which is less than the pool capacity of 512 ECPUs.

These are examples, you can add pool members to a pool to match the number of instances and the number ECPUs per instance to meet your needs, based on the pool size you select.

About Elastic Pool Leader Operations

The Autonomous Database instance that creates an elastic pool is the pool leader. Autonomous Database instances that are added to an existing pool are pool members. Depending on your role, either leader or member, you can perform operations on an elastic pool.
The following operations are valid only for the pool leader:

Operation	Description
Create an elastic pool	The Autonomous Database instance that creates an elastic pool is the pool leader. See Create an Elastic Pool for more information.
Remove an elastic pool member	An elastic pool leader can remove a member from the elastic pool. See As Pool Leader Remove Members from an Elastic Pool for more information.
Terminate an elastic pool	When an elastic pool has no pool members, the pool leader can terminate the elastic pool. See Terminate an Elastic Pool for more information.
Modify elastic pool size	An elastic pool leader can modify the pool size. See Change the Elastic Pool Shape for more information.
List pool members	A pool leader can list pool members. See List Elastic Pool Members for more information.

About Elastic Pool Member Operations

The Autonomous Database instance that creates an elastic pool is the pool leader. Autonomous Database instances that are added to an existing pool are pool members. Depending on your role, either leader or member, you can perform operations on an elastic pool.
The following operations are valid for a pool member or for the pool leader:

Operation	Description
Add instance to elastic pool	An Autonomous Database instance can be added as a pool member as long as the instance is one of the supported workload types, the instance uses the ECPU compute model, and the instance is not a pool member of a different pool. The supported workload types are: **Transaction Processing**, **Data Warehouse**, **JSON Database**, or **APEX**. See Join an Existing Elastic Pool for more information.
Remove an elastic pool member	An elastic pool member can remove themselves from the elastic pool. See Remove Pool Members from an Elastic Pool for more information.

Use Elastic Pools with Oracle Cloud Infrastructure Organization Management (Parent and Child Tenancies)

Oracle Cloud Infrastructure Organization Management provides two types of tenancies:

- **Parent**: A tenancy that's associated with the primary funded subscription.
- **Child**: Tenancies that join an organization, whereby a parent tenancy manages the child's cost and governance. Child tenancies can either be created as entirely new tenancies, or,

existing tenancies can be invited to join the same organization and to change your default subscription.

You can combine Organization Management with the benefits of elastic pools. If your organization uses the parent/child tenancy model you can apply elastic pool cost savings by using an elastic pool that spans parent and child tenancies. In this way an elastic pool can operate across tenancies, where the elastic pool leader is in the parent tenancy and the elastic pool member is in a child tenancy.

See the following for more information: and for more information.

- Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies
- Elastic Pool Notes
- Organization Management Overview

About Elastic Pool Billing

Elastic pool usage is billed to the pool leader and billing is based on the elastic pool size and the actual hourly ECPU usage of the pool leader and the members. Elastic pool usage can exceed the pool size (pool capacity can be up to four times greater than the pool size).
The billing for an elastic pool consists of only compute resources, that is ECPU usage, and all compute usage is charged to the Autonomous Database instance that is the pool leader. Any billing for storage usage is charged separately to individual Autonomous Database instances, independent of whether the instance is in an elastic pool.

An elastic pool allows you to consolidate your Autonomous Database instances in terms of their compute resource billing. You can think of an elastic pool like a mobile phone service “family plan”, except this applies to your Autonomous Database instances. Instead of paying individually for each database, the databases are grouped into a pool in which one instance, the leader, is charged for the compute usage associated with the entire pool.

Using an elastic pool you are able to provision up to four times the number of ECPUs, over your selected pool size, and you can provision database instances that are in the elastic pool with as little as 1 ECPU per database instance. Outside of an elastic pool the minimum number of ECPUs per database instance is 2 ECPUs. For example, with a pool size of 128 you can provision 512 Autonomous Database instances (when each instance has 1 ECPU). In this example you are billed for the pool size compute resources, based on the pool size of 128 ECPUs, while you have access to 512 Autonomous Database instances. In contrast, when you individually provision 512 Autonomous Database instances without using an elastic pool you are required to allocate a minimum of 2 ECPUs for each Autonomous Database instance, and in this example you would pay for 1024 ECPUs. Using an elastic pool provides **up to 87% compute cost savings**.

After you create an elastic pool, the total ECPU usage for a given hour is charged to the Autonomous Database instance that is the pool leader. With the exception of the pool leader, individual Autonomous Database instances that are pool members are not charged for ECPU usage while they are members of an elastic pool.

Elastic pool billing is as follows:

- If the total aggregated peak ECPU utilization is equal to or below the pool size for a given hour, you are charged for the pool size number of ECPUs (one times the pool size).

  After an elastic pool is created ECPU billing continues at a minimum of one times the pool size rate, even when databases that are part of the pool are stopped. This applies to pool member databases and to the pool leader.

In other words, if the aggregated peak ECPU utilization of the pool is less than or equal to the pool size for a given hour, you are charged for the pool size number of ECPUs (one times the pool size). This represents **up to 87% compute cost savings** over the case in which these databases are billed separately without using elastic pools.

- If the aggregated peak ECPU utilization of the pool leader and the members exceeds the pool size at any point in time in a given billing hour:
  - **Aggregated peak ECPU utilization of the pool is equal to or less than two times of the pool size number of ECPUs**: For usage that is greater than one times the pool size number of ECPUs and up to and including two times the number of ECPUs in a given billing hour: Hourly billing is two times the pool size number of ECPUs.

    In other words, if the aggregated peak ECPU utilization of the pool exceeds the pool size, but is less than or equal to two times the pool size for a given hour, you are charged for twice the pool size number of ECPUs (two times the pool size). This represents **up to 75% compute cost savings** over the case in which these databases are billed separately without using elastic pools.
  - **Aggregated peak ECPU utilization of the pool is equal to or less than four times the pool size number of ECPUs**: For usage that is greater than two times the pool size number of ECPUs and up and including to four times the pool size number of ECPUs in a given billing hour: Hourly billing is four times the pool size number of ECPUs.

    In other words, if the aggregated peak ECPU utilization of the pool exceeds twice the pool size for a given hour, you are charged for four times the pool size number of ECPUs (four times the pool size). This represents **up to 50% compute cost savings** over the case in which these databases are billed separately without using elastic pools.

  For example, consider an elastic pool with a pool size of 128 ECPUs and a pool capacity of 512 ECPUs:

  - **Case-1**: The aggregated peak ECPU utilization of the pool leader and the members is 40 ECPUs between 2:00pm and 2:30pm, and 128 ECPUs between 2:30pm and 3:00pm.

    The elastic pool is billed 128 ECPUs, one times the pool size, for this billing hour (2-3pm). This case applies when the peak aggregated ECPU usage of the elastic pool for the billing hour is less than or equal to 128 ECPUs.
  - **Case-2**: The aggregated peak ECPU utilization of the pool leader and the members is 40 ECPUs between 2:00pm and 2:30pm, and 250 ECPUs between 2:30pm and 3:00pm.

    The elastic pool is billed 256 ECPUs, two times the pool size, for this billing hour (2-3pm). This case applies when the peak aggregated ECPU usage of the elastic pool for the billing hour is less than or equal to 256 ECPUs and greater than 128 ECPUs.
  - **Case-3**: The aggregated peak ECPU utilization of the pool leader and the members is 80 ECPUs between 2:00pm and 2:30pm, and 509 ECPUs between 2:30pm and 3:00pm.

    The elastic pool is billed 512 ECPUs, four times the pool size, for this billing hour (2-3pm). This case applies when the peak aggregated ECPU usage of the elastic pool for the billing hour is less than or equal to 512 ECPUs and greater than 256 ECPUs.

See How to Achieve up to 87% Compute Cost Savings with Elastic Resource Pools on Autonomous Database for more details.

Elastic Pool Billing when a Pool is Created or Terminated

When an elastic pool is created or terminated, the leader is billed for the full hour for the elastic pool. In addition, individual instances that are either added or removed from the pool are billed for any compute usage that occurs while the instance is not in the elastic pool (in this case the billing applies to the individual Autonomous Database instance).

- **Pool Creation Example**: Assume there is an Autonomous Database instance with 4 ECPUs that is not part of any elastic pool. At 2:15pm, if you create an elastic pool with this instance with a pool size of 128 ECPUs, the instance becomes a pool leader. Assuming the Autonomous Database idles between 2-3pm, and there are no other Autonomous Database instances in the pool, billing for the hour between 2-3pm is as follows:

  The bill for the period 2-3pm is: (4 * 0.25) + 128 = 129 ECPUs

  Where the (4 * 0.25) is the billing for compute for the fifteen minutes before the Autonomous Database instance created the elastic pool, and 128 ECPUs is the billing for the elastic pool for the hour when the elastic pool is created.
- **Pool Termination Example**: Assume an Autonomous Database instance with 4 ECPUs is the leader of an elastic pool and the pool size is 128 ECPUs. At 4:30pm, if you terminate the elastic pool, the database becomes a standalone Autonomous Database instance that is not part of any elastic pool. Assuming the Autonomous Database idles between 4-5pm, and there are no other Autonomous Database instances in the pool, billing for the hour between 4-5pm is as follows:

  The bill for 4-5pm is: (4 * 0.5) + 128 = 130 ECPUs

  Where the (4 * 0.5) is the billing for compute for the thirty minutes after the Autonomous Database instance terminates the elastic pool, and 128 ECPUs is the billing for the elastic pool for the hour when the elastic pool was terminated.

Elastic Pool Billing with Built-in Tools

For either the pool leader or the members, compute resources that are allocated to the built-in tools, OML, Graph, or Data Transforms, are separate and do not count towards the elastic pool total allocation. For billing purposes, the elastic pool leader is billed for any built-in tool ECPU usage by either the leader or elastic pool members, in addition to the elastic pool ECPU usage.

For example, assume there is an elastic pool with a pool size of 128 ECPUs; if in a given billing hour the aggregated peak ECPU utilization of the pool leader and the members is 80 ECPUs for the billing hour, and during this hour the combined total ECPU utilization for instances using built-in tools is 30 ECPUs, the leader is charged for the pool size (128 ECPUs), plus the built-in tool ECPU usage (30 ECPUs), for a total of 158 ECPUs for that hour.

Elastic Pool Billing with Autonomous Data Guard

An elastic pool leader or a member can enable either local or cross-region Autonomous Data Guard, or both local and cross-region Autonomous Data Guard. Depending on whether the standby is local or for a cross-region standby, depending on whether the standby is the pool leader, a pool member, or not an elastic pool leader or a pool member, there are differences in billing. For an Autonomous Data Guard standby database, either the elastic pool leader is charged for the standby's compute usage or the individual standby instance is charged independently.

Elastic Pool Usage Details in OCI Usage Reports and `OCI_USAGE_DATA` View (for records until January 31, 2025)

You can obtain a detailed breakdown of elastic pool usage in the Oracle Cloud Infrastructure (OCI) usage reports and this information is also shown in the `OCI_USAGE_DATA` view. See Cost and Usage Reports and OCI_USAGE_DATA View for more information.

> **Note:**
>
> You can use OCI usage reports and `OCI_USAGE_DATA` view for records until January 31, 2025. The OCI usage reports are deprecated. You can continue to access your existing usage report CSV files until July 31, 2025. See Cost and Usage Reports for more information.

The following table shows the `product/resource` column values in an OCI usage report. The OCI usage report provides details on elastic pool usage for the pool leader and for pool members a given billing hour (similar information is available in `OCI_USAGE_DATA` view):

Elastic Pool Usage Type	Billing Hour Values Shown
Member Compute Usage	For a given pool member where the `product/resourceId` column of the OCI usage report is equal to pool member's OCID and the `product/resource` column of the OCI usage report is equal to `PIC_ADBS_DB_ECPU_PEAK`, the `usage/billedQuantity` of the OCI usage report shows the peak ECPU usage of the member in a specified billing hour. You can use the following query to view the same usage details in the `OCI_USAGE_DATA` view: `SELECT billed_quantity FROM OCI_USAGE_DATA WHERE resource_name='PIC_ADBS_DB_ECPU_PEAK' and resource_id=OCID_of_the_pool_member and interval_usage_start=start_time and interval_usage_end=end_time` **Note:** If a member has a local a local Autonomous Data Guard standby, its peak usage will be reported as two times (2 x) the peak usage. See About Elastic Pool Billing with Autonomous Data Guard Enabled for more information.

Elastic Pool Usage Type	Billing Hour Values Shown
Leader Compute Usage	For a given pool leader where the `product/resourceId` column of the OCI usage report is equal to pool leader's OCID and the `product/resource` column of the OCI usage report is equal to `PIC_ADBS_DB_ECPU_PEAK`, the `usage/billedQuantity` of the OCI usage report shows the peak ECPU usage of the leader in a specified billing hour. You can use the following query to view the same usage details in the `OCI_USAGE_DATA` view: `SELECT billed_quantity FROM OCI_USAGE_DATA WHERE resource_name='PIC_ADBS_DB_ECPU_PEAK' and resource_id=`*`OCID_of_the_pool_leader`* `and interval_usage_start=`*`start_time`*` and interval_usage_end=`*`end_time`* **Note:** If the leader has a local a local Autonomous Data Guard standby, its peak usage will be reported as two times (2 x) the peak usage. See About Elastic Pool Billing with Autonomous Data Guard Enabled for more information.
Aggregated Pool Compute Usage	For a given pool leader where the `product/resourceId` column of the OCI usage report is equal to pool leader's OCID and the `product/resource` column of the OCI usage report is equal to `PIC_ADBS_ELASTIC_POOL_DB_ECPU`, the `usage/billedQuantity` of the OCI usage report shows the aggregated peak ECPU usage of the leader and all members in the specified billing hour. You can use the following query to view the same usage details in the `OCI_USAGE_DATA` view: `SELECT billed_quantity FROM OCI_USAGE_DATA WHERE resource_name='PIC_ADBS_ELASTIC_POOL_DB_ECPU' and resource_id=`*`OCID_of_the_pool_leader`* `and interval_usage_start=`*`start_time`*` and interval_usage_end=`*`end_time`*

Notes for elastic pool billing information in the OCI usage report and the `OCI_USAGE_DATA` view:

- Elastic pool aggregate peak ECPU usage is shown for terminated databases.
- Elastic pool aggregate peak ECPU usage is shown for non-pool databases that were part of an elastic pool during a billing hour when the database was a member of an elastic pool.

See Billing Information: Autonomous Transaction Processing ECPU Compute Model and Track Oracle Cloud Infrastructure Resources, Cost and Usage Reports with Autonomous Database Views for more information.

Elastic Pool Usage Details in OCI Cost Reports and `OCI_COST_DATA` View for Records After January 31, 2025

> **Note:**
>
> Usage details are in the cost reports and the `OCI_COST_DATA` view for usage after January 31, 2025. See Cost and Usage Reports for more information.

You can obtain a detailed breakdown of elastic pool usage in the Oracle Cloud Infrastructure (OCI) cost reports and this information is also shown in the `OCI_COST_DATA` view. See Cost and Usage Reports and OCI_COST_DATA View for more information.

The following table shows the `product/resource` column values in an OCI cost report. The OCI cost report provides details on elastic pool usage for the pool leader and for pool members for a given billing hour and similar information is available in `OCI_COST_DATA` view.

Elastic Pool Usage Type	Billing Hour Values Shown
Member Compute Usage	For a given pool member where the `product/resourceId` column of the OCI cost report is equal to a pool member's OCID and the `product/Description` column is equal to '`Autonomous Database - Elastic Pool Individual DB Peak ECPU`', the `usage/billedQuantity` column of the OCI cost report shows the peak ECPU usage of the member in a specified billing hour. You can use the following query to view the same usage details in the `OCI_COST_DATA` view: `SELECT billed_quantity FROM OCI_COST_DATA WHERE product_description='Autonomous Database - Elastic Pool Individual DB Peak ECPU' and resource_id=`*`OCID_of_the_pool_member`*` and interval_usage_start=`*`start_time`*` and interval_usage_end=`*`end_time`* **Note:** If a member has a local a local Autonomous Data Guard standby, its peak usage will be reported as two times (2 `x`) the peak usage. See About Elastic Pool Billing with Autonomous Data Guard Enabled for more information.

Elastic Pool Usage Type	Billing Hour Values Shown
Leader Compute Usage	For a given pool leader where the `product/resourceId` column of the OCI cost report is equal to pool leader's OCID, and the `product/Description` column is equal to '`Autonomous Database - Elastic Pool Individual DB Peak ECPU`', the `usage/billedQuantity` column of the cost report shows the peak ECPU usage of the leader in a specified billing hour. You can use the following query to view the same usage details in the `OCI_COST_DATA` view: `SELECT billed_quantity FROM OCI_COST_DATA WHERE product_description='Autonomous Database - Elastic Pool Individual DB Peak ECPU' and resource_id=`*`OCID_of_the_pool_leader`*` and interval_usage_start=`*`start_time`*` and interval_usage_end=`*`end_time`* **Note:** If the leader has a local a local Autonomous Data Guard standby, its peak usage will be reported as two times (2 `x`) the peak usage. See About Elastic Pool Billing with Autonomous Data Guard Enabled for more information.
Aggregated Pool Compute Usage	For a given pool leader where the `product/resourceId` column of the cost report is equal to pool leader's OCID and the `product/Description` column of the cost report is equal to `product/Description` column is equal to '`Autonomous Database - Elastic Pool ECPU`', the `usage/billedQuantity` column of the cost report shows the aggregated peak ECPU usage of the leader and all members in the specified billing hour. You can use the following query to view the same usage details in the `OCI_COST_DATA` view: `SELECT billed_quantity FROM OCI_COST_DATA WHERE product_description='Autonomous Database - Elastic Pool ECPU' and resource_id=`*`OCID_of_the_pool_leader`*` and interval_usage_start=`*`start_time`*` and interval_usage_end=`*`end_time`*

Notes for elastic pool billing information in the OCI cost report and the `OCI_COST_DATA` view:

- Elastic pool aggregate peak ECPU usage is shown for terminated databases.
- Elastic pool aggregate peak ECPU usage is shown for non-pool databases that were part of an elastic pool during a billing hour when the database was a member of an elastic pool.

See Billing Information: Autonomous Transaction Processing ECPU Compute Model and Track Oracle Cloud Infrastructure Resources, Cost and Usage Reports with Autonomous Database Views for more information.

About Elastic Pool Billing with Autonomous Data Guard Enabled

An Autonomous Data Guard primary database can use a local or a cross-region standby that is part of an elastic pool, either as a leader or a member.

- About Elastic Pool Billing with Autonomous Data Guard Enabled with a Local Standby
  When an elastic pool leader or an elastic pool member enables a local Autonomous Data Guard standby, the standby database is part of the elastic pool and you are billed accordingly.
- About Elastic Pool Billing with a Cross-Region Standby
  Describes billing and elastic pool capacity details for a cross-region Autonomous Data Guard standby when the cross-region standby is added to an elastic pool.

About Elastic Pool Billing with Autonomous Data Guard Enabled with a Local Standby

When an elastic pool leader or an elastic pool member enables a local Autonomous Data Guard standby, the standby database is part of the elastic pool and you are billed accordingly.

When you add a local standby, a total of two times (2 x) the primary's ECPU allocation is counted towards the pool capacity (1 x for the primary and 1 x for the standby). Meaning a local standby multiplies the primary's peak usage by 2.

For example, if you create an elastic pool with a pool size of 128 ECPUs, with a pool capacity of 512 ECPUs, adding the following Autonomous Database instance uses the elastic pool capacity:

- 1 instance with 256 ECPUs with local Autonomous Data Guard enabled, for a total of 512 ECPUs allocation from the pool.

  When using this instance, if the peak ECPU utilization is 256 ECPUs for a given billing hour, the overall peak ECPU utilization will be reported as 512 ECPUs because of the local standby database's 2x multiplication factor. And the billing for that hour will be 512 ECPUs (4x pool size).

Similarly, if you create an elastic pool with a pool size of 128 ECPUs, with a pool capacity of 512 ECPUs, adding the following Autonomous Database instances uses the elastic pool capacity as follows:

- 128 instances with 2 ECPUs each, with local Autonomous Data Guard enabled, for a total of 512 ECPUs allocation from the pool.

  When using all of these instances, if the peak ECPU utilization is 256 ECPUs, 128 *2 ECPUs per instance, for a given billing hour, the overall peak ECPU utilization will be reported as 512 ECPUs because of the local standby database's 2x multiplication factor. And the billing for that hour will be 512 ECPUs (4x pool size)

See Enable Autonomous Data Guard for more information.

About Elastic Pool Billing with a Cross-Region Standby

Describes billing and elastic pool capacity details for a cross-region Autonomous Data Guard standby when the cross-region standby is added to an elastic pool.

The databases in an elastic pool must be located in the same region. If you have a cross-region Autonomous Data Guard standby, you can place it in an elastic pool in the standby's region.

- If you increase the primary database's compute resources, the remote elastic pool where the cross-region standby runs must have enough available capacity to accommodate the increase.

  See About Elastic Pools for more information on elastic pool capacity.

- It is not possible to terminate a primary database when its cross-region Autonomous Data Guard standby is a pool leader. In this case you must terminate the elastic pool before you terminate the primary database."

  See Terminate an Elastic Pool for more information.

- A cross-region Autonomous Data Guard standby that is in an elastic pool is billed based on the peak usage of the primary. This applies independent of whether the primary is in an elastic pool.

  For example, in a given billing hour from 1pm to 2pm where the primary's peak usage is 30 ECPUs, the cross-region Autonomous Data Guard standby also shows its peak ECPU usage as 30 ECPUs and this usage is reported to the remote region elastic pool leader.

- A cross-region Autonomous Data Guard standby that is not in an elastic pool, neither as a pool leader nor as a pool member, is billed just like a regular cross-region standby.

  See Oracle Autonomous Database Serverless Features Billing for more information.

Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies

Provides information on required policies for working with elastic pools with a pool member in a child tenancy and the pool leader in the parent tenancy.

To use an elastic pool across tenancies you must define OCI Identity and Access Management policies that allow an Autonomous Database instance in a child tenancy to join an elastic pool in the parent tenancy.

> **Note:**
>
> Adding policies for parent and child tenancies is only required when you use elastic pools across tenancies where a member Autonomous Database instance in a child tenancy is added to an elastic pool in a parent tenancy.

Consider the following cases:

- You want to allow a user in the parent tenancy to create an instance as a pool member in the child tenancy, or add an existing instance from the child tenancy as a pool member to an elastic pool in the parent tenancy. To do this, a user in the parent tenancy should have the following OCI Identity and Access Management policies:

  Policies needed in the parent tenancy:

```
define tenancy ChildTenancy as ocid1.tenancy.oc1....
endorse group ParentTenancyUserGroup to manage autonomous-databases in
tenancy ChildTenancy
```

```
allow group ParentTenancyUserGroup to manage autonomous-databases in
tenancy
```

Policies needed in the child tenancy:

```
define tenancy ParentTenancy as ocid1.tenancy.oc1...
define group ParentTenancyUserGroup as ocid1.group.oc1...
admit group ParentTenancyUserGroup of tenancy ParentTenancy to manage
autonomous-databases in tenancy
```

- You want to allow a user in the child tenancy to create an instance as a member of an elastic pool in the parent tenancy, or add an existing instance from the child tenancy as a pool member to an elastic pool in the parent tenancy. To do this, a user in the child tenancy should have the following OCI Identity and Access Management policies:

  Policies needed in the parent tenancy:

  ```
  define tenancy ChildTenancy as ocid1.tenancy.oc1....
  define group ChildTenancyUserGroup as ocid1.group.oc1...
  admit group ChildTenancyUserGroup of tenancy ChildTenancy to manage
  autonomous-databases in tenancy
  ```

  Policies needed in the child tenancy:

  ```
  define tenancy ParentTenancy as ocid1.tenancy.oc1...
  define group ParentTenancyUserGroup as ocid1.group.oc1...
  endorse group ChildTenancyUserGroup to manage autonomous-databases in
  tenancy ParentTenancy
  allow group ChildTenancyUserGroup to manage autonomous-databases in tenancy
  ```

Create, Join or Manage an Elastic Pool

Shows the steps to create, join, or manage an elastic pool.

- Create an Elastic Pool
  Shows the steps to create an elastic pool in an existing Autonomous Database instance.
- Create an Elastic Pool While Provisioning or Cloning an Instance
  You can create or join an elastic pool when you provision or clone an Autonomous Database instance.
- Join an Existing Elastic Pool
  Shows the steps to join an existing elastic pool.
- Join an Elastic Pool While Provisioning or Cloning an Instance
  You can create or join an elastic pool when you provision or clone an Autonomous Database instance.
- Change the Elastic Pool Shape
  Shows the steps for the pool leader to change the elastic pool shape for an existing elastic pool.

Create an Elastic Pool

Shows the steps to create an elastic pool in an existing Autonomous Database instance.

> **Note:**
>
> To create an elastic pool the instance must use the ECPU compute model.

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To create an elastic pool:

1. On the Autonomous Database Details page click **More actions** and select **Manage resource allocation**.

   If **Compute auto scaling** switch is on:

   a. Switch off **Compute auto scaling**.

   b. Click **Apply**.

      The **Lifecycle state** changes to **Scaling in Progress**. After some time the **Lifecycle state** changes to **Available**.

   c. On the Autonomous Database Details page click **More actions** and select **Manage resource allocation** to display the **Manage resource allocation** area.
2. In the **Manage resource allocation** area expand **Advanced options**.
3. Switch **Enable elastic pool** on.
4. Select **Create an elastic pool**.
5. Choose a pool size in the **Pool ECPU count** field.

   Select a pool size from the list of pool shapes: 128, 256, 512, 1024, 2048, or 4096.

   By default each instance in an elastic pool is automatically assigned a maintenance window. By selecting a **Pool ECPU count** that is 1024 greater, you have the option of assigning a custom 2-hour maintenance window during which the leader and all elastic pool members are patched together. To select a custom maintenance window for your elastic pool, file a Service Request at Oracle Cloud Support.

   See About Scheduled Maintenance and Patching for more information.
6. Click **Apply** to create the elastic pool.

When you click **Apply** the **Lifecycle state** changes to **Updating**. After the **Lifecycle state** changes to **Available** the changes apply immediately.

After you create an elastic pool, click **More actions** and select **Manage resource allocation** to display the elastic pool information. In the **Manage resource allocation** area, the **Elastic pool** field shows **Enabled**, the **Pool role** field shows **Leader**, and the **Pool ECPU count** field shows the pool size you selected.

Create an Elastic Pool While Provisioning or Cloning an Instance

You can create or join an elastic pool when you provision or clone an Autonomous Database instance.

See Provision an Autonomous Database Instance for details on how to create an Autonomous Database for your workload type using the Create Autonomous Database dialog.

See Clone an Autonomous Database Instance or Clone an Autonomous Database from a Backup for details on cloning.

See Join an Elastic Pool While Provisioning or Cloning an Instance for details on joining an elastic pool while provisioning or cloning.

> **Note:**
>
> To create an elastic pool the instance must use the ECPU compute model.

To create an elastic pool while provisioning or cloning:

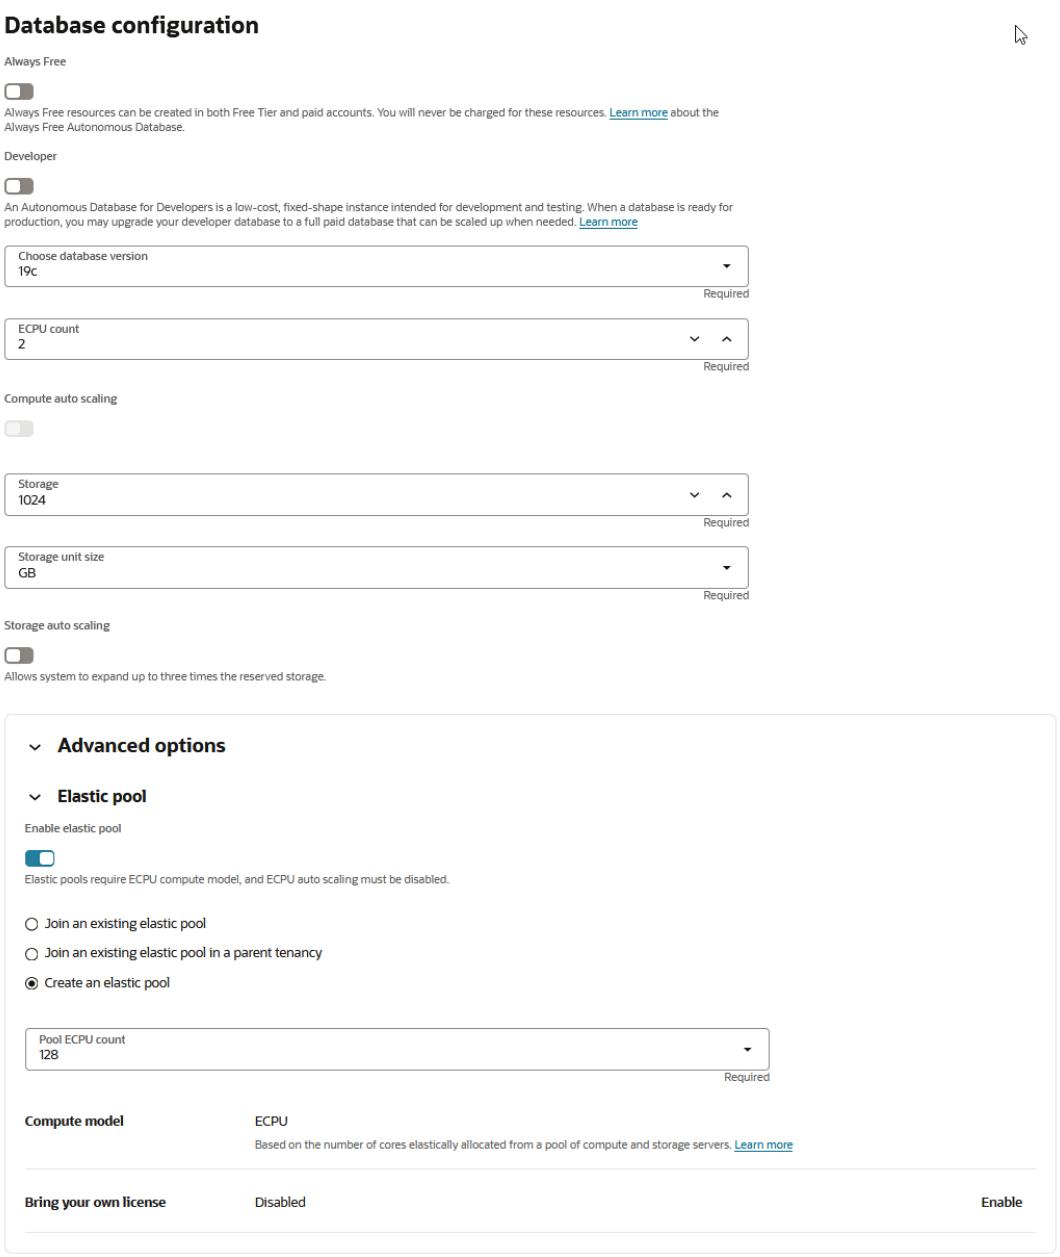
1. In the **Database configuration** area, switch off **Compute auto scaling**.
2. In the **Database configuration** area, expand **Advanced options**.
3. Switch on **Enable elastic pool**.
4. Select **Create an elastic pool**.
5. In the **Pool ECPU count** field, select a pool size from the list of pool shapes.

   The valid values that you can select are: 128, 256, 512, 1024, 2048, or 4096.

   By default each instance in an elastic pool is automatically assigned a maintenance window. By selecting a **Pool ECPU count** that is 1024 greater, you have the option of assigning a custom 2-hour maintenance window during which the leader and all elastic pool members are patched together. To select a custom maintenance window for your elastic pool, file a Service Request at Oracle Cloud Support.

   See About Scheduled Maintenance and Patching for more information.

   For example:



6. If applicable, enable the **Bring your own license** option.

   See Choose Bring Your Own License Option While Provisioning or Cloning for more information.

7. Complete the remaining provisioning or cloning steps, as specified in Provision an Autonomous Database Instance, Clone an Autonomous Database Instance, or Clone an Autonomous Database from a Backup.

Join an Existing Elastic Pool

Shows the steps to join an existing elastic pool.

To join an elastic pool, the following is required for the Autonomous Database instance:

- The instance must use the ECPU compute model.

  See Compute Models in Autonomous Database for more information.

- Auto scaling must be disabled.
- The instance must not be a member of an elastic pool.

To join an elastic pool:

1. On the Autonomous Database Details page click **More actions** and select **Manage resource allocation**.

   If **Compute auto scaling** is on, switch this option off.

   a. Switch **Compute auto scaling** off.

   b. Click **Apply**.

      The **Lifecycle state** changes to **Scaling in Progress**. After some time the **Lifecycle state** changes to **Available**.

   c. On the Autonomous Database Details page click **More actions** and select **Manage resource allocation**.

2. In the **Manage resource allocation** area, expand **Advanced options**.
3. Switch **Enable elastic pool** on.
4. Select one of the following:

   - **Join an existing elastic pool**: Select this option when you want to join an elastic pool leader and the pool leader is in the same tenancy as the instance that is joining the elastic pool.

     In the **Compartment** field choose a compartment.

     In the **Select pool leader** field select the pool leader.

   - **Join an existing elastic pool in a parent tenancy**: Select this option when your tenancy is a child tenancy and you want to join an elastic pool leader in the parent tenancy.

     In the text field enter the OCID of the elastic pool leader.

     See Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies for details on the required policies.

5. Click **Apply** to add the instance to the elastic pool.

When you click **Apply** the **Lifecycle state** changes to **Updating**. After the **Lifecycle state** changes to **Available** the changes apply immediately.

After you create an elastic pool, click **More actions** and select **Manage resource allocation** to see the elastic pool details. In the Manage resource allocations area, under **Elastic pool**, the **Elastic pool** field shows **Enabled**, the **Pool role** field shows **Member**, and the **Elastic pool leader** field shows a link to the pool leader.

Join an Elastic Pool While Provisioning or Cloning an Instance

You can create or join an elastic pool when you provision or clone an Autonomous Database instance.

See Provision an Autonomous Database Instance for details on how to create an Autonomous Database for your workload type using the Create Autonomous Database dialog.

See Clone an Autonomous Database Instance or Clone an Autonomous Database from a Backup for details on cloning.

See Create an Elastic Pool While Provisioning or Cloning an Instance for details on creating an elastic pool while provisioning or cloning.

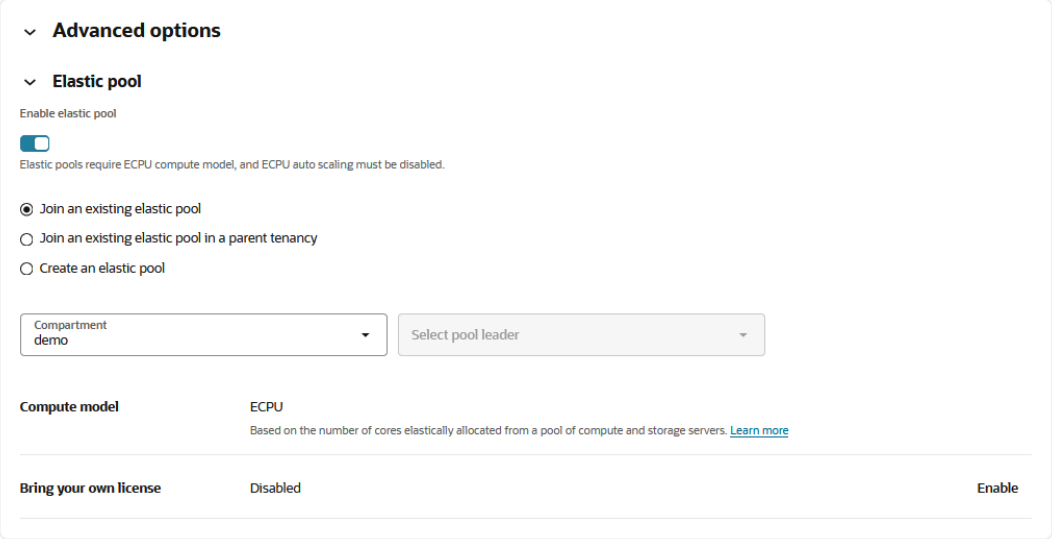
> **Note:**
>
> To join an elastic pool the instance must use the ECPU compute model.

To join an existing elastic pool while provisioning or cloning:

1. In the **Database configuration** area, switch off **Compute auto scaling**.
2. In the **Database configuration** area, expand **Advanced options**.
3. Switch **Enable elastic pool** on.
4. Select one of the following:
   - **Join an existing elastic pool** When you want to join an elastic pool leader in the same tenancy:
     In the **Compartment** field choose a compartment.

     In the **Select pool leader** field select a pool leader.
   - **Join an existing elastic pool in a parent tenancy**: When your tenancy is a child tenancy and you want to join an elastic pool leader in the parent tenancy.
     In the text field enter the OCID of the elastic pool leader in the parent tenancy.

     See Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies for the required policies.



Complete the remaining provisioning or cloning steps, as specified in Provision an Autonomous Database Instance, Clone an Autonomous Database Instance, or Clone an Autonomous Database from a Backup.

Change the Elastic Pool Shape

Shows the steps for the pool leader to change the elastic pool shape for an existing elastic pool.

> **Note:**
>
> Only a pool leader can modify the pool shape.

To change the shape of an elastic pool (update the pool size):

1. On the Autonomous Database Details page click **More actions** and select **Manage resource allocation** to display the **Manage resource allocation** area.
2. In the **Pool ECPU count** field, select a value that is different than the current value.

   By default each instance in an elastic pool is automatically assigned a maintenance window. By selecting a **Pool ECPU count** that is 1024 greater, you have the option of assigning a custom 2-hour maintenance window during which the leader and all elastic pool members are patched together. To select a custom maintenance window for your elastic pool, file a Service Request at Oracle Cloud Support.

   See About Scheduled Maintenance and Patching for more information.
3. Click **Apply**.

   When you click **Apply**, the **Lifecycle state** changes to **Updating**. After the **Lifecycle state** changes to **Available** the changes apply immediately.

> **Note:**
>
> Decreasing the CPU allocation, **Pool ECPU count**, to a value that cannot accommodate all the members of the elastic pool is not allowed.

For example, for an elastic pool with a **Pool ECPU count** of 256 ECPUs and a pool capacity of 1024 ECPUs: If the elastic pool contains eight (8) Autonomous Database instances with 80 ECPUs each for a total of 640 ECPUs, the elastic pool leader cannot decrease the **Pool ECPU count** to 128 ECPUs. In this case, if the pool size were reduced to 128 ECPUs, the pool capacity would be 512 ECPUs, which is less than the total allocation for the pool members (640 ECPUs).

List Elastic Pool Members

Shows the steps for the pool leader to list elastic pool members.

To list elastic pool members:

1. On the elastic pool leader's Autonomous Database details page, select the **Elastic pool members** tab.
2. The **Elastic pool members** tab shows a list of elastic pool members.

This shows the list of elastic pool members for the leader Autonomous Database instance.

If you click ... at the end of a row in the list, you can select an action to perform for the member. The possible actions are:

- **View details**: Shows the member's Oracle Cloud Infrastructure Console
- **Copy OCID**: Copies the member's Autonomous Database instance OCID.
- **Remove from pool**: Brings up a dialog where you can confirm to remove the Autonomous Database instance from the pool.

Note for listing elastic pool members:

- When you list pool members for an elastic pool in a parent tenancy, the listing includes all the pool members in the parent tenancy and the members in all child tenancies. See "Use Elastic Pools with Oracle Cloud Infrastructure Organization Management (Parent and Child Tenancies)" in About Elastic Pools for more information.

Offload Queries to Member Refreshable Clones

When you have heavy read workloads, where a relatively small amount of data is scanned by multiple queries, you can offload queries (reads) either from an elastic pool leader or from an elastic pool member to Refreshable Clones.

- About Query Offloading
  Provides information about using query offload with an elastic pool and describes the query offload features.
- Enable Query Offload
  Describes how to enable query offload for an elastic pool leader or for an elastic pool member.
- Disable Query Offload
  Describes how to disable query offload for an elastic pool leader or for an elastic pool member.
- Query Offload from PL/SQL
  When query offload is enabled, queries are offloaded to Refreshable Clones even if they are embedded within PL/SQL. The PL/SQL can be stored procedures, functions, packages, or anonymous blocks.
- Query Offload from a Scheduler Job
  When query offload is enabled, queries from within an Oracle Scheduler job action are offloaded to Refreshable Clones. The queries are offloaded whether the job runs in the foreground or in the background.
- Notes for Offloading Queries
  Provides additional notes for the query offload feature.

About Query Offloading

Provides information about using query offload with an elastic pool and describes the query offload features.

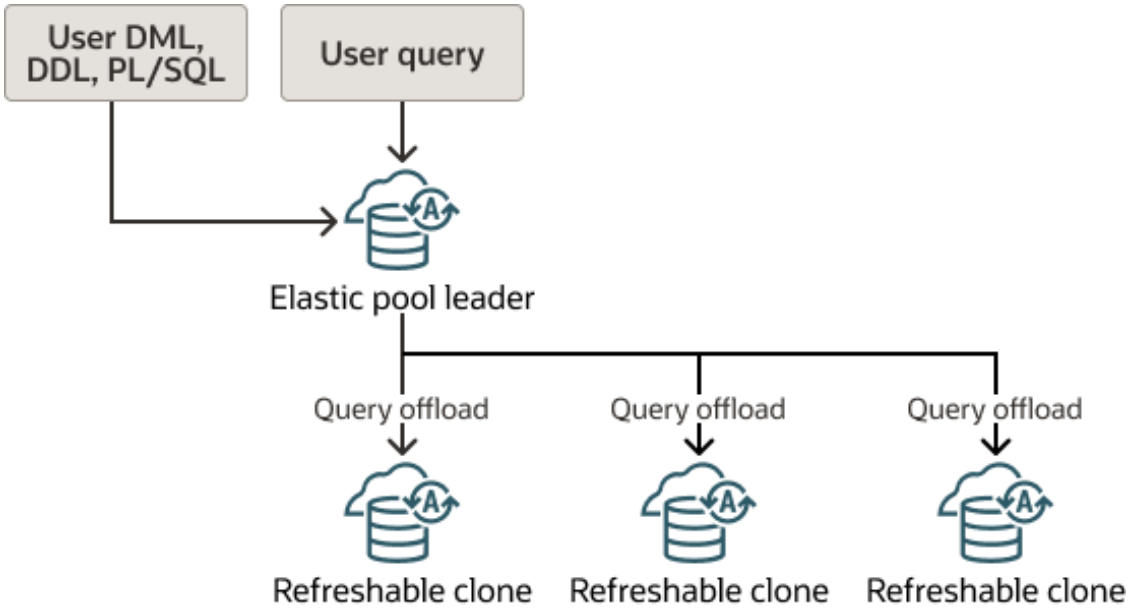
Elastic pool query offload provides performance benefits by allowing one or more Refreshable Clones to handle queries for either an elastic pool leader or for an elastic pool member. This feature also allows you to add Refreshable Clones to accommodate increasing query (read) demand. Offloading queries allows your application to scale horizontally, where you can add Refreshable Clones to maintain overall system performance as needed to satisfy your query request volume.

When query offload is enabled, queries are submitted either to the elastic pool leader or to an elastic pool member and one or more available Refreshable Clones become candidates for query offloading. In addition, when more Refreshable Clones are added, query offload dynamically adjusts to make use of the new resources.

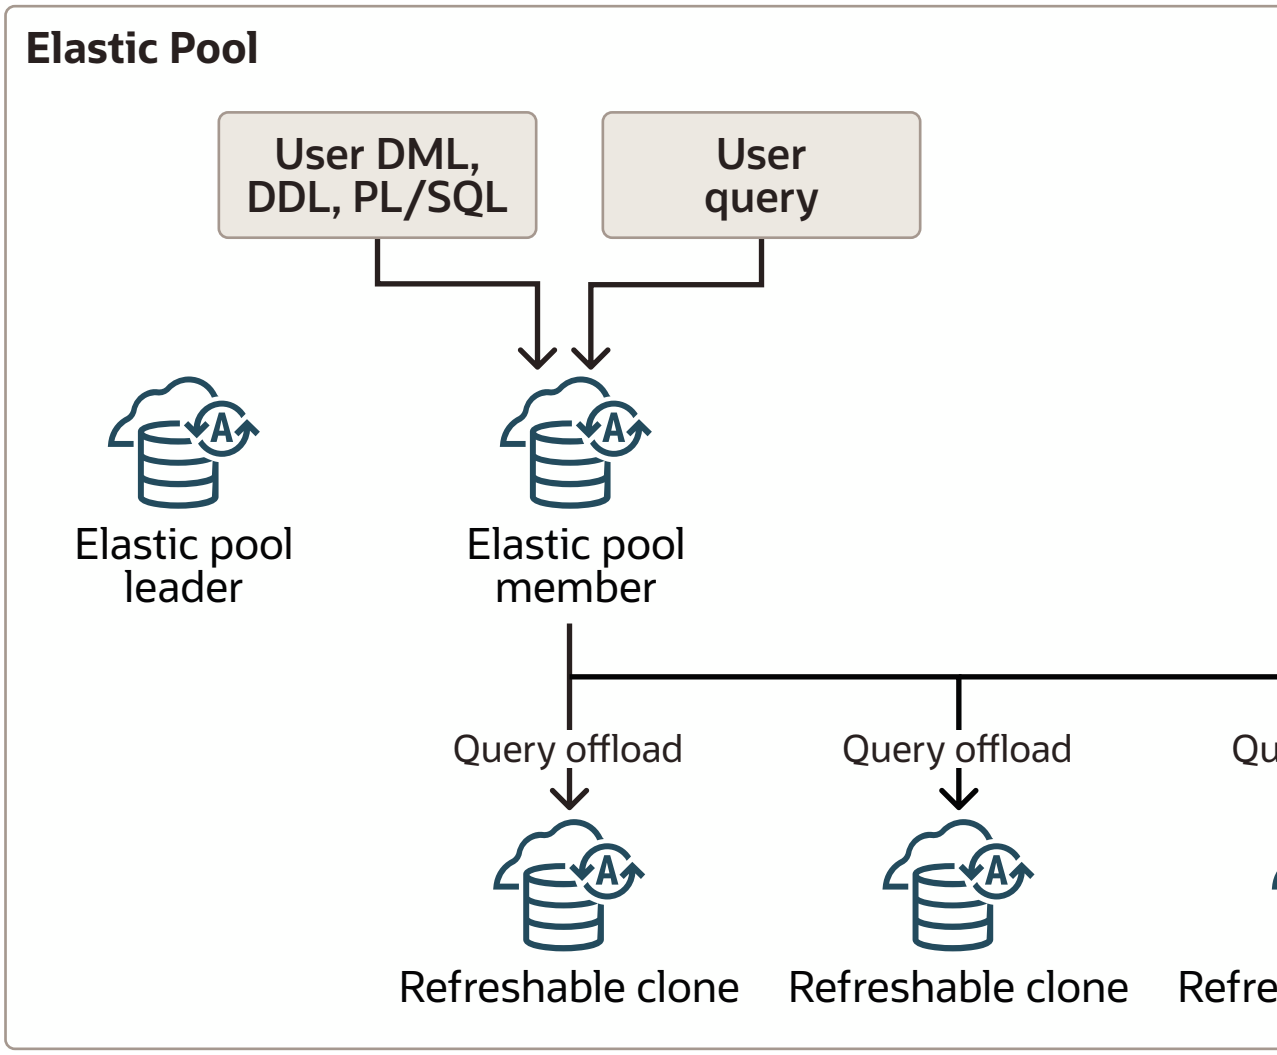
One use case for query offload is to enable the feature during peak hours to take load off of either the elastic pool leader or an elastic pool member. During quiet hours, you can disable query offload to perform maintenance operations such as refreshing the Refreshable Clones.

By default query offload considers queries from any session. Alternatively you can offload queries from a list of sessions that you specify by module or action name.

The following figure shows offloading queries from the elastic pool leader.



The following figure shows offloading queries from an elastic pool member.



Data on the Refreshable Clones is up to date based on the last refresh time for each refreshable clone. This means when query offload is enabled you perform all DDL, DML and PL/SQL operations either on the elastic pool leader or on the elastic pool member that is offloading queries. Then, after a Refreshable Clone is refreshed, the changes are reflected on the Refreshable Clone.

See Use Refreshable Clones with Autonomous Database for more information.

Query Offload Features

- **Dynamic Addition**: Refreshable Clones may be added as members of the elastic pool at any time. Query offload dynamically adjusts to make use of new members.
- **Dynamic Removal**: Refreshable Clones may be removed as members of the elastic pool at any time. Query offload dynamically adjusts to stop offloading queries to a Refreshable Clone that has been removed from the elastic pool.
- **Session Based Sticky Offload**: Query offload is sticky within a session, meaning if a query in a session has been offloaded to a particular Refreshable Clone, then query offload uses the same Refreshable Clone to offload subsequent queries in the same session.
- **One-to-One Service Mapping**: There is a one-to-one mapping between the service used in either in the elastic pool leader or the elastic pool member by the original query and the

service used in a Refreshable Clone for any offloaded query. For example, if a session is connected to the MEDIUM service, then query offload for that session also uses the MEDIUM service on the Refreshable Clone.

- **Determine if Session is Offloaded**: Using a `SYS_CONTEXT` query you can determine if a session runs on the elastic pool leader or member, or is offloaded to a Refreshable Clone.
- **Query Offload from PL/SQL**: Queries are offloaded to a Refreshable Clone even if they are embedded within PL/SQL. The PL/SQL can be stored procedures, functions, packages, or anonymous blocks.
- **Query Offload from Scheduler Job**: Queries from within an Oracle Scheduler job actions are offloaded. Oracle Scheduler job queries are offloaded whether the job runs in the foreground or in the background.

DBA_PROXY_SQL Views

Use the `DBA_PROXY_SQL` views `DBA_PROXY_SQL_ACTIONS` and `DBA_PROXY_SQL_MODULES` to display the list of modules or actions that are configured for query offload. You must query these views from a session that is not enabled for query offload.

Enable Query Offload

Describes how to enable query offload for an elastic pool leader or for an elastic pool member.

The following are requirements for enabling query offload:
